**GENERAL DESCRIPTION**

The ADG701/ADG702 are monolithic CMOS SPST switches. These switches are designed on an advanced submicron process that provides low power dissipation yet high switching speed, low on resistance, low leakage currents and -3 dB bandwidths of greater than 200 MHz can be achieved.

The ADG701/ADG702 can operate from a single +1.8 V to +5.5 V supply making it ideal for use in battery powered instruments and with the new generation of DACs and ADCs from Analog Devices.

As can be seen from the Functional Block Diagrams, with a logic input of "1" the switch of the ADG701 is closed, while that of the ADG702 is open. Each switch conducts equally well in both directions when ON.

The ADG701/ADG702 are available in 6-lead SOT-23 and 8-lead  $\mu$ SOIC packages.

**PRODUCT HIGHLIGHTS**

1. +1.8 V to +5.5 V Single Supply Operation. The ADG701/ADG702 offer high performance, including low on resistance and fast switching times and is fully specified and guaranteed with +3 V and +5 V supply rails.
2. Very Low  $R_{ON}$  (3  $\Omega$  max at 5 V, 5  $\Omega$  max at 3 V). At 1.8 V operation,  $R_{ON}$  is typically 40  $\Omega$  over the temperature range.
3. On-Resistance Flatness  $R_{FLAT(ON)}$  (1  $\Omega$  max).
4. -3 dB Bandwidth >200 MHz.
5. Low Power Dissipation. CMOS construction ensures low power dissipation.
6. Fast  $t_{ON}/t_{OFF}$ .
7. Tiny 6-Lead SOT-23 and 8-Lead  $\mu$ SOIC.

## NOTES

<sup>1</sup>Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one absolute maximum rating may be applied at any one time.

<sup>2</sup>Overvoltages at IN, S or D will be clamped by internal diodes. Current should be limited to the maximum ratings given.

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the ADG701/ADG702 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## APPLICATIONS INFORMATION

The ADG701/ADG702 belongs to Analog Devices' new family of CMOS switches. This series of general purpose switches have improved switching times, lower on resistance, higher bandwidth, low power consumption and low leakage currents.

### ADG701/ADG702 Supply Voltages

Functionality of the ADG701/ADG702 extends from +1.8 V to +5.5 V single supply, which makes it ideal for battery powered instruments, where important design parameters are power efficiency and performance.

It is important to note that the supply voltage effects the input signal range, the on resistance and the switching times of the part. By taking a look at the typical performance characteristics and the specifications, the effects of the power supplies can be clearly seen.

For  $V_{DD} = +1.8$  V operation,  $R_{ON}$  is typically 40  $\Omega$  over the temperature range.

### On Response vs. Frequency

Figure 7 illustrates the parasitic components that affect the ac performance of CMOS switches (the switch is shown surrounded by a box). Additional external capacitances will further degrade some performance. These capacitances affect feedthrough, crosstalk and system bandwidth.

Figure 7. Switch Represented by Equivalent Parasitic Components

The transfer function that describes the equivalent diagram of the switch (Figure 7) is of the form  $A(s)$  shown below.

$$A(s) = R_T \left[ \frac{s(R_{ON} C_{DS}) + 1}{s(R_{ON} C_T R_T) + 1} \right]$$

where:

$$C_T = C_{LOAD} + C_D + C_{DS}$$

$$R_T = R_{LOAD} / (R_{LOAD} + R_{ON})$$

The signal transfer characteristic is dependent on the switch channel capacitance,  $C_{DS}$ . This capacitance creates a frequency zero in the numerator of the transfer function  $A(s)$ . Because the switch on resistance is small, this zero usually occurs at high frequencies. The bandwidth is a function of the switch output capacitance combined with  $C_{DS}$  and the load capacitance. The frequency pole corresponding to these capacitances appears in the denominator of  $A(s)$ .

The dominant effect of the output capacitance,  $C_D$ , causes the pole breakpoint frequency to occur first. Therefore, in order to maximize bandwidth a switch must have a low input and output capacitance and low on resistance. The On Response vs. Frequency plot for the ADG701/ADG702 can be seen in Figure 6.

### Off Isolation

Off isolation is a measure of the input signal coupled through an off switch to the switch output. The capacitance,  $C_{DS}$ , couples the input signal to the output load, when the switch is off, as shown in Figure 8.

Figure 8. Off Isolation Is Affected by External Load Resistance and Capacitance

The larger the value of  $C_{DS}$ , larger values of feedthrough will be produced. The typical performance characteristic graph of Figure 5 illustrates the drop in off-isolation as a function of frequency. From dc to roughly 1 MHz, the switch shows better than -75 dB isolation. Up to frequencies of 10 MHz, the off isolation remains better than -55 dB. As the frequency increases, more and more of the input signal is coupled through to the output. Off-isolation can be maximized by choosing a switch with the smallest  $C_{DS}$  as possible. The values of load resistance and capacitance affect off isolation also, as they contribute to the coefficients of the poles and zeros in the transfer function of the switch when open.

$$A(s) = \left[ \frac{s(R_{LOAD} C_{DS})}{s(R_{LOAD})(C_T) + 1} \right]$$
