

ADS8866 16-bit, 100-kSPS, serial interface, micropower, miniature, single-ended input, SAR analog-to-digital converter

1 Features

- Sample rate: 100 kHz
- No latency output
- Unipolar, single-ended input range: 0 to $+V_{REF}$
- SPI™-compatible serial interface with daisy-chain option
- Excellent AC and DC performance:
 - SNR: 93 dB, THD: –108 dB
 - INL: ± 1.0 LSB (typ), ± 2.0 LSB (max)
 - DNL: ± 1.0 LSB (max), 16-bit NMC
- Wide operating range:
 - AVDD: 2.7 V to 3.6 V
 - DVDD: 1.65 V to 3.6 V (independent of AVDD)
 - REF: 2.5 V to 5 V (independent of AVDD)
 - Operating temperature: –40°C to +85°C
- Low-power dissipation:
 - 0.7 mW at 100 kSPS
 - 70 μ W at 10 kSPS
- Power-down current (AVDD): 50 nA
- Full-scale step settling to 16 Bits: 1200 ns
- Packages: VSSOP-10 and VSON-10

2 Applications

- Automatic test equipment (ATE)
- Instrumentation and process controls
- Precision medical equipment
- Low-power, battery-operated instruments

3 Description

The ADS8866 is a 16-bit, 100-kSPS, single-ended input, analog-to-digital converter (ADC). The device operates with a 2.5-V to 5-V external reference, offering a wide selection of signal ranges without additional input signal scaling. The reference voltage setting is independent of, and can exceed, the analog supply voltage (AVDD).

The device offers an SPI-compatible serial interface that also supports daisy-chain operation for cascading multiple devices.

The device supports unipolar single-ended analog inputs in the range of -0.1 V to $V_{REF} + 0.1$ V.

Device operation is optimized for very low-power operation. Power consumption directly scales with speed. This feature makes the ADS8866 excellent for lower-speed applications.

6 Pin Configuration and Functions

Pin Functions

PIN		TYPE	DESCRIPTION
NAME	NO.		
AINN	4	Analog input	Inverting analog signal input
AINP	3	Analog input	Noninverting analog signal input
AVDD	2	Analog	Analog power supply. This pin must be decoupled to GND with a 1- μ F capacitor.
CONVST	6	Digital input	Convert input. This pin also functions as the \overline{CS} input in 3-wire interface mode; see the Description and Timing Requirements sections for more details.
DIN	9	Digital input	Serial data input. The DIN level at the start of a conversion selects the mode of operation (such as \overline{CS} or daisy-chain mode). This pin also serves as the \overline{CS} input in 4-wire interface mode; see the Description and Timing Requirements sections for more details.
DOUT	7	Digital output	Serial data output
DVDD	10	Power supply	Digital interface power supply. This pin must be decoupled to GND with a 1- μ F capacitor.
GND	5	Analog, digital	Device ground. Note that this pin is a common ground pin for both the analog power supply (AVDD) and digital I/O supply (DVDD). The reference return line is also internally connected to this pin.
REF	1	Analog	Positive reference input. This pin must be decoupled with a 10- μ F or larger capacitor.
SCLK	8	Digital input	Clock input for serial interface. Data output (on DOUT) are synchronized with this clock.
Thermal pad	—	—	Exposed thermal pad (only for the DRC package option). Texas Instruments recommends connecting the thermal pad to the printed circuit board (PCB) ground.

7 Specifications

7.1 Absolute Maximum Ratings

Operating temperature, T _A	-40	85	°C
Storage temperature, T _{stg}	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

9 Detailed Description

9.1 Overview

The ADS8866 is a high-speed, successive approximation register (SAR), analog-to-digital converter (ADC) from a 16- and 18-bit device family. This compact device features high performance. Power consumption is inherently low and scales linearly with sampling speed. The architecture is based on charge redistribution that inherently includes a sample-and-hold (S/H) function.

The ADS8866 supports a single-ended analog input across two pins (INP and INN). When a conversion is initiated, the differential input on these pins is sampled on the internal capacitor array. While a conversion is in progress, both the INP and INN inputs are disconnected from the internal circuit.

The ADS8866 uses an internal clock to perform conversions. The device reconnects the sampling capacitors to the INP and INN pins after conversion and then enters an acquisition phase. During the acquisition phase, the device is powered down and the conversion result can be read.

The device digital output is available in SPI-compatible format, thus making interfacing with microprocessors, digital signal processors (DSPs), or field-programmable gate arrays (FPGAs) easy.

9.2 Functional Block Diagram

Figure 39 shows the detailed functional block diagram for the device.

Figure 39. Detailed Block Diagram

9.3 Feature Description

9.3.1 Analog Input

As shown in Figure 39, the device features a single-ended analog input. AINP can swing from $GND - 0.1\text{ V}$ to $V_{REF} + 0.1\text{ V}$ and AINN can swing from $GND - 0.1\text{ V}$ to $GND + 0.1\text{ V}$. Both positive and negative inputs are individually sampled on 55-pF sampling capacitors and the device converts for the voltage difference between the two sampled values: $V_{INP} - V_{INN}$. The single-ended signal range is 0 V to V_{REF} .

Feature Description (continued)

Figure 40 shows an equivalent circuit of the input sampling stage. The sampling switch is represented by a 96- Ω resistance in series with the ideal switch; see the [ADC Input Driver](#) section for more details on the recommended driving circuits.

Figure 40. Input Sampling Stage Equivalent Circuit

Figure 39 and Figure 40 illustrate electrostatic discharge (ESD) protection diodes to REF and GND from both analog inputs. Make sure that these diodes do not turn on by keeping the analog inputs within the specified range.

9.3.2 Reference

The device operates with an external reference voltage and switches binary-weighted capacitors onto the reference terminal (REF pin) during the conversion process. The switching frequency is proportional to the internal conversion clock frequency but the dynamic charge requirements are a function of the absolute value of the input voltage and reference voltage. This dynamic load must be supported by a reference driver circuit without degrading the noise and linearity performance of the device. During the acquisition process, the device automatically powers down and does not take any dynamic current from the external reference source. The basic circuit diagram for such a reference driver circuit for precision ADCs is shown in Figure 41; see the [ADC Reference Driver](#) section for more details on the application circuits.

Figure 41. Reference Driver Schematic

9.3.3 Clock

The device uses an internal clock for conversion. Conversion duration may vary but is bounded by the minimum and maximum value of t_{conv} , as specified in the [Timing Requirements](#) section. An external SCLK is only used for a serial data read operation. Data are read after a conversion completes and when the device is in acquisition phase for the next sample.

Feature Description (continued)

9.3.4 ADC Transfer Function

The ADS8866 is a unipolar, single-ended input device. The device output is in straight binary format.

Figure 42 shows ideal characteristics for the device. The full-scale range for the ADC input (AINP – AINN) is equal to the reference input voltage to the ADC (V_{REF}). One LSB is equal to $[(V_{REF} / 2^{16})]$.

Figure 42. Single-Ended Transfer Characteristics

9.4 Device Functional Modes

The ADS8866 is a low pin-count device. However, the device offers three different options for interfacing with the digital host.

These options can be broadly classified as being either \overline{CS} mode (in either a 3- or 4-wire interface) or *daisy-chain mode*. The device operates in \overline{CS} mode if \overline{DIN} is high at the \overline{CONVST} rising edge. If \overline{DIN} is low at the \overline{CONVST} rising edge, or if \overline{DIN} and \overline{CONVST} are connected together, the device operates in daisy-chain mode.

The 3-wire interface in \overline{CS} mode is useful for applications that need galvanic isolation on-board. The 4-wire interface in \overline{CS} mode allows the user to sample the analog input independent of the serial interface timing and, therefore, allows easier control of an individual device while having multiple, similar devices on-board. The daisy-chain mode is provided to hook multiple devices in a chain similar to a shift register and is useful in reducing component count and the number of signal traces on the board.

9.4.1 \overline{CS} Mode

\overline{CS} mode is selected if \overline{DIN} is high at the \overline{CONVST} rising edge. There are three different interface options available in this mode: 3-wire \overline{CS} mode, and 4-wire \overline{CS} mode. The following sections discuss these interface options in detail.

Device Functional Modes (continued)

9.4.1.1 3-Wire \overline{CS} Mode

This interface option is most useful when a single ADC is connected to an SPI-compatible digital host. In this interface option, DIN can be connected to DVDD and CONVST functions as \overline{CS} (as shown in Figure 43). As shown in Figure 44, a CONVST rising edge forces DOUT to 3-state, samples the input signal, and causes the device to enter a conversion phase. Conversion is done with the internal clock and continues regardless of the state of CONVST. As a result, CONVST (functioning as \overline{CS}) can be pulled low after the start of the conversion to select other devices on the board. However, CONVST must return high before the minimum conversion time ($t_{conv-min}$) elapses and is held high until the maximum possible conversion time ($t_{conv-max}$) elapses.

Figure 43. Connection Diagram: 3-Wire \overline{CS} Mode (DIN = 1)

Figure 44. Interface Timing Diagram: 3-Wire \overline{CS} Mode (DIN = 1)

When conversion is complete, the device enters an acquisition phase and powers down. CONVST (functioning as \overline{CS}) can be brought low after the maximum conversion time ($t_{conv-max}$) elapses. On the CONVST falling edge, DOUT comes out of 3-state and the device outputs the MSB of the data. The lower data bits are output on subsequent SCLK falling edges. Data can be read at either SCLK falling or rising edges. Note that with any SCLK frequency, reading data at SCLK falling edge requires the digital host to clock in the data during the $t_{h_CK_DO-min}$ time frame. DOUT goes to 3-state after the 16th SCLK falling edge or when CONVST goes high, whichever occurs first.

Device Functional Modes (continued)
9.4.1.2 4-Wire $\overline{\text{CS}}$ Mode

This interface option is useful when one or more ADCs are connected to an SPI-compatible digital host. [Figure 45](#) shows the connection diagram for single ADC; see [Figure 47](#) for the connection diagram for two ADCs.

Figure 45. Connection Diagram: Single ADC With 4-Wire $\overline{\text{CS}}$ Mode

In this interface option, DIN is controlled by the digital host and functions as $\overline{\text{CS}}$. As shown in [Figure 46](#), with DIN high, a CONVST rising edge selects $\overline{\text{CS}}$ mode, forces DOUT to 3-state, samples the input signal, and causes the device to enter a conversion phase. In this interface option, CONVST must be held at a high level from the start of the conversion until all data bits are read. Conversion is done with the internal clock and continues regardless of the state of DIN. As a result, DIN (functioning as $\overline{\text{CS}}$) can be pulled low to select other devices on the board. However, DIN must be pulled high before the minimum conversion time ($t_{\text{conv-min}}$) elapses and remains high until the maximum possible conversion time ($t_{\text{conv-max}}$) elapses.

Figure 46. Interface Timing Diagram: Single ADC With 4-Wire $\overline{\text{CS}}$ Mode

Device Functional Modes (continued)

When conversion is complete, the device enters acquisition phase and powers down. DIN (functioning as \overline{CS}) can be brought low after the maximum conversion time ($t_{conv-max}$) elapses. On the DIN falling edge, DOUT comes out of 3-state and the device outputs the MSB of the data. The lower data bits are output on subsequent SCLK falling edges. Data can be read at either SCLK falling or rising edges. Note that with any SCLK frequency, reading data at SCLK falling edge requires the digital host to clock in the data during the $t_{h_CK_DO-min}$ time frame. DOUT goes to 3-state after the 16th SCLK falling edge or when DIN goes high, whichever occurs first.

As shown in Figure 47, multiple devices can be hooked together on the same data bus. In this case, as shown in Figure 48, the DIN of the second device (functioning as \overline{CS} for the second device) can go low after the first device data are read and the DOUT of the first device is in 3-state.

Care must be taken so that CONVST and DIN are not both low together at any time during the cycle.

9.4.2 Daisy-Chain Mode

Daisy-chain mode is selected if DIN is low at the time of a CONVST rising edge or if DIN and CONVST are connected together. The following section discusses this interface option in detail.

Device Functional Modes (continued)

9.4.2.1 Daisy-Chain Mode

This interface option is most useful in applications where multiple ADC devices are used but the digital host has limited interfacing capability. Figure 49 shows a connection diagram with N ADCs connected in the daisy-chain. The CONVST pins of all ADCs in the chain are connected together and are controlled by a single pin of the digital host. Similarly, the SCLK pins of all ADCs in the chain are connected together and are controlled by a single pin of the digital host. The DIN pin for ADC 1 (DIN-1) is connected to GND. The DOUT pin of ADC 1 (DOUT-1) is connected to the DIN pin of ADC 2 (DIN-2), and so on. The DOUT pin of the last ADC in the chain (DOUT-N) is connected to the SDI pin of the digital host.

Figure 49. Connection Diagram: Daisy-Chain Mode (DIN = 0)

As shown in Figure 50, the device DOUT pin is driven low when DIN and CONVST are low together. With DIN low, a CONVST rising edge selects daisy-chain mode, samples the analog input, and causes the device to enter a conversion phase. In this interface option, CONVST must remain high from the start of the conversion until all data bits are read. When started, the conversion continues regardless of the state of SCLK, however SCLK must be low at the CONVST rising edge.

Figure 50. Interface Timing Diagram: For Two Devices in Daisy-Chain Mode

Device Functional Modes (continued)

At the end of conversion, every ADC in the chain loads its own conversion result into the internal, 16-bit, shift register and also outputs the MSB bit of this conversion result on its own DOUT pin. All ADCs enter an acquisition phase and power-down. On every subsequent SCLK falling edge, the internal shift register of each ADC latches the data available on its DIN pin and shifts out the next bit of data on its DOUT pin. Therefore, the digital host receives the data of ADC N, followed by the data of ADC N–1, and so on (in MSB-first fashion). A total of $16 \times N$ SCLK falling edges are required to capture the outputs of all N devices in the chain. Data can be read at either SCLK falling or rising edges. Note that with any SCLK frequency, reading data at SCLK falling edge requires the digital host to clock in the data during the $t_{h_CK_DO-min}$ time frame.

10 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

The two primary circuits required to maximize the performance of a high-precision, successive approximation register (SAR), analog-to-digital converter (ADC) are the input driver and the reference driver circuits. This section details some general principles for designing these circuits, followed by some application circuits designed using the ADS8866.

10.1.1 ADC Reference Driver

The external reference source to the ADS8866 must provide low-drift and very accurate voltage for the ADC reference input and support the dynamic charge requirements without affecting the noise and linearity performance of the device. The output broadband noise of most references can be in the order of a few hundred μV_{RMS} . Therefore, to prevent any degradation in the noise performance of the ADC, the output of the voltage reference must be appropriately filtered by using a low-pass filter with a cutoff frequency of a few hundred hertz.

After band-limiting the noise of the reference circuit, the next important step is to design a reference buffer that can drive the dynamic load posed by the reference input of the ADC. The reference buffer must regulate the voltage at the reference pin such that the value of V_{REF} stays within the 1-LSB error at the start of each conversion. This condition necessitates the use of a large capacitor, $C_{\text{BUF_FLT}}$ (see [Figure 41](#)) for regulating the voltage at the reference input of the ADC. The amplifier selected to drive the reference pin must have an extremely low offset and temperature drift with a low output impedance to drive the capacitor at the ADC reference pin without any stability issues.

10.1.2 ADC Input Driver

The input driver circuit for a high-precision ADC mainly consists of two parts: a driving amplifier and a fly-wheel RC filter. The amplifier is used for signal conditioning of the input voltage and its low output impedance provides a buffer between the signal source and the switched capacitor inputs of the ADC. The RC filter helps attenuate the sampling charge injection from the switched-capacitor input stage of the ADC and functions as an antialiasing filter to band-limit the wideband noise contributed by the front-end circuit. Careful design of the front-end circuit is critical to meet the linearity and noise performance of a high-precision, 16-bit ADC such as the ADS8866.

10.1.2.1 Input Amplifier Selection

Selection criteria for the input amplifiers is highly dependent on the input signal type as well as the performance goals of the data acquisition system. Some key amplifier specifications to consider while selecting an appropriate amplifier to drive the inputs of the ADC are:

- **Small-signal bandwidth.** Select the small-signal bandwidth of the input amplifiers to be as high as possible after meeting the power budget of the system. Higher bandwidth reduces the closed-loop output impedance of the amplifier, thus allowing the amplifier to more easily drive the low cutoff frequency RC filter (see the [Antialiasing Filter](#) section) at the inputs of the ADC. Higher bandwidth also minimizes the harmonic distortion at higher input frequencies. In order to maintain the overall stability of the input driver circuit, select the amplifier bandwidth as described in [Equation 1](#):

$$\text{Unity - Gain Bandwidth} \geq 4 \times \left(\frac{1}{2\pi \times (R_{\text{FLT}} + R_{\text{FLT}}) \times C_{\text{FLT}}} \right) \quad (1)$$

- **Noise.** Noise contribution of the front-end amplifiers must be as low as possible to prevent any degradation in SNR performance of the system. As a rule of thumb, to ensure that the noise performance of the data acquisition system is not limited by the front-end circuit, the total noise contribution from the front-end circuit must be kept below 20% of the input-referred noise of the ADC. Noise from the input driver circuit is band-limited by designing a low cutoff frequency RC filter, as explained in [Equation 2](#).

Application Information (continued)

$$N_G \times \sqrt{2} \times \sqrt{\left(\frac{V_{1/f_AMP_PP}}{6.6}\right)^2 + e_{n_RMS}^2 \times \frac{\pi}{2} \times f_{-3dB}} \leq \frac{1}{5} \times \frac{V_{REF}}{\sqrt{2}} \times 10^{\left(\frac{SNR(dB)}{20}\right)}$$

where:

- V_{1/f_AMP_PP} is the peak-to-peak flicker noise in μV ,
 - e_{n_RMS} is the amplifier broadband noise density in nV/\sqrt{Hz} ,
 - f_{-3dB} is the 3-dB bandwidth of the RC filter, and
 - N_G is the noise gain of the front-end circuit, which is equal to 1 in a buffer configuration. (2)
- *Distortion.* Both the ADC and the input driver introduce nonlinearity in a data acquisition block. As a rule of thumb, to ensure that the distortion performance of the data acquisition system is not limited by the front-end circuit, the distortion of the input driver must be at least 10 dB lower than the distortion of the ADC, as shown in Equation 3.

$$THD_{AMP} \leq THD_{ADC} - 10 \text{ (dB)} \quad (3)$$

- *Settling Time.* For dc signals with fast transients that are common in a multiplexed application, the input signal must settle within an 16-bit accuracy at the device inputs during the acquisition time window. This condition is critical to maintain the overall linearity performance of the ADC. Typically, the amplifier data sheets specify the output settling performance only up to 0.1% to 0.001%, which may not be sufficient for the desired 16-bit accuracy. Therefore, always verify the settling behavior of the input driver by TINA™-SPICE simulations before selecting the amplifier.

10.1.2.2 Charge-Kickback Filter

The charge-kickback filter is an RC filter at the input pins of the ADC that filters the broadband noise from the front-end drive circuitry and attenuates the sampling charge injection from the switched-capacitor input stage of the ADC. As shown in Figure 51, a filter capacitor (C_{FLT}) is connected from each input pin of the ADC to ground. This capacitor helps reduce the sampling charge injection and provides a charge bucket to quickly charge the internal sample-and-hold capacitors during the acquisition process. Generally, the value of this capacitor must be at least 20 times the specified value of the ADC sampling capacitance. For the ADS8866, the input sampling capacitance is equal to 59 pF; therefore, for optimal performance, keep C_{FLT} greater than 590 pF. This capacitor must be a COG- or NPO-type. The type of dielectric used in COG or NPO ceramic capacitors provides the most stable electrical properties over voltage, frequency, and temperature changes.

Driving capacitive loads can degrade the phase margin of the input amplifier, thus making the amplifier marginally unstable. To avoid amplifier stability issues, series isolation resistors (R_{FLT}) are used at the output of the amplifiers. A higher value of R_{FLT} helps with amplifier stability, but adds distortion as a result of interactions with the nonlinear input impedance of the ADC. Distortion increases with source impedance, input signal frequency, and input signal amplitude. Therefore, the selection of R_{FLT} requires balancing the stability of the driver amplifier and distortion performance of the design. Always verify the stability and settling behavior of the driving amplifier and charge-kickback filter by a TINA-TI™ SPICE simulation. Keep the tolerance of the selected resistors less than 1% to keep the inputs balanced.

Figure 51. Charge-Kickback Filter

Application Information (continued)

This section describes some common application circuits using the ADS8866. These data acquisition (DAQ) blocks are optimized for specific input types and performance requirements of the system. For simplicity, power-supply decoupling capacitors are not shown in these circuit diagrams; see the [Power-Supply Decoupling](#) section for suggested guidelines.

10.2 Typical Applications

10.2.1 DAQ Circuit for a 10- μ s, Full-Scale Step Response

Figure 52. DAQ Circuit for a 10- μ s, Full-Scale Step Response

10.2.1.1 Design Requirements

Step input signals are common in multiplexed applications when switching between different channels. In the worst-case scenario, one channel is at the negative full-scale (NFS) and the other channel is at the positive full-scale (PFS) voltage, in which case the step size is the full-scale range (FSR) of the ADC when the MUX channel is switched.

Design an application circuit optimized for using the ADS8866 to achieve

- Full-scale step input settling to 16-bit accuracy and
- INL of $< \pm 2$ LSB and
- Maximum specified throughput of 100 kSPS

10.2.1.2 Detailed Design Procedure

The application circuit is shown in [Figure 52](#).

In such applications, the primary design requirement is to ensure that the full-scale step input signal settles to 16-bit accuracy at the ADC inputs. This condition is critical to achieve the excellent linearity specifications of the ADC. Therefore, the bandwidth of the charge-kickback RC filter must be large enough to allow optimal settling of the input signal during the ADC acquisition time. The filter capacitor helps reduce the sampling charge injection at the ADC inputs, but degrades the phase margin of the driving amplifier, thereby leading to stability issues. Amplifier stability is maintained by the series isolation resistor.

During the conversion process, binary-weighted capacitors are switched onto the REF pin. In order to support this dynamic load the output of the voltage reference must be buffered with a low-output impedance (high-bandwidth) buffer.

The REF60xx family of voltage references are able to maintain an output voltage within 1 LSB (16-bit) with minimal droop, even during the first conversion while driving the REF pin of the ADS8866. This feature is useful in burst-mode, event-triggered, equivalent-time sampling, and variable-sampling-rate data-acquisition systems.

Typical Applications (continued)

For the input driving amplifiers, key specifications include rail-to-rail input and output swing, high bandwidth, high slew rate, and fast settling time. The CMOS amplifier meets all these specification requirements for this circuit with a single-supply and low quiescent current. The component values of the antialiasing filter are selected to meet the settling requirements of the system as well as to maintain the stability of the input driving amplifiers.

10.2.2 DAQ Circuit for Lowest Distortion and Noise Performance at 100 kSPS

Figure 53. DAQ Circuit for Lowest Distortion and Noise at 100 kSPS

10.2.2.1 Design Requirements

Design an application circuit optimized for using the ADS8866 to achieve

- > 94.5-dB SNR, < -110-dB THD and
- ± 1 -LSB linearity and
- maximum specified throughput of 100 kSPS

10.2.2.2 Detailed Design Procedure

This section describes an application circuit (as shown in [Figure 53](#)) optimized for using the ADS8866 with lowest distortion and noise performance at a throughput of 100 kSPS. The input signal is processed through a high-bandwidth, low-distortion amplifier in an inverting gain configuration and a low-pass RC filter before being fed into the ADC.

As a rule of thumb, the distortion from the input driver must be at least 10 dB less than the ADC distortion. The distortion resulting from variation in the common-mode signal is eliminated by using the amplifier in an inverting gain configuration that establishes a fixed common-mode level for the circuit. This configuration also eliminates the requirement of a rail-to-rail swing at the input of the amplifier. Therefore, the circuit uses the low-power OPA836 as an input driver, which provides exceptional ac performance because of its extremely low-distortion, high-bandwidth specifications.

In addition, the components of the charge-kickback filter are such that the noise from the front-end circuit is kept low without adding distortion to the input signal.

Typical Applications (continued)

10.2.3 Ultralow-Power DAQ Circuit at 10 kSPS

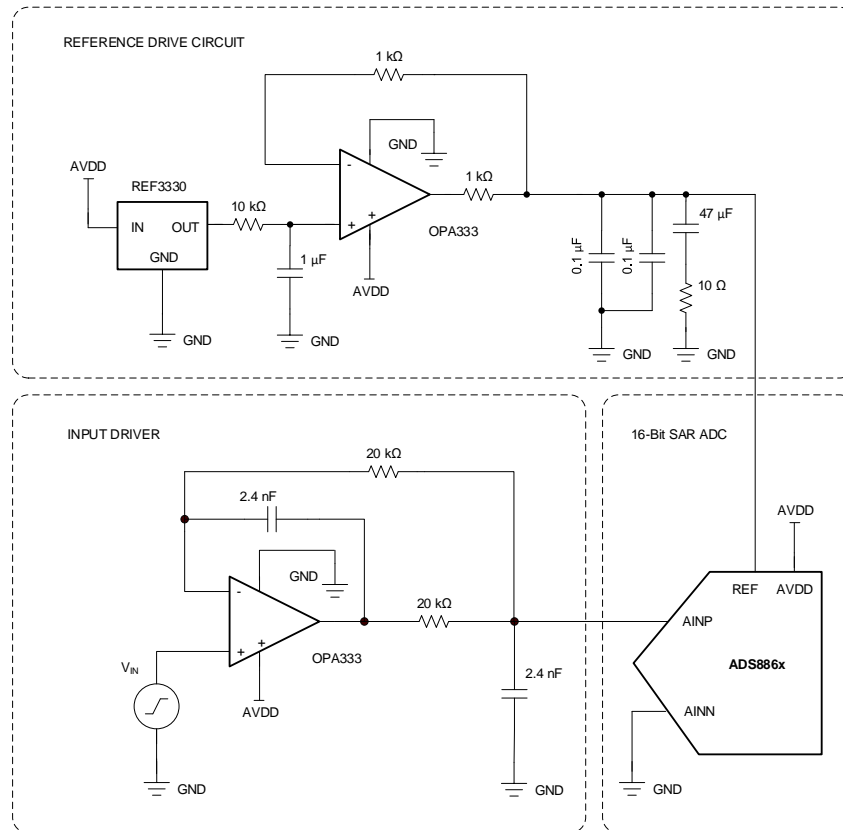

Figure 54. Ultralow-Power DAQ Circuit at 10 kSPS

10.2.3.1 Design Requirements

Portable and battery-powered applications require ultralow-power consumption and do not need very high throughput from the ADC.

Design a single-supply, data acquisition circuit optimized for using the ADS8866 to achieve

- ENOB > 14.5 bits and
- Ultralow-power consumption of < 1 mW at throughput of 10 kSPS

10.2.3.2 Detailed Design Procedure

The data acquisition circuit shown in [Figure 54](#) is optimized for using the ADS8866 at a reduced throughput of 10 kSPS

In order to save power, this circuit is operated on a single 3.3-V supply. The circuit uses the [OPA333](#) with a maximum quiescent current of 28 μ A in order to drive the ADC input. The input amplifier is configured in a modified unity-gain buffer configuration. The filter capacitor at the ADC inputs attenuates the sampling charge injection noise from the ADC but effects the stability of the input amplifiers by degrading the phase margin. This attenuation requires a series isolation resistor to maintain amplifier stability. The value of the series resistor is directly proportional to the open-loop output impedance of the driving amplifier to maintain stability, which is high (in the order of k Ω) in the case of low-power amplifiers such as the OPA333. Therefore, a high value of 1 k Ω is selected for the series resistor at the ADC inputs. However, this series resistor creates an additional voltage drop in the signal path, thereby leading to linearity and distortion issues. The dual-feedback configuration used in [Figure 54](#) corrects for this additional voltage drop and maintains system performance at ultralow-power consumption.

11 Power Supply Recommendations

The device has two separate power supplies: AVDD and DVDD. The internal circuits of the device operate on AVDD; DVDD is used for the digital interface. AVDD and DVDD can be independently set to any value within the permissible range. During normal operation, if the voltage on the AVDD supply drops below the AVDD minimum specification, then TI recommends ramping the AVDD supply down to ≤ 0.7 V before power up. Also, during power-up, AVDD must monotonously rise to the desired operating voltage above the minimum AVDD specification.

11.1 Power-Supply Decoupling

Decouple the AVDD and DVDD pins with GND, using individual 1- μ F decoupling capacitors placed in close proximity to the pin, as shown in Figure 55.

Figure 55. Supply Decoupling

11.2 Power Saving

The device has an auto power-down feature that powers down the internal circuitry at the end of every conversion. Referring to Figure 56, the input signal is acquired on the sampling capacitors when the device is in a power-down state (t_{acq}); at the same time, the result for the previous conversion is available for reading. The device powers up on the start of the next conversion. During conversion phase (t_{conv}), the device also consumes current from the reference source (connected to the REF pin).

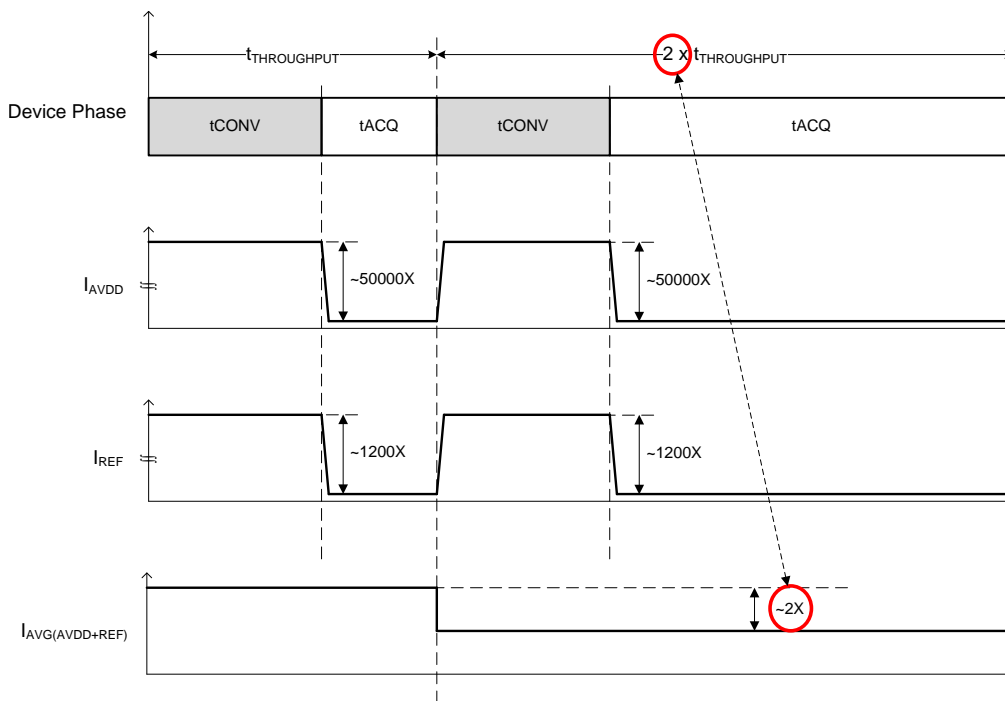

Figure 56. Power Scaling With Throughput

Power Saving (continued)

The conversion time, t_{conv} , is independent of the SCLK frequency. When operating the device at speeds lower than the maximum rated throughput, the conversion time, t_{conv} , does not change; the device spends more time in power-down state. Therefore, as shown in [Figure 57](#), the device power consumption from the AVDD supply and the external reference source is directly proportional to the speed of operation. Extremely low AVDD power-down current (50 nA, typical) and extremely low external reference leakage current (250 nA, typical), make this device ideal for very low throughput applications (such as pulsed measurements).

Figure 57. Power Scaling With Throughput

12 Layout

12.1 Layout Guidelines

Figure 58 shows a board layout example for the device. Appropriate layout that interconnects accompanying capacitors and converters with low inductance is critical for achieving optimum performance. Thus, a PCB board with at least four layers is recommended to keep all critical components on the top layer and interconnected to a solid (low inductance) analog ground plane at the subsequent inner layer using 15-mil vias. Avoid crossing digital lines with the analog signal path and keep the analog input signals and the reference input signals away from noise sources. As shown in Figure 58, the analog input and reference input signals are routed on the left side of the board and the digital connections are routed on the right side of the device.

As a result of dynamic currents during conversion and data transfer, each supply pin (AVDD and DVDD) must have a decoupling capacitor to keep the supply voltage stable. To maximize decoupling capabilities, inductance between each supply capacitor and the supply pin of the converter is kept less than 5 nH by placing the capacitor within 0.2-inches from the pin and connecting it with 20-mil traces and a 15-mil grounding via, as shown in Figure 58. TI recommends using one 1- μ F ceramic capacitor at each supply pin. Avoid placing vias between the supply pin and its decoupling capacitor.

Dynamic currents are also present at the REF pin during the conversion phase and very good decoupling is critical to achieve optimum performance. The inductance between the reference capacitor and the REF pin is kept less than 2 nH by placing the capacitor within 0.1-inches from the pin and connecting it with 20-mil traces and multiple 15-mil grounding vias, as shown in Figure 58. A single, 10- μ F, X7R-grade, 0805-size, ceramic capacitor with at least a 10-V rating is recommended for good performance over the rated temperature range. Avoid using additional lower value capacitors because the interactions between multiple capacitors may affect the ADC performance at higher sampling rates. A small, 0.1- Ω to 0.47- Ω , 0603-size resistor placed in series with the reference capacitor (as shown in Figure 58) keeps the overall impedance low and constant, especially at very high frequencies.

The fly-wheel RC filters are placed immediately next to the input pins. Among ceramic surface-mount capacitors, COG (NPO) ceramic capacitors provide the best capacitance precision. The type of dielectric used in COG (NPO) ceramic capacitors provides the most stable electrical properties over voltage, frequency, and temperature changes.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.** - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) **Lead finish/Ball material** - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

PACKAGE OUTLINE

VSSOP - 1.1 mm max height

SMALL OUTLINE PACKAGE

4221984/A 05/2015

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.25 mm per side.
5. Reference JEDEC registration MO-187, variation BA.
