## Dual-Supply, Low-On-Resistance, SPST, CMOS Analog Switches

Features
Available in SOT23-5 Package
$\pm 1 \mathrm{~V}$ to $\pm 6 \mathrm{~V}$ Dual-Supply Operation
Guaranteed On-Resistance: $20 \Omega$ with $\pm 5 \mathrm{~V}$
Supplies
Guaranteed Low Off-Leakage Currents:
1 nA at $+25^{\circ} \mathrm{C}$
20 nA at $+85^{\circ} \mathrm{C}$
Guaranteed Low On-Leakage Currents:
2 nA at $+25^{\circ} \mathrm{C}$
40 nA at $+85^{\circ} \mathrm{C}$
Low Charge Injection: 20 pC Max
Fast Switching Speed: toN $=100 \mathrm{~ns}$, toff $=75 \mathrm{~ns}$
toN $>$ toff at $\pm 5 \mathrm{~V}$
CMOS Logic Compatible with $\pm 5 \mathrm{~V}$ Supplies

ABSOLUTE MAXIMUM RATINGS
(Voltages Referenced to V-)

Note 1: Voltages exceeding $\mathrm{V}+$ or V - on any signal terminal are clamped by internal diodes. Limit forward-diode current to maximum current rating.
Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## Applications Information

## Power-Supply Considerations

The MAX4516/MAX4517 operate with power-supply voltages from $\pm 1 \mathrm{~V}$ to $\pm 6 \mathrm{~V}$, but are tested and guaranteed only with $\pm 5 \mathrm{~V}$ supplies. Similarly, they will operate with a single +2 V to +12 V supply, but logic-level inputs can shift with higher voltages. The pin-compatible MAX4514/MAX4515 are recommended for use with a single supply.
The MAX4516/MAX4517 construction is typical of most CMOS analog switches, except that they have only two supply pins: $\mathrm{V}_{+}$and V -. $\mathrm{V}_{+}$and V - drive the internal CMOS switches and set their analog voltage limits. Reverse ESD-protection diodes are internally connected between each analog-signal pin and both $\mathrm{V}_{+}$and V -. One of these diodes conducts if any analog signal exceeds $\mathrm{V}+$ or V -.
Virtually all the analog leakage current comes from the ESD diodes to $\mathrm{V}_{+}$or V -. Although the ESD diodes on a given signal pin are identical and therefore fairly well balanced, they are reverse biased differently. Each is biased by either $\mathrm{V}+$ or V - and the analog signal. This means their leakages will vary as the signal varies. The difference in the two diode leakages to the $\mathrm{V}_{+}$and V pins constitutes the analog-signal-path leakage current. All analog leakage current flows between each pin and one of the supply terminals, not to the other switch terminal. This is why both sides of a given switch can show leakage currents of the same or opposite polarity.
There is no connection between the analog-signal paths and $\mathrm{V}+$ or V -.

V+ and V - also power the internal logic and logic-level translators. The logic-level translators convert the logic levels to switched $\mathrm{V}+$ and V - signals to drive the analog signal gates.

Logic-Level Thresholds
The logic-level thresholds are CMOS-compatible but not TTL-compatible. Since these parts have no ground pin, the logic-level threshold is referenced to $\mathrm{V}+$. The threshold limits are $\mathrm{V}_{+}=-1.5 \mathrm{~V}$ and $\mathrm{V}_{+}=-3.5 \mathrm{~V}$ for $\mathrm{V}+$ levels between +6 V and +3 V . When $\mathrm{V}+=+2 \mathrm{~V}$, the logic threshold is approximately 0.6 V .
Do not connect the MAX4516/MAX4517's V+ to +3V and then connect the logic-level pins to logic-level signals that operate from a +5 V supply. TTL levels can exceed +3 V and violate the absolute maximum ratings, damaging the part and/or external circuits.

High-Frequency Performance In $50 \Omega$ systems, signal response is reasonably flat up to 250 MHz (see Typical Operating Characteristics). Above 20 MHz , the on response has several minor peaks that are highly layout dependent. The problem is not in turning the switch on; it's in turning it off. The offstate switch acts like a capacitor and passes higher frequencies with less attenuation. At 10 MHz , off isolation is about -48 dB in $50 \Omega$ systems, decreasing (approximately 20 dB per decade) as frequency increases. Higher circuit impedances also cause off isolation to decrease. Off isolation is about 3dB above that of a bare IC socket, and is due entirely to capacitive coupling.
