# LINEAR TECHNOLOGY

# 7V, 500mA Synchronous Buck-Boost DC/DC Converter

## FEATURES

- **Regulated Output with Input Voltages Above, Below or Equal to the Output**
- **2.4V to 7V $V_{IN}$ and 1.8V to 7V $V_{OUT}$ Ranges**
- **5V $V_{OUT}$ at 500mA from 4 AA Cells**
- **Single Inductor**
- **Synchronous Rectification: Up to 94% Efficiency**
- **Burst Mode® Operation with 25µA $I_Q$**
- **Output Disconnect in Shutdown**
- 1MHz Switching Frequency
- <1µA Shutdown Current
- Small Thermally Enhanced 16-Lead (5mm × 3mm × 0.75mm) DFN and 16-Lead GN Packages

## APPLICATIONS

- Medical Instruments
- Portable Barcode Readers
- Portable Inventory Terminals
- USB to 5V Supply
- Handheld GPS

## DESCRIPTION

The LTC®3534 is a wide $V_{IN}$ range, highly efficient, fixed frequency, buck-boost DC/DC converter that operates from input voltages above, below or equal to the output voltage. The topology incorporated in the IC provides a continuous transfer function through all operating modes, making the product ideal for multi-cell Alkaline/NiMH or single Lithium-Ion/Polymer applications where the output voltage is within the battery voltage range.

The LTC3534 offers extended $V_{IN}$ and $V_{OUT}$ ranges of 2.4V to 7V and 1.8V to 7V, respectively. Quiescent current is only 25µA in Burst Mode operation, maximizing battery life in portable applications. Burst Mode operation is user controlled and can be enabled by driving the PWM pin low. If the PWM pin is driven high then fixed frequency switching is enabled.

Other features include fixed 1MHz operating frequency, a <1µA shutdown, short-circuit protection, programmable soft-start, current limit and thermal overload protection. The LTC3534 is available in the thermally enhanced 16-lead (3mm × 5mm) DFN and 16-lead GN packages.
## TYPICAL APPLICATION

4 AA Cells to 5V at 500mA Buck-Boost Converter

4 AA Cells to 5V Efficiency vs $V_{IN}$

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** The LTC3534E is guaranteed to meet performance specifications from 0°C to 85°C. Specifications over the –40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls.
**Note 3:** This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed 125°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may result in device degradation or failure.

**Note 4:** The IC is tested in a feedback loop to make this measurement.

**Note 5:** Current Measurements are performed when the outputs are not switching.

# PIN FUNCTIONS

**GND Pads (Pins 1, 8, 9, 16; GN Package):** IC Substrate Grounds. These pins **MUST** be soldered to the printed circuit board ground to provide both electrical contact and a good thermal contact to the PCB.

**RUN/SS (Pin 2):** Combined Shutdown and Soft-Start. Applying a voltage below 400mV shuts down the IC. Apply a voltage above 1.4V to enable the IC and above 2.4V to ensure that the error amp is not clamped from soft-start. An R-C from the enable command signal to this pin will provide a soft-start function by limiting the rise time of the $V_C$ pin. PWM mode operation *must* be commanded to properly enable the IC.

**GND (Pin 3):** Signal Ground for the IC.

**PGND1, PGND2 (Pins 4, 7):** Power Ground for the Internal N-channel MOSFET Power Switches (Switches B and C).

**SW1 (Pin 5):** Switch Pin where Internal Switches A and B are Connected. Connect inductor from SW1 to SW2. Minimize trace length to reduce EMI.

**SW2 (Pin 6):** Switch Pin where Internal Switches C and D are Connected. Minimize trace length to reduce EMI.

**PWM (Pin 10):** Burst Mode Select. PWM must be driven HIGH during start-up. When $V_{OUT}$ is in regulation, the PWM pin may be driven LOW to command Burst Mode operation. Applying a voltage below 400mV enables Burst Mode operation, providing a significant efficiency improvement at light loads. Burst Mode operation will continue until this pin is driven high. Applying a voltage above 1.4V disables Burst Mode operation, enabling low noise, fixed frequency operation.

**$V_{OUT}$ (Pin 11):** Output of the Synchronous Rectifier. A filter capacitor is placed from $V_{OUT}$ to GND. A ceramic bypass capacitor is recommended as close to the $V_{OUT}$ and GND pins as possible. $V_{OUT}$ is given by the following equation:

$$V_{OUT} = 1.000 \bullet \frac{R1+R2}{R2} V$$

**$PV_{IN}$ (Pin 12):** Power $V_{IN}$ Supply Pin. A 10µF ceramic capacitor is recommended as close to the $PV_{IN}$ and PGND pins as possible.

**$V_{IN}$ (Pin 13):** Input Supply Pin. Connect the power source to this pin.

**$V_C$ (Pin 14):** Error Amp Output. An R-C network is connected from this pin to FB for loop compensation. Refer to "Closing the Feedback Loop" section for component selection guidelines.

**FB (Pin 15):** Feedback Pin. Connect $V_{OUT}$ resistor divider tap to this pin. The output voltage can be adjusted from 1.8V to 7V. The feedback reference voltage is typically 1V.

**Exposed Pad (Pin 17; DHC Package):** IC Substrate Ground. This pin **MUST** be soldered to the printed circuit board ground to provide both electrical contact and a good thermal contact to the PCB.

# BLOCK DIAGRAM
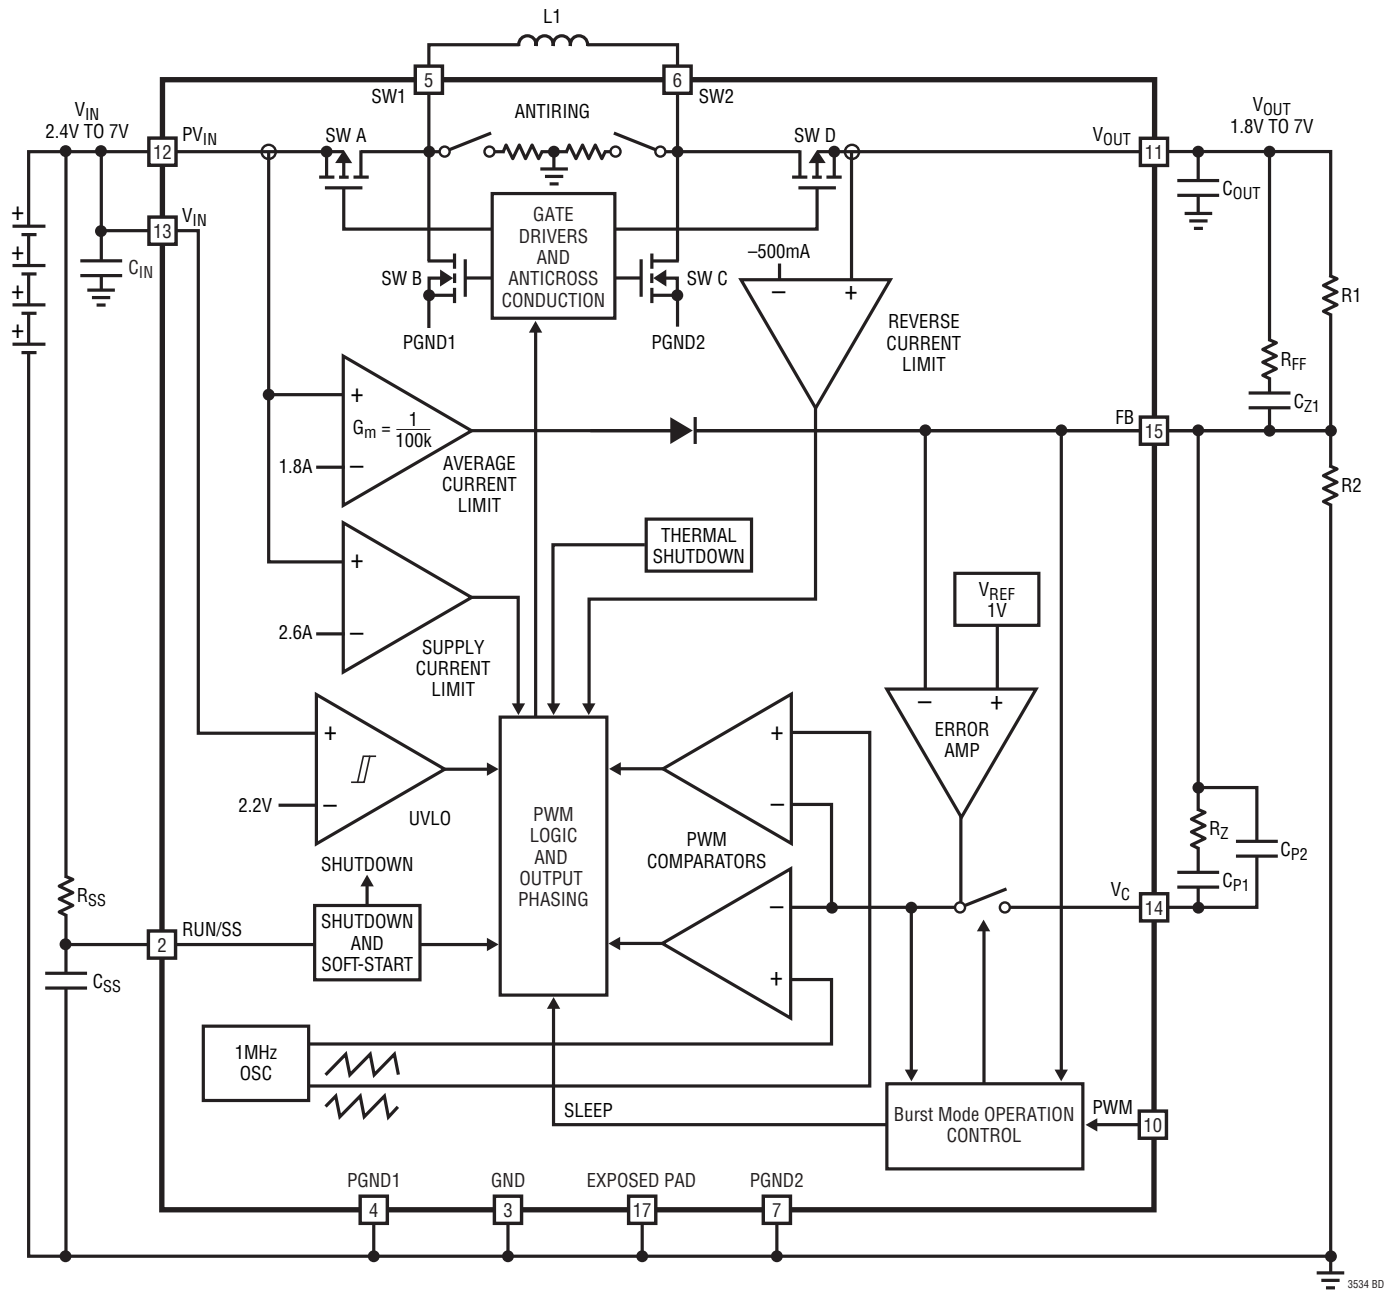

# OPERATION

The LTC3534 provides high efficiency, low noise power for a wide variety of handheld electronic devices. Linear Technology's proprietary topology allows input voltages above, below or equal to the output voltage by properly phasing the output switches. The error amplifier output voltage on $V_C$ determines the output duty cycle of the switches. Since $V_C$ is a filtered signal, it provides rejection of frequencies from well below the switching frequency. The low $R_{DS(ON)}$, low gate charge synchronous switches provide high frequency pulse width modulation control at high efficiency. High efficiency is achieved at light loads when Burst Mode operation is invoked and the LTC3534's quiescent current drops to a mere 25µA.

## LOW NOISE FIXED FREQUENCY OPERATION

### Oscillator

The frequency of operation is internally set to 1MHz.

### Error Amplifier

The error amplifier is a voltage mode amplifier. The loop compensation components are configured around the amplifier (from FB to $V_C$) to obtain stability of the converter. For improved bandwidth, an additional R-C feedforward network can be placed across the upper feedback divider resistor. The voltage on RUN/SS clamps the error amplifier output, $V_C$, to provide a soft-start function.

### Supply Current Limits

There are two different supply current limit circuits in the LTC3534, each having internally fixed thresholds.
The first circuit is an average current limit amplifier, sourcing current out of FB to drop the output voltage should the peak input current exceed 1.8A typical. This method provides a closed loop means of clamping the input current. During conditions where $V_{OUT}$ is near ground, such as during a short circuit or start-up, this threshold is cut to 800mA typical, providing a foldback feature. For this current limit feature to be most effective, the Thevenin resistance from FB to ground should be greater than 100k.

Should the peak input current exceed 2.6A typical, the second circuit, a high speed peak current limit comparator, shuts off PMOS switch A. The delay to output of this comparator is typically 50ns.

### Reverse Current Limit

During fixed frequency operation, the LTC3534 operates in forced continuous conduction mode. The reverse current limit comparator monitors the inductor current from the output through PMOS switch D. Should this negative inductor current exceed 500mA typical, the LTC3534 shuts off switch D.

### Four-Switch Control

Figure 1 shows a simplified diagram of how the four internal switches are connected to the inductor, $PV_{IN}$, $V_{OUT}$, PGND1 and PGND2. Figure 2 shows the regions of operation for the LTC3534 as a function of the internal control voltage, $V_{CI}$. Dependent on the magnitude of $V_{CI}$, the LTC3534 will operate in buck, buck-boost or boost mode. $V_{CI}$ is a level
Figure 1. Simplified Diagram of Output Switches

Figure 2. Switch Control vs Internal Control Voltage, $V_{CI}$

3534fb

# OPERATION

shifted voltage from the output of the error amplifier ($V_C$ pin), see Figure 3. The four power switches are properly phased so the transfer between operating modes is continuous, smooth and transparent to the user. When $V_{IN}$ approaches $V_{OUT}$ the buck-boost region is entered, where the conduction time of the four switch region is typically 125ns. Referring to Figures 1 and 2, the various regions of operation will now be described.

### Buck Region ($V_{IN} > V_{OUT}$)

Switch D is always on and switch C is always off during this mode. When the internal control voltage, $V_{CI}$, is above voltage V1, output A begins to switch. During the off-time of switch A, synchronous switch B turns on for the remainder of the period. Switches A and B will alternate similar to a typical synchronous buck regulator. As the control voltage increases, the duty cycle of switch A increases until the maximum duty cycle of the converter in buck mode reaches $D_{MAX\_BUCK}$, given by:

$$D_{MAX\_BUCK} = (100 - D4_{SW})\%$$

where $D4_{SW}$ = duty cycle % of the four switch range.

$$D4_{SW} = (125ns \bullet f) \bullet 100\%$$

where f = operating frequency in Hz, typically 1MHz.

Hence, $D4_{SW}$ = 12.5% for the LTC3534.

$$D_{MAX\_BUCK} = 87.5\%$$

Beyond this point the "four switch", or buck-boost region is reached.

### Buck-Boost or Four Switch ($V_{IN} \sim V_{OUT}$)

When the internal control voltage, $V_{CI}$, is above voltage V2, switch pair AD remain on for duty cycle $D_{MAX\_BUCK}$, and the switch pair AC begins to phase in. As switch pair AC phases in, switch pair BD phases out accordingly. When $V_{CI}$ reaches the edge of the buck-boost range, at voltage V3, the AC switch pair completely phase out the BD pair, and the boost phase begins at duty cycle $D4_{SW}$.

The input voltage, $V_{IN}$, where the four switch region begins is given by:

$$V_{IN} = \frac{V_{OUT}}{1 - (125ns \bullet f)} \text{ V}$$

The $V_{IN}$ potential at which the four switch region ends is given by:

$$V_{IN} = V_{OUT} \bullet (1 - D) = V_{OUT} \bullet (1 - 125ns \bullet f) \text{ V}$$

where f = operating frequency in Hz, typically 1MHz.

Hence, for the LTC3534,

$$V_{IN(ENTER4SW)} \cong \frac{V_{OUT}}{0.875} \text{ V}$$

Approximate $V_{IN}$ potential at which the four switch region is entered.

$$V_{IN(4SWEXIT)} \cong 0.875 \bullet V_{OUT} \text{ V}$$

Approximate $V_{IN}$ potential at which the four switch region is exited.

### Boost Region ($V_{IN} < V_{OUT}$)

Switch A is always on and switch B is always off during this mode. When the internal control voltage, $V_{CI}$, is above voltage V3, switch pair CD will alternately switch to provide a boosted output voltage. This operation is typical to a synchronous boost regulator. The maximum duty cycle of the converter is limited to 85% typical and is reached when $V_{CI}$ is above V4.

### Burst Mode OPERATION

Burst Mode operation reduces the LTC3534's quiescent current consumption at light loads and improves overall conversion efficiency, increasing battery life. During Burst Mode operation the LTC3534 delivers energy to the output until it is regulated and then enters a sleep state where the switches are off and the quiescent current drops to 25µA typical. In this mode the output ripple has a variable frequency component that depends upon load current, and will typically be about 2% peak-to-peak. Burst Mode operation ripple can be reduced slightly by using more output capacitance (47µF or greater). Another method of reducing Burst Mode operation ripple is to place a small feedforward capacitor across the upper resistor in the $V_{OUT}$ feedback divider network (as in Type III compensation), see Figure 6.

3534fb

# OPERATION

In Burst Mode operation the typical maximum average output currents in the three operating regions, buck, four switch, and boost are given by:

$I_{OUT(MAX)BURST-BUCK} \approx 100mA;$

Burst Mode operation – buck region: $V_{IN} > V_{OUT}$

$I_{OUT(MAX)BURST-FOUR\_SWITCH} \approx 125mA;$

Burst Mode operation – four switch region: $V_{IN} \approx V_{OUT}$

$I_{OUT(MAX)BURST-BOOST} \approx \dfrac{125 \cdot V_{IN}}{V_{OUT}}$ mA;

Burst Mode operation – boost region: $V_{IN} < V_{OUT}$

The efficiency below 1mA becomes dominated primarily by the quiescent current. The Burst Mode operation efficiency is given by:

$$Efficiency \cong \frac{\eta \cdot I_{LOAD}}{25\mu A + I_{LOAD}}$$

where $\eta$ is typically 90% during Burst Mode operation.

A graph of Burst Mode operation maximum output current vs $V_{IN}$ (for $V_{OUT} = 5V$) is provided in the Typical Performance Characteristics section.

**Burst Mode Operation to Fixed Frequency Transient Response**

In Burst Mode operation, the compensation network is not used and $V_C$ is disconnected from the error amplifier.

During long periods of Burst Mode operation, leakage currents in the external components or on the PC board could cause the compensation capacitor to charge (or discharge), which could result in a large output transient when returning to fixed frequency mode operation, even at the same load current. To prevent this, the LTC3534 incorporates an active clamp circuit that holds the voltage on $V_C$ at an optimal voltage during Burst Mode operation. This minimizes any output transient when returning to fixed frequency mode operation. For optimum transient response, Type III compensation is also recommended to broad band the control loop and roll off past the two pole response of the output LC filter. (See Closing the Feedback Loop).

**Soft-Start**

The soft-start function is combined with shutdown. When the RUN/SS pin is brought above 1V typical, the LTC3534 is enabled but the error amplifier duty cycle is clamped from $V_C$. A detailed diagram of this function is shown in Figure 3. The components $R_{SS}$ and $C_{SS}$ provide a slow ramping voltage on RUN/SS to provide a soft-start function. To ensure that $V_C$ is not being clamped, RUN/SS must be raised to 2.4V or above. The IC must be enabled (even with a soft-start) commanding PWM mode. Once the LTC3534 is in regulation, then Burst Mode operation can be commanded.

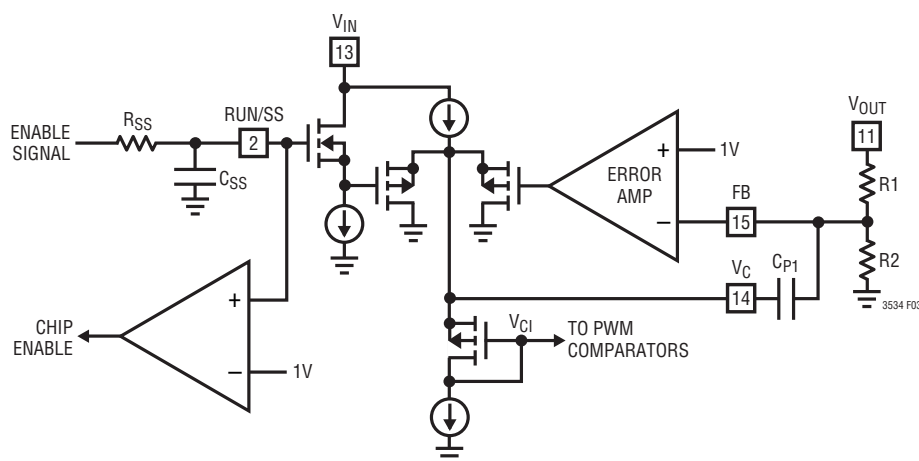

**Figure 3. Soft-Start Circuitry**

# APPLICATIONS INFORMATION
## COMPONENT SELECTION

**Figure 4. Recommended Component Placement. Traces Carrying High Current are Direct. Trace Area at FB and V_C Pins are Kept Low. Lead Length to Battery Should be Kept Short. Keep V_OUT and V_IN Ceramic Capacitors Close to their IC Pins.**

### Inductor Selection

The high frequency operation of the LTC3534 allows the use of small surface mount inductors. The inductor ripple current is typically set to 20% to 40% of the maximum inductor current. For a given ripple the inductance terms are given as follows:

$$L_{BOOST} > \frac{V_{IN(MIN)} \bullet \left(V_{OUT} - V_{IN(MIN)}\right)}{f \bullet \Delta I_L \bullet V_{OUT}} \; H$$

$$L_{BUCK} > \frac{V_{OUT} \bullet \left(V_{IN(MAX)} - V_{OUT}\right)}{f \bullet \Delta I_L \bullet V_{IN(MAX)}} \; H$$

where f = switching frequency in Hz, typically 1MHz.

$\Delta I_L$ = maximum allowable inductor ripple current, A

$V_{IN(MIN)}$ = minimum input voltage, V

$V_{IN(MAX)}$ = maximum input voltage, V

$V_{OUT}$ = output voltage, V

For high efficiency, choose a ferrite inductor with a high frequency core material to reduce core loses. The inductor should have low ESR (equivalent series resistance) to reduce the $I^2R$ losses, and must be able to handle the peak inductor current without saturating. Molded chokes or chip inductors usually do not have enough core to support the peak inductor currents in the 1A to 2A region. To minimize radiated noise, use a shielded inductor. See Table 1 for a suggested list of inductor suppliers.

**Table 1. Inductor Vendor Information**

# APPLICATIONS INFORMATION

## Output Capacitor Selection

The bulk value of the output filter capacitor is set to reduce the ripple due to charge into the capacitor each cycle. The steady state ripple due to charge is given by:

$$\Delta V_{P-P} \text{Boost} = \frac{I_{OUT} \bullet \left( V_{OUT} - V_{IN(MIN)} \right)}{C_{OUT} \bullet V_{OUT} \bullet f} \text{ V}$$

$$\Delta V_{P-P} \text{Buck} = \frac{1}{8 \bullet L \bullet C_{OUT} \bullet f^2} \bullet \frac{\left( V_{IN(MAX)} - V_{OUT} \right) \bullet V_{OUT}}{V_{IN(MAX)}} \text{ V}$$

where f = switching frequency in Hz, typically 1MHz.

$C_{OUT}$ = output filter capacitor, F

$I_{OUT}$ = output load current, A

The output capacitance is usually many times larger than the minimum value in order to handle the transient response requirements of the converter. As a rule of thumb, the ratio of the operating frequency to the unity-gain bandwidth of the converter is the amount the output capacitance will have to increase from the above calculations in order to maintain the desired transient response. A 22µF or larger ceramic capacitor is appropriate for most applications.

The other component of ripple is due to the ESR (equivalent series resistance) of the output capacitor. Low ESR capacitors should be used to minimize output voltage ripple. For surface mount applications, Taiyo Yuden or TDK ceramic capacitors, AVX TPS series tantalum capacitors or Sanyo POSCAP are recommended. See Table 2 for contact information.

## Input Capacitor Selection

Since $V_{IN}$ is the supply voltage for the IC, as well as the input to the power stage of the converter, it is recommended to place at least a 10µF, low ESR ceramic bypass capacitor close to the $PV_{IN}/V_{IN}$ and PGND/GND pins. It is also important to minimize any stray resistance from the converter to the battery or other power source.

## Optional Schottky Diodes

Schottky diodes across the synchronous switches B and D are not required, but do provide a lower drop during the break-before-make time (typically 15ns), thus improving efficiency. Use a surface mount Schottky diode such as an MBRM120T3 or equivalent. Do not use ordinary rectifier diodes since their slow recovery times will compromise efficiency.

## Output Voltage < 1.8V

The LTC3534 can operate as a buck converter with output voltages as low as 400mV. Since synchronous switch D is powered from $V_{OUT}$ and the $R_{DS(ON)}$ will increase significantly at output voltages below 1.8V typical, a Schottky diode is required from SW2 to $V_{OUT}$ to provide the conduction path to the output at low $V_{OUT}$ voltages. The current limit is folded back to 800mA when $V_{OUT} <$ 0.9V typical which will significantly reduce the output current capability of the application. Note that Burst Mode operation is inhibited at output voltages below 1.6V typical.

## Closing the Feedback Loop

The LTC3534 incorporates voltage mode PWM control. The control to output gain varies with operation region (buck, boost, buck-boost), but is usually no greater than 15. The output filter exhibits a double pole response, as given by:

$$f_{FILTER\_POLE} = \frac{1}{2 \bullet \pi \bullet \sqrt{L1 \bullet C_{OUT}}} \text{ Hz (in buck mode)}$$

$$f_{FILTER\_POLE} = \frac{V_{IN}}{2 \bullet V_{OUT} \bullet \pi \bullet \sqrt{L1 \bullet C_{OUT}}} \text{ Hz (in boost mode)}$$

where L1 is in Henries and $C_{OUT}$ is in Farads.

The output filter zero is given by:

## APPLICATIONS INFORMATION

$$f_{FILTER\_ZERO} = \frac{1}{2 \bullet \pi \bullet R_{ESR} \bullet C_{OUT}} \text{ Hz}$$

where $R_{ESR}$ is the equivalent series resistance of the output capacitor.

A troublesome feature in boost mode is the right-half plane zero (RHP), given by:

$$f_{RHPZ} = \frac{V_{IN}^2}{2 \bullet \pi \bullet I_{OUT} \bullet L1 \bullet V_{OUT}} \text{ Hz}$$

The loop gain is typically rolled off before the RHP zero frequency.

A simple Type I compensation network can be incorporated to stabilize the loop, but at a cost of reduced bandwidth and slower transient response. To ensure proper phase margin using Type I compensation, the loop must be crossed over a decade before the LC double pole. Referring to Figure 5, the unity-gain frequency of the error amplifier utilizing Type I compensation is given by:

$$f_{UG} = \frac{1}{2 \bullet \pi \bullet R1 \bullet C_{P1}} \text{ Hz}$$
Most applications demand an improved transient response to allow a smaller output filter capacitor. To achieve a higher bandwidth, Type III compensation is required, providing two zeros to compensate for the double-pole response of the output filter. Referring to Figure 6, the location of the poles and zeros are given by:

$$f_{POLE1} \cong \frac{1}{2 \bullet \pi \bullet 5 \times 10^3 \bullet R1 \bullet C_{P1}} \text{ Hz}$$

(which is extremely close to DC)

$$f_{ZERO1} = \frac{1}{2 \bullet \pi \bullet R_Z \bullet C_{P1}} \text{ Hz}$$

$$f_{ZERO2} = \frac{1}{2 \bullet \pi \bullet R1 \bullet C_{Z1}} \text{ Hz}$$

$$f_{POLE2} = \frac{1}{2 \bullet \pi \bullet R_Z \bullet C_{P2}} \text{ Hz}$$

where resistance is in Ohms and capacitance is in Farads.
