## MAXI M

## Quad SPST CMOS Analog Switches

## General Description

The DG202/DG212 are normally open, quad singlepole single-throw (SPST) analog switches. These CMOS switches can be continuously operated with power supplies ranging from $\pm 4.5 \mathrm{~V}$ to $\pm 18 \mathrm{~V}$. Maxim guarantees that these switches will not latch up if the power supplies are disconnected with input signals still connected.
The DG202/DG212 are similar to the DG201/DG211 except for inverted control inputs. All devices have guaranteed break-before-make switching, as well as essentially constant on-resistance over the analog signal range. All switches conduct current in either direction and add no offset to the output signal.
Compared to the original manufacturer's products, Maxim's DG202/DG212 consume very little power, making them better suited for portable applications. Maxim has also eliminated the need for the third logic power supply $\left(V_{\mathrm{L}}\right)$ that is required for the operation of the original manufacturer's DG212 without sacrificing compatibility.

## Switching Time Test Circuit

Switch output waveform shown for $V_{S}=$ constant with logic input waveform as shown. Note that $\mathrm{V}_{\mathrm{S}}$ may be + ve or -ve as per switching times test circuit. Vo is the steady state output with switch on. Feedthrough via gate capacitance may result in spikes at leading and trailing edge of output waveform.

Protecting Against Fault Conditions
Fault conditions occur when power supplies are turned off when input signals are still present, or when overvoltages occur at the inputs during normal operation. In either case, source-to-body diodes can be forward biased and conduct current from the signal source. If

this current is required to be kept to low ( $\mu \mathrm{A}$ ) levels then the addition of external protection diodes is recommended.
To provide protection for overvoltages up to 20 V above the supplies, a 1N4001 or 1N914 type diode should be placed in series with the positive and negative supplies as shown in Figure 2. The addition of these diodes will reduce the analog signal range to 1 V below the positive supply and 1 V above the negative supply.
