C8051F330/1/2/3/4/5

## Analog Peripherals

## - 10-Bit ADC ('F330/2/4 only)

- Up to 200 ksps
- Up to 16 external single-ended or differential inputs
- VREF from internal VREF, external pin or $V_{D D}$
- Internal or external start of conversion source
- Built-in temperature sensor
- 10-Bit Current Output DAC ('F330 only)
- Comparator
- Programmable hysteresis and response time
- Configurable as interrupt or reset source
- Low current $(0.4 \mu \mathrm{~A})$

## On-Chip Debug

- On-chip debug circuitry facilitates full speed, nonintrusive in-system debug (no emulator required)
- Provides breakpoints, single stepping, inspect/modify memory and registers
- Superior performance to emulation systems using ICE-chips, target pods, and sockets
- Low cost, complete development kit

## Supply Voltage 2.7 to 3.6 V

- Typical operating current: 6.4 mA at 25 MHz ; $9 \mu \mathrm{~A}$ at 32 kHz
- Typical stop mode current: $0.1 \mu \mathrm{~A}$

Temperature Range: $\mathbf{- 4 0}$ to $+85{ }^{\circ} \mathrm{C}$

High Speed $8051 \mu \mathrm{C}$ Core

- Pipelined instruction architecture; executes 70\% of instructions in 1 or 2 system clocks
- Up to 25 MIPS throughput with 25 MHz clock
- Expanded interrupt handler

## Memory

- 768 bytes internal data RAM $(256+512)$
- 8 kB ('F330/1), 4 kB ('F332/3), or 2 kB ('F334/5) Flash; In-system programmable in 512-byte Sec-tors- 512 bytes are reserved in the 8 kB devices
Digital Peripherals
- 17 Port I/O; All 5 V tolerant with high sink current
- Hardware enhanced UART, SMBus ${ }^{\text {TM }}$, and enhanced SPI ${ }^{\text {TM }}$ serial ports
- Four general purpose 16-bit counter/timers
- 16-Bit programmable counter array (PCA) with three capture/compare modules
- Real time clock mode using PCA or timer and external clock source

## Clock Sources

- Two internal oscillators:
- $\quad 24.5 \mathrm{MHz}$ with $\pm 2 \%$ accuracy supports crystal-less UART operation
- 80/40/20/10 kHz low frequency, low power
- External oscillator: Crystal, RC, C, or clock (1 or 2 pin modes)
- Can switch between clock sources on-the-fly; useful in power saving modes
20-Pin QFN Package

## C8051F330/1/2/3/4/5

## 1. System Overview

C8051F330/1/2/3/4/5 devices are fully integrated mixed-signal System-on-a-Chip MCUs. Highlighted features are listed below. Refer to Table 1.1 for specific product feature selection.

- High-speed pipelined 8051-compatible microcontroller core (up to 25 MIPS)
- In-system, full-speed, non-intrusive debug interface (on-chip)
- True 10-bit 200 ksps 16-channel single-ended/differential ADC with analog multiplexer
- 10-bit Current Output DAC
- Precision programmable 25 MHz internal oscillator
- Up to 8 kB of on-chip Flash memory-512 bytes are reserved
- 768 bytes of on-chip RAM
- SMBus/I2C, Enhanced UART, and Enhanced SPI serial interfaces implemented in hardware
- Four general-purpose 16-bit timers
- Programmable Counter/Timer Array (PCA) with three capture/compare modules and Watchdog Timer function
- On-chip Power-On Reset, $\mathrm{V}_{\mathrm{DD}}$ Monitor, and Temperature Sensor
- On-chip Voltage Comparator
- 17 Port I/O (5 V tolerant)

With on-chip Power-On Reset, $V_{D D}$ monitor, Watchdog Timer, and clock oscillator, the C8051F330/1/2/3/4/5 devices are truly stand-alone System-on-a-Chip solutions. The Flash memory can be reprogrammed even in-circuit, providing non-volatile data storage, and also allowing field upgrades of the 8051 firmware. User software has complete control of all peripherals, and may individually shut down any or all peripherals for power savings.

The on-chip Silicon Labs 2-Wire (C2) Development Interface allows non-intrusive (uses no on-chip resources), full speed, in-circuit debugging using the production MCU installed in the final application. This debug logic supports inspection and modification of memory and registers, setting breakpoints, single stepping, run and halt commands. All analog and digital peripherals are fully functional while debugging using C2. The two C2 interface pins can be shared with user functions, allowing in-system debugging without occupying package pins.

Each device is specified for 2.7 to 3.6 V operation over the industrial temperature range ( -40 to $+85^{\circ} \mathrm{C}$ ). The Port I/O and $\overline{\mathrm{RST}}$ pins are tolerant of input signals up to 5 V . The C8051F330/1/2/3/4/5 are available in 20-pin QFN packages (also referred to as MLP or MLF packages). Lead-free (RoHS compliant) packages are also available. See Table 1.1 for ordering part numbers. Block diagrams are included in Figure 1.1, Figure 1.2, Figure 1.3, Figure 1.4, Figure 1.5, and Figure 1.6.

## C8051F330/1/2/3/4/5

### 1.1. CIP-51 ${ }^{\text {TM }}$ Microcontroller Core

### 1.1.1. Fully 8051 Compatible

The C8051F330/1/2/3/4/5 family utilizes Silicon Labs' proprietary CIP-51 microcontroller core. The CIP-51 is fully compatible with the MCS-51 $1^{\text {TM }}$ instruction set; standard $803 \mathrm{x} / 805 \mathrm{x}$ assemblers and compilers can be used to develop software. The CIP-51 core offers all the peripherals included with a standard 8052, including four 16-bit counter/timers, a full-duplex UART with extended baud rate configuration, an enhanced SPI port, 768 bytes of internal RAM, 128 byte Special Function Register (SFR) address space, and $17 \mathrm{I} / \mathrm{O}$ pins.

### 1.1.2. Improved Throughput

The CIP-51 employs a pipelined architecture that greatly increases its instruction throughput over the standard 8051 architecture. In a standard 8051, all instructions except for MUL and DIV take 12 or 24 system clock cycles to execute with a maximum system clock of 12 -to- 24 MHz . By contrast, the CIP-51 core executes $70 \%$ of its instructions in one or two system clock cycles, with only four instructions taking more than four system clock cycles.

The CIP-51 has a total of 109 instructions. The table below shows the total number of instructions that require each execution time.

| Clocks to Execute | 1 | 2 | $2 / 3$ | 3 | $3 / 4$ | 4 | $4 / 5$ | 5 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Number of Instructions | 26 | 50 | 5 | 14 | 7 | 3 | 1 | 2 | 1 |

With the CIP-51's maximum system clock at 25 MHz , it has a peak throughput of 25 MIPS . Figure 1.7 shows a comparison of peak throughputs for various 8 -bit microcontroller cores with their maximum system clocks.

Figure 1.7. Comparison of Peak MCU Execution Speeds

# C8051F330/1/2/3/4/5 

### 1.1.3. Additional Features

The C8051F330/1/2/3/4/5 SoC family includes several key enhancements to the CIP-51 core and peripherals to improve performance and ease of use in end applications.

The extended interrupt handler provides 14 interrupt sources into the CIP-51 (as opposed to 7 for the standard 8051), allowing numerous analog and digital peripherals to interrupt the controller. An interrupt driven system requires less intervention by the MCU, giving it more effective throughput. The extra interrupt sources are very useful when building multi-tasking, real-time systems.

Eight reset sources are available: power-on reset circuitry (POR), an on-chip $\mathrm{V}_{\mathrm{DD}}$ monitor (forces reset when power supply voltage drops below $\mathrm{V}_{\text {RST }}$ as given in Table 10.1 on page 102), a Watchdog Timer, a Missing Clock Detector, a voltage level detection from ComparatorO, a forced software reset, an external reset pin, and an illegal Flash access protection circuit. Each reset source except for the POR, Reset Input Pin, or Flash error may be disabled by the user in software. The WDT may be permanently enabled in software after a power-on reset during MCU initialization.

The internal oscillator factory calibrated to $24.5 \mathrm{MHz} \pm 2 \%$. This internal oscillator period may be user programmed in $\sim 0.5 \%$ increments. An additional low-frequency oscillator is also available which facilitates low-power operation. An external oscillator drive circuit is included, allowing an external crystal, ceramic resonator, capacitor, RC, or CMOS clock source to generate the system clock. If desired, the system clock source may be switched on-the-fly between both internal and external oscillator circuits. An external oscillator can also be extremely useful in low power applications, allowing the MCU to run from a slow (power saving) source, while periodically switching to the fast (up to 25 MHz ) internal oscillator as needed.

Figure 1.8. On-Chip Clock and Reset

## C8051F330/1/2/3/4/5

### 1.2. On-Chip Memory

The CIP-51 has a standard 8051 program and data address configuration. It includes 256 bytes of data RAM, with the upper 128 bytes dual-mapped. Indirect addressing accesses the upper 128 bytes of general purpose RAM, and direct addressing accesses the 128 byte SFR address space. The lower 128 bytes of RAM are accessible via direct and indirect addressing. The first 32 bytes are addressable as four banks of general purpose registers, and the next 16 bytes can be byte addressable or bit addressable.

Program memory consists of $2 / 4 / 8 \mathrm{kB}$ of Flash. This memory may be reprogrammed in-system in 512 byte sectors, and requires no special off-chip programming voltage. See Figure 1.9 for the MCU system memory map.

Figure 1.9. On-Board Memory Map

## C8051F330/1/2/3/4/5

### 1.3. On-Chip Debug Circuitry

The C8051F330/1/2/3/4/5 devices include on-chip Silicon Labs 2-Wire (C2) debug circuitry that provides non-intrusive, full speed, in-circuit debugging of the production part installed in the end application.

Silicon Labs' debugging system supports inspection and modification of memory and registers, breakpoints, and single stepping. No additional target RAM, program memory, timers, or communications channels are required. All the digital and analog peripherals are functional and work correctly while debugging. All the peripherals (except for the ADC and SMBus) are stalled when the MCU is halted, during single stepping, or at a breakpoint in order to keep them synchronized.

The C8051F330DK development kit provides all the hardware and software necessary to develop application code and perform in-circuit debugging with the C8051F330/1/2/3/4/5 MCUs. The kit includes software with a developer's studio and debugger, an integrated 8051 assembler, and a debug adapter. It also has a target application board with the associated MCU installed and prototyping area, plus the required cables, and wall-mount power supply. The Development Kit requires a PC running Windows98SE or later.

The Silicon Labs IDE interface is a vastly superior developing and debugging configuration, compared to standard MCU emulators that use on-board "ICE Chips" and require the MCU in the application board to be socketed. Silicon Labs' debug paradigm increases ease of use and preserves the performance of the precision analog peripherals.

Figure 1.10. Development/In-System Debug Diagram

## C8051F330/1/2/3/4/5

### 1.4. Programmable Digital I/O and Crossbar

C8051F330/1/2/3/4/5 devices include 17 I/O pins (two byte-wide Ports and one 1-bit-wide Port). The C8051F330/1/2/3/4/5 Ports behave like typical 8051 Ports with a few enhancements. Each Port pin may be configured as an analog input or a digital I/O pin. Pins selected as digital I/Os may additionally be configured for push-pull or open-drain output. The "weak pullups" that are fixed on typical 8051 devices may be globally disabled, providing power savings capabilities.

The Digital Crossbar allows mapping of internal digital system resources to Port I/O pins. (See Figure 1.11.) On-chip counter/timers, serial buses, HW interrupts, comparator output, and other digital signals in the controller can be configured to appear on the Port I/O pins specified in the Crossbar Control registers. This allows the user to select the exact mix of general purpose Port I/O and digital resources needed for the particular application.

Figure 1.11. Digital Crossbar Diagram

### 1.5. Serial Ports

The C8051F330/1/2/3/4/5 Family includes an SMBus/I ${ }^{2}$ C interface, a full-duplex UART with enhanced baud rate configuration, and an Enhanced SPI interface. Each of the serial buses is fully implemented in hardware and makes extensive use of the CIP-51's interrupts, thus requiring very little CPU intervention.

## C8051F330/1/2/3/4/5

### 1.6. Programmable Counter Array

An on-chip Programmable Counter/Timer Array (PCA) is included in addition to the four 16-bit general purpose counter/timers. The PCA consists of a dedicated 16-bit counter/timer time base with three programmable capture/compare modules. The PCA clock is derived from one of six sources: the system clock divided by 12 , the system clock divided by 4 , Timer 0 overflows, an External Clock Input (ECI), the system clock, or the external oscillator clock source divided by 8 . The external clock source selection is useful for real-time clock functionality, where the PCA is clocked by an external source while the internal oscillator drives the system clock.

Each capture/compare module can be configured to operate in one of six modes: Edge-Triggered Capture, Software Timer, High Speed Output, 8- or 16-bit Pulse Width Modulator, or Frequency Output. Additionally, Capture/Compare Module 2 offers watchdog timer (WDT) capabilities. Following a system reset, Module 2 is configured and enabled in WDT mode. The PCA Capture/Compare Module I/O and External Clock Input may be routed to Port I/O via the Digital Crossbar.

Figure 1.13. PCA Block Diagram

## C8051F330/1/2/3/4/5

## 1.7. $\quad 10$-Bit Analog to Digital Converter

The C8051F330/2/4 devices include an on-chip 10-bit SAR ADC with a 16 -channel differential input multiplexer. With a maximum throughput of 200 ksps , the ADC offers true 10-bit linearity with an INL and DNL of $\pm 1$ LSB. The ADC system includes a configurable analog multiplexer that selects both positive and negative ADC inputs. Ports0-1 are available as an ADC inputs; additionally, the on-chip Temperature Sensor output and the power supply voltage ( $\mathrm{V}_{\mathrm{DD}}$ ) are available as ADC inputs. User firmware may shut down the ADC to save power.

Conversions can be started in six ways: a software command, an overflow of Timer $0,1,2$, or 3 , or an external convert start signal. This flexibility allows the start of conversion to be triggered by software events, a periodic signal (timer overflows), or external HW signals. Conversion completions are indicated by a status bit and an interrupt (if enabled). The resulting 10-bit data word is latched into the ADC data SFRs upon completion of a conversion.

Window compare registers for the ADC data can be configured to interrupt the controller when ADC data is either within or outside of a specified range. The ADC can monitor a key voltage continuously in background mode, but not interrupt the controller unless the converted data is within/outside the specified range.

Figure 1.14. 10-Bit ADC Block Diagram

## C8051F330/1/2/3/4/5

### 1.8. Comparators

C8051F330/1/2/3/4/5 devices include an on-chip voltage comparator that is enabled/disabled and configured via user software. Port I/O pins may be configured as comparator inputs via a selection mux. Two comparator outputs may be routed to a Port pin if desired: a latched output and/or an unlatched (asynchronous) output. Comparator response time is programmable, allowing the user to select between high-speed and low-power modes. Positive and negative hysteresis are also configurable.

Comparator interrupts may be generated on rising, falling, or both edges. When in IDLE mode, these interrupts may be used as a "wake-up" source. Comparator0 may also be configured as a reset source. Figure 1.15 shows the Comparator0 block diagram.

Figure 1.15. Comparator0 Block Diagram

## C8051F330/1/2/3/4/5

### 1.9. 10-bit Current Output DAC

The C8051F330 device includes a 10-bit current-mode Digital-to-Analog Converter (IDA0). The maximum current output of the IDAO can be adjusted for three different current settings; $0.5 \mathrm{~mA}, 1 \mathrm{~mA}$, and 2 mA . IDAO features a flexible output update mechanism which allows for seamless full-scale changes and supports jitter-free updates for waveform generation. Three update modes are provided, allowing IDA0 output updates on a write to IDAOH, on a Timer overflow, or on an external pin edge.

Figure 1.16. IDAO Functional Block Diagram

## 2. Absolute Maximum Ratings

Table 2.1. Absolute Maximum Ratings

| Parameter | Conditions | Min | Typ | Max | Units |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Ambient temperature under bias |  | -55 | - | 125 | ${ }^{\circ} \mathrm{C}$ |
| Storage Temperature |  | -65 | - | 150 | ${ }^{\circ} \mathrm{C}$ |
| Voltage on any Port I/O Pin or $\overline{\mathrm{RST}}$ with <br> respect to GND |  | -0.3 | - | 5.8 | V |
| Voltage on V ${ }_{\text {DD }}$ with respect to GND |  | -0.3 | - | 4.2 | V |
| Maximum Total current through VDD or GND |  | - | - | 500 | mA |
| Maximum output current sunk by $\overline{\mathrm{RST}}$ or any <br> Port pin |  | - | - | 100 | mA |

Note: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the devices at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

| Digital Supply Current (Stop Mode, shutdown) | Oscillator not running, $V_{\text {DD }}$ Monitor Disabled | - | < 0.1 | - | A |
| Notes: <br> 1. Given in Table 10.1 on page 102. <br> 2. SYSCLK must be at least 32 kHz to enable debugging. <br> 3. Based on device characterization data; Not production tested. <br> 4. IDD can be estimated for frequencies $<=15 \mathrm{MHz}$ by simply multiplying the frequency of interest by the frequency sensitivity number for that range. When using these numbers to estimate $\mathrm{I}_{\mathrm{DD}}$ for $>15 \mathrm{MHz}$, the estimate should be the current at 25 MHz minus the difference in current indicated by the frequency sensitivity number. For example: $\mathrm{V}_{\mathrm{DD}}=3.0 \mathrm{~V} ; \mathrm{F}=20 \mathrm{MHz}, \mathrm{I}_{\mathrm{DD}}=7.8 \mathrm{~mA}-(25 \mathrm{MHz}-$ $20 \mathrm{MHz})^{*} 0.21 \mathrm{~mA} / \mathrm{MHz}=6.75 \mathrm{~mA} .$ <br> 5. Idle IDD can be estimated for frequencies $<=1 \mathrm{MHz}$ by simply multiplying the frequency of interest by the frequency sensitivity number for that range. When using these numbers to estimate Idle $I_{D D}$ for $>1 \mathrm{MHz}$, the estimate should be the current at 25 MHz minus the difference in current indicated by the frequency sensitivity number. For example: $\mathrm{V}_{\mathrm{DD}}=3.0 \mathrm{~V} ; \mathrm{F}=5 \mathrm{MHz}$, Idle $\mathrm{I}_{\mathrm{DD}}=4.8 \mathrm{~mA}-(25 \mathrm{MHz}-$ $5 \mathrm{MHz}) * 0.15 \mathrm{~mA} / \mathrm{MHz}=1.8 \mathrm{~mA} .$ |  |  |  |  |  |

Other electrical characteristics tables are found in the data sheet section corresponding to the associated peripherals. For more information on electrical characteristics for a specific peripheral, refer to the page indicated in Table 3.2.

| E2 | 2.00 | 2.15 | 2.25 | Y | - | 0.18 | - |

## Notes:

1. All dimensions shown are in millimeters (mm) unless otherwise noted.
2. Dimensioning and Tolerancing per ANSI Y14.5M-1994.
3. This drawing conforms to the JEDEC Solid State Outline MO-220, variation VGGD except for custom features D2, E2, Z, Y, and L which are toleranced per supplier designation.
4. Recommended card reflow profile is per the JEDEC/IPC J-STD-020C specification for Small Body Components.

Figure 4.3. QFN-20 Recommended PCB Land Pattern

Table 4.3. QFN-20 PCB Land Pattern Dimesions

| Dimension | Min | Max | Dimension | Min | Max |
| :---: | :---: | :---: | :---: | :---: | :---: |
| C1 | 3.70 |  | X2 | 2.15 | 2.25 |
| C2 | 3.70 |  | Y1 | 0.90 | 1.00 |
| E | 0.50 |  | Y2 | 2.15 | 2.25 |
| X1 | 0.20 | 0.30 |  |  |  |

## Notes:

General

1. All dimensions shown are in millimeters ( mm ) unless otherwise noted.
2. Dimensioning and Tolerancing is per the ANSI Y14.5M-1994 specification.
3. This Land Pattern Design is based on the IPC-7351 guidelines.

## Solder Mask Design

4. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be $60 \mu \mathrm{~m}$ minimum, all the way around the pad.

Stencil Design
5. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
6. The stencil thickness should be 0.125 mm ( 5 mils).
7. The ratio of stencil aperture to land pad size should be $1: 1$ for all perimeter pins.
8. A $2 \times 2$ array of 0.95 mm openings on a 1.1 mm pitch should be used for the center pad to assure the proper paste volume (71\% Paste Coverage).

Card Assembly
9. A No-Clean, Type-3 solder paste is recommended.
10. The recommended card reflow profile is per the JEDEC/IPC J-STD-020 specification for Small Body Components.

## C8051F330/1/2/3/4/5

## C8051F330/1/2/3/4/5

## 5. 10-Bit ADC (ADC0, C8051F330/2/4 only)

The ADC0 subsystem for the C8051F330/2/4 consists of two analog multiplexers (referred to collectively as AMUXO) with 16 total input selections, and a 200 ksps , 10-bit successive-approximation-register ADC with integrated track-and-hold and programmable window detector. The AMUXO, data conversion modes, and window detector are all configurable under software control via the Special Function Registers shown in Figure 5.1. ADCO operates in both Single-ended and Differential modes, and may be configured to measure Ports0-1, the Temperature Sensor output, or $\mathrm{V}_{\text {DD }}$ with respect to Ports0-1 or GND. The ADC0 subsystem is enabled only when the ADOEN bit in the ADCO Control register (ADCOCN) is set to logic 1 . The ADCO subsystem is in low power shutdown when this bit is logic 0 .

Figure 5.1. ADC0 Functional Block Diagram

### 5.1. Analog Multiplexer

AMUXO selects the positive and negative inputs to the ADC. Any of the following may be selected as the positive input: Ports0-1, the on-chip temperature sensor, or the positive power supply ( $\mathrm{V}_{\mathrm{DD}}$ ). Any of the following may be selected as the negative input: Ports0-1, $\mathrm{V}_{\text {REF, }}$ or GND. When GND is selected as the negative input, ADCO operates in Single-ended Mode; all other times, ADC0 operates in Differential Mode. The ADCO input channels are selected in the AMXOP and AMXON registers as described in SFR Definition 5.1 and SFR Definition 5.2.

The conversion code format differs between Single-ended and Differential modes. The registers ADCOH and ADCOL contain the high and low bytes of the output conversion code from the ADC at the completion of each conversion. Data can be right-justified or left-justified, depending on the setting of the ADOLJST. When in Single-ended Mode, conversion codes are represented as 10 -bit unsigned integers. Inputs are

## C8051F330/1/2/3/4/5

measured from '0' to VREF x 1023/1024. Example codes are shown below for both right-justified and leftjustified data. Unused bits in the ADCOH and ADCOL registers are set to '0'.

| Input Voltage | Right-Justified ADCOH:ADCOL <br> (ADOLJST = 0) | Left-Justified ADC0H:ADCOL <br> (ADOLJST = 1) |
| :---: | :---: | :---: |
| VREF $\times 1023 / 1024$ | $0 \times 03 F F$ | $0 \times F F C 0$ |
| VREF $\times 512 / 1024$ | $0 \times 0200$ | $0 \times 8000$ |
| VREF $\times 256 / 1024$ | $0 \times 0100$ | $0 \times 4000$ |
| 0 | $0 \times 0000$ | $0 \times 0000$ |

When in Differential Mode, conversion codes are represented as 10-bit signed 2's complement numbers. Inputs are measured from -VREF to VREF x 511/512. Example codes are shown below for both right-justified and left-justified data. For right-justified data, the unused MSBs of ADCOH are a sign-extension of the data word. For left-justified data, the unused LSBs in the ADCOL register are set to ' 0 '.

| Input Voltage | Right-Justified ADC0H:ADCOL <br> (ADOLJST = 0) | Left-Justified ADC0H:ADC0L <br> (AD0LJST = 1) |
| :---: | :---: | :---: |
| VREF $\times 511 / 512$ | $0 \times 01 F F$ | $0 \times 7 F C 0$ |
| VREF $\times 256 / 512$ | $0 \times 0100$ | $0 \times 4000$ |
| 0 | $0 \times 0000$ | $0 \times 0000$ |
| - VREF $\times 256 / 512$ | $0 \times F F 00$ | $0 \times C 000$ |
| - VREF | $0 \times F E 00$ | $0 \times 8000$ |

Important Note About ADCO Input Configuration: Port pins selected as ADC0 inputs should be configured as analog inputs, and should be skipped by the Digital Crossbar. To configure a Port pin for analog input, set to ' 0 ' the corresponding bit in register PnMDIN (for $n=0,1$ ). To force the Crossbar to skip a Port pin, set to ' 1 ' the corresponding bit in register PnSKIP (for $\mathrm{n}=0,1$ ). See Section "14. Port Input/Output" on page 123 for more Port I/O configuration details.

### 5.2. Temperature Sensor

The typical temperature sensor transfer function is shown in Figure 5.2. The output voltage $\left(\mathrm{V}_{\text {TEMP }}\right)$ is the positive ADC input when the temperature sensor is selected by bits AMXOP4-0 in register AMXOP.

## C8051F330/1/2/3/4/5

Figure 5.2. Typical Temperature Sensor Transfer Function

### 5.3. Modes of Operation

ADC0 has a maximum conversion speed of 200 ksps . The ADC0 conversion clock is a divided version of the system clock, determined by the ADOSC bits in the ADCOCF register (system clock divided by (ADOSC +1 ) for $0 \leq$ ADOSC $\leq 31$ ).

## C8051F330/1/2/3/4/5

### 5.3.1. Starting a Conversion

A conversion can be initiated in one of six ways, depending on the programmed states of the ADCO Start of Conversion Mode bits (ADOCM2-0) in register ADCOCN. Conversions may be initiated by one of the following:

1. Writing a ' 1 ' to the ADOBUSY bit of register ADCOCN
2. A Timer 0 overflow (i.e., timed continuous conversions)
3. A Timer 2 overflow
4. A Timer 1 overflow
5. A rising edge on the CNVSTR input signal (pin P0.6)
6. A Timer 3 overflow

Writing a ' 1 ' to ADOBUSY provides software control of ADC0 whereby conversions are performed "ondemand". During conversion, the ADOBUSY bit is set to logic 1 and reset to logic 0 when the conversion is complete. The falling edge of ADOBUSY triggers an interrupt (when enabled) and sets the ADCO interrupt flag (ADOINT). Note: When polling for ADC conversion completions, the ADC0 interrupt flag (ADOINT) should be used. Converted data is available in the ADCO data registers, ADCOH:ADCOL, when bit ADOINT is logic 1. Note that when Timer 2 or Timer 3 overflows are used as the conversion source, Low Byte overflows are used if Timer $2 / 3$ is in 8 -bit mode; High byte overflows are used if Timer $2 / 3$ is in 16 -bit mode. See Section "18. Timers" on page 177 for timer configuration.

Important Note About Using CNVSTR: The CNVSTR input pin also functions as Port pin P0.6. When the CNVSTR input is used as the ADC0 conversion source, Port pin P0.6 should be skipped by the Digital Crossbar. To configure the Crossbar to skip P0.6, set to '1’ Bit6 in register POSKIP. See Section "14. Port Input/Output" on page $\mathbf{1 2 3}$ for details on Port I/O configuration.

## C8051F330/1/2/3/4/5

### 5.3.2. Tracking Modes

Each ADC0 conversion must be preceded by a minimum tracking time in order for the converted result to be accurate. The minimum tracking time is given in Table 5.1. The ADOTM bit in register ADC0CN controls the ADC0 track-and-hold mode. In its default state, the ADC0 input is continuously tracked, except when a conversion is in progress. When the ADOTM bit is logic 1, ADC0 operates in low-power track-and-hold mode. In this mode, each conversion is preceded by a tracking period of 3 SAR clocks (after the start-ofconversion signal). When the CNVSTR signal is used to initiate conversions in low-power tracking mode, ADCO tracks only when CNVSTR is low; conversion begins on the rising edge of CNVSTR (see Figure 5.3). Tracking can also be disabled (shutdown) when the device is in low power standby or sleep modes. Low-power track-and-hold mode is also useful when AMUX settings are frequently changed, due to the settling time requirements described in Section "5.3.3. Settling Time Requirements" on page 46.

Figure 5.3. 10-Bit ADC Track and Conversion Example Timing

## C8051F330/1/2/3/4/5

### 5.3.3. Settling Time Requirements

When the ADCO input configuration is changed (i.e., a different AMUXO selection is made), a minimum tracking time is required before an accurate conversion can be performed. This tracking time is determined by the AMUXO resistance, the ADC0 sampling capacitance, any external source resistance, and the accuracy required for the conversion. Note that in low-power tracking mode, three SAR clocks are used for tracking at the start of every conversion. For most applications, these three SAR clocks will meet the minimum tracking time requirements.

Figure 5.4 shows the equivalent ADC0 input circuits for both Differential and Single-ended modes. Notice that the equivalent time constant for both input circuits is the same. The required ADC0 settling time for a given settling accuracy (SA) may be approximated by Equation 5.1. When measuring the Temperature Sensor output or $V_{D D}$ with respect to $G N D, R_{\text {TOTAL }}$ reduces to $R_{M U X}$. See Table 5.1 for ADC0 minimum settling time requirements.

$$
t=\ln \left(\frac{2^{n}}{S A}\right) \times R_{\text {TOTAL }} C_{S A M P L E}
$$

## Equation 5.1. ADCO Settling Time Requirements

Where:
SA is the settling accuracy, given as a fraction of an LSB (for example, 0.25 to settle within $1 / 4$ LSB) $t$ is the required settling time in seconds
$R_{\text {TOTAL }}$ is the sum of the AMUXO resistance and any external source resistance.
$n$ is the ADC resolution in bits (10).

Single-Ended Mode

### 5.4. Programmable Window Detector

The ADC Programmable Window Detector continuously compares the ADC0 output registers to user-programmed limits, and notifies the system when a desired condition is detected. This is especially effective in an interrupt-driven system, saving code space and CPU bandwidth while delivering faster system response times. The window detector interrupt flag (ADOWINT in register ADCOCN) can also be used in polled mode. The ADC0 Greater-Than (ADCOGTH, ADCOGTL) and Less-Than (ADCOLTH, ADCOLTL) registers hold the comparison values. The window detector flag can be programmed to indicate when measured data is inside or outside of the user-programmed limits, depending on the contents of the ADC0 Less-Than and ADCO Greater-Than registers.

### 5.4.1. Window Detector In Single-Ended Mode

Figure 5.5 shows two example window comparisons for right-justified, single-ended data, with ADCOLTH:ADCOLTL = 0x0080 (128d) and ADC0GTH:ADC0GTL = 0x0040 (64d). In single-ended mode, the input voltage can range from ' 0 ' to VREF $\times(1023 / 1024$ ) with respect to GND, and is represented by a 10 -bit unsigned integer value. In the left example, an ADOWINT interrupt will be generated if the ADC0 conversion word (ADCOH:ADCOL) is within the range defined by ADCOGTH:ADCOGTL and ADCOLTH:ADCOLTL (if $0 x 0040$ < ADCOH:ADCOL < 0x0080). In the right example, and ADOWINT interrupt will be generated if the ADCO conversion word is outside of the range defined by the ADCOGT and ADCOLT registers (if ADCOH:ADCOL < $0 x 0040$ or ADCOH:ADCOL > 0x0080). Figure 5.6 shows an example using left-justified data with the same comparison values.

### 5.4.2. Window Detector In Differential Mode

Figure 5.7 shows two example window comparisons for right-justified, differential data, with ADC0LTH:ADC0LTL = 0x0040 (+64d) and ADC0GTH:ADC0GTH = 0xFFFF ( -1 d ). In differential mode, the measurable voltage between the input pins is between -VREF and VREF x (511/512). Output codes are represented as 10-bit 2 s complement signed integers. In the left example, an ADOWINT interrupt will be generated if the ADC0 conversion word (ADCOH:ADCOL) is within the range defined by ADC0GTH:ADC0GTL and ADC0LTH:ADCOLTL (if 0xFFFF (-1d) < ADCOH:ADCOL < 0x0040 (64d)). In the right example, an ADOWINT interrupt will be generated if the ADCO conversion word is outside of the range defined by the ADCOGT and ADCOLT registers (if ADCOH:ADCOL < 0xFFFF ( -1 d ) or ADCOH:ADCOL > $0 \times 0040$ (+64d)). Figure 5.8 shows an example using left-justified data with the same comparison values.

## 6. 10-Bit Current Mode DAC (IDA0, C8051F330 only)

The C8051F330 device includes a 10-bit current-mode Digital-to-Analog Converter (IDAC). The maximum current output of the IDAC can be adjusted for three different current settings; $0.5 \mathrm{~mA}, 1 \mathrm{~mA}$, and 2 mA . The IDAC is enabled or disabled with the IDAOEN bit in the IDAO Control Register (see SFR Definition 6.1). When IDAOEN is set to ' 0 ', the IDAC port pin (P0.1) behaves as a normal GPIO pin. When IDAOEN is set to ' 1 ', the digital output drivers and weak pullup for the IDAC pin are automatically disabled, and the pin is connected to the IDAC output. An internal bandgap bias generator is used to generate a reference current for the IDAC whenever it is enabled. When using the IDAC, bit 1 in the POSKIP register should be set to ' 1 ', to force the Crossbar to skip the IDAC pin.

### 6.1. IDAO Output Scheduling

IDAO features a flexible output update mechanism which allows for seamless full-scale changes and supports jitter-free updates for waveform generation. Three update modes are provided, allowing IDAC output updates on a write to IDAOH, on a Timer overflow, or on an external pin edge.

### 6.1.1. Update Output On-Demand

In its default mode (IDAOCN.[6:4] = '111') the IDAO output is updated "on-demand" on a write to the highbyte of the IDAO data register (IDAOH). It is important to note that writes to IDAOL are held in this mode, and have no effect on the IDAO output until a write to IDAOH takes place. If writing a full 10-bit word to the IDAC data registers, the 10-bit data word is written to the low byte (IDAOL) and high byte (IDAOH) data registers. Data is latched into IDAO after a write to the IDAOH register, so the write sequence should be IDAOL followed by IDAOH if the full 10-bit resolution is required. The IDAC can be used in 8 -bit mode by initializing IDAOL to the desired value (typically 0x00), and writing data to only IDAOH (see Section 6.2 for information on the format of the 10-bit IDAC data word within the 16 -bit SFR space).

Figure 6.1. IDA0 Functional Block Diagram

## C8051F330/1/2/3/4/5

### 6.1.2. Update Output Based on Timer Overflow

Similar to the ADC operation, in which an ADC conversion can be initiated by a timer overflow independently of the processor, the IDAC outputs can use a Timer overflow to schedule an output update event. This feature is useful in systems where the IDAC is used to generate a waveform of a defined sampling rate by eliminating the effects of variable interrupt latency and instruction execution on the timing of the IDAC output. When the IDA0CM bits (IDA0CN.[6:4]) are set to '000', '001', '010' or '011', writes to both IDAC data registers (IDAOL and IDAOH) are held until an associated Timer overflow event (Timer 0, Timer 1, Timer 2 or Timer 3, respectively) occurs, at which time the IDAOH:IDAOL contents are copied to the IDAC input latches, allowing the IDAC output to change to the new value.

### 6.1.3. Update Output Based on CNVSTR Edge

The IDAC output can also be configured to update on a rising edge, falling edge, or both edges of the external CNVSTR signal. When the IDA0CM bits (IDA0CN.[6:4]) are set to '100', '101', or '110', writes to both IDAC data registers (IDAOL and IDAOH) are held until an edge occurs on the CNVSTR input pin. The particular setting of the IDAOCM bits determines whether IDAC outputs are updated on rising, falling, or both edges of CNVSTR. When a corresponding edge occurs, the IDAOH:IDAOL contents are copied to the IDAC input latches, allowing the IDAC output to change to the new value.

### 6.2. IDAC Output Mapping

The IDAC data registers (IDAOH and IDAOL) are left-justified, meaning that the eight MSBs of the IDAC output word are mapped to bits 7-0 of the IDAOH register, and the two LSBs of the IDAC output word are mapped to bits 7 and 6 of the IDAOL register. The data word mapping for the IDAC is shown in Figure 6.2.

# C8051F330/1/2/3/4/5 

## 7. Voltage Reference (C8051F330/2/4 only)

The Voltage reference MUX on the C8051F330/2/4 devices is configurable to use an externally connected voltage reference, the internal reference voltage generator, or the $\mathrm{V}_{\mathrm{DD}}$ power supply voltage (see Figure 7.1). The REFSL bit in the Reference Control register (REFOCN) selects the reference source. For an external source or the internal reference, REFSL should be set to ' 0 '. To use $V_{D D}$ as the reference source, REFSL should be set to ' 1 '.

The BIASE bit enables the internal voltage bias generator, which is used by the ADC, Temperature Sensor, internal oscillators, and Current DAC. This bias is enabled when any of the aforementioned peripherals are enabled. The bias generator may be enabled manually by writing a ' 1 ' to the BIASE bit in register REFOCN; see SFR Definition 7.1 for REFOCN register details. The electrical specifications for the voltage reference circuit are given in Table 7.1.

The internal voltage reference circuit consists of a 1.2 V , temperature stable bandgap voltage reference generator and a gain-of-two output buffer amplifier. The internal voltage reference can be driven out on the VREF pin by setting the REFBE bit in register REFOCN to a '1' (see SFR Definition 7.1). The maximum load seen by the VREF pin must be less than $200 \mu \mathrm{~A}$ to GND. When using the internal voltage reference, bypass capacitors of $0.1 \mu \mathrm{~F}$ and $4.7 \mu \mathrm{~F}$ are recommended from the VREF pin to GND. If the internal reference is not used, the REFBE bit should be cleared to ' 0 '. Electrical specifications for the internal voltage reference are given in Table 7.1.

Important Note about the VREF Pin: Port pin P0.0 is used as the external VREF input and as an output for the internal VREF. When using either an external voltage reference or the internal reference circuitry, PO.0 should be configured as an analog pin, and skipped by the Digital Crossbar. To configure P0.0 as an analog pin, set to ' 0 ' Bit0 in register POMDIN. To configure the Crossbar to skip P0.0, set Bit 0 in register POSKIP to ' 1 '. Refer to Section "14. Port Input/Output" on page 123 for complete Port I/O configuration details. The TEMPE bit in register REFOCN enables/disables the temperature sensor. While disabled, the temperature sensor defaults to a high impedance state and any ADCO measurements performed on the sensor result in meaningless data.

## C8051F330/1/2/3/4/5

## 8. Comparator0

C8051F330/1/2/3/4/5 devices include an on-chip programmable voltage comparator, Comparator0, shown in Figure 8.1.

The Comparator offers programmable response time and hysteresis, an analog input multiplexer, and two outputs that are optionally available at the Port pins: a synchronous "latched" output (CPO), or an asynchronous "raw" output (CPOA). The asynchronous CPOA signal is available even when in when the system clock is not active. This allows the Comparator to operate and generate an output with the device in STOP mode. When assigned to a Port pin, the Comparator output may be configured as open drain or push-pull (see Section "14.2. Port I/O Initialization" on page 127). Comparator0 may also be used as a reset source (see Section "10.5. Comparator0 Reset" on page 100).

The Comparator0 inputs are selected in the CPTOMX register (SFR Definition 8.2). The CMXOP1-CMXOPO bits select the Comparator0 positive input; the CMXON1-CMXONO bits select the Comparator0 negative input. Important Note About Comparator Inputs: The Port pins selected as comparator inputs should be configured as analog inputs in their associated Port configuration register, and configured to be skipped by the Crossbar (for details on Port configuration, see Section "14.3. General Purpose Port I/O" on page 129).

Figure 8.1. Comparator0 Functional Block Diagram

## C8051F330/1/2/3/4/5

The Comparator output can be polled in software, used as an interrupt source, and/or routed to a Port pin. When routed to a Port pin, the Comparator output is available asynchronous or synchronous to the system clock; the asynchronous output is available even in STOP mode (with no system clock active). When disabled, the Comparator output (if assigned to a Port I/O pin via the Crossbar) defaults to the logic low state, and its supply current falls to less than 100 nA . See Section "14.1. Priority Crossbar Decoder" on page 125 for details on configuring Comparator outputs via the digital Crossbar. Comparator inputs can be externally driven from -0.25 V to (VDD) +0.25 V without damage or upset. The complete Comparator electrical specifications are given in Table 8.1.

The Comparator response time may be configured in software via the CPTOMD register (see SFR Definition 8.3). Selecting a longer response time reduces the Comparator supply current. See Table 8.1 for complete timing and power consumption specifications.

Figure 8.2. Comparator Hysteresis Plot

The Comparator hysteresis is software-programmable via its Comparator Control register CPTOCN. The user can program both the amount of hysteresis voltage (referred to the input voltage) and the positive and negative-going symmetry of this hysteresis around the threshold voltage.

The Comparator hysteresis is programmed using Bits3-0 in the Comparator Control Register CPT0CN (shown in SFR Definition 8.1). The amount of negative hysteresis voltage is determined by the settings of the CPOHYN bits. As shown in Figure 8.2, settings of 20,10 or 5 mV of negative hysteresis can be programmed, or negative hysteresis can be disabled. In a similar way, the amount of positive hysteresis is determined by the setting the CPOHYP bits.

Comparator interrupts can be generated on both rising-edge and falling-edge output transitions. (For Interrupt enable and priority control, see Section "8.3. Interrupt Handler" on page 58). The CP0FIF flag is set to

## C8051F330/1/2/3/4/5

logic 1 upon a Comparator falling-edge occurrence, and the CPORIF flag is set to logic 1 upon the Comparator rising-edge occurrence. Once set, these bits remain set until cleared by software. The Comparator rising-edge interrupt mask is enabled by setting CPORIE to a logic 1. The Comparator0 falling-edge interrupt mask is enabled by setting CPOFIE to a logic 1.

The output state of the Comparator can be obtained at any time by reading the CPOOUT bit. The Comparator is enabled by setting the CPOEN bit to logic 1, and is disabled by clearing this bit to logic 0 .

Note that false rising edges and falling edges can be detected when the comparator is first powered on or if changes are made to the hysteresis or response time control bits. Therefore, it is recommended that the rising-edge and falling-edge flags be explicitly cleared to logic 0 a short time after the comparator is enabled or its mode bits have been changed. This Power Up Time is specified in Table 8.1 on page 70.

## C8051F330/1/2/3/4/5

## 9. CIP-51 Microcontroller

The MCU system controller core is the CIP-51 microcontroller. The CIP-51 is fully compatible with the MCS-51 ${ }^{\text {TM }}$ instruction set; standard $803 x / 805 x$ assemblers and compilers can be used to develop software. The MCU family has a superset of all the peripherals included with a standard 8051. Included are four 16-bit counter/timers (see description in Section 18), an enhanced full-duplex UART (see description in Section 16), an Enhanced SPI (see description in Section 17), 256 bytes of internal RAM, 128 byte Special Function Register (SFR) address space (Section 9.2.6), and 17 Port I/O (see description in Section 14). The CIP-51 also includes on-chip debug hardware (see description in Section 20), and interfaces directly with the analog and digital subsystems providing a complete data acquisition or control-system solution in a single integrated circuit.

The CIP-51 Microcontroller core implements the standard 8051 organization and peripherals as well as additional custom peripherals and functions to extend its capability (see Figure 9.1 for a block diagram). The CIP-51 includes the following features:

- Fully Compatible with MCS-51 Instruction Set
- 25 MIPS Peak Throughput with 25 MHz Clock
- 0 to 25 MHz Clock Frequency
- 256 Bytes of Internal RAM
- 17 Port I/O
- Extended Interrupt Handler
- Reset Input
- Power Management Modes

## Performance

The CIP-51 employs a pipelined architecture that greatly increases its instruction throughput over the standard 8051 architecture. In a standard 8051, all instructions except for MUL and DIV take 12 or 24 system clock cycles to execute, and usually have a maximum system clock of 12 MHz . By contrast, the CIP-51 core executes $70 \%$ of its instructions in one or two system clock cycles, with no instructions taking more than eight system clock cycles.

Figure 9.1. CIP-51 Block Diagram

## C8051F330/1/2/3/4/5

With the CIP-51's maximum system clock at 25 MHz , it has a peak throughput of 25 MIPS. The CIP-51 has a total of 109 instructions. The table below shows the total number of instructions that require each execution time.

| Clocks to Execute | 1 | 2 | $2 / 3$ | 3 | $3 / 4$ | 4 | $4 / 5$ | 5 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Number of Instructions | 26 | 50 | 5 | 14 | 7 | 3 | 1 | 2 | 1 |

## Programming and Debugging Support

In-system programming of the Flash program memory and communication with on-chip debug support logic is accomplished via the Silicon Labs 2-Wire Development Interface (C2). Note that the re-programmable Flash can also be read and changed a single byte at a time by the application software using the MOVC and MOVX instructions. This feature allows program memory to be used for non-volatile data storage as well as updating program code under software control.

The on-chip debug support logic facilitates full speed in-circuit debugging, allowing the setting of hardware breakpoints, starting, stopping and single stepping through program execution (including interrupt service routines), examination of the program's call stack, and reading/writing the contents of registers and memory. This method of on-chip debugging is completely non-intrusive, requiring no RAM, Stack, timers, or other on-chip resources. C2 details can be found in Section "20. C2 Interface" on page 209.

The CIP-51 is supported by development tools from Silicon Labs and third party vendors. Silicon Labs provides an integrated development environment (IDE) including editor, macro assembler, debugger and programmer. The IDE's debugger and programmer interface to the CIP-51 via the C2 interface to provide fast and efficient in-system device programming and debugging. Third party macro assemblers and C compilers are also available.

### 9.1. Instruction Set

The instruction set of the CIP-51 System Controller is fully compatible with the standard MCS-51 ${ }^{\text {TM }}$ instruction set. Standard 8051 development tools can be used to develop software for the CIP-51. All CIP-51 instructions are the binary and functional equivalent of their MCS-51 ${ }^{\text {TM }}$ counterparts, including opcodes, addressing modes and effect on PSW flags. However, instruction timing is different than that of the standard 8051.

### 9.1.1. Instruction and CPU Timing

In many 8051 implementations, a distinction is made between machine cycles and clock cycles, with machine cycles varying from 2 to 12 clock cycles in length. However, the CIP- 51 implementation is based solely on clock cycle timing. All instruction timings are specified in terms of clock cycles.

Due to the pipelined architecture of the CIP-51, most instructions execute in the same number of clock cycles as there are program bytes in the instruction. Conditional branch instructions take one less clock cycle to complete when the branch is not taken as opposed to when the branch is taken. Table 9.1 is the CIP-51 Instruction Set Summary, which includes the mnemonic, number of bytes, and number of clock cycles for each instruction.

### 9.1.2. MOVX Instruction and Program Memory

The MOVX instruction is typically used to access external data memory (Note: the C8051F330/1/2/3/4/5 does not support off-chip data or program memory). In the CIP-51, the MOVX instruction can be used to access on-chip XRAM or on-chip program memory space implemented as re-programmable Flash memory. The Flash access feature provides a mechanism for the CIP-51 to update program code and use the

## C8051F330/1/2/3/4/5

program memory space for non-volatile data storage. Refer to Section "11. Flash Memory" on page 103 for further details.

Table 9.1. CIP-51 Instruction Set Summary

| Mnemonic | Description | Bytes | Clock Cycles |
| :---: | :---: | :---: | :---: |
| Arithmetic Operations |  |  |  |
| ADD A, Rn | Add register to A | 1 | 1 |

## C8051F330/1/2/3/4/5

## Notes on Registers, Operands and Addressing Modes:

Rn - Register R0-R7 of the currently selected register bank.
@Ri - Data RAM location addressed indirectly through R0 or R1.
rel - 8-bit, signed (two's complement) offset relative to the first byte of the following instruction. Used by SJMP and all conditional jumps.
direct - 8-bit internal data location's address. This could be a direct-access Data RAM location ( $0 \times 00-0 \times 7 \mathrm{~F}$ ) or an SFR ( $0 \times 80-0 \times \mathrm{FF}$ ).
\#data - 8-bit constant
\#data16-16-bit constant
bit - Direct-accessed bit in Data RAM or SFR
addr11-11-bit destination address used by ACALL and AJMP. The destination must be within the same 2 kB page of program memory as the first byte of the following instruction.
addr16-16-bit destination address used by LCALL and LJMP. The destination may be anywhere within the 8 kB program memory space.

There is one unused opcode (0xA5) that performs the same function as NOP.
All mnemonics copyrighted © Intel Corporation 1980.

### 9.2. Memory Organization

The memory organization of the CIP-51 System Controller is similar to that of a standard 8051. There are two separate memory spaces: program memory and data memory. Program and data memory share the same address space but are accessed via different instruction types. The CIP-51 memory organization is shown in Figure 9.2

## C8051F330/1/2/3/4/5

Figure 9.2. Memory Map

### 9.2.1. Program Memory

The CIP-51 core has a 64 kB program memory space. The C8051F330/1 implements 8 kB of this program memory space as in-system, re-programmable Flash memory, organized in a contiguous block from addresses $0 \times 0000$ to $0 \times 1$ DFF. Addresses above 0x1DFF are reserved on the 8 kB devices. The C8051F332/3 and C8051F334/5 implement, in contiguous blocks, 2 and 4 kB , from addresses $0 \times 0000$ to 0x07FF or $0 \times 0000$ to $0 \times 0 F F F$, respectively. Addresses above $0 \times 0800$ and $0 \times 1000$ are reserved on the 2 and 4 kB devices, respectively.

Program memory is normally assumed to be read-only. However, the CIP-51 can write to program memory by setting the Program Store Write Enable bit (PSCTL.0) and using the MOVX write instruction. This feature provides a mechanism for the CIP-51 to update program code and use the program memory space for non-volatile data storage. Refer to Section "11. Flash Memory" on page 103 for further details.

## C8051F330/1/2/3/4/5

### 9.2.2. Data Memory

The CIP-51 includes 256 bytes of internal RAM mapped into the data memory space from $0 \times 00$ through $0 x F F$. The lower 128 bytes of data memory are used for general purpose registers and scratch pad memory. Either direct or indirect addressing may be used to access the lower 128 bytes of data memory. Locations $0 \times 00$ through $0 \times 1 \mathrm{~F}$ are addressable as four banks of general purpose registers, each bank consisting of eight byte-wide registers. The next 16 bytes, locations $0 \times 20$ through $0 \times 2 F$, may either be addressed as bytes or as 128 bit locations accessible with the direct addressing mode.

The upper 128 bytes of data memory are accessible only by indirect addressing. This region occupies the same address space as the Special Function Registers (SFR) but is physically separate from the SFR space. The addressing mode used by an instruction when accessing locations above 0x7F determines whether the CPU accesses the upper 128 bytes of data memory space or the SFRs. Instructions that use direct addressing will access the SFR space. Instructions using indirect addressing above 0x7F access the upper 128 bytes of data memory. Figure 9.2 illustrates the data memory organization of the CIP-51.

### 9.2.3. General Purpose Registers

The lower 32 bytes of data memory, locations $0 \times 00$ through $0 \times 1 \mathrm{~F}$, may be addressed as four banks of gen-eral-purpose registers. Each bank consists of eight byte-wide registers designated RO through R7. Only one of these banks may be enabled at a time. Two bits in the program status word, RS0 (PSW.3) and RS1 (PSW.4), select the active register bank (see description of the PSW in SFR Definition 9.4). This allows fast context switching when entering subroutines and interrupt service routines. Indirect addressing modes use registers R0 and R1 as index registers.

### 9.2.4. Bit Addressable Locations

In addition to direct access to data memory organized as bytes, the sixteen data memory locations at $0 \times 20$ through $0 \times 2 \mathrm{~F}$ are also accessible as 128 individually addressable bits. Each bit has a bit address from $0 \times 00$ to $0 \times 7$ F. Bit 0 of the byte at $0 \times 20$ has bit address $0 \times 00$ while bit 7 of the byte at $0 \times 20$ has bit address $0 \times 07$. Bit 7 of the byte at $0 \times 2 \mathrm{~F}$ has bit address $0 \times 7 \mathrm{~F}$. A bit access is distinguished from a full byte access by the type of instruction used (bit source or destination operands as opposed to a byte source or destination).

The MCS-51 ${ }^{\text {TM }}$ assembly language allows an alternate notation for bit addressing of the form XX.B where $X X$ is the byte address and $B$ is the bit position within the byte. For example, the instruction:

MOV C, 22.3h
moves the Boolean value at $0 \times 13$ (bit 3 of the byte at location $0 \times 22$ ) into the Carry flag.

### 9.2.5. Stack

A programmer's stack can be located anywhere in the 256-byte data memory. The stack area is designated using the Stack Pointer (SP, 0x81) SFR. The SP will point to the last location used. The next value pushed on the stack is placed at $\mathrm{SP}+1$ and then SP is incremented. A reset initializes the stack pointer to location $0 \times 07$. Therefore, the first value pushed on the stack is placed at location $0 \times 08$, which is also the first register (R0) of register bank 1. Thus, if more than one register bank is to be used, the SP should be initialized to a location in the data memory not being used for data storage. The stack depth can extend up to 256 bytes.

# C8051F330/1/2/3/4/5 

### 9.2.6. Special Function Registers

The direct-access data memory locations from 0x80 to 0xFF constitute the special function registers (SFRs). The SFRs provide control and data exchange with the CIP-51's resources and peripherals. The CIP-51 duplicates the SFRs found in a typical 8051 implementation as well as implementing additional SFRs used to configure and access the sub-systems unique to the MCU. This allows the addition of new functionality while retaining compatibility with the MCS-51 ${ }^{\text {TM }}$ instruction set. Table 9.2 lists the SFRs implemented in the CIP-51 System Controller.

The SFR registers are accessed anytime the direct addressing mode is used to access memory locations from $0 \times 80$ to $0 x F F$. SFRs with addresses ending in $0 \times 0$ or $0 \times 8$ (e.g. P0, TCON, SCONO, IE, etc.) are bitaddressable as well as byte-addressable. All other SFRs are byte-addressable only. Unoccupied addresses in the SFR space are reserved for future use. Accessing these areas will have an indeterminate effect and should be avoided. Refer to the corresponding pages of the data sheet, as indicated in Table 9.3, for a detailed description of each register.

## C8051F330/1/2/3/4/5

### 9.2.7. Register Descriptions

Following are descriptions of SFRs related to the operation of the CIP-51 System Controller. Reserved bits should not be set to logic I. Future product versions may use these bits to implement new features in which case the reset value of the bit will be logic 0 , selecting the feature's default state. Detailed descriptions of the remaining SFRs are included in the sections of the datasheet associated with their corresponding system function.

### 9.3. Interrupt Handler

The CIP-51 includes an extended interrupt system supporting a total of 13 interrupt sources with two priority levels. The allocation of interrupt sources between on-chip peripherals and external inputs pins varies according to the specific version of the device. Each interrupt source has one or more associated interruptpending flag(s) located in an SFR. When a peripheral or external source meets a valid interrupt condition, the associated interrupt-pending flag is set to logic 1.
If interrupts are enabled for the source, an interrupt request is generated when the interrupt-pending flag is set. As soon as execution of the current instruction is complete, the CPU generates an LCALL to a predetermined address to begin execution of an interrupt service routine (ISR). Each ISR must end with an RETI instruction, which returns program execution to the next instruction that would have been executed if the interrupt request had not occurred. If interrupts are not enabled, the interrupt-pending flag is ignored by the hardware and program execution continues as normal. (The interrupt-pending flag is set to logic 1 regardless of the interrupt's enable/disable state.)
Each interrupt source can be individually enabled or disabled through the use of an associated interrupt enable bit in an SFR (IE-EIE1). However, interrupts must first be globally enabled by setting the EA bit (IE.7) to logic 1 before the individual interrupt enables are recognized. Setting the EA bit to logic 0 disables all interrupt sources regardless of the individual interrupt-enable settings.
Note: Any instruction that clears the EA bit should be immediately followed by an instruction that has two or more opcode bytes. For example:

```
// in 'C':
EA = 0; // clear EA bit.
```

## C8051F330/1/2/3/4/5

```
EA = 0; // this is a dummy instruction with two-byte opcode.
; in assembly:
CLR EA ; clear EA bit.
CLR EA ; this is a dummy instruction with two-byte opcode.
```

If an interrupt is posted during the execution phase of a "CLR EA" opcode (or any instruction which clears the EA bit), and the instruction is followed by a single-cycle instruction, the interrupt may be taken. However, a read of the EA bit will return a ' 0 ' inside the interrupt service routine. When the "CLR EA" opcode is followed by a multi-cycle instruction, the interrupt will not be taken.
Some interrupt-pending flags are automatically cleared by the hardware when the CPU vectors to the ISR. However, most are not cleared by the hardware and must be cleared by software before returning from the ISR. If an interrupt-pending flag remains set after the CPU completes the return-from-interrupt (RETI) instruction, a new interrupt request will be generated immediately and the CPU will re-enter the ISR after the completion of the next instruction.

### 9.3.1. MCU Interrupt Sources and Vectors

The MCUs support 13 interrupt sources. Software can simulate an interrupt by setting any interrupt-pending flag to logic 1. If interrupts are enabled for the flag, an interrupt request will be generated and the CPU will vector to the ISR address associated with the interrupt-pending flag. MCU interrupt sources, associated vector addresses, priority order and control bits are summarized in Table 9.4 on page 88. Refer to the datasheet section associated with a particular on-chip peripheral for information regarding valid interrupt conditions for the peripheral and the behavior of its interrupt-pending flag(s).

# C8051F330/1/2/3/4/5 

### 9.3.2. External Interrupts

The /INT0 and /INT1 external interrupt sources are configurable as active high or low, edge or level sensitive. The INOPL (/INT0 Polarity) and IN1PL (/INT1 Polarity) bits in the IT01CF register select active high or active low; the IT0 and IT1 bits in TCON (Section "18.1. Timer 0 and Timer 1" on page 177) select level or edge sensitive. The table below lists the possible configurations.

| ITO | INOPL | IINTO Interrupt |
| :---: | :---: | :--- |
| 1 | 0 | Active low, edge sensitive |
| 1 | 1 | Active high, edge sensitive |
| 0 | 0 | Active low, level sensitive |
| 0 | 1 | Active high, level sensitive |

| IT1 | IN1PL | INT1 Interrupt |
| :---: | :---: | :--- |
| 1 | 0 | Active low, edge sensitive |
| 1 | 1 | Active high, edge sensitive |
| 0 | 0 | Active low, level sensitive |
| 0 | 1 | Active high, level sensitive |

/INT0 and /INT1 are assigned to Port pins as defined in the IT01CF register (see SFR Definition 9.11). Note that /INTO and /INTO Port pin assignments are independent of any Crossbar assignments. /INT0 and /INT1 will monitor their assigned Port pins without disturbing the peripheral that was assigned the Port pin via the Crossbar. To assign a Port pin only to /INT0 and/or /INT1, configure the Crossbar to skip the selected pin(s). This is accomplished by setting the associated bit in register XBRO (see Section "14.1. Priority Crossbar Decoder" on page 125 for complete details on configuring the Crossbar).

IEO (TCON.1) and IE1 (TCON.3) serve as the interrupt-pending flags for the /INT0 and /INT1 external interrupts, respectively. If an /INT0 or /INT1 external interrupt is configured as edge-sensitive, the corresponding interrupt-pending flag is automatically cleared by the hardware when the CPU vectors to the ISR. When configured as level sensitive, the interrupt-pending flag remains logic 1 while the input is active as defined by the corresponding polarity bit (INOPL or IN1PL); the flag remains logic 0 while the input is inactive. The external interrupt source must hold the input active until the interrupt request is recognized. It must then deactivate the interrupt request before execution of the ISR completes or another interrupt request will be generated.

### 9.3.3. Interrupt Priorities

Each interrupt source can be individually programmed to one of two priority levels: low or high. A low priority interrupt service routine can be preempted by a high priority interrupt. A high priority interrupt cannot be preempted. Each interrupt has an associated interrupt priority bit in an SFR (IP or EIP1) used to configure its priority level. Low priority is the default. If two interrupts are recognized simultaneously, the interrupt with the higher priority is serviced first. If both interrupts have the same priority level, a fixed priority order is used to arbitrate, given in Table 9.4.

### 9.3.4. Interrupt Latency

Interrupt response time depends on the state of the CPU when the interrupt occurs. Pending interrupts are sampled and priority decoded each system clock cycle. Therefore, the fastest possible response time is 5 system clock cycles: 1 clock cycle to detect the interrupt and 4 clock cycles to complete the LCALL to the ISR. If an interrupt is pending when a RETI is executed, a single instruction is executed before an LCALL is made to service the pending interrupt. Therefore, the maximum response time for an interrupt (when no other interrupt is currently being serviced or the new interrupt is of greater priority) occurs when the CPU is performing an RETI instruction followed by a DIV as the next instruction. In this case, the response time is 18 system clock cycles: 1 clock cycle to detect the interrupt, 5 clock cycles to execute the RETI, 8 clock cycles to complete the DIV instruction and 4 clock cycles to execute the LCALL to the ISR. If the CPU is executing an ISR for an interrupt with equal or higher priority, the new interrupt will not be serviced until the current ISR completes, including the RETI and following instruction.

## C8051F330/1/2/3/4/5

Table 9.4. Interrupt Summary

| Interrupt Source | Interrupt Vector | Priority Order | Pending Flag |  |  | Enable Flag | Priority Control |

## C8051F330/1/2/3/4/5

### 9.4. Power Management Modes

The CIP-51 core has two software programmable power management modes: Idle and Stop. Idle mode halts the CPU while leaving the peripherals and clocks active. In Stop mode, the CPU is halted, all interrupts and timers (except the Missing Clock Detector) are inactive, and the internal oscillator is stopped (analog peripherals remain in their selected states; the external oscillator is not effected). Since clocks are running in Idle mode, power consumption is dependent upon the system clock frequency and the number of peripherals left in active mode before entering Idle. Stop mode consumes the least power. SFR Definition 9.12 describes the Power Control Register (PCON) used to control the CIP-51's power management modes.

Although the CIP-51 has Idle and Stop modes built in (as with any standard 8051 architecture), power management of the entire MCU is better accomplished by enabling/disabling individual peripherals as needed. Each analog peripheral can be disabled when not in use and placed in low power mode. Digital peripherals, such as timers or serial buses, draw little power when they are not in use. Turning off the oscillators lowers power consumption considerably; however a reset is required to restart the MCU.

### 9.4.1. Idle Mode

Setting the Idle Mode Select bit (PCON.0) causes the CIP-51 to halt the CPU and enter Idle mode as soon as the instruction that sets the bit completes execution. All internal registers and memory maintain their original data. All analog and digital peripherals can remain active during Idle mode.

Idle mode is terminated when an enabled interrupt is asserted or a reset occurs. The assertion of an enabled interrupt will cause the Idle Mode Selection bit (PCON.0) to be cleared and the CPU to resume operation. The pending interrupt will be serviced and the next instruction to be executed after the return from interrupt (RETI) will be the instruction immediately following the one that set the Idle Mode Select bit. If Idle mode is terminated by an internal or external reset, the CIP-51 performs a normal reset sequence and begins program execution at address $0 \times 0000$.

Note: If the instruction following the write of the IDLE bit is a single-byte instruction and an interrupt occurs during the execution phase of the instruction that sets the IDLE bit, the CPU may not wake from Idle mode when a future interrupt occurs. Therefore, instructions that set the IDLE bit should be followed by an instruction that has two or more opcode bytes, for example:

```
// in 'C':
; in assembly:
```

PCON $\mid=0 x 01 ; \quad / /$ set IDLE bit
PCON = PCON; // ... followed by a 3-cycle dummy instruction
ORL PCON, \#O1h ; set IDLE bit
MOV PCON, PCON ; ... followed by a 3-cycle dummy instruction

If enabled, the Watchdog Timer (WDT) will eventually cause an internal watchdog reset and thereby terminate the Idle mode. This feature protects the system from an unintended permanent shutdown in the event of an inadvertent write to the PCON register. If this behavior is not desired, the WDT may be disabled by software prior to entering the Idle mode if the WDT was initially configured to allow this operation. This provides the opportunity for additional power savings, allowing the system to remain in the Idle mode indefinitely, waiting for an external stimulus to wake up the system. Refer to Section "10.6. PCA Watchdog Timer Reset" on page 100 for more information on the use and configuration of the WDT.

## C8051F330/1/2/3/4/5

### 9.4.2. Stop Mode

Setting the Stop Mode Select bit (PCON.1) causes the CIP-51 to enter Stop mode as soon as the instruction that sets the bit completes execution. In Stop mode the internal oscillator, CPU, and all digital peripherals are stopped; the state of the external oscillator circuit is not affected. Each analog peripheral (including the external oscillator circuit) may be shut down individually prior to entering Stop Mode. Stop mode can only be terminated by an internal or external reset. On reset, the CIP-51 performs the normal reset sequence and begins program execution at address 0x0000.

If enabled, the Missing Clock Detector will cause an internal reset and thereby terminate the Stop mode. The Missing Clock Detector should be disabled if the CPU is to be put to in STOP mode for longer than the MCD timeout of $100 \mu \mathrm{~s}$.

## C8051F330/1/2/3/4/5

## 10. Reset Sources

Reset circuitry allows the controller to be easily placed in a predefined default condition. On entry to this reset state, the following occur:

- CIP-51 halts program execution
- Special Function Registers (SFRs) are initialized to their defined reset values
- External Port pins are forced to a known state
- Interrupts and timers are disabled.

All SFRs are reset to the predefined values noted in the SFR detailed descriptions. The contents of internal data memory are unaffected during a reset; any previously stored data is preserved. However, since the stack pointer SFR is reset, the stack is effectively lost, even though the data on the stack is not altered.

The Port I/O latches are reset to 0xFF (all logic ones) in open-drain mode. Weak pullups are enabled during and after the reset. For VDD Monitor and power-on resets, the RST pin is driven low until the device exits the reset state.

On exit from the reset state, the program counter (PC) is reset, and the system clock defaults to the internal oscillator. Refer to Section "13. Oscillators" on page 113 for information on selecting and configuring the system clock source. The Watchdog Timer is enabled with the system clock divided by 12 as its clock source (Section "19.3. Watchdog Timer Mode" on page 201 details the use of the Watchdog Timer). Program execution begins at location $0 \times 0000$.

Figure 10.1. Reset Sources

## C8051F330/1/2/3/4/5

### 10.1. Power-On Reset

During power-up, the device is held in a reset state and the $\overline{\mathrm{RST}}$ pin is driven low until $\mathrm{V}_{\mathrm{DD}}$ settles above $\mathrm{V}_{\mathrm{RST}}$. A delay occurs before the device is released from reset; the delay decreases as the $\mathrm{V}_{\mathrm{DD}}$ ramp time increases ( $\mathrm{V}_{\mathrm{DD}}$ ramp time is defined as how fast $\mathrm{V}_{\mathrm{DD}}$ ramps from 0 V to $\mathrm{V}_{\mathrm{RST}}$ ). Figure 10.2. plots the power-on and $V_{D D}$ monitor reset timing. The maximum $V_{D D}$ ramp time is 1 ms ; slower ramp times may cause the device to be released from reset before $\mathrm{V}_{\mathrm{DD}}$ reaches the $\mathrm{V}_{\mathrm{RST}}$ level. For ramp times less than 1 ms , the power-on reset delay ( $T_{\text {PORDelay }}$ ) is typically less than 0.3 ms .

On exit from a power-on reset, the PORSF flag (RSTSRC.1) is set by hardware to logic 1 . When PORSF is set, all of the other reset flags in the RSTSRC Register are indeterminate (PORSF is cleared by all other resets). Since all resets cause program execution to begin at the same location (0x0000) software can read the PORSF flag to determine if a power-up was the cause of reset. The content of internal data memory should be assumed to be undefined after a power-on reset. The $\mathrm{V}_{\mathrm{DD}}$ monitor is disabled following a power-on reset.

Figure 10.2. Power-On and $\mathrm{V}_{\mathrm{DD}}$ Monitor Reset Timing

### 10.2. Power-Fail Reset/VDD Monitor

When a power-down transition or power irregularity causes $\mathrm{V}_{\mathrm{DD}}$ to drop below $\mathrm{V}_{\mathrm{RST}}$, the power supply monitor will drive the $\overline{\mathrm{RST}}$ pin low and hold the CIP-51 in a reset state (see Figure 10.2). When $\mathrm{V}_{\mathrm{DD}}$ returns to a level above $\mathrm{V}_{\text {RST }}$, the CIP-51 will be released from the reset state. Note that even though internal data memory contents are not altered by the power-fail reset, it is impossible to determine if $\mathrm{V}_{\mathrm{DD}}$ dropped below the level required for data retention. If the PORSF flag reads ' 1 ', the data may no longer be valid. The $\mathrm{V}_{\mathrm{DD}}$ monitor is disabled after power-on resets; however its defined state (enabled/disabled) is not altered by any other reset source. For example, if the $\mathrm{V}_{\mathrm{DD}}$ monitor is enabled and a software reset is performed, the $V_{D D}$ monitor will still be enabled after the reset.

## C8051F330/1/2/3/4/5

Important Note: The $\mathrm{V}_{\mathrm{DD}}$ monitor must be enabled before it is selected as a reset source. Selecting the $V_{D D}$ monitor as a reset source before it is enabled and stabilized may cause a system reset. The procedure for configuring the $\mathrm{V}_{\mathrm{DD}}$ monitor as a reset source is shown below:

Step 1. Enable the $\mathrm{V}_{\mathrm{DD}}$ monitor (VDMEN bit in VDMOCN = ' 1 ').
Step 2. Wait for the $V_{D D}$ monitor to stabilize (see Table 10.1 for the $V_{D D}$ Monitor turn-on time).
Step 3. Select the $\mathrm{V}_{\mathrm{DD}}$ monitor as a reset source (PORSF bit in RSTSRC = ' 1 ').
See Figure 10.2 for $\mathrm{V}_{\mathrm{DD}}$ monitor timing; note that the reset delay is not incurred after a $\mathrm{V}_{\mathrm{DD}}$ monitor reset. See Table 10.1 for complete electrical characteristics of the $V_{D D}$ monitor.

## SFR Definition 10.1. VDMOCN: VDD Monitor Control

### 10.3. External Reset

The external $\overline{\operatorname{RST}}$ pin provides a means for external circuitry to force the device into a reset state. Asserting an active-low signal on the RST pin generates a reset; an external pullup and/or decoupling of the RST pin may be necessary to avoid erroneous noise-induced resets. See Table 10.1 for complete $\overline{\text { RST }}$ pin specifications. The PINRSF flag (RSTSRC. 0 ) is set on exit from an external reset.

### 10.4. Missing Clock Detector Reset

The Missing Clock Detector (MCD) is a one-shot circuit that is triggered by the system clock. If the system clock remains high or low for more than $100 \mu \mathrm{~s}$, the one-shot will time out and generate a reset. After a MCD reset, the MCDRSF flag (RSTSRC.2) will read ' 1 ', signifying the MCD as the reset source; otherwise, this bit reads ' 0 '. Writing a ' 1 ' to the MCDRSF bit enables the Missing Clock Detector; writing a ' 0 ' disables it. The state of the $\overline{\text { RST }}$ pin is unaffected by this reset.

## C8051F330/1/2/3/4/5

### 10.5. Comparator0 Reset

Comparator0 can be configured as a reset source by writing a ' 1 ' to the CORSEF flag (RSTSRC.5). Comparator0 should be enabled and allowed to settle prior to writing to CORSEF to prevent any turn-on chatter on the output from generating an unwanted reset. The Comparator0 reset is active-low: if the non-inverting input voltage (on CPO+) is less than the inverting input voltage (on CPO-), the device is put into the reset state. After a Comparator0 reset, the CORSEF flag (RSTSRC.5) will read ' 1 ' signifying Comparator0 as the reset source; otherwise, this bit reads ' 0 '. The state of the RST pin is unaffected by this reset.

### 10.6. PCA Watchdog Timer Reset

The programmable Watchdog Timer (WDT) function of the Programmable Counter Array (PCA) can be used to prevent software from running out of control during a system malfunction. The PCA WDT function can be enabled or disabled by software as described in Section "19.3. Watchdog Timer Mode" on page 201; the WDT is enabled and clocked by SYSCLK / 12 following any reset. If a system malfunction prevents user software from updating the WDT, a reset is generated and the WDTRSF bit (RSTSRC.3) is set to ' 1 '. The state of the RST pin is unaffected by this reset.

### 10.7. Flash Error Reset

If a Flash read/write/erase or program read targets an illegal address, a system reset is generated. This may occur due to any of the following:

- A Flash write or erase is attempted above user code space. This occurs when PSWE is set to ' 1 ' and a MOVX write operation targets an address above address 0x1DFF.
- A Flash read is attempted above user code space. This occurs when a MOVC operation targets an address above address 0x1DFF.
- A Program read is attempted above user code space. This occurs when user code attempts to branch to an address above 0x1DFF.
- A Flash read, write or erase attempt is restricted due to a Flash security setting (see Section "11.3. Security Options" on page 105).
The FERROR bit (RSTSRC.6) is set following a Flash error reset. The state of the $\overline{\text { RST }}$ pin is unaffected by this reset.

### 10.8. Software Reset

Software may force a reset by writing a ' 1 ' to the SWRSF bit (RSTSRC.4). The SWRSF bit will read ' 1 ' following a software forced reset. The state of the $\overline{\text { RST }}$ pin is unaffected by this reset.

## 11. Flash Memory

On-chip, re-programmable Flash memory is included for program code and non-volatile data storage. The Flash memory can be programmed in-system, a single byte at a time, through the C2 interface or by software using the MOVX instruction. Once cleared to logic 0 , a Flash bit must be erased to set it back to logic 1 . Flash bytes would typically be erased (set to 0xFF) before being reprogrammed. The write and erase operations are automatically timed by hardware for proper execution; data polling to determine the end of the write/erase operation is not required. Code execution is stalled during a Flash write/erase operation. Refer to Table 11.1 for complete Flash memory electrical characteristics.

### 11.1. Programming The Flash Memory

The simplest means of programming the Flash memory is through the C2 interface using programming tools provided by Silicon Labs or a third party vendor. This is the only means for programming a non-initialized device. For details on the C2 commands to program Flash memory, see Section "20. C2 Interface" on page 209.

To ensure the integrity of Flash contents, it is strongly recommended that the on-chip $\mathrm{V}_{\mathrm{DD}}$ Monitor be enabled in any system that includes code that writes and/or erases Flash memory from software. See Section 11.4 for more details.

### 11.1.1. Flash Lock and Key Functions

Flash writes and erases by user software are protected with a lock and key function. The Flash Lock and Key Register (FLKEY) must be written with the correct key codes, in sequence, before Flash operations may be performed. The key codes are: 0xA5, 0xF1. The timing does not matter, but the codes must be written in order. If the key codes are written out of order, or the wrong codes are written, Flash writes and erases will be disabled until the next system reset. Flash writes and erases will also be disabled if a Flash write or erase is attempted before the key codes have been written properly. The Flash lock resets after each write or erase; the key codes must be written again before a following Flash operation can be performed. The FLKEY register is detailed in SFR Definition 11.2.

### 11.1.2. Flash Erase Procedure

The Flash memory can be programmed by software using the MOVX write instruction with the address and data byte to be programmed provided as normal operands. Before writing to Flash memory using MOVX, Flash write operations must be enabled by: (1) setting the PSWE Program Store Write Enable bit (PSCTL.0) to logic 1 (this directs the MOVX writes to target Flash memory); and (2) Writing the Flash key codes in sequence to the Flash Lock register (FLKEY). The PSWE bit remains set until cleared by software.

A write to Flash memory can clear bits to logic 0 but cannot set them; only an erase operation can set bits to logic 1 in Flash. A byte location to be programmed should be erased before a new value is written. The Flash memory is organized in 512-byte pages. The erase operation applies to an entire page (setting all bytes in the page to 0xFF). To erase an entire 512-byte page, perform the following steps:

Step 1. Disable interrupts (recommended).
Step 2. Set thePSEE bit (register PSCTL).
Step 3. Set the PSWE bit (register PSCTL).
Step 4. Write the first key code to FLKEY: OxA5.
Step 5. Write the second key code to FLKEY: 0xF1.
Step 6. Using the MOVX instruction, write a data byte to any location within the 512-byte page to be erased.
Step 7. Clear the PSWE and PSEE bits.

## C8051F330/1/2/3/4/5

### 11.1.3. Flash Write Procedure

Flash bytes are programmed by software with the following sequence:
Step 1. Disable interrupts (recommended).
Step 2. Erase the 512-byte Flash page containing the target location, as described in Section 11.1.2.

Step 3. Set the PSWE bit (register PSCTL).
Step 4. Clear the PSEE bit (register PSCTL).
Step 5. Write the first key code to FLKEY: 0xA5.
Step 6. Write the second key code to FLKEY: OxF1.
Step 7. Using the MOVX instruction, write a single data byte to the desired location within the 512byte sector.
Step 8. Clear the PSWE bit.
Steps 5-7 must be repeated for each byte to be written. After Flash writes are complete, PSWE should be cleared so that MOVX instructions do not target program memory.

Table 11.1. Flash Electrical Characteristics
$V_{D D}=2.7$ to $3.6 \mathrm{~V} ;-40$ to $+85^{\circ} \mathrm{C}$ unless otherwise specified.

| Parameter | Conditions | Min | Typ | Max | Units |
| :--- | :--- | :---: | :---: | :---: | :---: |
| Flash Size | C8051F330/1 | $8192^{*}$ | - | - |  |
|  | C8051F332/3 | 4096 | - | - | bytes |
|  | C8051F334/5 | 2048 | - | - |  |
| Endurance |  | 20 k | 100 k | - | Erase/Write |
| Erase Cycle Time | 25 MHz System Clock | 10 | 15 | 20 | ms |
| Write Cycle Time | 25 MHz System Clock | 40 | 55 | 70 | $\mu \mathrm{~s}$ |

*Note: 512 bytes at addresses $0 \times 1 \mathrm{E} 00$ to $0 \times 1$ FFF are reserved.

### 11.2. Non-volatile Data Storage

The Flash memory can be used for non-volatile data storage as well as program code. This allows data such as calibration coefficients to be calculated and stored at run time. Data is written using the MOVX write instruction and read using the MOVC instruction. Note: MOVX read instructions always target XRAM.

## C8051F330/1/2/3/4/5

### 11.3. Security Options

The CIP-51 provides security options to protect the Flash memory from inadvertent modification by software as well as to prevent the viewing of proprietary program code and constants. The Program Store Write Enable (bit PSWE in register PSCTL) and the Program Store Erase Enable (bit PSEE in register PSCTL) bits protect the Flash memory from accidental modification by software. PSWE must be explicitly set to ' 1 ' before software can modify the Flash memory; both PSWE and PSEE must be set to ' 1 ' before software can erase Flash memory. Additional security features prevent proprietary program code and data constants from being read or altered across the C2 interface.

A Security Lock Byte located at the last byte of Flash user space offers protection of the Flash program memory from access (reads, writes, or erases) by unprotected code or the C2 interface. The Flash security mechanism allows the user to lock $n 512$-byte Flash pages, starting at page 0 (addresses $0 \times 0000$ to $0 \times 01 F F$ ), where $n$ is the 1's complement number represented by the Security Lock Byte. Note that the page containing the Flash Security Lock Byte is unlocked when no other Flash pages are locked (all bits of the Lock Byte are ' 1 ') and locked when any other Flash pages are locked (any bit of the Lock Byte is ' 0 '). See example below.

Figure 11.2. Flash Program Memory Map

## C8051F330/1/2/3/4/5

The level of Flash security depends on the Flash access method. The three Flash access methods that can be restricted are reads, writes, and erases from the C2 debug interface, user firmware executing on unlocked pages, and user firmware executing on locked pages. Table 11.2 summarizes the Flash security features of the 'F330/1/2/3/4/5 devices.

Table 11.2. Flash Security Summary

|  | Action | C2 Debug <br> Interface | User Firmware executing from: |  |
| :--- | :---: | :---: | :---: | :---: |
|  | an unlocked page |  |  |  |
| Read, Write or Erase unlocked pages <br> (except page with Lock Byte) | Permitted | Permitted | Permitted |  |
| Read, Write or Erase locked pages <br> (except page with Lock Byte) | Not Permitted | Flash Error Reset | Permitted |  |
| Read or Write page containing Lock Byte <br> (if no pages are locked) | Permitted | Permitted | Permitted |  |
| Read or Write page containing Lock Byte <br> (if any page is locked) | Not Permitted | Flash Error Reset | Permitted |  |
| Read contents of Lock Byte <br> (if no pages are locked) | Permitted | Permitted | Permitted |  |
| Read contents of Lock Byte <br> (if any page is locked) | Not Permitted | Flash Error Reset | Permitted |  |
| Erase page containing Lock Byte <br> (if no pages are locked) | Permitted | Flash Error Reset | Flash Error Reset |  |
| Erase page containing Lock Byte - Unlock all <br> pages (if any page is locked) | C2 Device <br> Erase Only | Flash Error Reset | Flash Error Reset |  |
| Lock additional pages <br> (change '1's to '0's in the Lock Byte) | Not Permitted | Flash Error Reset | Flash Error Reset |  |
| Unlock individual pages <br> (change '0's to '1's in the Lock Byte) | Not Permitted | Flash Error Reset | Flash Error Reset |  |
| Read, Write or Erase Reserved Area | Not Permitted | Flash Error Reset | Flash Error Reset |  |

C2 Device Erase - Erases all Flash pages including the page containing the Lock Byte.
Flash Error Reset - Not permitted; Causes Flash Error Device Reset (FERROR bit in RSTSRC is '1' after reset).

- All prohibited operations that are performed via the C2 interface are ignored (do not cause device reset).
- Locking any Flash page also locks the page containing the Lock Byte.
- Once written to, the Lock Byte cannot be modified except by performing a C2 Device Erase.
- If user code writes to the Lock Byte, the Lock does not take effect until the next device reset.

# C8051F330/1/2/3/4/5 

### 11.4. Flash Write and Erase Guidelines

Any system which contains routines which write or erase Flash memory from software involves some risk that the write or erase routines will execute unintentionally if the CPU is operating outside its specified operating range of $\mathrm{V}_{\mathrm{DD}}$, system clock frequency, or temperature. This accidental execution of Flash modifying code can result in alteration of Flash memory contents causing a system failure that is only recoverable by re-Flashing the code in the device.

The following guidelines are recommended for any system which contains routines which write or erase Flash from code.

### 11.4.1. $\mathrm{V}_{\mathrm{DD}}$ Maintenance and the $\mathrm{V}_{\mathrm{DD}}$ monitor

1. If the system power supply is subject to voltage or current "spikes," add sufficient transient protection devices to the power supply to ensure that the supply voltages listed in the Absolute Maximum Ratings table are not exceeded.
2. Make certain that the minimum $V_{D D}$ rise time specification of 1 ms is met. If the system cannot meet this rise time specification, then add an external $V_{D D}$ brownout circuit to the $\overline{\mathrm{RST}}$ pin of the device that holds the device in reset until $\mathrm{V}_{\mathrm{DD}}$ reaches 2.7 V and re-asserts $\overline{\mathrm{RST}}$ if $\mathrm{V}_{\mathrm{DD}}$ drops below 2.7 V .
3. Enable the on-chip $V_{D D}$ monitor and enable the $V_{D D}$ monitor as a reset source as early in code as possible. This should be the first set of instructions executed after the Reset Vector. For 'C'-based systems, this will involve modifying the startup code added by the 'C' compiler. See your compiler documentation for more details. Make certain that there are no delays in software between enabling the $\mathrm{V}_{\mathrm{DD}}$ monitor and enabling the $\mathrm{V}_{\mathrm{DD}}$ monitor as a reset source. Code examples showing this can be found in "AN201: Writing to Flash from Firmware", available from the Silicon Laboratories web site.
4. As an added precaution, explicitly enable the $V_{D D}$ monitor and enable the $V_{D D}$ monitor as a reset source inside the functions that write and erase Flash memory. The $\mathrm{V}_{\mathrm{DD}}$ monitor enable instructions should be placed just after the instruction to set PSWE to a '1', but before the Flash write or erase operation instruction.
5. Make certain that all writes to the RSTSRC (Reset Sources) register use direct assignment operators and explicitly DO NOT use the bit-wise operators (such as AND or OR). For example, "RSTSRC $=0 \times 02$ " is correct. "RSTSRC $\mid=0 \times 02$ " is incorrect.
6. Make certain that all writes to the RSTSRC register explicitly set the PORSF bit to a ' 1 '. Areas to check are initialization code which enables other reset sources, such as the Missing Clock Detector or Comparator, for example, and instructions which force a Software Reset. A global search on "RSTSRC" can quickly verify this.

### 11.4.2. PSWE Maintenance

7. Reduce the number of places in code where the PSWE bit (b0 in PSCTL) is set to a ' 1 '. There should be exactly one routine in code that sets PSWE to a ' 1 ' to write Flash bytes and one routine in code that sets PSWE and PSEE both to a '1' to erase Flash pages.
8. Minimize the number of variable accesses while PSWE is set to a '1'. Handle pointer address updates and loop variable maintenance outside the "PSWE $=1 ; \ldots$ PSWE $=0 ;$ area. Code examples showing this can be found in AN201, "Writing to Flash from Firmware", available from the Silicon Laboratories web site.
9. Disable interrupts prior to setting PSWE to a '1' and leave them disabled until after PSWE has been reset to ' 0 '. Any interrupts posted during the Flash write or erase operation will be ser-

## C8051F330/1/2/3/4/5

viced in priority order after the Flash operation has been completed and interrupts have been re-enabled by software.
10. Make certain that the Flash write and erase pointer variables are not located in XRAM. See your compiler documentation for instructions regarding how to explicitly locate variables in different memory areas.
11. Add address bounds checking to the routines that write or erase Flash memory to ensure that a routine called with an illegal address does not result in modification of the Flash.

### 11.4.3. System Clock

12. If operating from an external crystal, be advised that crystal performance is susceptible to electrical interference and is sensitive to layout and to changes in temperature. If the system is operating in an electrically noisy environment, use the internal oscillator or use an external CMOS clock.
13. If operating from the external oscillator, switch to the internal oscillator during Flash write or erase operations. The external oscillator can continue to run, and the CPU can switch back to the external oscillator after the Flash operation has completed.

Additional Flash recommendations and example code can be found in AN201, "Writing to Flash from Firmware", available from the Silicon Laboratories web site.

SFR Definition 11.1. PSCTL: Program Store R/W Control

| R | R | R | R | R | R | R/W | R/W | $\begin{aligned} & \text { Reset Value } \\ & 00000000 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - | - | PSEE | PSWE |  |
| Bit7 | Bit6 | Bit5 | Bit4 | Bit3 | Bit2 | Bit1 | Bit0 |  |

Bits7-2: UNUSED: Read = 000000b, Write = don't care.
Bit1: PSEE: Program Store Erase Enable
Setting this bit (in combination with PSWE) allows an entire page of Flash program memory to be erased. If this bit is logic 1 and Flash writes are enabled (PSWE is logic 1), a write to Flash memory using the MOVX instruction will erase the entire page that contains the location addressed by the MOVX instruction. The value of the data byte written does not matter.
0 : Flash program memory erasure disabled.
1: Flash program memory erasure enabled.
Bit0: PSWE: Program Store Write Enable
Setting this bit allows writing a byte of data to the Flash program memory using the MOVX write instruction. The Flash location should be erased before writing data.
0 : Writes to Flash program memory disabled.
1: Writes to Flash program memory enabled; the MOVX write instruction targets Flash memory.

## C8051F330/1/2/3/4/5

## 12. External RAM

The C8051F330/1/2/3/4/5 devices include 512 bytes of RAM mapped into the external data memory space. All of these address locations may be accessed using the external move instruction (MOVX) and the data pointer (DPTR), or using MOVX indirect addressing mode. If the MOVX instruction is used with an 8-bit address operand (such as @R1), then the high byte of the 16-bit address is provided by the External Memory Interface Control Register (EMIOCN as shown in SFR Definition 12.1). Note: the MOVX instruction is also used for writes to the Flash memory. See Section "11. Flash Memory" on page 103 for details. The MOVX instruction accesses XRAM by default.

For a 16-bit MOVX operation (@DPTR), the upper 7 bits of the 16-bit external data memory address word are "don't cares". As a result, the 512-byte RAM is mapped modulo style over the entire 64 k external data memory address range. For example, the XRAM byte at address 0x0000 is shadowed at addresses $0 \times 0200,0 \times 0400,0 \times 0600,0 x 0800$, etc. This is a useful feature when performing a linear memory fill, as the address pointer doesn't have to be reset when reaching the RAM block boundary.

SFR Definition 12.1. EMIOCN: External Memory Interface Control

| R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | Reset Value 00000000 |

| Bits7-1: <br> Bit 0: | UNUSED. Read $=0000000$ b. Write $=$ don't care. <br> PGSEL: XRAM Page Select. <br> The EMIOCN register provides the high byte of the 16-bit external data memory address when using an 8-bit MOVX command, effectively selecting a 256-byte page of RAM. Since the upper (unused) bits of the register are always zero, the PGSEL determines which page of XRAM is accessed. |  |  |  |  |  |  |  |
|  | For Example: If EMIOCN $=0 \times 01$, addresses $0 \times 0100$ through $0 \times 01 \mathrm{FF}$ will be accessed. |  |  |  |  |  |  |  |

## C8051F330/1/2/3/4/5

# C8051F330/1/2/3/4/5 

## 13. Oscillators

C8051F330/1/2/3/4/5 devices include a programmable internal high-frequency oscillator, a programmable internal low-frequency oscillator, and an external oscillator drive circuit. The internal high-frequency oscillator can be enabled/disabled and calibrated using the OSCICN and OSCICL registers, as shown in Figure 13.1. The internal low-frequency oscillator can be enabled/disabled and calibrated using the OSCLCN register, as shown in SFR Definition 13.3. The system clock can be sourced by the external oscillator circuit or either internal oscillator. Both internal oscillators offer a selectable post-scaling feature. The internal oscillators' electrical specifications are given in Table 13.1 on page 122.

Figure 13.1. Oscillator Diagram

### 13.1. Programmable Internal High-Frequency (H-F) Oscillator

All C8051F330/1/2/3/4/5 devices include a programmable internal high-frequency oscillator that defaults as the system clock after a system reset. The internal oscillator period can be adjusted via the OSCICL register as defined by SFR Definition 13.1.

On C8051F330/1/2/3/4/5 devices, OSCICL is factory calibrated to obtain a 24.5 MHz base frequency.
Electrical specifications for the precision internal oscillator are given in Table 13.1 on page 122. Note that the system clock may be derived from the programmed internal oscillator divided by $1,2,4$, or 8 , as defined by the IFCN bits in register OSCICN. The divide value defaults to 8 following a reset.

### 13.2. Programmable Internal Low-Frequency (L-F) Oscillator

All C8051F330/1/2/3/4/5 devices include a programmable low-frequency internal oscillator, which is calibrated to a nominal frequency of 80 kHz . The low-frequency oscillator circuit includes a divider that can be changed to divide the clock by $1,2,4$, or 8 , using the OSCLD bits in the OSCLCN register (see SFR Definition 13.3). Additionally, the OSCLF bits (OSCLCN5:2) can be used to adjust the oscillator's output frequency.

### 13.2.1. Calibrating the Internal L-F Oscillator

Timers 2 and 3 include capture functions that can be used to capture the oscillator frequency, when running from a known time base. When either Timer 2 or Timer 3 is configured for L-F Oscillator Capture Mode, a falling edge (Timer 2) or rising edge (Timer 3) of the low-frequency oscillator's output will cause a capture event on the corresponding timer. As a capture event occurs, the current timer value (TMRnH:TMRnL) is copied into the timer reload registers (TMRnRLH:TMRnRLL). By recording the difference between two successive timer capture values, the low-frequency oscillator's period can be calculated. The OSCLF bits can then be adjusted to produce the desired oscillator frequency.

### 13.3. External Oscillator Drive Circuit

The external oscillator circuit may drive an external crystal, ceramic resonator, capacitor, or RC network. A CMOS clock may also provide a clock input. For a crystal or ceramic resonator configuration, the crystal/resonator must be wired across the XTAL1 and XTAL2 pins as shown in Option 1 of Figure 13.1. A $10 \mathrm{M} \Omega$ resistor also must be wired across the XTAL2 and XTAL1 pins for the crystal/resonator configuration. In RC, capacitor, or CMOS clock configuration, the clock source should be wired to the XTAL2 pin as shown in Option 2, 3, or 4 of Figure 13.1. The type of external oscillator must be selected in the OSCXCN register, and the frequency control bits (XFCN) must be selected appropriately (see SFR Definition 13.4).

Important Note on External Oscillator Usage: Port pins must be configured when using the external oscillator circuit. When the external oscillator drive circuit is enabled in crystal/resonator mode, Port pins P0.2 and P0.3 are used as XTAL1 and XTAL2 respectively. When the external oscillator drive circuit is enabled in capacitor, RC, or CMOS clock mode, Port pin P0.3 is used as XTAL2. The Port I/O Crossbar should be configured to skip the Port pins used by the oscillator circuit; see Section "14.1. Priority Crossbar Decoder" on page 125 for Crossbar configuration. Additionally, when using the external oscillator circuit in crystal/resonator, capacitor, or RC mode, the associated Port pins should be configured as analog inputs. In CMOS clock mode, the associated pin should be configured as a digital input. See Section "14.2. Port I/O Initialization" on page 127 for details on Port input mode selection.

# C8051F330/1/2/3/4/5 

SFR Definition 13.4. OSCXCN: External Oscillator Control

## C8051F330/1/2/3/4/5

### 13.3.1. External Crystal Example

If a crystal or ceramic resonator is used as an external oscillator source for the MCU, the circuit should be configured as shown in Figure 13.1, Option 1. The External Oscillator Frequency Control value (XFCN) should be chosen from the Crystal column of the table in SFR Definition 13.4 (OSCXCN register). For example, an 11.0592 MHz crystal requires an XFCN setting of 111 b and a 32.768 kHz Watch Crystal requires an XFCN setting of 001b. After an external 32.768 kHz oscillator is stabilized, the XFCN setting can be switched to 000 to save power. It is recommended to enable the missing clock detector before switching the system clock to any external oscillator source.

When the crystal oscillator is first enabled, the oscillator amplitude detection circuit requires a settling time to achieve proper bias. Introducing a delay of 1 ms between enabling the oscillator and checking the XTLVLD bit will prevent a premature switch to the external oscillator as the system clock. Switching to the external oscillator before the crystal oscillator has stabilized can result in unpredictable behavior. The recommended procedure is:

Step 1. Force XTAL1 and XTAL2 to a low state. This involves enabling the Crossbar and writing ' 0 ' to port latches P0.2 and P0.3.
Step 2. Configure XTAL1 and XTAL2 as analog inputs using register POMDIN.
Step 3. Enable the external oscillator.
Step 4. Wait at least 1 ms .
Step 5. Poll for XTLVLD => ' 1 '.
Step 6. Enable the Missing Clock Detector.
Step 7. Switch the system clock to the external oscillator.
Important Note on External Crystals: Crystal oscillator circuits are quite sensitive to PCB layout. The crystal should be placed as close as possible to the XTAL pins on the device. The traces should be as short as possible and shielded with ground plane from any other traces which could introduce noise or interference.

## C8051F330/1/2/3/4/5

The capacitors shown in the external crystal configuration provide the load capacitance required by the crystal for correct oscillation. These capacitors are "in series" as seen by the crystal and "in parallel" with the stray capacitance of the XTAL1 and XTAL2 pins.

Note: The desired load capacitance depends upon the crystal and the manufacturer. Please refer to the crystal data sheet when completing these calculations.

For example, a tuning-fork crystal of 32.768 kHz with a recommended load capacitance of 12.5 pF should use the configuration shown in Figure 13.1, Option 1. The total value of the capacitors and the stray capacitance of the XTAL pins should equal 25 pF . With a stray capacitance of 3 pF per pin, the 22 pF capacitors yield an equivalent capacitance of 12.5 pF across the crystal, as shown in Figure 13.2.

Figure 13.2. External 32.768 kHz Quartz Crystal Oscillator Connection Diagram

## C8051F330/1/2/3/4/5

### 13.3.2. External RC Example

If an RC network is used as an external oscillator source for the MCU, the circuit should be configured as shown in Figure 13.1, Option 2. The capacitor should be no greater than 100 pF ; however for very small capacitors, the total capacitance may be dominated by parasitic capacitance in the PCB layout. To determine the required External Oscillator Frequency Control value (XFCN) in the OSCXCN Register, first select the RC network value to produce the desired frequency of oscillation. If the frequency desired is 100 kHz , let $\mathrm{R}=246 \mathrm{k} \Omega$ and $\mathrm{C}=50 \mathrm{pF}$ :
$\mathrm{f}=1.23\left(10^{3}\right) / \mathrm{RC}=1.23\left(10^{3}\right) /[246 \times 50]=0.1 \mathrm{MHz}=100 \mathrm{kHz}$
Referring to the table in SFR Definition 13.4, the required XFCN setting is 010b.

### 13.3.3. External Capacitor Example

If a capacitor is used as an external oscillator for the MCU, the circuit should be configured as shown in Figure 13.1, Option 3. The capacitor should be no greater than 100 pF ; however for very small capacitors, the total capacitance may be dominated by parasitic capacitance in the PCB layout. To determine the required External Oscillator Frequency Control value (XFCN) in the OSCXCN Register, select the capacitor to be used and find the frequency of oscillation from the equations below. Assume $\mathrm{V}_{\mathrm{DD}}=3.0 \mathrm{~V}$ and $\mathrm{f}=150 \mathrm{kHz}$ :

```
f=KF / (C x VDD)
0.150 MHz = KF / (C x 3.0)
```

Since the frequency of roughly 150 kHz is desired, select the K Factor from the table in SFR Definition 13.4 (OSCXCN) as KF = 22:
$0.150 \mathrm{MHz}=22 /(\mathrm{C} \times 3.0)$
C $\times 3.0=22 / 0.150 \mathrm{MHz}$
$\mathrm{C}=146.6 / 3.0 \mathrm{pF}=48.8 \mathrm{pF}$
Therefore, the XFCN value to use in this example is 011 b and $\mathrm{C}=50 \mathrm{pF}$.

## C8051F330/1/2/3/4/5

### 13.4. System Clock Selection

The internal oscillator requires little start-up time and may be selected as the system clock immediately following the OSCICN write that enables the internal oscillator. External crystals and ceramic resonators typically require a start-up time before they are settled and ready for use. The Crystal Valid Flag (XTLVLD in register OSCXCN) is set to '1' by hardware when the external oscillator is settled. In crystal mode, to avoid reading a false XTLVLD, software should delay at least 1 ms between enabling the external oscillator and checking XTLVLD. RC and C modes typically require no startup time.

The CLKSL[1:0] bits in register CLKSEL select which oscillator source is used as the system clock. CLKSL[1:0] must be set to 01b for the system clock to run from the external oscillator; however the external oscillator may still clock certain peripherals (timers, PCA) when the internal oscillator is selected as the system clock. The system clock may be switched on-the-fly between the internal oscillator, external oscillator, and Clock Multiplier so long as the selected clock source is enabled and has settled.

## 14. Port Input/Output

Digital and analog resources are available through 17 I/O pins. Port pins are organized as two byte-wide Ports and one 1-bit Port. Each of the Port pins can be defined as general-purpose I/O (GPIO) or analog input; Port pins P0.0 - P1.7 can be assigned to one of the internal digital resources as shown in Figure 14.3. The designer has complete control over which functions are assigned, limited only by the number of physical I/O pins. This resource assignment flexibility is achieved through the use of a Priority Crossbar Decoder. Note that the state of a Port I/O pin can always be read in the corresponding Port latch, regardless of the Crossbar settings.

The Crossbar assigns the selected internal digital resources to the I/O pins based on the Priority Decoder (Figure 14.3 and Figure 14.4). The registers XBR0 and XBR1, defined in SFR Definition 14.1 and SFR Definition 14.2, are used to select internal digital functions.

All Port I/Os are 5 V tolerant (refer to Figure 14.2 for the Port cell circuit). The Port I/O cells are configured as either push-pull or open-drain in the Port Output Mode registers (PnMDOUT, where $\mathrm{n}=0,1$ ). Complete Electrical Specifications for Port I/O are given in Table 14.1 on page 134.

Figure 14.1. Port I/O Functional Block Diagram

## C8051F330/1/2/3/4/5

Figure 14.2. Port I/O Cell Block Diagram

## C8051F330/1/2/3/4/5

### 14.1. Priority Crossbar Decoder

The Priority Crossbar Decoder (Figure 14.3) assigns a priority to each I/O function, starting at the top with UARTO. When a digital resource is selected, the least-significant unassigned Port pin is assigned to that resource (excluding UARTO, which is always at pins 4 and 5). If a Port pin is assigned, the Crossbar skips that pin when assigning the next selected resource. Additionally, the Crossbar will skip Port pins whose associated bits in the PnSKIP registers are set. The PnSKIP registers allow software to skip Port pins that are to be used for analog input, dedicated functions, or GPIO.

Important Note on Crossbar Configuration: If a Port pin is claimed by a peripheral without use of the Crossbar, its corresponding PnSKIP bit should be set. This applies to P0.0 if VREF is used, P0.3 and/or P0.2 if the external oscillator circuit is enabled, P0.6 if the ADC or IDAC is configured to use the external conversion start signal (CNVSTR), and any selected ADC or Comparator inputs. The Crossbar skips selected pins as if they were already assigned, and moves to the next unassigned pin. Figure 14.3 shows the Crossbar Decoder priority with no Port pins skipped (P0SKIP, P1SKIP = 0x00); Figure 14.4 shows the Crossbar Decoder priority with the XTAL1 (P0.2) and XTAL2 (P0.3) pins skipped (POSKIP = 0x0C).

|  | Port pin potentially available to peripheral |
| :--- | :--- |
| SF Signals | Special Function Signals are not assigned by the crossbar. |
|  | When these signals are enabled, the CrossBar must be <br>  <br>  <br> manually configured to skip their corresponding port pins. |

Figure 14.3. Crossbar Priority Decoder with No Pins Skipped

## C8051F330/1/2/3/4/5

> Port pin potentially available to peripheral
> SF Signals Special Function Signals are not assigned by the crossbar.
> When these signals are enabled, the CrossBar must be manually configured to skip their corresponding port pins.

Figure 14.4. Crossbar Priority Decoder with Crystal Pins Skipped
Registers XBRO and XBR1 are used to assign the digital I/O resources to the physical I/O Port pins. Note that when the SMBus is selected, the Crossbar assigns both pins associated with the SMBus (SDA and SCL); when the UART is selected, the Crossbar assigns both pins associated with the UART (TX and RX). UARTO pin assignments are fixed for bootloading purposes: UART TX0 is always assigned to P0.4; UART RXO is always assigned to P0.5. Standard Port I/Os appear contiguously after the prioritized functions have been assigned.

Important Note: The SPI can be operated in either 3-wire or 4-wire modes, pending the state of the NSS-MD1-NSSMDO bits in register SPIOCN. According to the SPI mode, the NSS signal may or may not be routed to a Port pin.

## C8051F330/1/2/3/4/5

### 14.2. Port I/O Initialization

Port I/O initialization consists of the following steps:
Step 1. Select the input mode (analog or digital) for all Port pins, using the Port Input Mode register (PnMDIN).
Step 2. Select the output mode (open-drain or push-pull) for all Port pins, using the Port Output Mode register (PnMDOUT).
Step 3. Select any pins to be skipped by the I/O Crossbar using the Port Skip registers (PnSKIP).
Step 4. Assign Port pins to desired peripherals.
Step 5. Enable the Crossbar (XBARE = ' 1 ').
All Port pins must be configured as either analog or digital inputs. Any pins to be used as Comparator or ADC inputs should be configured as an analog inputs. When a pin is configured as an analog input, its weak pullup, digital driver, and digital receiver are disabled. This process saves power and reduces noise on the analog input. Pins configured as digital inputs may still be used by analog peripherals; however this practice is not recommended.

Additionally, all analog input pins should be configured to be skipped by the Crossbar (accomplished by setting the associated bits in PnSKIP). Port input mode is set in the PnMDIN register, where a ' 1 ' indicates a digital input, and a ' 0 ' indicates an analog input. All pins default to digital inputs on reset. See SFR Definition 14.4 for the PnMDIN register details.

The output driver characteristics of the I/O pins are defined using the Port Output Mode registers (PnMDOUT). Each Port Output driver can be configured as either open drain or push-pull. This selection is required even for the digital resources selected in the XBRn registers, and is not automatic. The only exception to this is the SMBus (SDA, SCL) pins, which are configured as open-drain regardless of the PnMDOUT settings. When the WEAKPUD bit in XBR1 is ' 0 ', a weak pullup is enabled for all Port I/O configured as open-drain. WEAKPUD does not affect the push-pull Port I/O. Furthermore, the weak pullup is turned off on an output that is driving a ' 0 ' to avoid unnecessary power dissipation.

Registers XBRO and XBR1 must be loaded with the appropriate values to select the digital I/O functions required by the design. Setting the XBARE bit in XBR1 to ' 1 ' enables the Crossbar. Until the Crossbar is enabled, the external pins remain as standard Port I/O (in input mode), regardless of the XBRn Register settings. For given XBRn Register settings, one can determine the I/O pin-out using the Priority Decode Table; as an alternative, the Configuration Wizard utility of the Silicon Labs IDE software will determine the Port I/O pin-assignments based on the XBRn Register settings.

The Crossbar must be enabled to use Port pins as standard Port I/O in output mode. Port output drivers are disabled while the Crossbar is disabled.

### 14.3. General Purpose Port I/O

Port pins that remain unassigned by the Crossbar and are not used by analog peripherals can be used for general purpose I/O. Ports2-0 are accessed through corresponding special function registers (SFRs) that are both byte addressable and bit addressable. When writing to a Port, the value written to the SFR is latched to maintain the output data value at each pin. When reading, the logic levels of the Port's input pins are returned regardless of the XBRn settings (i.e., even when the pin is assigned to another signal by the Crossbar, the Port register can always read its corresponding Port I/O pin). The exception to this is the execution of the read-modify-write instructions that target a Port Latch register as the destination. The read-modify-write instructions when operating on a Port SFR are the following: ANL, ORL, XRL, JBC, CPL, INC, DEC, DJNZ and MOV, CLR or SETB, when the destination is an individual bit in a Port SFR. For these instructions, the value of the register (not the pin) is read, modified, and written back to the SFR.

## 15. SMBus

The SMBus I/O interface is a two-wire, bi-directional serial bus. The SMBus is compliant with the System Management Bus Specification, version 1.1, and compatible with the I2C serial bus. Reads and writes to the interface by the system controller are byte oriented with the SMBus interface autonomously controlling the serial transfer of the data. Data can be transferred at up to $1 / 20$ th of the system clock as a master or slave (this can be faster than allowed by the SMBus specification, depending on the system clock used). A method of extending the clock-low duration is available to accommodate devices with different speed capabilities on the same bus.

The SMBus interface may operate as a master and/or slave, and may function on a bus with multiple masters. The SMBus provides control of SDA (serial data), SCL (serial clock) generation and synchronization, arbitration logic, and START/STOP control and generation. Three SFRs are associated with the SMBus: SMBOCF configures the SMBus; SMBOCN controls the status of the SMBus; and SMBODAT is the data register, used for both transmitting and receiving SMBus data and slave addresses.

Figure 15.1. SMBus Block Diagram

SILICON LABS

## C8051F330/1/2/3/4/5

### 15.1. Supporting Documents

It is assumed the reader is familiar with or has access to the following supporting documents:

1. The I2C-Bus and How to Use It (including specifications), Philips Semiconductor.
2. The I2C-Bus Specification-Version 2.0, Philips Semiconductor.
3. System Management Bus Specification-Version 1.1, SBS Implementers Forum.

### 15.2. SMBus Configuration

Figure 15.2 shows a typical SMBus configuration. The SMBus specification allows any recessive voltage between 3.0 V and 5.0 V ; different devices on the bus may operate at different voltage levels. The bi-directional SCL (serial clock) and SDA (serial data) lines must be connected to a positive power supply voltage through a pullup resistor or similar circuit. Every device connected to the bus must have an open-drain or open-collector output for both the SCL and SDA lines, so that both are pulled high (recessive state) when the bus is free. The maximum number of devices on the bus is limited only by the requirement that the rise and fall times on the bus not exceed 300 ns and 1000 ns , respectively.

Figure 15.2. Typical SMBus Configuration

### 15.3. SMBus Operation

Two types of data transfers are possible: data transfers from a master transmitter to an addressed slave receiver (WRITE), and data transfers from an addressed slave transmitter to a master receiver (READ). The master device initiates both types of data transfers and provides the serial clock pulses on SCL. The SMBus interface may operate as a master or a slave, and multiple master devices on the same bus are supported. If two or more masters attempt to initiate a data transfer simultaneously, an arbitration scheme is employed with a single master always winning the arbitration. Note that it is not necessary to specify one device as the Master in a system; any device who transmits a START and a slave address becomes the master for the duration of that transfer.

A typical SMBus transaction consists of a START condition followed by an address byte (Bits7-1: 7-bit slave address; Bit0: R/W direction bit), one or more bytes of data, and a STOP condition. Each byte that is received (by a master or slave) must be acknowledged (ACK) with a low SDA during a high SCL (see Figure 15.3). If the receiving device does not ACK, the transmitting device will read a NACK (not acknowledge), which is a high SDA during a high SCL.

## C8051F330/1/2/3/4/5

The direction bit (R/W) occupies the least-significant bit position of the address byte. The direction bit is set to logic 1 to indicate a "READ" operation and cleared to logic 0 to indicate a "WRITE" operation.

All transactions are initiated by a master, with one or more addressed slave devices as the target. The master generates the START condition and then transmits the slave address and direction bit. If the transaction is a WRITE operation from the master to the slave, the master transmits the data a byte at a time waiting for an ACK from the slave at the end of each byte. For READ operations, the slave transmits the data waiting for an ACK from the master at the end of each byte. At the end of the data transfer, the master generates a STOP condition to terminate the transaction and free the bus. Figure 15.3 illustrates a typical SMBus transaction.

Figure 15.3. SMBus Transaction

### 15.3.1. Arbitration

A master may start a transfer only if the bus is free. The bus is free after a STOP condition or after the SCL and SDA lines remain high for a specified time (see Section "15.3.4. SCL High (SMBus Free) Timeout" on page 138). In the event that two or more devices attempt to begin a transfer at the same time, an arbitration scheme is employed to force one master to give up the bus. The master devices continue transmitting until one attempts a HIGH while the other transmits a LOW. Since the bus is open-drain, the bus will be pulled LOW. The master attempting the HIGH will detect a LOW SDA and lose the arbitration. The winning master continues its transmission without interruption; the losing master becomes a slave and receives the rest of the transfer if addressed. This arbitration scheme is non-destructive: one device always wins, and no data is lost.

## C8051F330/1/2/3/4/5

### 15.3.2. Clock Low Extension

SMBus provides a clock synchronization mechanism, similar to I2C, which allows devices with different speed capabilities to coexist on the bus. A clock-low extension is used during a transfer in order to allow slower slave devices to communicate with faster masters. The slave may temporarily hold the SCL line LOW to extend the clock low period, effectively decreasing the serial clock frequency.

### 15.3.3. SCL Low Timeout

If the SCL line is held low by a slave device on the bus, no further communication is possible. Furthermore, the master cannot force the SCL line high to correct the error condition. To solve this problem, the SMBus protocol specifies that devices participating in a transfer must detect any clock cycle held low longer than 25 ms as a "timeout" condition. Devices that have detected the timeout condition must reset the communication no later than 10 ms after detecting the timeout condition.

When the SMBTOE bit in SMBOCF is set, Timer 3 is used to detect SCL low timeouts. Timer 3 is forced to reload when SCL is high, and allowed to count when SCL is low. With Timer 3 enabled and configured to overflow after 25 ms (and SMBTOE set), the Timer 3 interrupt service routine can be used to reset (disable and re-enable) the SMBus in the event of an SCL low timeout.

### 15.3.4. SCL High (SMBus Free) Timeout

The SMBus specification stipulates that if the SCL and SDA lines remain high for more that $50 \mu \mathrm{~s}$, the bus is designated as free. When the SMBFTE bit in SMBOCF is set, the bus will be considered free if SCL and SDA remain high for more than 10 SMBus clock source periods. If the SMBus is waiting to generate a Master START, the START will be generated following this timeout. Note that a clock source is required for free timeout detection, even in a slave-only implementation.

### 15.4. Using the SMBus

The SMBus can operate in both Master and Slave modes. The interface provides timing and shifting control for serial transfers; higher level protocol is determined by user software. The SMBus interface provides the following application-independent features:

- Byte-wise serial data transfers
- Clock signal generation on SCL (Master Mode only) and SDA data synchronization
- Timeout/bus error recognition, as defined by the SMBOCF configuration register
- START/STOP timing, detection, and generation
- Bus arbitration
- Interrupt generation
- Status information

SMBus interrupts are generated for each data byte or slave address that is transferred. When transmitting, this interrupt is generated after the ACK cycle so that software may read the received ACK value; when receiving data, this interrupt is generated before the ACK cycle so that software may define the outgoing ACK value. See Section "15.5. SMBus Transfer Modes" on page 146 for more details on transmission sequences.

Interrupts are also generated to indicate the beginning of a transfer when a master (START generated), or the end of a transfer when a slave (STOP detected). Software should read the SMBOCN (SMBus Control register) to find the cause of the SMBus interrupt. The SMBOCN register is described in Section "15.4.2. SMBOCN Control Register" on page 143; Table 15.4 provides a quick SMBOCN decoding reference.

## C8051F330/1/2/3/4/5

SMBus configuration options include:

- Timeout detection (SCL Low Timeout and/or Bus Free Timeout)
- SDA setup and hold time extensions
- Slave event enable/disable
- Clock source selection

These options are selected in the SMBOCF register, as described in Section "15.4.1. SMBus Configuration Register" on page 140.

## C8051F330/1/2/3/4/5

### 15.4.1. SMBus Configuration Register

The SMBus Configuration register (SMBOCF) is used to enable the SMBus Master and/or Slave modes, select the SMBus clock source, and select the SMBus timing and timeout options. When the ENSMB bit is set, the SMBus is enabled for all master and slave events. Slave events may be disabled by setting the INH bit. With slave events inhibited, the SMBus interface will still monitor the SCL and SDA pins; however, the interface will NACK all received addresses and will not generate any slave interrupts. When the INH bit is set, all slave events will be inhibited following the next START (interrupts will continue for the duration of the current transfer).

Table 15.1. SMBus Clock Source Selection

| SMBCS1 | SMBCS0 | SMBus Clock Source |
| :---: | :---: | :---: |
| 0 | 0 | Timer 0 Overflow |
| 0 | 1 | Timer 1 Overflow |
| 1 | 0 | Timer 2 High Byte Overflow |
| 1 | 1 | Timer 2 Low Byte Overflow |

The SMBCS1-0 bits select the SMBus clock source, which is used only when operating as a master or when the Free Timeout detection is enabled. When operating as a master, overflows from the selected source determine the absolute minimum SCL low and high times as defined in Equation 15.1. Note that the selected clock source may be shared by other peripherals so long as the timer is left running at all times. For example, Timer 1 overflows may generate the SMBus and UART baud rates simultaneously. Timer configuration is covered in Section "18. Timers" on page 177.

$$
T_{\text {HighMin }}=T_{\text {LowMin }}=\frac{1}{f_{\text {ClockSourceOverflow }}}
$$

## Equation 15.1. Minimum SCL High and Low Times

The selected clock source should be configured to establish the minimum SCL High and Low times as per Equation 15.1. When the interface is operating as a master (and SCL is not driven or extended by any other devices on the bus), the typical SMBus bit rate is approximated by Equation 15.2.

$$
\text { BitRate }=\frac{f_{\text {ClockSourceOverflow }}}{3}
$$

Equation 15.2. Typical SMBus Bit Rate

## C8051F330/1/2/3/4/5

Figure 15.4 shows the typical SCL generation described by Equation 15.2. Notice that $\mathrm{T}_{\text {HIGH }}$ is typically twice as large as $\mathrm{T}_{\text {Low. }}$. The actual SCL output may vary due to other devices on the bus (SCL may be extended low by slower slave devices, or driven low by contending master devices). The bit rate when operating as a master will never exceed the limits defined by equation Equation 15.1.

Figure 15.4. Typical SMBus SCL Generation
Setting the EXTHOLD bit extends the minimum setup and hold times for the SDA line. The minimum SDA setup time defines the absolute minimum time that SDA is stable before SCL transitions from low-to-high. The minimum SDA hold time defines the absolute minimum time that the current SDA value remains stable after SCL transitions from high-to-low. EXTHOLD should be set so that the minimum setup and hold times meet the SMBus Specification requirements of 250 ns and 300 ns , respectively. Table 15.2 shows the minimum setup and hold times for the two EXTHOLD settings. Setup and hold time extensions are typically necessary when SYSCLK is above 10 MHz .

Table 15.2. Minimum SDA Setup and Hold Times

| EXTHOLD | Minimum SDA Setup Time | Minimum SDA Hold Time |
| :---: | :---: | :---: |
| 0 | $\mathrm{T}_{\text {low }}-4$ system clocks <br> or | 3 system clocks |
| 1 system clock + s/w delay |  |  |

With the SMBTOE bit set, Timer 3 should be configured to overflow after 25 ms in order to detect SCL low timeouts (see Section "15.3.3. SCL Low Timeout" on page 138). The SMBus interface will force Timer 3 to reload while SCL is high, and allow Timer 3 to count when SCL is low. The Timer 3 interrupt service routine should be used to reset SMBus communication by disabling and re-enabling the SMBus.

SMBus Free Timeout detection can be enabled by setting the SMBFTE bit. When this bit is set, the bus will be considered free if SDA and SCL remain high for more than 10 SMBus clock source periods (see Figure 15.4). When a Free Timeout is detected, the interface will respond as if a STOP was detected (an interrupt will be generated, and STO will be set).

## C8051F330/1/2/3/4/5

### 15.4.2. SMBOCN Control Register

SMBOCN is used to control the interface and to provide status information (see SFR Definition 15.2). The higher four bits of SMBOCN (MASTER, TXMODE, STA, and STO) form a status vector that can be used to jump to service routines. MASTER and TXMODE indicate the master/slave state and transmit/receive modes, respectively.

STA and STO indicate that a START and/or STOP has been detected or generated since the last SMBus interrupt. STA and STO are also used to generate START and STOP conditions when operating as a master. Writing a ' 1 ' to STA will cause the SMBus interface to enter Master Mode and generate a START when the bus becomes free (STA is not cleared by hardware after the START is generated). Writing a ' 1 ' to STO while in Master Mode will cause the interface to generate a STOP and end the current transfer after the next ACK cycle. If STO and STA are both set (while in Master Mode), a STOP followed by a START will be generated.

As a receiver, writing the ACK bit defines the outgoing ACK value; as a transmitter, reading the ACK bit indicates the value received on the last ACK cycle. ACKRQ is set each time a byte is received, indicating that an outgoing ACK value is needed. When ACKRQ is set, software should write the desired outgoing value to the ACK bit before clearing SI. A NACK will be generated if software does not write the ACK bit before clearing SI. SDA will reflect the defined ACK value immediately following a write to the ACK bit; however SCL will remain low until SI is cleared. If a received slave address is not acknowledged, further slave events will be ignored until the next START is detected.

The ARBLOST bit indicates that the interface has lost an arbitration. This may occur anytime the interface is transmitting (master or slave). A lost arbitration while operating as a slave indicates a bus error condition. ARBLOST is cleared by hardware each time SI is cleared.

The SI bit (SMBus Interrupt Flag) is set at the beginning and end of each transfer, after each byte frame, or when an arbitration is lost; see Table 15.3 for more details.

Important Note About the SI Bit: The SMBus interface is stalled while SI is set; thus SCL is held low, and the bus is stalled until software clears SI .

Table 15.3 lists all sources for hardware changes to the SMBOCN bits. Refer to Table 15.4 for SMBus status decoding using the SMBOCN register.

## C8051F330/1/2/3/4/5

SFR Definition 15.2. SMB0CN: SMBus Control

Table 15.3. Sources for Hardware Changes to SMB0CN

| Bit | Set by Hardware When: | Cleared by Hardware When: |
| :---: | :--- | :--- |

| TXMODE | - START is generated. <br> - SMBODAT is written before the start of an <br> SMBus frame. | - A START is detected. <br> - Arbitration is lost. <br> - SMBODAT is not written before the <br> start of an SMBus frame. |
| STA | - A START followed by an address byte is <br> received. | - Must be cleared by software. |

## C8051F330/1/2/3/4/5

### 15.4.3. Data Register

The SMBus Data register SMBODAT holds a byte of serial data to be transmitted or one that has just been received. Software may safely read or write to the data register when the SI flag is set. Software should not attempt to access the SMBODAT register when the SMBus is enabled and the SI flag is cleared to logic 0 , as the interface may be in the process of shifting a byte of data into or out of the register.

Data in SMBODAT is always shifted out MSB first. After a byte has been received, the first bit of received data is located at the MSB of SMBODAT. While data is being shifted out, data on the bus is simultaneously being shifted in. SMBODAT always contains the last data byte present on the bus. In the event of lost arbitration, the transition from master transmitter to slave receiver is made with the correct data or address in SMBODAT.

SFR Definition 15.3. SMBODAT: SMBus Data

### 15.5. SMBus Transfer Modes

The SMBus interface may be configured to operate as master and/or slave. At any particular time, it will be operating in one of the following four modes: Master Transmitter, Master Receiver, Slave Transmitter, or Slave Receiver. The SMBus interface enters Master Mode any time a START is generated, and remains in Master Mode until it loses an arbitration or generates a STOP. An SMBus interrupt is generated at the end of all SMBus byte frames; however, note that the interrupt is generated before the ACK cycle when operating as a receiver, and after the ACK cycle when operating as a transmitter.

### 15.5.1. Master Transmitter Mode

Serial data is transmitted on SDA while the serial clock is output on SCL. The SMBus interface generates the START condition and transmits the first byte containing the address of the target slave and the data direction bit. In this case the data direction bit (R/W) will be logic 0 (WRITE). The master then transmits one or more bytes of serial data. After each byte is transmitted, an acknowledge bit is generated by the slave. The transfer is ended when the STO bit is set and a STOP is generated. Note that the interface will switch to Master Receiver Mode if SMBODAT is not written following a Master Transmitter interrupt. Figure 15.5 shows a typical Master Transmitter sequence. Two transmit data bytes are shown, though any number of bytes may be transmitted. Notice that the 'data byte transferred' interrupts occur after the ACK cycle in this mode.

Figure 15.5. Typical Master Transmitter Sequence

## C8051F330/1/2/3/4/5

### 15.5.2. Master Receiver Mode

Serial data is received on SDA while the serial clock is output on SCL. The SMBus interface generates the START condition and transmits the first byte containing the address of the target slave and the data direction bit. In this case the data direction bit (R/W) will be logic 1 (READ). Serial data is then received from the slave on SDA while the SMBus outputs the serial clock. The slave transmits one or more bytes of serial data. After each byte is received, ACKRQ is set to ' 1 ' and an interrupt is generated. Software must write the ACK bit (SMBOCN.1) to define the outgoing acknowledge value (Note: writing a ' 1 ' to the ACK bit generates an ACK; writing a ' 0 ' generates a NACK). Software should write a ' 0 ' to the ACK bit after the last byte is received, to transmit a NACK. The interface exits Master Receiver Mode after the STO bit is set and a STOP is generated. The interface will switch to Master Transmitter Mode if SMBODAT is written while an active Master Receiver. Figure 15.6 shows a typical Master Receiver sequence. Two received data bytes are shown, though any number of bytes may be received. Notice that the 'data byte transferred' interrupts occur before the ACK cycle in this mode.

Figure 15.6. Typical Master Receiver Sequence

## C8051F330/1/2/3/4/5

### 15.5.3. Slave Receiver Mode

Serial data is received on SDA and the clock is received on SCL. When slave events are enabled (INH = 0 ), the interface enters Slave Receiver Mode when a START followed by a slave address and direction bit (WRITE in this case) is received. Upon entering Slave Receiver Mode, an interrupt is generated and the ACKRQ bit is set. Software responds to the received slave address with an ACK, or ignores the received slave address with a NACK. If the received slave address is ignored, slave interrupts will be inhibited until the next START is detected. If the received slave address is acknowledged, zero or more data bytes are received. Software must write the ACK bit after each received byte to ACK or NACK the received byte. The interface exits Slave Receiver Mode after receiving a STOP. Note that the interface will switch to Slave Transmitter Mode if SMBODAT is written while an active Slave Receiver. Figure 15.7 shows a typical Slave Receiver sequence. Two received data bytes are shown, though any number of bytes may be received. Notice that the 'data byte transferred' interrupts occur before the ACK cycle in this mode.

Figure 15.7. Typical Slave Receiver Sequence

## C8051F330/1/2/3/4/5

### 15.5.4. Slave Transmitter Mode

Serial data is transmitted on SDA and the clock is received on SCL. When slave events are enabled (INH $=0$ ), the interface enters Slave Receiver Mode (to receive the slave address) when a START followed by a slave address and direction bit (READ in this case) is received. Upon entering Slave Transmitter Mode, an interrupt is generated and the ACKRQ bit is set. Software responds to the received slave address with an ACK, or ignores the received slave address with a NACK. If the received slave address is ignored, slave interrupts will be inhibited until a START is detected. If the received slave address is acknowledged, data should be written to SMBODAT to be transmitted. The interface enters Slave Transmitter Mode, and transmits one or more bytes of data. After each byte is transmitted, the master sends an acknowledge bit; if the acknowledge bit is an ACK, SMBODAT should be written with the next data byte. If the acknowledge bit is a NACK, SMBODAT should not be written to before SI is cleared (Note: an error condition may be generated if SMBODAT is written following a received NACK while in Slave Transmitter Mode). The interface exits Slave Transmitter Mode after receiving a STOP. Note that the interface will switch to Slave Receiver Mode if SMBODAT is not written following a Slave Transmitter interrupt. Figure 15.8 shows a typical Slave Transmitter sequence. Two transmitted data bytes are shown, though any number of bytes may be transmitted. Notice that the 'data byte transferred' interrupts occur after the ACK cycle in this mode.

Figure 15.8. Typical Slave Transmitter Sequence

### 15.6. SMBus Status Decoding

The current SMBus status can be easily decoded using the SMBOCN register. In the table below, STATUS VECTOR refers to the four upper bits of SMBOCN: MASTER, TXMODE, STA, and STO. The shown response options are only the typical responses; application-specific procedures are allowed as long as they conform to the SMBus specification. Highlighted responses are allowed but do not conform to the SMBus specification.

## C8051F330/1/2/3/4/5

## 16. UARTO

UARTO is an asynchronous, full duplex serial port offering modes 1 and 3 of the standard 8051 UART. Enhanced baud rate support allows a wide range of clock sources to generate standard baud rates (details in Section "16.1. Enhanced Baud Rate Generation" on page 154). Received data buffering allows UARTO to start reception of a second incoming data byte before software has finished reading the previous data byte.

UART0 has two associated SFRs: Serial Control Register 0 (SCONO) and Serial Data Buffer 0 (SBUF0). The single SBUFO location provides access to both transmit and receive registers. Writes to SBUF0 always access the Transmit register. Reads of SBUF0 always access the buffered Receive register; it is not possible to read data from the Transmit register.

With UARTO interrupts enabled, an interrupt is generated each time a transmit is completed (TIO is set in SCONO), or a data byte has been received (RIO is set in SCONO). The UARTO interrupt flags are not cleared by hardware when the CPU vectors to the interrupt service routine. They must be cleared manually by software, allowing software to determine the cause of the UART0 interrupt (transmit complete or receive complete).

Figure 16.1. UARTO Block Diagram

## C8051F330/1/2/3/4/5

### 16.1. Enhanced Baud Rate Generation

The UARTO baud rate is generated by Timer 1 in 8-bit auto-reload mode. The TX clock is generated by TL1; the RX clock is generated by a copy of TL1 (shown as RX Timer in Figure 16.2), which is not useraccessible. Both TX and RX Timer overflows are divided by two to generate the TX and RX baud rates. The RX Timer runs when Timer 1 is enabled, and uses the same reload value (TH1). However, an RX Timer reload is forced when a START condition is detected on the RX pin. This allows a receive to begin any time a START is detected, independent of the TX Timer state.

Figure 16.2. UARTO Baud Rate Logic

Timer 1 should be configured for Mode 2, 8-bit auto-reload (see Section "18.1.3. Mode 2: 8-bit Counter/Timer with Auto-Reload" on page 179). The Timer 1 reload value should be set so that overflows will occur at two times the desired UART baud rate frequency. Note that Timer 1 may be clocked by one of six sources: SYSCLK, SYSCLK / 4, SYSCLK / 12, SYSCLK / 48, the external oscillator clock / 8, or an external input T1. For any given Timer 1 clock source, the UART0 baud rate is determined by Equation 16.1-A and Equation 16.1-B.
A) UartBaudRate $=\frac{1}{2} \times$ T1_Overflow_Rate
B) $\quad \mathrm{T} 1 \_$Overflow_Rate $=\frac{\mathrm{T} 1_{\mathrm{CLK}}}{256-\mathrm{TH} 1}$

## Equation 16.1. UARTO Baud Rate

Where $T 1_{C L K}$ is the frequency of the clock supplied to Timer 1 , and $T 1 H$ is the high byte of Timer 1 (reload value). Timer 1 clock frequency is selected as described in Section "18. Timers" on page 177. A quick reference for typical baud rates and system clock frequencies is given in Table 16.1 through Table 16.6. Note that the internal oscillator may still generate the system clock when the external oscillator is driving Timer 1.

# C8051F330/1/2/3/4/5 

### 16.2. Operational Modes

UARTO provides standard asynchronous, full duplex communication. The UART mode (8-bit or 9-bit) is selected by the SOMODE bit (SCON0.7). Typical UART connection options are shown below.

Figure 16.3. UART Interconnect Diagram

### 16.2.1. 8-Bit UART

8-Bit UART mode uses a total of 10 bits per data byte: one start bit, eight data bits (LSB first), and one stop bit. Data are transmitted LSB first from the TX0 pin and received at the RX0 pin. On receive, the eight data bits are stored in SBUF0 and the stop bit goes into RB80 (SCON0.2).

Data transmission begins when software writes a data byte to the SBUFO register. The TIO Transmit Interrupt Flag (SCON0.1) is set at the end of the transmission (the beginning of the stop-bit time). Data reception can begin any time after the RENO Receive Enable bit (SCONO.4) is set to logic 1. After the stop bit is received, the data byte will be loaded into the SBUFO receive register if the following conditions are met: RIO must be logic 0 , and if MCEO is logic 1, the stop bit must be logic 1 . In the event of a receive data overrun, the first received 8 bits are latched into the SBUFO receive register and the following overrun data bits are lost.

If these conditions are met, the eight bits of data is stored in SBUF0, the stop bit is stored in RB80 and the RIO flag is set. If these conditions are not met, SBUF0 and RB80 will not be loaded and the RIO flag will not be set. An interrupt will occur if enabled when either TIO or RIO is set.

Figure 16.4. 8-Bit UART Timing Diagram

## C8051F330/1/2/3/4/5

### 16.2.2. 9-Bit UART

9-bit UART mode uses a total of eleven bits per data byte: a start bit, 8 data bits (LSB first), a programmable ninth data bit, and a stop bit. The state of the ninth transmit data bit is determined by the value in TB80 (SCON0.3), which is assigned by user software. It can be assigned the value of the parity flag (bit P in register PSW) for error detection, or used in multiprocessor communications. On receive, the ninth data bit goes into RB80 (SCON0.2) and the stop bit is ignored.

Data transmission begins when an instruction writes a data byte to the SBUF0 register. The TIO Transmit Interrupt Flag (SCON0.1) is set at the end of the transmission (the beginning of the stop-bit time). Data reception can begin any time after the RENO Receive Enable bit (SCONO.4) is set to ' 1 '. After the stop bit is received, the data byte will be loaded into the SBUFO receive register if the following conditions are met: (1) RIO must be logic 0 , and (2) if MCEO is logic 1 , the 9 th bit must be logic 1 (when MCEO is logic 0 , the state of the ninth data bit is unimportant). If these conditions are met, the eight bits of data are stored in SBUFO, the ninth bit is stored in RB80, and the RIO flag is set to ' 1 '. If the above conditions are not met, SBUF0 and RB80 will not be loaded and the RIO flag will not be set to ' 1 '. A UART0 interrupt will occur if enabled when either TIO or RIO is set to ' 1 '.

Figure 16.5. 9-Bit UART Timing Diagram

### 16.3. Multiprocessor Communications

9-Bit UART mode supports multiprocessor communication between a master processor and one or more slave processors by special use of the ninth data bit. When a master processor wants to transmit to one or more slaves, it first sends an address byte to select the target(s). An address byte differs from a data byte in that its ninth bit is logic 1 ; in a data byte, the ninth bit is always set to logic 0 .

Setting the MCEO bit (SCON0.5) of a slave processor configures its UART such that when a stop bit is received, the UART will generate an interrupt only if the ninth bit is logic 1 (RB80 = 1) signifying an address byte has been received. In the UART interrupt handler, software will compare the received address with the slave's own assigned 8-bit address. If the addresses match, the slave will clear its MCE0 bit to enable interrupts on the reception of the following data byte(s). Slaves that weren't addressed leave their MCE0 bits set and do not generate interrupts on the reception of the following data bytes, thereby ignoring the data. Once the entire message is received, the addressed slave resets its MCEO bit to ignore all transmissions until it receives the next address byte.

Multiple addresses can be assigned to a single slave and/or a single address can be assigned to multiple slaves, thereby enabling "broadcast" transmissions to more than one slave simultaneously. The master processor can be configured to receive all transmissions or a protocol can be implemented such that the master/slave role is temporarily reversed to enable half-duplex transmission between the original master and slave(s).

## 17. Enhanced Serial Peripheral Interface (SPIO)

The Enhanced Serial Peripheral Interface (SPIO) provides access to a flexible, full-duplex synchronous serial bus. SPIO can operate as a master or slave device in both 3-wire or 4-wire modes, and supports multiple masters and slaves on a single SPI bus. The slave-select (NSS) signal can be configured as an input to select SPIO in slave mode, or to disable Master Mode operation in a multi-master environment, avoiding contention on the SPI bus when more than one master attempts simultaneous data transfers. NSS can also be configured as a chip-select output in master mode, or disabled for 3-wire operation. Additional general purpose port I/O pins can be used to select multiple slave devices in master mode.

Figure 17.1. SPI Block Diagram

## C8051F330/1/2/3/4/5

### 17.1. Signal Descriptions

The four signals used by SPIO (MOSI, MISO, SCK, NSS) are described below.

### 17.1.1. Master Out, Slave In (MOSI)

The master-out, slave-in (MOSI) signal is an output from a master device and an input to slave devices. It is used to serially transfer data from the master to the slave. This signal is an output when SPIO is operating as a master and an input when SPIO is operating as a slave. Data is transferred most-significant bit first. When configured as a master, MOSI is driven by the MSB of the shift register in both 3 - and 4 -wire mode.

### 17.1.2. Master In, Slave Out (MISO)

The master-in, slave-out (MISO) signal is an output from a slave device and an input to the master device. It is used to serially transfer data from the slave to the master. This signal is an input when SPIO is operating as a master and an output when SPIO is operating as a slave. Data is transferred most-significant bit first. The MISO pin is placed in a high-impedance state when the SPI module is disabled and when the SPI operates in 4 -wire mode as a slave that is not selected. When acting as a slave in 3 -wire mode, MISO is always driven by the MSB of the shift register.

### 17.1.3. Serial Clock (SCK)

The serial clock (SCK) signal is an output from the master device and an input to slave devices. It is used to synchronize the transfer of data between the master and slave on the MOSI and MISO lines. SPIO generates this signal when operating as a master. The SCK signal is ignored by a SPI slave when the slave is not selected (NSS = 1) in 4-wire slave mode.

### 17.1.4. Slave Select (NSS)

The function of the slave-select (NSS) signal is dependent on the setting of the NSSMD1 and NSSMDO bits in the SPIOCN register. There are three possible modes that can be selected with these bits:

1. NSSMD[1:0] = 00: 3-Wire Master or 3-Wire Slave Mode: SPI0 operates in 3-wire mode, and NSS is disabled. When operating as a slave device, SPIO is always selected in 3 -wire mode. Since no select signal is present, SPIO must be the only slave on the bus in 3 -wire mode. This is intended for point-to-point communication between a master and one slave.
2. NSSMD[1:0] = 01: 4-Wire Slave or Multi-Master Mode: SPIO operates in 4 -wire mode, and NSS is enabled as an input. When operating as a slave, NSS selects the SPIO device. When operating as a master, a 1-to-0 transition of the NSS signal disables the master function of SPIO so that multiple master devices can be used on the same SPI bus.
3. NSSMD[1:0] = 1x: 4-Wire Master Mode: SPIO operates in 4 -wire mode, and NSS is enabled as an output. The setting of NSSMDO determines what logic level the NSS pin will output. This configuration should only be used when operating SPIO as a master device.

See Figure 17.2, Figure 17.3, and Figure 17.4 for typical connection diagrams of the various operational modes. Note that the setting of NSSMD bits affects the pinout of the device. When in 3 -wire master or 3 -wire slave mode, the NSS pin will not be mapped by the crossbar. In all other modes, the NSS signal will be mapped to a pin on the device. See Section "14. Port Input/Output" on page 123 for general purpose port I/O and crossbar information.

# C8051F330/1/2/3/4/5 

### 17.2. SPIO Master Mode Operation

A SPI master device initiates all data transfers on a SPI bus. SPIO is placed in master mode by setting the Master Enable flag (MSTEN, SPIOCN.6). Writing a byte of data to the SPIO data register (SPIODAT) when in master mode writes to the transmit buffer. If the SPI shift register is empty, the byte in the transmit buffer is moved to the shift register, and a data transfer begins. The SPIO master immediately shifts out the data serially on the MOSI line while providing the serial clock on SCK. The SPIF (SPIOCN.7) flag is set to logic 1 at the end of the transfer. If interrupts are enabled, an interrupt request is generated when the SPIF flag is set. While the SPIO master transfers data to a slave on the MOSI line, the addressed SPI slave device simultaneously transfers the contents of its shift register to the SPI master on the MISO line in a full-duplex operation. Therefore, the SPIF flag serves as both a transmit-complete and receive-data-ready flag. The data byte received from the slave is transferred MSB-first into the master's shift register. When a byte is fully shifted into the register, it is moved to the receive buffer where it can be read by the processor by reading SPIODAT.

When configured as a master, SPIO can operate in one of three different modes: multi-master mode, 3-wire single-master mode, and 4 -wire single-master mode. The default, multi-master mode is active when NSSMD1 (SPIOCN.3) $=0$ and NSSMDO $($ SPIOCN.2 $)=1$. In this mode, NSS is an input to the device, and is used to disable the master SPIO when another master is accessing the bus. When NSS is pulled low in this mode, MSTEN (SPIOCN.6) and SPIEN (SPIOCN.0) are set to 0 to disable the SPI master device, and a Mode Fault is generated (MODF, SPIOCN. $5=1$ ). Mode Fault will generate an interrupt if enabled. SPIO must be manually re-enabled in software under these circumstances. In multi-master systems, devices will typically default to being slave devices while they are not acting as the system master device. In multi-master mode, slave devices can be addressed individually (if needed) using general-purpose I/O pins. Figure 17.2 shows a connection diagram between two master devices in multiple-master mode.

3 -wire single-master mode is active when NSSMD1 (SPIOCN.3) $=0$ and NSSMDO (SPIOCN.2) $=0$. In this mode, NSS is not used, and is not mapped to an external port pin through the crossbar. Any slave devices that must be addressed in this mode should be selected using general-purpose I/O pins. Figure 17.3 shows a connection diagram between a master device in 3 -wire master mode and a slave device.

4-wire single-master mode is active when NSSMD1 (SPIOCN.3) $=1$. In this mode, NSS is configured as an output pin, and can be used as a slave-select signal for a single SPI device. In this mode, the output value of NSS is controlled (in software) with the bit NSSMDO (SPIOCN.2). Additional slave devices can be addressed using general-purpose I/O pins. Figure 17.4 shows a connection diagram for a master device in 4 -wire master mode and two slave devices.

Figure 17.4. 4-Wire Single Master Mode and 4-Wire Slave Mode Connection Diagram

# C8051F330/1/2/3/4/5 

### 17.3. SPIO Slave Mode Operation

When SPIO is enabled and not configured as a master, it will operate as a SPI slave. As a slave, bytes are shifted in through the MOSI pin and out through the MISO pin by a master device controlling the SCK signal. A bit counter in the SPIO logic counts SCK edges. When 8 bits have been shifted through the shift register, the SPIF flag is set to logic 1, and the byte is copied into the receive buffer. Data is read from the receive buffer by reading SPIODAT. A slave device cannot initiate transfers. Data to be transferred to the master device is pre-loaded into the shift register by writing to SPIODAT. Writes to SPIODAT are doublebuffered, and are placed in the transmit buffer first. If the shift register is empty, the contents of the transmit buffer will immediately be transferred into the shift register. When the shift register already contains data, the SPI will load the shift register with the transmit buffer's contents after the last SCK edge of the next (or current) SPI transfer.

When configured as a slave, SPIO can be configured for 4 -wire or 3 -wire operation. The default, 4 -wire slave mode, is active when NSSMD1 $($ SPIOCN.3) $=0$ and NSSMDO $($ SPIOCN. 2$)=1$. In 4 -wire mode, the NSS signal is routed to a port pin and configured as a digital input. SPIO is enabled when NSS is logic 0 , and disabled when NSS is logic 1 . The bit counter is reset on a falling edge of NSS. Note that the NSS signal must be driven low at least 2 system clocks before the first active edge of SCK for each byte transfer. Figure 17.4 shows a connection diagram between two slave devices in 4 -wire slave mode and a master device.

3-wire slave mode is active when NSSMD1 (SPIOCN.3) $=0$ and NSSMDO (SPIOCN.2) $=0$. NSS is not used in this mode, and is not mapped to an external port pin through the crossbar. Since there is no way of uniquely addressing the device in 3 -wire slave mode, SPIO must be the only slave device present on the bus. It is important to note that in 3 -wire slave mode there is no external means of resetting the bit counter that determines when a full byte has been received. The bit counter can only be reset by disabling and reenabling SPIO with the SPIEN bit. Figure 17.3 shows a connection diagram between a slave device in 3 wire slave mode and a master device.

### 17.4. SPIO Interrupt Sources

When SPIO interrupts are enabled, the following four flags will generate an interrupt when they are set to logic 1:

All of the following bits must be cleared by software.

1. The SPI Interrupt Flag, SPIF (SPIOCN.7) is set to logic 1 at the end of each byte transfer. This flag can occur in all SPIO modes.
2. The Write Collision Flag, WCOL (SPIOCN.6) is set to logic 1 if a write to SPIODAT is attempted when the transmit buffer has not been emptied to the SPI shift register. When this occurs, the write to SPIODAT will be ignored, and the transmit buffer will not be written. This flag can occur in all SPIO modes.
3. The Mode Fault Flag MODF (SPIOCN.5) is set to logic 1 when SPIO is configured as a master, and for multi-master mode and the NSS pin is pulled low. When a Mode Fault occurs, the MSTEN and SPIEN bits in SPIOCN are set to logic 0 to disable SPIO and allow another master device to access the bus.
4. The Receive Overrun Flag RXOVRN (SPIOCN.4) is set to logic 1 when configured as a slave, and a transfer is completed and the receive buffer still holds an unread byte from a previous transfer. The new byte is not transferred to the receive buffer, allowing the previously received data byte to be read. The data byte which caused the overrun is lost.

## C8051F330/1/2/3/4/5

### 17.5. Serial Clock Timing

Four combinations of serial clock phase and polarity can be selected using the clock control bits in the SPIO Configuration Register (SPIOCFG). The CKPHA bit (SPIOCFG.5) selects one of two clock phases (edge used to latch the data). The CKPOL bit (SPIOCFG.4) selects between an active-high or active-low clock. Both master and slave devices must be configured to use the same clock phase and polarity. SPIO should be disabled (by clearing the SPIEN bit, SPIOCN.0) when changing the clock phase or polarity. The clock and data line relationships for master mode are shown in Figure 17.5. For slave mode, the clock and data relationships are shown in Figure 17.6 and Figure 17.7. Note that CKPHA must be set to ' 0 ' on both the master and slave SPI when communicating between two of the following devices: C8051F04x, C8051F06x, C8051F12x, C8051F31x, C8051F32x, and C8051F33x

The SPIO Clock Rate Register (SPIOCKR) as shown in SFR Definition 17.3 controls the master mode serial clock frequency. This register is ignored when operating in slave mode. When the SPI is configured as a master, the maximum data transfer rate (bits/sec) is one-half the system clock frequency or 12.5 MHz , whichever is slower. When the SPI is configured as a slave, the maximum data transfer rate (bits/sec) for full-duplex operation is $1 / 10$ the system clock frequency, provided that the master issues SCK, NSS (in 4wire slave mode), and the serial input data synchronously with the slave's system clock. If the master issues SCK, NSS, and the serial input data asynchronously, the maximum data transfer rate (bits/sec) must be less than $1 / 10$ the system clock frequency. In the special case where the master only wants to transmit data to the slave and does not need to receive data from the slave (i.e. half-duplex operation), the SPI slave can receive data at a maximum data transfer rate (bits/sec) of $1 / 4$ the system clock frequency. This is provided that the master issues SCK, NSS, and the serial input data synchronously with the slave's system clock.

Figure 17.5. Master Mode Data/Clock Timing

Figure 17.6. Slave Mode Data/Clock Timing (CKPHA = 0)

Figure 17.7. Slave Mode Data/Clock Timing (CKPHA = 1)

### 17.6. SPI Special Function Registers

SPIO is accessed and controlled through four special function registers in the system controller: SPIOCN Control Register, SPIODAT Data Register, SPIOCFG Configuration Register, and SPIOCKR Clock Rate Register. The four special function registers related to the operation of the SPIO Bus are described in the following figures.

| SCR7 | SCR6 | SCR5 | SCR4 | SCR3 | SCR2 | SCR1 | SCR0 |  |
| Bit7 | Bit6 | Bit5 | Bit4 | Bit3 | Bit2 | Bit1 | Bit0 |  |

Bits 7-0: SCR7-SCRO: SPIO Clock Rate.
These bits determine the frequency of the SCK output when the SPIO module is configured for master mode operation. The SCK clock frequency is a divided version of the system clock, and is given in the following equation, where SYSCLK is the system clock frequency and SPIOCKR is the 8 -bit value held in the SPIOCKR register.
$f_{S C K}=\frac{S Y S C L K}{2 \times(S P I 0 C K R+1)}$
for $0<=$ SPIOCKR <= 255
Example: If SYSCLK $=2 \mathrm{MHz}$ and SPIOCKR $=0 \times 04$,

$$
\begin{aligned}
& f_{S C K}=\frac{2000000}{2 \times(4+1)} \\
& f_{S C K}=200 \mathrm{kHz}
\end{aligned}
$$

SFR Definition 17.4. SPIODAT: SPIO Data

| R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | Reset Value |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  | 00000000 |
| Bit7 | Bit6 | Bit5 | Bit4 | Bit3 | Bit2 | Bit1 | Bit0 |  |

Bits 7-0: SPIODAT: SPIO Transmit and Receive Data.
The SPIODAT register is used to transmit and receive SPIO data. Writing data to SPIODAT places the data into the transmit buffer and initiates a transfer when in Master Mode. A read of SPIODAT returns the contents of the receive buffer.

| $\mathrm{T}_{\text {SLH }}$ | Last SCK Edge to MISO Change (CKPHA = 1 ONLY) | $6 \times \mathrm{T}_{\text {SYSCLK }}$ | $8 \times \mathrm{T}_{\text {SYSCLK }}$ | ns |
| *Note: $\mathrm{T}_{\text {SYSCLK }}$ is equal to one period of the device system clock (SYSCLK). |  |  |  |  |

## C8051F330/1/2/3/4/5

# C8051F330/1/2/3/4/5 

## 18. Timers

Each MCU includes four counter/timers: two are 16-bit counter/timers compatible with those found in the standard 8051, and two are 16-bit auto-reload timer for use with the ADC, SMBus, or for general purpose use. These timers can be used to measure time intervals, count external events and generate periodic interrupt requests. Timer 0 and Timer 1 are nearly identical and have four primary modes of operation. Timer 2 and Timer 3 offer 16 -bit and split 8 -bit timer functionality with auto-reload

| Timer 0 and Timer 1 Modes: | Timer 2 Modes: | Timer 3 Modes: |
| :---: | :---: | :---: |
| 13-bit counter/timer | 16-bit timer with auto-reload | 16-bit timer with auto-reload |
| 16-bit counter/timer | Two 8-bit timers with auto-reload | Two 8-bit timers with auto-reload |
| 8-bit counter/timer with auto- <br> reload | Two 8-bit counter/timers (Timer 0 |  |
| only) |  |  |

Timers 0 and 1 may be clocked by one of five sources, determined by the Timer Mode Select bits (T1MTOM) and the Clock Scale bits (SCA1-SCA0). The Clock Scale bits define a pre-scaled clock from which Timer 0 and/or Timer 1 may be clocked (See SFR Definition 18.3 for pre-scaled clock selection).

Timer 0/1 may then be configured to use this pre-scaled clock signal or the system clock. Timer 2 and Timer 3 may be clocked by the system clock, the system clock divided by 12 , or the external oscillator clock source divided by 8 .

Timer 0 and Timer 1 may also be operated as counters. When functioning as a counter, a counter/timer register is incremented on each high-to-low transition at the selected input pin (T0 or T1). Events with a frequency of up to one-fourth the system clock frequency can be counted. The input signal need not be periodic, but it should be held at a given level for at least two full system clock cycles to ensure the level is properly sampled.

### 18.1. Timer 0 and Timer 1

Each timer is implemented as a 16 -bit register accessed as two separate bytes: a low byte (TLO or TL1) and a high byte (TH0 or TH1). The Counter/Timer Control register (TCON) is used to enable Timer 0 and Timer 1 as well as indicate status. Timer 0 interrupts can be enabled by setting the ETO bit in the IE register (Section "9.3.5. Interrupt Register Descriptions" on page 89); Timer 1 interrupts can be enabled by setting the ET1 bit in the IE register (Section 9.3.5). Both counter/timers operate in one of four primary modes selected by setting the Mode Select bits T1M1-TOMO in the Counter/Timer Mode register (TMOD). Each timer can be configured independently. Each operating mode is described below.

### 18.1.1. Mode 0: 13 -bit Counter/Timer

Timer 0 and Timer 1 operate as 13 -bit counter/timers in Mode 0 . The following describes the configuration and operation of Timer 0 . However, both timers operate identically, and Timer 1 is configured in the same manner as described for Timer 0 .

The THO register holds the eight MSBs of the 13-bit counter/timer. TLO holds the five LSBs in bit positions TLO.4-TLO.O. The three upper bits of TLO (TLO.7-TLO.5) are indeterminate and should be masked out or ignored when reading. As the 13 -bit timer register increments and overflows from 0x1FFF (all ones) to 0x0000, the timer overflow flag TFO (TCON.5) is set and an interrupt will occur if Timer 0 interrupts are enabled.

## C8051F330/1/2/3/4/5

The C/T0 bit (TMOD.2) selects the counter/timer's clock source. When C/T0 is set to logic 1, high-to-low transitions at the selected Timer 0 input pin (TO) increment the timer register (Refer to Section "14.1. Priority Crossbar Decoder" on page 125 for information on selecting and configuring external I/O pins). Clearing C/T selects the clock defined by the TOM bit (CKCON.3). When TOM is set, Timer 0 is clocked by the system clock. When TOM is cleared, Timer 0 is clocked by the source selected by the Clock Scale bits in CKCON (see SFR Definition 18.3).

Setting the TRO bit (TCON.4) enables the timer when either GATEO (TMOD.3) is logic 0 or the input signal /INTO is active as defined by bit INOPL in register ITO1CF (see SFR Definition 9.11). Setting GATE0 to ' 1 ' allows the timer to be controlled by the external input signal /INT0 (see Section "9.3.5. Interrupt Register Descriptions" on page 89), facilitating pulse width measurements

| TR0 | GATE0 | IINTO | Counter/Timer |
| :---: | :---: | :---: | :---: |
| 0 | $X$ | $X$ | Disabled |
| 1 | 0 | $X$ | Enabled |
| 1 | 1 | 0 | Disabled |
| 1 | 1 | 1 | Enabled |
| Note: $X=$ Don't Care |  |  |  |

Setting TRO does not force the timer to reset. The timer registers should be loaded with the desired initial value before the timer is enabled.

TL1 and TH1 form the 13-bit register for Timer 1 in the same manner as described above for TL0 and TH0. Timer 1 is configured and controlled using the relevant TCON and TMOD bits just as with Timer 0. The input signal /INT1 is used with Timer 1; the /INT1 polarity is defined by bit IN1PL in register IT01CF (see SFR Definition 9.11).

Figure 18.1. TO Mode 0 Block Diagram

### 18.1.2. Mode 1: $\mathbf{1 6}$-bit Counter/Timer

Mode 1 operation is the same as Mode 0 , except that the counter/timer registers use all 16 bits. The counter/timers are enabled and configured in Mode 1 in the same manner as for Mode 0.

## C8051F330/1/2/3/4/5

### 18.1.3. Mode 2: 8-bit Counter/Timer with Auto-Reload

Mode 2 configures Timer 0 and Timer 1 to operate as 8 -bit counter/timers with automatic reload of the start value. TLO holds the count and THO holds the reload value. When the counter in TLO overflows from all ones to $0 \times 00$, the timer overflow flag TFO (TCON.5) is set and the counter in TLO is reloaded from THO. If Timer 0 interrupts are enabled, an interrupt will occur when the TFO flag is set. The reload value in THO is not changed. TLO must be initialized to the desired value before enabling the timer for the first count to be correct. When in Mode 2, Timer 1 operates identically to Timer 0.

Both counter/timers are enabled and configured in Mode 2 in the same manner as Mode 0 . Setting the TRO bit (TCON.4) enables the timer when either GATEO (TMOD.3) is logic 0 or when the input signal /INTO is active as defined by bit INOPL in register ITO1CF (see Section "9.3.2. External Interrupts" on page 87 for details on the external input signals /INT0 and /INT1).

Figure 18.2. TO Mode 2 Block Diagram

## C8051F330/1/2/3/4/5

### 18.1.4. Mode 3: Two 8-bit Counter/Timers (Timer 0 Only)

In Mode 3, Timer 0 is configured as two separate 8 -bit counter/timers held in TLO and THO. The counter/timer in TLO is controlled using the Timer 0 control/status bits in TCON and TMOD: TRO, C/T0, GATE0 and TFO. TLO can use either the system clock or an external input signal as its timebase. The TH0 register is restricted to a timer function sourced by the system clock or prescaled clock. TH0 is enabled using the Timer 1 run control bit TR1. TH0 sets the Timer 1 overflow flag TF1 on overflow and thus controls the Timer 1 interrupt.

Timer 1 is inactive in Mode 3. When Timer 0 is operating in Mode 3, Timer 1 can be operated in Modes 0, 1 or 2, but cannot be clocked by external signals nor set the TF1 flag and generate an interrupt. However, the Timer 1 overflow can be used to generate baud rates for the SMBus and/or UART, and/or initiate ADC conversions. While Timer 0 is operating in Mode 3, Timer 1 run control is handled through its mode settings. To run Timer 1 while Timer 0 is in Mode 3, set the Timer 1 Mode as 0 , 1 , or 2 . To disable Timer 1, configure it for Mode 3.

## C8051F330/1/2/3/4/5

### 18.2. Timer 2

Timer 2 is a 16 -bit timer formed by two 8 -bit SFRs: TMR2L (low byte) and TMR2H (high byte). Timer 2 may operate in 16-bit auto-reload mode or (split) 8-bit auto-reload mode. The T2SPLIT bit (TMR2CN.3) defines the Timer 2 operation mode.

Timer 2 may be clocked by the system clock, the system clock divided by 12, or the external oscillator source divided by 8 . The external clock mode is ideal for real-time clock (RTC) functionality, where the internal oscillator drives the system clock while Timer 2 (and/or the PCA) is clocked by an external precision oscillator. Note that the external oscillator source divided by 8 is synchronized with the system clock.

### 18.2.1. 16-bit Timer with Auto-Reload

When T2SPLIT (TMR2CN.3) is zero, Timer 2 operates as a 16 -bit timer with auto-reload. Timer 2 can be clocked by SYSCLK, SYSCLK divided by 12, or the external oscillator clock source divided by 8 . As the 16-bit timer register increments and overflows from 0xFFFF to $0 x 0000$, the 16 -bit value in the Timer 2 reload registers (TMR2RLH and TMR2RLL) is loaded into the Timer 2 register as shown in Figure 18.4, and the Timer 2 High Byte Overflow Flag (TMR2CN.7) is set. If Timer 2 interrupts are enabled (if IE. 5 is set), an interrupt will be generated on each Timer 2 overflow. Additionally, if Timer 2 interrupts are enabled and the TF2LEN bit is set (TMR2CN.5), an interrupt will be generated each time the lower 8 bits (TMR2L) overflow from 0xFF to $0 \times 00$.

Figure 18.4. Timer 2 16-Bit Mode Block Diagram

## C8051F330/1/2/3/4/5

### 18.2.2. 8-bit Timers with Auto-Reload

When T2SPLIT is set, Timer 2 operates as two 8-bit timers (TMR2H and TMR2L). Both 8-bit timers operate in auto-reload mode as shown in Figure 18.5. TMR2RLL holds the reload value for TMR2L; TMR2RLH holds the reload value for TMR2H. The TR2 bit in TMR2CN handles the run control for TMR2H. TMR2L is always running when configured for 8-bit Mode.

Each 8-bit timer may be configured to use SYSCLK, SYSCLK divided by 12, or the external oscillator clock source divided by 8. The Timer 2 Clock Select bits (T2MH and T2ML in CKCON) select either SYSCLK or the clock defined by the Timer 2 External Clock Select bit (T2XCLK in TMR2CN), as follows:

| T2MH | T2XCLK | TMR2H Clock Source |
| :---: | :---: | :--- |
| 0 | 0 | SYSCLK / 12 |
| 0 | 1 | External Clock /8 |
| 1 | $X$ | SYSCLK |

| T2ML | T2XCLK | TMR2L Clock Source |
| :---: | :---: | :--- |
| 0 | 0 | SYSCLK / 12 |
| 0 | 1 | External Clock /8 |
| 1 | $X$ | SYSCLK |

The TF2H bit is set when TMR2H overflows from 0xFF to 0x00; the TF2L bit is set when TMR2L overflows from $0 x F F$ to $0 x 00$. When Timer 2 interrupts are enabled (IE.5), an interrupt is generated each time TMR2H overflows. If Timer 2 interrupts are enabled and TF2LEN (TMR2CN.5) is set, an interrupt is generated each time either TMR2L or TMR2H overflows. When TF2LEN is enabled, software must check the TF2H and TF2L flags to determine the source of the Timer 2 interrupt. The TF2H and TF2L interrupt flags are not cleared by hardware and must be manually cleared by software.

## C8051F330/1/2/3/4/5

### 18.3. Timer 3

Timer 3 is a 16 -bit timer formed by two 8 -bit SFRs: TMR3L (low byte) and TMR3H (high byte). Timer 3 may operate in 16 -bit auto-reload mode or (split) 8-bit auto-reload mode. The T3SPLIT bit (TMR3CN.3) defines the Timer 3 operation mode.

Timer 3 may be clocked by the system clock, the system clock divided by 12, or the external oscillator source divided by 8 . The external clock mode is ideal for real-time clock (RTC) functionality, where the internal oscillator drives the system clock while Timer 3 (and/or the PCA) is clocked by an external precision oscillator. Note that the external oscillator source divided by 8 is synchronized with the system clock.

### 18.3.1. 16-bit Timer with Auto-Reload

When T3SPLIT (TMR3CN.3) is zero, Timer 3 operates as a 16-bit timer with auto-reload. Timer 3 can be clocked by SYSCLK, SYSCLK divided by 12, or the external oscillator clock source divided by 8 . As the 16-bit timer register increments and overflows from 0xFFFF to $0 x 0000$, the 16 -bit value in the Timer 3 reload registers (TMR3RLH and TMR3RLL) is loaded into the Timer 3 register as shown in Figure 18.6, and the Timer 3 High Byte Overflow Flag (TMR3CN.7) is set. If Timer 3 interrupts are enabled (if EIE1.7 is set), an interrupt will be generated on each Timer 3 overflow. Additionally, if Timer 3 interrupts are enabled and the TF3LEN bit is set (TMR3CN.5), an interrupt will be generated each time the lower 8 bits (TMR3L) overflow from 0xFF to $0 \times 00$.

Figure 18.6. Timer 3 16-Bit Mode Block Diagram

## C8051F330/1/2/3/4/5

### 18.3.2 8-bit Timers with Auto-Reload

When T3SPLIT is set, Timer 3 operates as two 8-bit timers (TMR3H and TMR3L). Both 8-bit timers operate in auto-reload mode as shown in Figure 18.7. TMR3RLL holds the reload value for TMR3L; TMR3RLH holds the reload value for TMR3H. The TR3 bit in TMR3CN handles the run control for TMR3H. TMR3L is always running when configured for 8 -bit Mode.

Each 8-bit timer may be configured to use SYSCLK, SYSCLK divided by 12, or the external oscillator clock source divided by 8. The Timer 3 Clock Select bits (T3MH and T3ML in CKCON) select either SYSCLK or the clock defined by the Timer 3 External Clock Select bit (T3XCLK in TMR3CN), as follows:

| T3MH | T3XCLK | TMR3H Clock <br> Source |
| :---: | :---: | :--- |
| 0 | 0 | SYSCLK / 12 |
| 0 | 1 | External Clock /8 |
| 1 | $X$ | SYSCLK |

| T3ML | T3XCLK | TMR3L Clock <br> Source |
| :---: | :---: | :--- |
| 0 | 0 | SYSCLK / 12 |
| 0 | 1 | External Clock /8 |
| 1 | $X$ | SYSCLK |

The TF3H bit is set when TMR3H overflows from 0xFF to 0x00; the TF3L bit is set when TMR3L overflows from $0 \times F F$ to $0 \times 00$. When Timer 3 interrupts are enabled, an interrupt is generated each time TMR3H overflows. If Timer 3 interrupts are enabled and TF3LEN (TMR3CN.5) is set, an interrupt is generated each time either TMR3L or TMR3H overflows. When TF3LEN is enabled, software must check the TF3H and TF3L flags to determine the source of the Timer 3 interrupt. The TF3H and TF3L interrupt flags are not cleared by hardware and must be manually cleared by software.

## 19. Programmable Counter Array

The Programmable Counter Array (PCA0) provides enhanced timer functionality while requiring less CPU intervention than the standard 8051 counter/timers. The PCA consists of a dedicated 16-bit counter/timer and three 16-bit capture/compare modules. Each capture/compare module has its own associated I/O line (CEXn) which is routed through the Crossbar to Port I/O when enabled (See Section "14.1. Priority Crossbar Decoder" on page 125 for details on configuring the Crossbar). The counter/timer is driven by a programmable timebase that can select between six sources: system clock, system clock divided by four, system clock divided by twelve, the external oscillator clock source divided by 8 , Timer 0 overflow, or an external clock signal on the ECI input pin. Each capture/compare module may be configured to operate independently in one of six modes: Edge-Triggered Capture, Software Timer, High-Speed Output, Frequency Output, 8-Bit PWM, or 16-Bit PWM (each mode is described in Section "19.2. Capture/Compare Modules" on page 195). The external oscillator clock option is ideal for real-time clock (RTC) functionality, allowing the PCA to be clocked by a precision external oscillator while the internal oscillator drives the system clock. The PCA is configured and controlled through the system controller's Special Function Registers. The PCA block diagram is shown in Figure 19.1

Important Note: The PCA Module 2 may be used as a watchdog timer (WDT), and is enabled in this mode following a system reset. Access to certain PCA registers is restricted while WDT mode is enabled. See Section 19.3 for details.

Figure 19.1. PCA Block Diagram

## C8051F330/1/2/3/4/5

### 19.1. PCA Counter/Timer

The 16-bit PCA counter/timer consists of two 8-bit SFRs: PCAOL and PCAOH. PCAOH is the high byte (MSB) of the 16 -bit counter/timer and PCAOL is the low byte (LSB). Reading PCAOL automatically latches the value of PCAOH into a "snapshot" register; the following PCAOH read accesses this "snapshot" register. Reading the PCAOL Register first guarantees an accurate reading of the entire 16-bit PCAO counter. Reading PCAOH or PCAOL does not disturb the counter operation. The CPS2-CPSO bits in the PCAOMD register select the timebase for the counter/timer as shown in Table 19.1.

When the counter/timer overflows from 0xFFFF to 0x0000, the Counter Overflow Flag (CF) in PCAOMD is set to logic 1 and an interrupt request is generated if CF interrupts are enabled. Setting the ECF bit in PCAOMD to logic 1 enables the CF flag to generate an interrupt request. The CF bit is not automatically cleared by hardware when the CPU vectors to the interrupt service routine, and must be cleared by software (Note: PCAO interrupts must be globally enabled before CF interrupts are recognized. PCAO interrupts are globally enabled by setting the EA bit (IE.7) and the EPCAO bit in EIE1 to logic 1). Clearing the CIDL bit in the PCAOMD register allows the PCA to continue normal operation while the CPU is in Idle mode.

Table 19.1. PCA Timebase Input Options

| CPS2 | CPS1 | CPS0 | Timebase |  |  |
| :---: | :---: | :---: | :--- | :---: | :---: |
| 0 | 0 | 0 | System clock divided by 12 |  |  |
| 0 | 0 | 1 | System clock divided by 4 |  |  |
| 0 | 1 | 0 | Timer 0 overflow |  |  |
| 0 | 1 | 1 | High-to-low transitions on ECI (max rate = system clock divided <br> by 4) |  |  |
| 1 | 0 | 0 | System clock |  |  |
| 1 | 0 | 1 | External oscillator source divided by $8^{*}$ |  |  |
| Note: External oscillator source divided by 8 is synchronized with the system clock. |  |  |  |  |  |

Figure 19.2. PCA Counter/Timer Block Diagram

# C8051F330/1/2/3/4/5 

### 19.2. Capture/Compare Modules

Each module can be configured to operate independently in one of six operation modes: Edge-triggered Capture, Software Timer, High Speed Output, Frequency Output, 8-Bit Pulse Width Modulator, or 16-Bit Pulse Width Modulator. Each module has Special Function Registers (SFRs) associated with it in the CIP51 system controller. These registers are used to exchange data with a module and configure the module's mode of operation.

Table 19.2 summarizes the bit settings in the PCAOCPMn registers used to select the PCA capture/compare module's operating modes. Setting the ECCFn bit in a PCAOCPMn register enables the module's CCFn interrupt. Note: PCAO interrupts must be globally enabled before individual CCFn interrupts are recognized. PCAO interrupts are globally enabled by setting the EA bit and the EPCAO bit to logic 1 . See Figure 19.3 for details on the PCA interrupt configuration.

Table 19.2. PCAOCPM Register Settings for PCA Capture/Compare Modules

| PWM16 | ECOM | CAPP | CAPN | MAT | TOG | PWM | ECCF | Operation Mode |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :--- |
| X | X | 1 | 0 | 0 | 0 | 0 | X | Capture triggered by positive edge <br> on CEXn |

|  |  |  |  |  |  |  |  |  |

Figure 19.3. PCA Interrupt Block Diagram

## C8051F330/1/2/3/4/5

### 19.2.1. Edge-triggered Capture Mode

In this mode, a valid transition on the CEXn pin causes the PCA to capture the value of the PCA counter/timer and load it into the corresponding module's 16-bit capture/compare register (PCA0CPLn and PCA0CPHn). The CAPPn and CAPNn bits in the PCA0CPMn register are used to select the type of transition that triggers the capture: low-to-high transition (positive edge), high-to-low transition (negative edge), or either transition (positive or negative edge). When a capture occurs, the Capture/Compare Flag (CCFn) in PCAOCN is set to logic 1 and an interrupt request is generated if CCF interrupts are enabled. The CCFn bit is not automatically cleared by hardware when the CPU vectors to the interrupt service routine, and must be cleared by software. If both CAPPn and CAPNn bits are set to logic 1, then the state of the Port pin associated with CEXn can be read directly to determine whether a rising-edge or falling-edge caused the capture.

Figure 19.4. PCA Capture Mode Diagram

Note: The CEXn input signal must remain high or low for at least 2 system clock cycles to be recognized by the hardware.

## C8051F330/1/2/3/4/5

### 19.2.2. Software Timer (Compare) Mode

In Software Timer mode, the PCA counter/timer value is compared to the module's 16-bit capture/compare register (PCA0CPHn and PCA0CPLn). When a match occurs, the Capture/Compare Flag (CCFn) in PCAOCN is set to logic 1 and an interrupt request is generated if CCF interrupts are enabled. The CCFn bit is not automatically cleared by hardware when the CPU vectors to the interrupt service routine, and must be cleared by software. Setting the ECOMn and MATn bits in the PCAOCPMn register enables Software Timer mode.

Important Note About Capture/Compare Registers: When writing a 16-bit value to the PCAO Capture/Compare registers, the low byte should always be written first. Writing to PCAOCPLn clears the ECOMn bit to ' 0 '; writing to PCA0CPHn sets ECOMn to ' 1 '.

Figure 19.5. PCA Software Timer Mode Diagram

## C8051F330/1/2/3/4/5

### 19.2.3. High-Speed Output Mode

In High-Speed Output mode, a module's associated CEXn pin is toggled each time a match occurs between the PCA Counter and the module's 16-bit capture/compare register (PCAOCPHn and PCAOCPLn) Setting the TOGn, MATn, and ECOMn bits in the PCAOCPMn register enables the HighSpeed Output mode.

Important Note About Capture/Compare Registers: When writing a 16 -bit value to the PCAO Capture/Compare registers, the low byte should always be written first. Writing to PCAOCPLn clears the ECOMn bit to ' 0 '; writing to PCAOCPHn sets ECOMn to ' 1 '.

Figure 19.6. PCA High-Speed Output Mode Diagram

## C8051F330/1/2/3/4/5

### 19.2.4. Frequency Output Mode

Frequency Output Mode produces a programmable-frequency square wave on the module's associated CEXn pin. The capture/compare module high byte holds the number of PCA clocks to count before the output is toggled. The frequency of the square wave is then defined by Equation 19.3.

$$
F_{C E X n}=\frac{F_{P C A}}{2 \times P C A 0 C P H n}
$$

Note: A value of $0 \times 00$ in the PCAOCPHn register is equal to 256 for this equation.

## Equation 19.3. Square Wave Frequency Output

Where $F_{P C A}$ is the frequency of the clock selected by the CPS2-0 bits in the PCA mode register, PCAOMD. The lower byte of the capture/compare module is compared to the PCA counter low byte; on a match, CEXn is toggled and the offset held in the high byte is added to the matched value in PCAOCPLn. Frequency Output Mode is enabled by setting the ECOMn, TOGn, and PWMn bits in the PCAOCPMn register.

Figure 19.7. PCA Frequency Output Mode

## C8051F330/1/2/3/4/5

### 19.2.5. 8-Bit Pulse Width Modulator Mode

Each module can be used independently to generate a pulse width modulated (PWM) output on its associated CEXn pin. The frequency of the output is dependent on the timebase for the PCA counter/timer. The duty cycle of the PWM output signal is varied using the module's PCAOCPLn capture/compare register. When the value in the low byte of the PCA counter/timer (PCAOL) is equal to the value in PCAOCPLn, the output on the CEXn pin will be set. When the count value in PCAOL overflows, the CEXn output will be reset (see Figure 19.8). Also, when the counter/timer low byte (PCAOL) overflows from 0xFF to 0x00, PCAOCPLn is reloaded automatically with the value stored in the module's capture/compare high byte (PCA0CPHn) without software intervention. Setting the ECOMn and PWMn bits in the PCA0CPMn register enables 8-Bit Pulse Width Modulator mode. The duty cycle for 8 -Bit PWM Mode is given by Equation 19.4.

Important Note About Capture/Compare Registers: When writing a 16-bit value to the PCAO Capture/Compare registers, the low byte should always be written first. Writing to PCAOCPLn clears the ECOMn bit to ' 0 '; writing to PCA0CPHn sets ECOMn to ' 1 '.

$$
\text { DutyCycle }=\frac{(256-P C A 0 C P H n)}{256}
$$

## Equation 19.4. 8-Bit PWM Duty Cycle

Using Equation 19.4, the largest duty cycle is $100 \%$ ( $\mathrm{PCAOCPH}=0$ ), and the smallest duty cycle is $0.39 \%$ (PCA0CPHn = 0xFF). A 0\% duty cycle may be generated by clearing the ECOMn bit to '0'.

Figure 19.8. PCA 8-Bit PWM Mode Diagram

## C8051F330/1/2/3/4/5

### 19.2.6. 16-Bit Pulse Width Modulator Mode

A PCA module may also be operated in 16-Bit PWM mode. In this mode, the 16 -bit capture/compare module defines the number of PCA clocks for the low time of the PWM signal. When the PCA counter matches the module contents, the output on CEXn is asserted high; when the counter overflows, CEXn is asserted low. To output a varying duty cycle, new value writes should be synchronized with PCA CCFn match interrupts. 16-Bit PWM Mode is enabled by setting the ECOMn, PWMn, and PWM16n bits in the PCA0CPMn register. For a varying duty cycle, match interrupts should be enabled (ECCFn = 1 AND MATn = 1) to help synchronize the capture/compare register writes. The duty cycle for 16 -Bit PWM Mode is given by Equation 19.5.

Important Note About Capture/Compare Registers: When writing a 16 -bit value to the PCAO Capture/Compare registers, the low byte should always be written first. Writing to PCAOCPLn clears the ECOMn bit to ' 0 '; writing to PCAOCPHn sets ECOMn to ' 1 '.

$$
\text { DutyCycle }=\frac{(65536-P C A 0 C P n)}{65536}
$$

## Equation 19.5. 16-Bit PWM Duty Cycle

Using Equation 19.5, the largest duty cycle is $100 \%$ (PCAOCPn = 0), and the smallest duty cycle is $0.0015 \%$ (PCAOCPn = 0xFFFF). A 0\% duty cycle may be generated by clearing the ECOMn bit to ' 0 '.

Figure 19.9. PCA 16-Bit PWM Mode

### 19.3. Watchdog Timer Mode

A programmable watchdog timer (WDT) function is available through the PCA Module 2. The WDT is used to generate a reset if the time between writes to the WDT update register (PCAOCPH2) exceed a specified limit. The WDT can be configured and enabled/disabled as needed by software.

With the WDTE bit set in the PCAOMD register, Module 2 operates as a watchdog timer (WDT). The Module 2 high byte is compared to the PCA counter high byte; the Module 2 low byte holds the offset to be used when WDT updates are performed. The Watchdog Timer is enabled on reset. Writes to some PCA registers are restricted while the Watchdog Timer is enabled.

## C8051F330/1/2/3/4/5

### 19.3.1. Watchdog Timer Operation

While the WDT is enabled:

- PCA counter is forced on.
- Writes to PCAOL and PCAOH are not allowed.
- PCA clock source bits (CPS2-CPS0) are frozen.
- PCA Idle control bit (CIDL) is frozen.
- Module 2 is forced into software timer mode.
- Writes to the Module 2 mode register (PCAOCPM2) are disabled.

While the WDT is enabled, writes to the CR bit will not change the PCA counter state; the counter will run until the WDT is disabled. The PCA counter run control (CR) will read zero if the WDT is enabled but user software has not enabled the PCA counter. If a match occurs between PCAOCPH2 and PCAOH while the WDT is enabled, a reset will be generated. To prevent a WDT reset, the WDT may be updated with a write of any value to PCAOCPH2. Upon a PCAOCPH2 write, PCAOH plus the offset held in PCAOCPL2 is loaded into PCAOCPH2 (See Figure 19.10).

Figure 19.10. PCA Module 2 with Watchdog Timer Enabled

## C8051F330/1/2/3/4/5

Note that the 8-bit offset held in PCA0CPH2 is compared to the upper byte of the 16-bit PCA counter. This offset value is the number of PCA0L overflows before a reset. Up to 256 PCA clocks may pass before the first PCAOL overflow occurs, depending on the value of the PCAOL when the update is performed. The total offset is then given (in PCA clocks) by Equation 19.6, where PCAOL is the value of the PCAOL register at the time of the update.

$$
\text { Offset }=(256 \times P C A 0 C P L 2)+(256-P C A 0 L)
$$

## Equation 19.6. Watchdog Timer Offset in PCA Clocks

The WDT reset is generated when PCAOL overflows while there is a match between PCAOCPH2 and PCAOH. Software may force a WDT reset by writing a ' 1 ' to the CCF2 flag (PCAOCN.2) while the WDT is enabled.

### 19.3.2. Watchdog Timer Usage

To configure the WDT, perform the following tasks:

- Disable the WDT by writing a '0' to the WDTE bit.
- Select the desired PCA clock source (with the CPS2-CPS0 bits).
- Load PCA0CPL2 with the desired WDT update offset value.
- Configure the PCA Idle mode (set CIDL if the WDT should be suspended while the CPU is in Idle mode).
- Enable the WDT by setting the WDTE bit to ' 1 '.
- Write a value to PCAOCPH2 to reload the WDT.

The PCA clock source and Idle mode select cannot be changed while the WDT is enabled. The watchdog timer is enabled by setting the WDTE or WDLCK bits in the PCAOMD register. When WDLCK is set, the WDT cannot be disabled until the next system reset. If WDLCK is not set, the WDT is disabled by clearing the WDTE bit.

The WDT is enabled following any reset. The PCAO counter clock defaults to the system clock divided by 12, PCAOL defaults to 0x00, and PCA0CPL2 defaults to 0x00. Using Equation 19.6, this results in a WDT timeout interval of 256 PCA clock cycles, or 3072 system clock cycles. Table 19.4 lists some example timeout intervals for typical system clocks.

## C8051F330/1/2/3/4/5

Table 19.4. Watchdog Timer Timeout Intervals ${ }^{1}$

| System Clock (Hz) | PCA0CPL2 | Timeout Interval (ms) |
| :---: | :---: | :---: |
| $24,500,000$ | 255 | 32.1 |
| $24,500,000$ | 128 | 16.2 |
| $24,500,000$ | 32 | 4.1 |
| $18,432,000$ | 255 | 42.7 |
| $18,432,000$ | 128 | 21.5 |
| $18,432,000$ | 32 | 5.5 |
| $11,059,200$ | 255 | 71.1 |
| $11,059,200$ | 128 | 35.8 |
| $11,059,200$ | 32 | 9.2 |
| $3,062,500^{2}$ | 255 | 257 |
| $3,062,500^{2}$ | 128 | 129.5 |
| $3,062,500^{2}$ | 32 | 33.1 |
| 32,000 | 255 | 24576 |
| 32,000 | 128 | 12384 |
| 32,000 | 32 | 3168 |
|  |  |  |

Notes:

1. Assumes SYSCLK/12 as the PCA clock source, and a PCAOL value of $0 \times 00$ at the update time.
2. Internal SYSCLK reset frequency = Internal Oscillator divided by 8.

### 19.5. Register Descriptions for PCA

Following are detailed descriptions of the special function registers related to the operation of the PCA.

## C8051F330/1/2/3/4/5

## SFR Definition 19.1. PCAOCN: PCA Control

| R/w | R/W | R | R | R | R/W | R/W | R/W | Reset Value |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| CF | CR |  |  |  | CCF2 | CCF1 | CCFO | 00000000 |
| Bit7 | Bit6 | Bit5 | Bit4 | Bit3 | Bit2 | Bit1 | $\stackrel{\text { Bit0 }}{ }$ | $\begin{aligned} & \text { Bit } \\ & \text { Addressable } \\ & \text { OxD8 } \end{aligned}$ |
| Bit7: | CF: PCA Counter/Timer Overflow Flag. <br> Set by hardware when the PCA Counter/Timer overflows from 0xFFFF to $0 \times 0000$. When the Counter/Timer Overflow (CF) interrupt is enabled, setting this bit causes the CPU to vector to the PCA interrupt service routine. This bit is not automatically cleared by hardware and must be cleared by software. |  |  |  |  |  |  |  |
| Bit6: | CR: PCA <br> This bit en <br> 0: PCA Co <br> 1: PCA Co | 0: PCA Counter/Timer disabled. |  |  |  |  |  |  |
| Bits5-3: | UNUSED. Read $=000 \mathrm{~b}$, Write $=$ don't care . |  |  |  |  |  |  |  |
| Bit2: | This bit is set by hardware when a match or capture occurs. When the CCF2 interrupt is enabled, setting this bit causes the CPU to vector to the PCA interrupt service routine. This bit is not automatically cleared by hardware and must be cleared by software. |  |  |  |  |  |  |  |
| Bit1: | This bit is set by hardware when a match or capture occurs. When the CCF1 interrupt is enabled, setting this bit causes the CPU to vector to the PCA interrupt service routine. This bit is not automatically cleared by hardware and must be cleared by software. |  |  |  |  |  |  |  |
| Bit0: | This bit is set by hardware when a match or capture occurs. When the CCFO interrupt is enabled, setting this bit causes the CPU to vector to the PCA interrupt service routine. This bit is not automatically cleared by hardware and must be cleared by software. |  |  |  |  |  |  |  |

## C8051F330/1/2/3/4/5

## 20. C2 Interface

C8051F330/1/2/3/4/5 devices include an on-chip Silicon Labs 2-Wire (C2) debug interface to allow Flash programming and in-system debugging with the production part installed in the end application. The C2 interface uses a clock signal (C2CK) and a bi-directional C2 data signal (C2D) to transfer information between the device and a host system. See the C2 Interface Specification for details on the C2 protocol.

### 20.1. C2 Interface Registers

The following describes the C2 registers necessary to perform Flash programming through the C2 interface. All C2 registers are accessed through the C2 interface as described in the C2 Interface Specification.

## C2 Register Definition 20.1. C2ADD: C2 Address

C2 Register Definition 20.2. DEVICEID: C2 Device ID

|  |  |  |  |  |  |  |  | 00001010 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Bit5 |  |  |  | Bit1 |  |  |
| Bit7 | Bit6 |  | Bit4 | Bit3 | Bit2 |  | Bit0 |  |
| This read-only register returns the 8-bit device ID: 0x0A (C8051F330/1/2/3/4/5). |  |  |  |  |  |  |  |  |

## C8051F330/1/2/3/4/5

## C2 Register Definition 20.3. REVID: C2 Revision ID

This read-only register returns the 8-bit revision ID: 0x00 (Revision A).

## C2 Register Definition 20.4. FPCTL: C2 Flash Programming Control

Bits7-0 FPCTL: Flash Programming Control Register.
This register is used to enable Flash programming via the C2 interface. To enable C2 Flash programming, the following codes must be written in order: $0 \times 02,0 \times 01$. Note that once C2 Flash programming is enabled, a system reset must be issued to resume normal operation.

## C2 Register Definition 20.5. FPDAT: C2 Flash Programming Data

|  |  |  |  |  |  |  |  | Reset Value00000000 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Bits7-0: | FPDAT: C2 Flash Programming Data Register. |  |  |  |  |  |  |  |
|  | This register is used to pass Flash commands, addresses, and data during C2 Flash |  |  |  |  |  |  |  |
|  | Code | Command |  |  |  |  |  |  |
|  | 0x06 | Flash Block Read |  |  |  |  |  |  |
|  | $0 \times 07$ | Flash Block Write |  |  |  |  |  |  |
|  | 0x08 | Flash Page Erase |  |  |  |  |  |  |
|  | 0x03 | Device Erase |  |  |  |  |  |  |

## C8051F330/1/2/3/4/5

### 20.2. C2 Pin Sharing

The C2 protocol allows the C2 pins to be shared with user functions so that in-system debugging and Flash programming may be performed. This is possible because C2 communication is typically performed when the device is in the halt state, where all on-chip peripherals and user software are stalled. In this halted state, the C2 interface can safely 'borrow' the C2CK ( $\overline{\mathrm{RST}}$ ) and C2D (P2.0) pins. In most applications, external resistors are required to isolate C 2 interface traffic from the user application. A typical isolation configuration is shown in Figure 20.1.

Figure 20.1. Typical C2 Pin Sharing

The configuration in Figure 20.1 assumes the following:

1. The user input (b) cannot change state while the target device is halted.
2. The RST pin on the target device is used as an input only.

Additional resistors may be necessary depending on the specific application.

## C8051F330/1/2/3/4/5

## Document Change List

## Revision 1.3 to Revision 1.4

- Removed references to C8051F330D throughout the data sheet because the 'F330D device is functionally identical to the C8051F330 device (these two part numbers differ by package type only).
- Updated titles of Chapters 5, 6, and 7 to show supported devices.
- Updated Table 1.1, "Product Selection Guide," on page 18. - Added ordering part number information for lead-free parts.
- Added Table 3.2, "Index to Electrical Characteristics Tables," on page 34
- Added Table 11.2, "Flash Security Summary," on page 106 for clarity, replacing the Flash security summaries text.

## Revision 1.4 to Revision 1.5

- Updated Table 3.1 - Added supply current data from characterization.
- Updated Table 5.1 - Added MIN/MAX numbers for ADC Offset and Full Scale Error.
- Fixed SFR Definition 8.2 - Typo in bit descriptions - "2-0" changed to "3-0".
- Fixed SFR Definition 9.4 - Text at bottom of figure was cut off.
- Added Section "11.4. Flash Write and Erase Guidelines" on page 107.
- Fixed Section "12. External RAM" on page 111, paragraph 2 - Typo in description - "upper 6-bits" changed to "upper 7 bits".
- Fixed text in Section "19.3.2. Watchdog Timer Usage" on page 203 to read " 256 PCA clock cycles, or 3072 system clock cycles".
- $\quad$ Changed Table 19.4, Note 2 to refer to SYSCLK reset frequency = Internal Oscillator / 8.
- Fixed Equation 19.6, "Watchdog Timer Offset in PCA Clocks," - Typo in equation - "PCA0CPL4" changed to "PCA0CPL2".

## Revision 1.5 to Revision 1.6

- Updated package drawings.

## Revision 1.6 to Revision 1.7

- Removed PDIP package information.
