High Stability Isolated Error Amplifier

Data Sheet

ADuM4190

FEATURES

- **Stable over time and temperature**
  - **0.5% initial accuracy**
  - **1% accuracy over the full temperature range**
- **Compatible with Type II or Type III compensation networks**
- **Reference voltage: 1.225 V**
- **Compatible with DOSA**
- **Low power operation: <7 mA total**
- **Wide voltage supply range**
  - **V_{DD1}: 3 V to 20 V**
  - **V_{DD2}: 3 V to 20 V**
- **Bandwidth: 400 kHz**
- **Isolation voltage: 5 kV rms reinforced**
- **Safety and regulatory approvals (pending)**
  - **UL recognition: 5000 V rms for 1 minute per UL 1577**
  - **CSA Component Acceptance Notice #5A**
  - **VDE certificate of conformity**
    - **DIN V VDE V 0884-10 (VDE V 0884-10):2006-12**
    - **V_{IORM} = 849 V peak**
- **Wide temperature range**
  - **−40°C to +125°C ambient operation**
  - **150°C maximum junction temperature**

APPLICATIONS

- **Linear feedback power supplies**
- **Inverters**
- **Uninterruptible power supplies (UPS)**
- **DOSA-compatible modules**
- **Voltage monitors**

GENERAL DESCRIPTION

The ADuM4190[1] is an isolated error amplifier based on Analog Devices, Inc., *i*Coupler® technology. The ADuM4190 is ideal for linear feedback power supplies. The primary side controllers of the ADuM4190 enable improvements in transient response, power density, and stability as compared to commonly used optocoupler and shunt regulator solutions.

Unlike optocoupler-based solutions, which have an uncertain current transfer ratio over lifetime and at high temperatures, the ADuM4190 transfer function does not change over its lifetime and is stable over a wide temperature range of −40°C to +125°C.

Included in the ADuM4190 is a wideband operational amplifier for a variety of commonly used power supply loop compensation techniques. The ADuM4190 is fast enough to allow a feedback loop to react to fast transient conditions and overcurrent conditions. Also included is a high accuracy 1.225 V reference to compare with the supply output setpoint.

The ADuM4190 is packaged in a wide body, 16-lead SOIC package for a reinforced 5 kV rms isolation voltage rating.

ABSOLUTE MAXIMUM RATINGS

T_A = 25°C, unless otherwise noted.

Table 7.

Parameter	Rating
Storage Temperature (T_{ST}) Range	−65°C to +150°C
Ambient Operating Temperature (T_A) Range	−40°C to +125°C
Junction Temperature Range	−40°C to +150°C
Supply Voltages[1]	
V_{DD1}, V_{DD2}	−0.5 V to +24 V
V_{REG1}, V_{REG2}	−0.5 V to +3.6 V
Input Voltages (+IN, −IN)	−0.5 V to +3.6 V
Output Voltages	
REF_{OUT}, REF_{OUT1}, COMP, EA_{OUT}	−0.5 V to +3.6 V
EA_{OUT2}	−0.5 V to +5.5 V
Output Current per Output Pin	−11 mA to +11 mA
Common-Mode Transients[2]	−100 kV/µs to +100 kV/µs

[1] All voltages are relative to their respective grounds.
[2] Refers to common-mode transients across the insulation barrier. Common-mode transients exceeding the absolute maximum ratings may cause latch-up or permanent damage.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

Table 8. Maximum Continuous Working Voltage[1]

Parameter	Max	Unit	Constraint
AC Voltage, Bipolar Waveform	560	V peak	50-year minimum lifetime
AC Voltage, Unipolar Waveform	1131	V peak	50-year minimum lifetime
DC Voltage	1131	V peak	50-year minimum lifetime

[1] Refers to the continuous voltage magnitude imposed across the isolation barrier. See the Insulation Lifetime section for more information.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

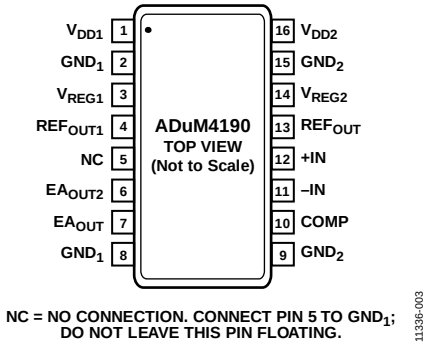

Figure 3. Pin Configuration

Table 9. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	V_{DD1}	Supply Voltage for Side 1 (3 V to 20 V). Connect a 1 µF capacitor between V_{DD1} and GND_1.
2, 8	GND_1	Ground Reference for Side 1.
3	V_{REG1}	Internal Supply Voltage for Side 1. Connect a 1 µF capacitor between V_{REG1} and GND_1.
4	REF_{OUT1}	Reference Output Voltage for Side 1. The maximum recommended capacitance for this pin ($C_{REFOUT1}$) is 15 pF.
5	NC	No Connection. Connect Pin 5 to GND_1; do not leave this pin floating.
6	EA_{OUT2}	Isolated Output Voltage 2, Open-Drain Output. Connect a pull-up resistor between EA_{OUT2} and V_{DD1} for current up to 1 mA.
7	EA_{OUT}	Isolated Output Voltage.
9, 15	GND_2	Ground Reference for Side 2.
10	COMP	Output of the Op Amp. A loop compensation network can be connected between the COMP pin and the –IN pin.
11	–IN	Inverting Op Amp Input. Pin 11 is the connection for the power supply setpoint and compensation network.
12	+IN	Noninverting Op Amp Input. Pin 12 can be used as a reference input.
13	REF_{OUT}	Reference Output Voltage for Side 2. The maximum recommended capacitance for this pin (C_{REFOUT}) is 15 pF.
14	V_{REG2}	Internal Supply Voltage for Side 2. Connect a 1 µF capacitor between V_{REG2} and GND_2.
16	V_{DD2}	Supply Voltage for Side 2 (3 V to 20 V). Connect a 1 µF capacitor between V_{DD2} and GND_2.

APPLICATIONS INFORMATION

In the test circuits of the ADuM4190 (see Figure 27 through Figure 29), external supply voltages from 3 V to 20 V are provided to the V_{DD1} and V_{DD2} pins, and internal regulators provide 3.0 V to operate the internal circuits of each side of the ADuM4190. An internal precision 1.225 V reference provides the reference for the ±1% accuracy of the isolated error amplifier. UVLO circuits monitor the V_{DDx} supplies to turn on the internal circuits when the 2.8 V rising threshold is met and to turn off the error amplifier outputs to a high impedance state when V_{DDx} falls below 2.6 V.

The op amp on the right side of the ADuM4190 has a noninverting +IN pin and an inverting −IN pin available for connecting a feedback voltage in an isolated dc-to-dc converter output, usually through a voltage divider. The COMP pin is the op amp output, which can be used to attach resistor and capacitor components in a compensation network. The COMP pin internally drives the Tx transmitter block, which converts the op amp output voltage into an encoded output that is used to drive the digital isolator transformer.

On the left side of the ADuM4190, the Rx block decodes the PWM signal that is output by the transformer and converts the signal into a voltage that drives an amplifier block; the amplifier block produces the error amplifier output available at the EA_{OUT} pin. The EA_{OUT} pin can deliver ±3 mA and has a voltage level from 0.4 V to 2.4 V, which is typically used to drive the input of a PWM controller in a dc-to-dc circuit.

For an application that requires more output voltage to drive its controller, the E_{AOUT2} pin can be used (see Figure 28). The E_{AOUT2} pin delivers up to ±1 mA with an output voltage of 0.6 V to 4.8 V for an output that has a pull-up resistor to a 5 V supply. If the EA_{OUT2} pull-up resistor is connected to a 10 V to 20 V supply, the output is specified to a minimum of 5.0 V to allow use with a PWM controller that requires a minimum input operation of 5 V.

ACCURACY CIRCUIT OPERATION

See Figure 27 and Figure 28 for accuracy circuit operation. The op amp on the right side of the ADuM4190, from the −IN pin to the COMP pin, has a unity-gain bandwidth (UGBW) of 10 MHz. Figure 30, Bode Plot 1, shows a dashed line for the op amp alone and its 10 MHz pole.

Figure 30 also shows the linear isolator alone (the blocks from the op amp output to the ADuM4190 output, labeled as the linear isolator), which introduces a pole at approximately 400 kHz. This total Bode plot of the op amp and linear isolator shows that the phase shift is approximately −180° from the −IN pin to the EA_{OUT} pin before the crossover frequency. Because a −180° phase shift can make the system unstable, adding an integrator configuration, consisting of a 2.2 nF capacitor and a 680 Ω resistor, helps to make the system stable (see Figure 27 and Figure 28).

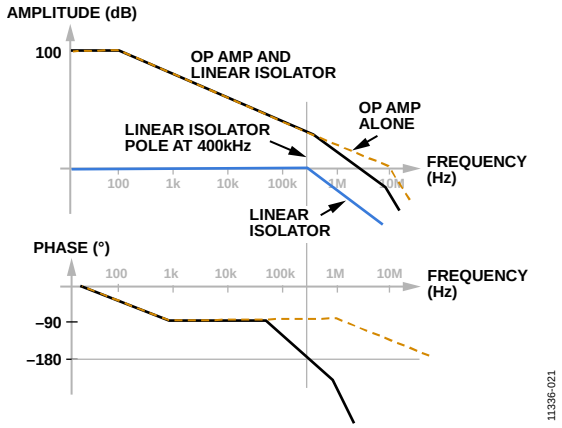

Figure 30. Bode Plot 1: Op Amp and Linear Isolator

In Figure 31, Bode Plot 2, with an integrator configuration added, the system crosses over 0 dB at approximately 100 kHz, but the circuit is more stable with a phase shift of approximately −120°, which yields a stable 60° phase margin. This circuit is used for accuracy tests only, not for real-world applications, because it has a 680 Ω resistor across the isolation barrier to close the loop for the error amplifier; this resistor causes leakage current to flow across the isolation barrier. For this test circuit only, GND_1 must be connected to GND_2 to create a return for the leakage current that is created by the 680 Ω resistor connection.

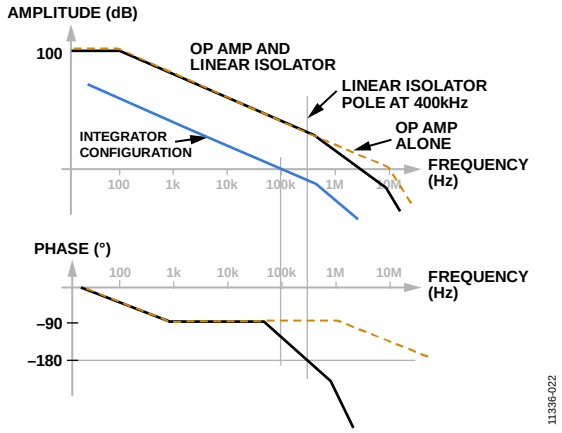

Figure 31. Bode Plot 2: Op Amp and Linear Isolator with Integrator Configuration

ISOLATED AMPLIFIER CIRCUIT OPERATION

Figure 29 shows an isolated amplifier circuit. In this circuit, the input side amplifier is set as a unity-gain buffer so that the EA_{OUT} output follows the +IN input. The EA_{OUT2} output follows the EA_{OUT} output, but with a voltage gain of 2.6.

This circuit has an open-drain output, which should be pulled up to a supply voltage from 3 V to 20 V using a resistor value set for an output current of up to 1 mA. The EA_{OUT2} output can be used to drive up to 1 mA to the input of a device that requires a minimum input operation of 5 V. The EA_{OUT2} circuit has an internal diode clamp to protect the internal circuits from voltages greater than 5 V.

The gain, offset, and linearity of EA_{OUT} and EA_{OUT2} are specified in Table 1 using this test circuit. When designing applications for voltage monitoring using an isolated amplifier, review these specifications, noting that the 1% accuracy specifications for the isolated error amplifier do not apply. In addition, the EA_{OUT} circuit in Figure 29 is shown with an optional external RC low-pass filter with a corner frequency of 500 kHz, which can reduce the 3 MHz output noise from the internal voltage to the PWM converter.

APPLICATION BLOCK DIAGRAM

Figure 32 shows a typical application for the ADuM4190: an isolated error amplifier in primary side control.

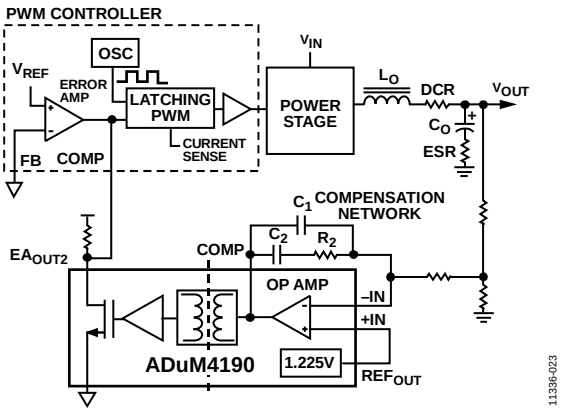

Figure 32. Application Block Diagram

The op amp of the ADuM4190 is used as the error amplifier for the feedback of the output voltage, V_{OUT}, using a resistor divider to the −IN pin of the op amp. This configuration inverts the output signal at the COMP pin when compared to the +IN pin, which is connected to the internal 1.225 V reference.

For example, when the output voltage, V_{OUT}, falls due to a load step, the divider voltage at the −IN pin falls below the +IN reference voltage, causing the COMP pin output signal to go high.

The COMP output of the op amp is encoded and then decoded by the digital isolator transformer block to a signal that drives the output of the ADuM4190 high. The output of the ADuM4190 drives the COMP pin of the PWM controller, which is designed to reset the PWM latch output to low only when its COMP pin is low. A high at the COMP pin of the PWM controller causes the latching PWM comparator to produce a PWM duty cycle output. This PWM duty cycle output drives the power stage to increase the V_{OUT} voltage until it returns to regulation.

The power stage output is filtered by output capacitance and, in some applications, by an inductor. Various elements contribute to the gain and phase of the control loop and the resulting stability. The output filter components (L_O and C_O) create a double pole; the op amp has a pole at 10 MHz (see Figure 30), and the linear isolator has a pole at 400 kHz (see Figure 30 and Figure 31).

The output capacitor and its ESR can add a zero at a frequency that is dependent on the component type and values. With the ADuM4190 providing the error amplifier, a compensation network is provided from the −IN pin to the COMP pin to compensate the control loop for stability. The compensation network values depend on both the application and the components that are selected; information about the component network values is provided in the data sheet of the selected PWM controller.

The ADuM4190 has two different error amplifier outputs: EA_{OUT} and EA_{OUT2}. The EA_{OUT} output, which can drive ±3 mA, has a guaranteed maximum high output voltage of at least 2.4 V, which may not be sufficient to drive the COMP pin of some PWM controllers. The EA_{OUT2} pin can drive ±1 mA and has an output range that guarantees 5.0 V for a V_{DD1} voltage range of 10 V to 20 V, which works well with the COMP pin of many PWM controllers.

Figure 32 shows how to use the ADuM4190 to provide isolated feedback in the control loop of an isolated dc-to-dc converter. In this application block diagram, the loop is closed at approximately the 1.225 V reference voltage, providing ±1% accuracy over temperature. The ADuM4190 op amp has a high gain bandwidth of 10 MHz to allow the dc-to-dc converter to operate at high switching speeds, enabling smaller values for the output filter components (L_O and C_O).

The 400 kHz bandwidth of the ADuM4190 error amplifier output offers faster loop response for better transient response than the typical shunt regulator and optocoupler solutions, which typically have bandwidths of only 25 kHz to 50 kHz maximum.

SETTING THE OUTPUT VOLTAGE

The output voltage in the application circuit shown in Figure 32 can be set with two resistors in a voltage divider (see Figure 33).

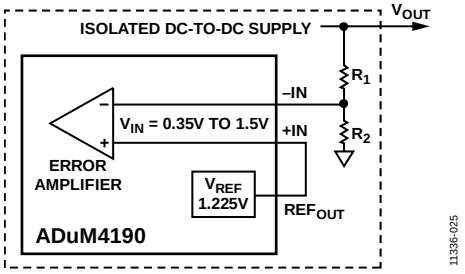

Figure 33. Setting the Output Voltage

The output voltage is determined by the following equation:

$$V_{OUT} = V_{REF} \times (R_1 + R_2)/R_2$$

where V_{REF} = 1.225 V.

DOSA MODULE APPLICATION

Figure 34 is a block diagram of a Distributed-power Open Standards Alliance (DOSA) circuit using the ADuM4190. The block diagram shows how to use the 1.225 V reference and the error amplifier of the ADuM4190 in a DOSA standard power supply module circuit to produce output voltage settings using a combination of resistors.

The 1.225 V reference of the ADuM4190 is specified for ±1% over the −40°C to +125°C temperature range. To set the output voltage of the module, use Table 10 to select the resistor values.

Two different ranges of V_{OUT} can be implemented, V_{OUT} > 1.5 V or V_{OUT} < 1.5 V, depending on the required module. Table 10 shows two sets of resistor values for the V_{OUT} > 1.5 V and V_{OUT} < 1.5 V ranges; the second set of resistor values (where 5.11 kΩ resistors are used) consumes less current than the first set.

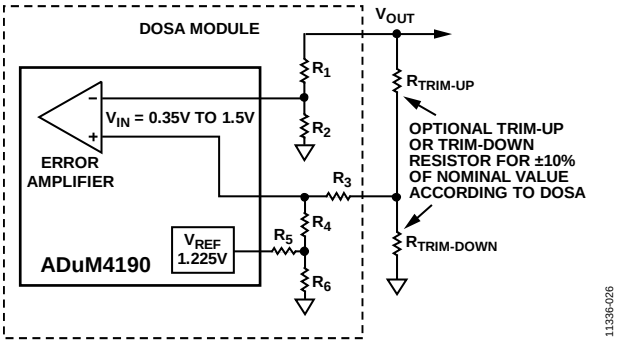

Figure 34. DOSA Module

Table 10. Resistor Values for DOSA Module

Module Nominal Output	R3	R4	R5	R6
V_{OUT} > 1.5 V	1 kΩ	1 kΩ	0 Ω	Open
V_{OUT} < 1.5 V	1 kΩ	0 Ω	2.05 kΩ	1.96 kΩ

DC CORRECTNESS AND MAGNETIC FIELD IMMUNITY

Positive and negative logic transitions at the isolator input cause narrow (~1 ns) pulses to be sent to the decoder via the transformer. The decoder is bistable and is, therefore, either set or reset by the pulses, indicating input logic transitions. If the decoder receives no internal pulses for more than approximately 3 µs, the input side is assumed to be unpowered or nonfunctional, and the isolator output is forced to a default high impedance state by the watchdog timer circuit. In addition, the outputs are in a default high impedance state while the power is increasing before the UVLO threshold is crossed.

The ADuM4190 is immune to external magnetic fields. The limitation on the magnetic field immunity of the ADuM4190 is set by the condition in which the induced voltage in the receiving coil of the transformer is sufficiently large to either falsely set or reset the decoder. The following analysis defines the conditions under which this can occur. The 3 V operating condition of the ADuM4190 is examined because the internal regulators provide 3 V to operate the internal circuits of each side of the device.

The pulses at the transformer output have an amplitude greater than 1.0 V. The decoder has a sensing threshold at approximately 0.5 V, thus establishing a 0.5 V margin within which induced voltages are tolerated. The voltage induced across the receiving coil is given by

$$V = (-d\beta/dt) \sum \pi r_n^2, n = 1, 2, \ldots, N$$

where:
β is the magnetic flux density (gauss).
r_n is the radius of the nth turn in the receiving coil (cm).
N is the number of turns in the receiving coil.

Given the geometry of the receiving coil in the ADuM4190 and an imposed requirement that the induced voltage be, at most, 50% of the 0.5 V margin at the decoder, a maximum allowable magnetic field is calculated as shown in Figure 35.

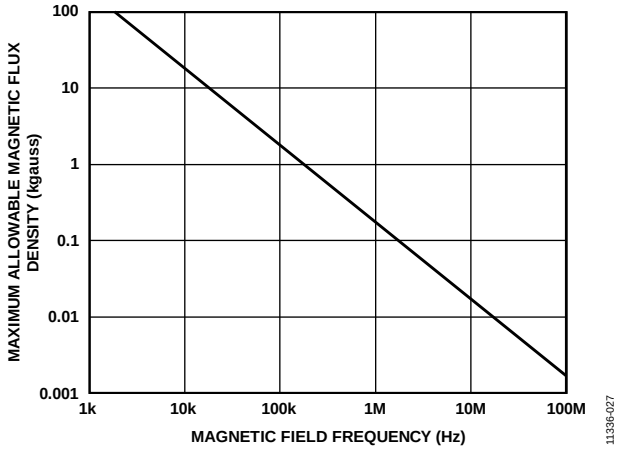

Figure 35. Maximum Allowable External Magnetic Flux Density

For example, at a magnetic field frequency of 1 MHz, the maximum allowable magnetic field of 0.2 kgauss induces a voltage of 0.25 V at the receiving coil. This voltage is approximately 50% of the sensing threshold and does not cause a faulty output transition. Similarly, if such an event occurs during a transmitted pulse (and is of the worst-case polarity), the received pulse is reduced from >1.0 V to 0.75 V—still well above the 0.5 V sensing threshold of the decoder.

The preceding magnetic flux density values correspond to specific current magnitudes at given distances from the ADuM4190 transformers. Figure 36 shows these allowable current magnitudes as a function of frequency for selected distances. As shown in Figure 36, the ADuM4190 is immune and can be affected only by extremely large currents operating at a high frequency very close to the component. For the 1 MHz example, a 0.7 kA current must be placed 5 mm away from the ADuM4190 to affect the operation of the device.

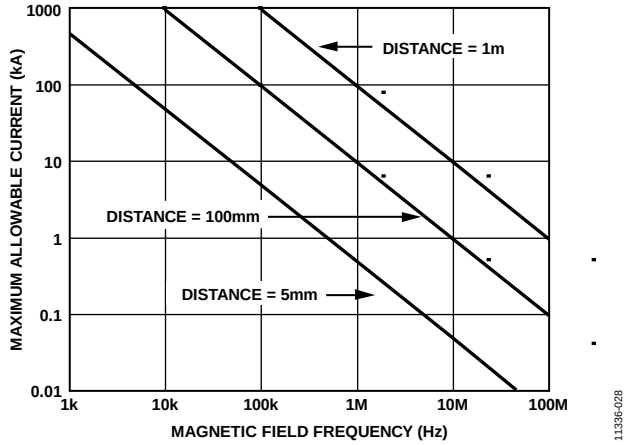

Figure 36. Maximum Allowable Current for Various Current-to-ADuM4190 Spacings

INSULATION LIFETIME

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation. In addition to the testing performed by the regulatory agencies, Analog Devices carries out an extensive set of evaluations to determine the lifetime of the insulation structure within the ADuM4190.

Analog Devices performs accelerated life testing using voltage levels higher than the rated continuous working voltage. Acceleration factors for several operating conditions are determined. These factors allow calculation of the time to failure at the actual working voltage.

The values shown in Table 8 summarize the peak voltage for 50 years of service life for a bipolar ac operating condition. In many cases, the approved working voltage is higher than the 50-year service life voltage. Operation at these high working voltages can lead to shortened insulation life in some cases.

The insulation lifetime of the ADuM4190 depends on the voltage waveform type imposed across the isolation barrier. The *i*Coupler insulation structure degrades at different rates depending on whether the waveform is bipolar ac, unipolar ac, or dc. Figure 37, Figure 38, and Figure 39 illustrate these different isolation voltage waveforms.

A bipolar ac voltage environment is the worst case for the *i*Coupler products yet meets the 50-year operating lifetime recommended by Analog Devices for maximum working voltage. In the case of unipolar ac or dc voltage, the stress on the insulation is significantly lower. This allows operation at higher working voltages while still achieving a 50-year service life. Treat any cross-insulation voltage waveform that does not conform to Figure 38 or Figure 39 as a bipolar ac waveform, and limit its peak voltage to the 50-year lifetime voltage value listed in Table 8.

Note that the voltage presented in Figure 38 is shown as sinusoidal for illustration purposes only. It is meant to represent any voltage waveform varying between 0 V and some limiting value. The limiting value can be positive or negative, but the voltage cannot cross 0 V.
