## $\pm 15 k V$ ESD-Protected, Low-Voltage, CMOS Analog Multiplexers/Switches

## General Description

The MAX4558/MAX4559/MAX4560 are low-voltage, CMOS analog ICs configured as an 8-to-1 multiplexer (MAX4558), a dual 4-to-1 multiplexer (MAX4559), and a triple single-pole/double-throw (SPDT) switch (MAX4560). Each switch is protected against $\pm 15 \mathrm{kV}$ electrostatic discharge (ESD) shocks, without latchup or damage.
These CMOS devices can operate continuously from dual supplies of $\pm 2 \mathrm{~V}$ to $\pm 6 \mathrm{~V}$ or from a +2 V to +12 V single supply. Each switch can handle Rail-to-Rail ${ }^{\circledR}$ analog signals. The off-leakage current is only 1 nA at $+25^{\circ} \mathrm{C}$ or 10 nA at $+85^{\circ} \mathrm{C}$ max.
All digital inputs have +0.8 V to +2.4 V logic thresholds, ensuring TTL/CMOS-logic compatibility when using a single +5 V supply or dual $\pm 5 \mathrm{~V}$ supplies.

## Applications

- Battery-Operated Equipment
- Audio and Video Signal Routing
- Low-Voltage Data-Acquisition Systems
- Communications Circuits
- High-ESD Environments

## Features

- ESD-Protected $X, Y, Z$ and $X_{-}, Y_{-}, Z_{-}$Pins
- $\pm 15 \mathrm{kV}$ (Human Body Model)
- $\pm 12 \mathrm{kV}$ (IEC 1000-4-2, Air-Gap Discharge)
- $\pm 8 k V$ (IEC 1000-4-2, Contact Discharge)
- Pin-Compatible with Industry-Standard
- 74HC4051/74HC4052/74HC4053
- Guaranteed On-Resistance
- $220 \Omega$ with Single +5 V Supply
- $160 \Omega$ with $\pm 5 \mathrm{~V}$ Supply
- RON Match Between Channels: $2 \Omega$ (typ)
- Guaranteed Low leakage Currents
- 1nA Off-Leakage (at $+25^{\circ} \mathrm{C}$ )
- 1nA On-Leakage (at $+25^{\circ} \mathrm{C}$ )
- TTL-Compatible Inputs with $+5 \mathrm{~V} / \pm 5 \mathrm{~V}$ Supplies
- Low Distortion: < 0.02\% (600 )
- Low Crosstalk: <-93dB (50ת)
- High Off-Isolation: <-96dB (50 )

## Ordering Information

| PART | TEMP. RANGE | PIN-PACKAGE |
| :--- | :--- | :--- |
| MAX4558CEE | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ | 16 QSOP |
| MAX4558CSE | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ | 16 Narrow SO |
| MAX4558CPE | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ | 16 Plastic DIP |

Ordering Information continued at end of data sheet.

Note 1: Signals on any terminal exceeding $\mathrm{V}_{\mathrm{CC}}$ or $\mathrm{V}_{\mathrm{EE}}$ are clamped by internal diodes. Limit forward diode current to maximum current rating.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## $\pm 15 \mathrm{kV}$ ESD-Protected, Low-Voltage, CMOS Analog Multiplexers/Switches

## Detailed Description

The MAX4558/MAX4559/MAX4560 are ESD protected (per IEC 1000-4-2) at their X, Y, Z output pins and X_, $Y_{-}, Z_{-}$input pins. These ICs feature on-chip bidirectional silicon-controlled rectifiers (SCRs) between the protected pins and GND. The SCRs are normally off and have a negligible effect on the switches' performance. During an ESD strike, the voltages at the protected pins go Beyond-the-Rails ${ }^{\text {TM }}$, causing the corresponding SCR(s) to turn on in a few nanoseconds. This bypasses the surge current safely to ground. This protection method is superior to using diode clamps to the supplies. Unless the supplies are very carefully decoupled through low-ESR capacitors, the ESD current through a diode clamp could cause a significant spike in the supplies, which might damage or compromise the reliability of any other chip powered by those same supplies.
In addition to the SCRs at the ESD-protected pins, these devices provide internal diodes connected to the supplies. Resistors placed in series with these diodes limit the current flowing into the supplies during an ESD strike. The diodes protect the $X, Y, Z_{\text {and }} X_{-}, Y_{-}, Z_{-}$pins from overvoltages due to improper power-supply sequencing.
Once the SCR turns on because of an ESD strike, it remains on until the current through it falls below its "holding current." The holding current is typically 110 mA in the positive direction (current flowing into the pin) and 95 mA in the negative direction at room temperature (see SCR Holding Current vs. Temperature in the Typical Operating Characteristics). The system should be designed so that any sources connected to the $\mathrm{X}, \mathrm{Y}, \mathrm{Z}$ or $\mathrm{X}_{-}, \mathrm{Y}_{-}, \mathrm{Z}_{-}$pins
are current limited to a value below the holding current. This ensures that the SCR turns off and normal operation resumes after an ESD event.
Keep in mind that the holding currents vary significantly with temperature; they drop to 70 mA (typ) in the positive direction and 65 mA (typ) in the negative direction, at $+85^{\circ} \mathrm{C}$ worst case. To guarantee turn-off of the SCRs under all conditions, current limit the sources connected to these pins to not more than half of these typical values. When the SCR is latched, the voltage across it is about $\pm 3 \mathrm{~V}$, depending on the polarity of the pin current. The supply voltages do not affect the holding currents appreciably. When one or more SCRs turn on because of an ESD event, all switches in the part turn off to prevent current through the switch(es) from sustaining latchup.
Even though most of the ESD current flows to GND through the SCRs, a small portion of it goes into the supplies. Therefore, it is a good idea to bypass the supply pins with 100 nF capacitors to the ground plane.

## Applications Information ESD Protection

The MAX4558/MAX4559/MAX4560 are characterized for protection to the following:

- $\pm 15 \mathrm{kV}$ using the Human Body Model
- $\quad \pm 8 \mathrm{kV}$ using the Contact Discharge method specified in IEC 1000-4-2 (formerly IEC 801-2)
- $\quad \pm 12 \mathrm{kV}$ using the Air-Gap Discharge method specified in IEC 1000-4-2 (formerly IEC 801-2).

Beyond-the-Rails is a trademark of Maxim Integrated Products, Inc.

## Table 1. Truth Table/Switch Programming

$X=$ Don't care * C not present on MAX4559.
Note: Input and output pins are identical and interchangeable. Either may be considered an input or output; signals pass equally well in either direction.

## $\pm 15 \mathrm{kV}$ ESD-Protected, Low-Voltage, CMOS Analog Multiplexers/Switches

## ESD Test Conditions

ESD performance depends on several conditions. Contact Maxim for a reliability report that documents test setup, methodology, and results.

## Human Body Model

Figure 6 shows the Human Body Model, and Figure 7 shows the current waveform it generates when discharged into a low impedance. This model consists of a 100 pF capacitor charged to the ESD voltage of interest, which is then discharged into the test device through a $1.5 \mathrm{k} \Omega$ resistor.

## Power-Supply Considerations

The MAX4558/MAX4559/MAX4560 are typical of most CMOS analog switches. They have three supply pins: $\mathrm{V}_{\mathrm{CC}}, \mathrm{V}_{\mathrm{EE}}$, and GND. $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{EE}}$ drive the internal CMOS switches and set the limits of the analog voltage on every switch. Internal reverse ESD-protection diodes connect between each analog signal pin and both $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{EE}}$. If any analog signal exceeds $\mathrm{V}_{\mathrm{CC}}$ or $\mathrm{V}_{\mathrm{EE}}$, one of these diodes conducts. The only currents drawn from $V_{C C}$ or $V_{E E}$ during normal operation are the leakage currents of these ESD diodes.

Although the ESD diodes on a given signal pin are identical and therefore fairly well balanced, they are reverse biased differently. Each is biased by either $\mathrm{V}_{\mathrm{CC}}$ or $\mathrm{V}_{\mathrm{EE}}$ and the analog signal. Their leakage currents vary as the signal varies. The difference in the two diode leakages to the $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\text {EE }}$ pins constitutes the analog signal-path leakage current. All analog leakage current flows between
each input and one of the supply terminals, not to the other switch terminal. This is why both sides of a given switch can show leakage currents of either the same or opposite polarity.
$V_{C C}$ and GND power the internal logic and logic-level translators, and set the input logic limits. The logic-level translators convert the logic levels into switched $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\text {EE }}$ signals to drive the gates of the analog switch. This drive signal is the only connection between the logic supplies and logic signals and the analog supplies. $\mathrm{V}_{\mathrm{CC}}$ and $V_{E E}$ have ESD-protection diodes to GND.

The logic-level thresholds are TTL/CMOS compatible when $V_{C C}$ is +5 V . As $\mathrm{V}_{\mathrm{CC}}$ rises, the threshold increases slightly. When $\mathrm{V}_{\mathrm{CC}}$ reaches +12 V , the threshold is about 3.1 V (above the TTL-guaranteed high-level minimum of 2.4 V , but still compatible with CMOS outputs).

## High-Frequency Performance

In $50 \Omega$ systems, signal response is reasonably flat up to 50 MHz (see Typical Operating Characteristics). Above 20 MHz , the on response has several minor peaks that are highly layout dependent. The problem is not turning the switch on, but turning it off. The off-state switch acts like a capacitor and passes higher frequencies with less attenuation. At 1 MHz , off-isolation is about -68 dB in $50 \Omega$ systems, becoming worse (approximately 20 dB per decade) as the frequency increases. Higher circuit impedance also degrades off-isolation. Adjacent channel attenuation is about 3dB above that of a bare IC socket and is entirely due to capacitive coupling.

## Test Circuits/Timing Diagrams

V- 0 FOR SINGLE-SUPPLY OPERATION. REPEAT TEST FOR EACH SECTION.
