NCV7357

CAN FD Transceiver, High Speed

Description

The NCV7357 CAN transceiver is the interface between a controller area network (CAN) protocol controller and the physical bus. The transceiver provides differential transmit capability to the bus and differential receive capability to the CAN controller.

The NCV7357 is an addition to the CAN high-speed transceiver family complementing NCV7344 CAN stand-alone transceivers and previous generations such as AMIS42665, AMIS3066x, etc.

The NCV7357 guarantees additional timing parameters to ensure robust communication at data rates beyond 1 Mbps to cope with CAN flexible data rate requirements (CAN FD). FUNCTIONAL DESCRIPTION

High speed CAN FD transceiver

NCV7357 implements high-speed physical layer CAN FD transceiver compatible with ISO11898-2, implementing following optional features or alternatives:

- Extended bus load range

- Transmit dominant timeout, long
- Support of bit rates up to 5 Mbps
- Normal Bus biasing

Operating Modes

NCV7357 provides two modes of operation as illustrated in Table 2. These modes are selectable through pin S.

Table 2. OPERATING MODES

Pin S	Mode	Pin TxD	BUS	Pin RxD
Low	Normal	0	Dominant	0
		1	Recessive	1
High	Silent	X	Dominant (1)	0
		X	Recessive	1

1. CAN BUS driven by another transceiver on the BUS
2. 'X' = don't care

Power-off

This virtual mode is entered as soon as the V_{CC} or V_{IO} undervoltage condition is detected. The internal logic is reset and the transceiver is disabled. CAN bus pins are kept floating. As soon as both V_{CC} and V_{IO} voltages rise above corresponding undervoltage recovery thresholds, the device proceeds to Normal or Silent mode, depending on S pin state.

Normal Mode

In the normal mode, the transceiver is able to communicate via the bus lines. The signals are transmitted and received to the CAN controller via the pins TxD and RxD. The slopes on the bus lines outputs are optimized to give low EME.

Silent Mode

In the silent mode, the transmitter is disabled. The bus pins are in recessive state independent of TxD input. Transceiver listens to the bus and provides data to controller, but controller is prevented from sending any data to the bus.

Overtemperature Detection

A thermal protection circuit protects the IC from damage by switching off the transmitter if the junction temperature exceeds $T_{J(sd)}$ value. Because the transmitter dissipates most of the power, the power dissipation and temperature of the IC is reduced. All other IC functions continue to operate. The transmitter off-state resets when the temperature decreases below the shutdown threshold and pin TxD goes high. The thermal protection circuit is particularly needed when a bus line short circuits.

TxD Dominant Timeout Function

A TxD dominant timeout timer circuit prevents the bus lines being driven to a permanent dominant state (blocking all network communication) if pin TxD is forced permanently low by a hardware and/or software application failure. The timer is triggered by a negative edge on pin TxD. If the duration of the low-level on pin TxD exceeds the internal timer value $t_{dom(TxD)}$, the transmitter is disabled, driving the bus into a recessive state. The timer is reset by a positive edge on pin TxD.

This TxD dominant timeout time $t_{dom(TxD)}$ defines the minimum possible bit rate to 17 kbps.

Fail Safe Features

A current-limiting circuit protects the transmitter output stage from damage caused by accidental short circuit to either positive or negative supply voltage, although power dissipation increases during this fault condition.

Detection of undervoltage on supply pin (V_{CC} or V_{IO}) causes switching off device. After supply voltage is recovered TxD pin must be first released to high to allow sending dominant bits again.

The pins CANH and CANL are protected from automotive electrical transients (according to ISO 7637; see

Figure 7). Pins TxD and S are biased internally should the input become disconnected. Pins TxD, S and RxD will be floating, preventing reverse supply should the VCC supply be removed.

V_{IO} Supply Pin

The V_{IO} pin (available only on NCV7357-3 version) should be connected to microcontroller supply pin. By using V_{IO} supply pin shared with microcontroller the I/O levels

between microcontroller and transceiver are properly adjusted. See Figure 4.

Definitions

All voltages are referenced to GND (pin 2). Positive currents flow into the IC. Sinking current means the current is flowing into the pin; sourcing current means the current is flowing out of the pin.
