RXVALID	SPDIF0_RXVALID_INT	SPDIF1_RXVALID_INT	SPDIF0 or SPDIF1 RX Valid interrupt
RXLOCK	SPDIF0_RXLOCK_INT	SPDIF1_RXLOCK_INT	SPDIF0 or SPDIF1 RX Lock interrupt
RXLOSSOFLOCK	SPDIF0_RXLOSSOFLOCK_INT	SPDIF1_RXLOSSOFLOCK_INT	SPDIF0 or SPDIF1 RX Loss of Lock interrupt

Table 33-26: Interrupt Events (Continued)

Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
RXNONAUDIO	SPDIF0_RXNONAUDIO_INT	SPDIF1_RXNONAUDIO_INT	SPDIF0 or SPDIF1 RX Non-audio interrupt
SRC0MUTE	SRC0_MUTE_INT	SRC4_MUTE_INT	DAI0 or DAI1 ASRC0 Mute interrupt
SRC1MUTE	SRC1_MUTE_INT	SRC5_MUTE_INT	DAI0 or DAI1 ASRC1 Mute interrupt
SRC2MUTE	SRC2_MUTE_INT	SRC6_MUTE_INT	DAI0 or DAI1 ASRC2 Mute interrupt
SRC3MUTE	SRC3_MUTE_INT	SRC7_MUTE_INT	DAI0 or DAI1 ASRC3 Mute interrupt
MISCINT0	DAI0_INT_00	DAI1_INT_00	DAI0 or DAI1 Miscellaneous Interrupt 0
MISCINT1	DAI0_INT_01	DAI1_INT_01	DAI0 or DAI1 Miscellaneous Interrupt 1
MISCINT2	DAI0_INT_02	DAI1_INT_02	DAI0 or DAI1 Miscellaneous Interrupt 2
MISCINT3	DAI0_INT_03	DAI1_INT_03	DAI0 or DAI1 Miscellaneous Interrupt 3
MISCINT4	DAI0_INT_04	DAI1_INT_04	DAI0 or DAI1 Miscellaneous Interrupt 4
MISCINT5	DAI0_INT_05	DAI1_INT_05	DAI0 or DAI1 Miscellaneous Interrupt 5
MISCINT6	DAI0_EXTMISCA0_INT/ DAI0_INT_06	DAI1_EXTMISCA0_INT/ DAI1_INT_06	DAI0 or DAI1 Miscellaneous Interrupt 6 / External Miscellaneous A0 Interrupt
MISCINT7	DAI0_EXTMISCA1_INT/ DAI0_INT_07	DAI1_EXTMISCA1_INT/ DAI1_INT_07	DAI0 or DAI1 Miscellaneous Interrupt 7 / External Miscellaneous A1 Interrupt
MISCINT8	DAI0_EXTMISCA2_INT/ DAI0_INT_08	DAI1_EXTMISCA2_INT/ DAI1_INT_08	DAI0 or DAI1 Miscellaneous Interrupt 8 / External Miscellaneous A2 Interrupt
MISCINT9	DAI0_EXTMISCA3_INT/ DAI0_INT_09	DAI1_EXTMISCA3_INT/ DAI1_INT_09	DAI0 or DAI1 Miscellaneous Interrupt 9 / External Miscellaneous A3 Interrupt

ADSP-SC58x DAI Register Descriptions

The Digital Audio Interface (DAIn) registers are used to configure DAI destinations for the DAI sources shown in the Group A - F Routing tables. (DAI) contains the following registers.

Table 33-27: ADSP-SC58x DAI Register List

Name	Description
DAI_CLK0	Clock Routing Control Register 0
DAI_CLK1	Clock Routing Control Register 1
DAI_CLK2	Clock Routing Control Register 2
DAI_CLK3	Clock Routing Control Register 3
DAI_CLK4	Clock Routing Control Register 4
DAI_CLK5	Clock Routing Control Register 5
DAI_DAT0	Serial Data Routing Control Register 0
DAI_DAT1	Serial Data Routing Control Register 1
DAI_DAT2	Serial Data Routing Control Register 2
DAI_DAT3	Serial Data Routing Control Register 3
DAI_DAT4	Serial Data Routing Control Register 4
DAI_DAT5	Serial Data Routing Control Register 5
DAI_DAT6	Serial Data Routing Control Register 6
DAI_FS0	Frame Sync Routing Control Register 0
DAI_FS1	Frame Sync Routing Control Register 1
DAI_FS2	Frame Sync Routing Control Register 2
DAI_FS4	Frame Sync Routing Control Register 4
DAI_IMSK_FE	Falling-Edge Interrupt Mask Register
DAI_IMSK_PRI	Core Interrupt Priority Assignment Register
DAI_IMSK_RE	Rising-Edge Interrupt Mask Register
DAI_IRPTL_H	High Priority Interrupt Latch Register
DAI_IRPTL_HS	Shadow High Priority Interrupt Latch Register
DAI_IRPTL_L	Low Priority Interrupt Latch Register
DAI_IRPTL_LS	Shadow Low Priority Interrupt Latch Register
DAI_MISC0	Miscellaneous Control Register 0
DAI_MISC1	Miscellaneous Control Register 1
DAI_PBEN0	Pin Buffer Enable Register 0
DAI_PBEN1	Pin Buffer Enable Register 1
DAI_PBEN2	Pin Buffer Enable Register 2
DAI_PBEN3	Pin Buffer Enable Register 3
DAI_PIN0	Pin Buffer Assignment Register 0

Table 33-27: ADSP-SC58x DAI Register List (Continued)

Name	Description
`DAI_PIN1`	Pin Buffer Assignment Register 1
`DAI_PIN2`	Pin Buffer Assignment Register 2
`DAI_PIN3`	Pin Buffer Assignment Register 3
`DAI_PIN4`	Pin Buffer Assignment Register 4
`DAI_PIN_STAT`	Pin Status Register

Clock Routing Control Register 0

The `DAI_CLK0` register provides clock routing connections for the serial ports (SPORTs).

Table 33-45: DAI_IMSK_FE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. Setting the `DAI_IMSK_FE.MISCINT9` bit unmasks the interrupt for the falling edge of the routed signal.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. Setting the `DAI_IMSK_FE.MISCINT8` bit unmasks the interrupt for the falling edge of the routed signal.
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. Setting the `DAI_IMSK_FE.MISCINT7` bit unmasks the interrupt for the falling edge of the routed signal.

Table 33-45: DAI_IMSK_FE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. Setting the `DAI_IMSK_FE.MISCINT6` bit unmasks the interrupt for the falling edge of the routed signal.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. Setting the `DAI_IMSK_FE.MISCINT5` bit unmasks the interrupt for the falling edge of the routed signal.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. Setting the `DAI_IMSK_FE.MISCINT4` bit unmasks the interrupt for the falling edge of the routed signal.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. Setting the `DAI_IMSK_FE.MISCINT3` bit unmasks the interrupt for the falling edge of the routed signal.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. Setting the `DAI_IMSK_FE.MISCINT2` bit unmasks the interrupt for the falling edge of the routed signal.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. Setting the `DAI_IMSK_FE.MISCINT1` bit unmasks the interrupt for the falling edge of the routed signal.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. Setting the `DAI_IMSK_FE.MISCINT0` bit unmasks the interrupt for the falling edge of the routed signal.
21 (R/W)	SRC3MUTE	SRC3 Mute. The `DAI_IMSK_FE.SRC3MUTE` bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
20 (R/W)	SRC2MUTE	SRC2 Mute. The `DAI_IMSK_FE.SRC2MUTE` bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
19 (R/W)	SRC1MUTE	SRC1 Mute. The `DAI_IMSK_FE.SRC1MUTE` bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.

Table 33-45: DAI_IMSK_FE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	SRC0MUTE	SRC0 Mute. The `DAI_IMSK_FE.SRC0MUTE` bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
4 (R/W)	RXNONAUDIO	Receive Non Audio. The `DAI_IMSK_FE.RXNONAUDIO` bit masks or unmasks the non audio frame mode interrupt for the falling edge of this interrupt. If the channel status indicates non-PCM audio, the NONAUDIO bit flag is set.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The `DAI_IMSK_FE.RXLOSSOFLOCK` bit masks or unmasks the emphasis loss of lock interrupt for the falling edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver looses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. The `DAI_IMSK_FE.RXLOCK` bit masks or unmasks the S/PDIF receiver lock for the falling edge of this interrupt. This interrupt occurs when the S/PDIF receiver locks to the S/PDIF stream.
0 (R/W)	RXVALID	Receive Valid. Setting the `DAI_IMSK_FE.RXVALID` bit unmasks the interrupt for the falling edge of the routed signal. This interrupt is set based on whether data received by the S/PDIF is linear PCM or non-linear audio data.

Core Interrupt Priority Assignment Register

The `DAI_IMSK_PRI` register masks interrupts for DAI high or DAI low interrupt priority.

Figure 33-35: DAI_IMSK_PRI Register Diagram

Table 33-46: DAI_IMSK_PRI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. If the `DAI_IMSK_PRI.MISCINT9` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT9` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. If the `DAI_IMSK_PRI.MISCINT8` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT8` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Table 33-46: DAI_IMSK_PRI Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. If the `DAI_IMSK_PRI.MISCINT7` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT7` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. If the `DAI_IMSK_PRI.MISCINT6` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT6` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. If the `DAI_IMSK_PRI.MISCINT5` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT5` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. If the `DAI_IMSK_PRI.MISCINT4` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT4` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. If the `DAI_IMSK_PRI.MISCINT3` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT3` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. If the `DAI_IMSK_PRI.MISCINT2` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT2` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. If the `DAI_IMSK_PRI.MISCINT1` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT1` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. If the `DAI_IMSK_PRI.MISCINT0` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.MISCINT0` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
21 (R/W)	SRC3MUTE	SRC3 Mute. If the `DAI_IMSK_PRI.SRC3MUTE` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.SRC3MUTE` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Table 33-46: DAI_IMSK_PRI Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	SRC2MUTE	SRC2 Mute. If the `DAI_IMSK_PRI.SRC2MUTE` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.SRC2MUTE` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
19 (R/W)	SRC1MUTE	SRC1 Mute. If the `DAI_IMSK_PRI.SRC1MUTE` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.SRC1MUTE` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
18 (R/W)	SRC0MUTE	SRC0 Mute. If the `DAI_IMSK_PRI.SRC0MUTE` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.SRC0MUTE` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
4 (R/W)	RXNONAUDIO	Receiver Non-Audio. If the `DAI_IMSK_PRI.RXNONAUDIO` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.RXNONAUDIO` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The `DAI_IMSK_PRI.RXLOSSOFLOCK` bit masks or unmasks the emphasis loss of lock interrupt for the falling edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver looses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. If the `DAI_IMSK_PRI.RXLOCK` bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the `DAI_IMSK_PRI.RXLOCK` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
0 (R/W)	RXVALID	Receive Valid. If the `DAI_IMSK_PRI.RXVALID` bit is cleared (=0), the interrupt is mapped to the INTR_DAI_IRQL from the SEC. If the `DAI_IMSK_PRI.RXVALID` bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Rising-Edge Interrupt Mask Register

The `DAI_IMSK_RE` register masks and unmasks interrupts generated on the rising edge of a waveform. Note that any of the Group E signals can be mapped to any of the miscellaneous interrupts (9-0).

Table 33-47: DAI_IMSK_RE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. Setting the `DAI_IMSK_RE.MISCINT9` bit unmasks the interrupt for the rising edge of the routed signal.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. Setting the `DAI_IMSK_RE.MISCINT8` bit unmasks the interrupt for the rising edge of the routed signal.
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. Setting the `DAI_IMSK_RE.MISCINT7` bit unmasks the interrupt for the rising edge of the routed signal.

Table 33-47: DAI_IMSK_RE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. Setting the `DAI_IMSK_RE.MISCINT6` bit unmasks the interrupt for the rising edge of the routed signal.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. Setting the `DAI_IMSK_RE.MISCINT5` bit unmasks the interrupt for the rising edge of the routed signal.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. Setting the `DAI_IMSK_RE.MISCINT4` bit unmasks the interrupt for the rising edge of the routed signal.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. Setting the `DAI_IMSK_RE.MISCINT3` bit unmasks the interrupt for the rising edge of the routed signal.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. Setting the `DAI_IMSK_RE.MISCINT2` bit unmasks the interrupt for the rising edge of the routed signal.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. Setting the `DAI_IMSK_RE.MISCINT1` bit unmasks the interrupt for the rising edge of the routed signal.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. Setting the `DAI_IMSK_RE.MISCINT0` bit unmasks the interrupt for the rising edge of the routed signal.
21 (R/W)	SRC3MUTE	SRC3 Mute. The `DAI_IMSK_RE.SRC3MUTE` bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
20 (R/W)	SRC2MUTE	SRC2 Mute. The `DAI_IMSK_RE.SRC2MUTE` bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
19 (R/W)	SRC1MUTE	SRC1 Mute. The `DAI_IMSK_RE.SRC1MUTE` bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.

Table 33-47: DAI_IMSK_RE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	SRC0MUTE	SRC0 Mute. The `DAI_IMSK_RE.SRC0MUTE` bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
4 (R/W)	RXNONAUDIO	Receive Non Audio. The `DAI_IMSK_RE.RXNONAUDIO` bit masks or unmasks the non audio frame mode interrupt for the rising edge of this interrupt. If the channel status indicates non-PCM audio, the NONAUDIO bit flag is set.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The `DAI_IMSK_RE.RXLOSSOFLOCK` bit masks or unmasks the emphasis loss of lock interrupt for the rising edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver looses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. The `DAI_IMSK_RE.RXLOCK` bit masks or unmasks the S/PDIF receiver lock for the rising edge of this interrupt. This interrupt occurs when the S/PDIF receiver locks to the S/PDIF stream.
0 (R/W)	RXVALID	Receive Valid. Setting the `DAI_IMSK_RE.RXVALID` bit unmasks the interrupt for the rising edge of the routed signal. This interrupt is set based on whether data received by the S/PDIF is linear PCM or non-linear audio data.

High Priority Interrupt Latch Register

The DAI_IRPTL_H register holds the high priority latched interrupt status for interrupt requests that have been unmasked (enabled) by the DAI_IMSK_FE, DAI_IMSK_RE registers and mapped to the INTR_DAI_IRQH signal in the SEC by DAI_IMSK_PRI registers. If a bit in this register is already set and the corresponding interrupt is masked in the DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers, the latch holds its old value, leaving the interrupt asserted until it is reset by software with a W1C operation.

27 (R/NW)	MISCINT5	Miscellaneous Interrupt 5. The `DAI_IRPTL_HS.MISCINT5` bit is the shadow of the `DAI_IRPTL_H.MISCINT5` bit and contains the same content. Reading the `DAI_IRPTL_HS.MISCINT5` bit does not affect its contents while reading the `DAI_IRPTL_H.MISCINT5` bit clears it.
26 (R/NW)	MISCINT4	Miscellaneous Interrupt 4. The `DAI_IRPTL_HS.MISCINT4` bit is the shadow of the `DAI_IRPTL_H.MISCINT4` bit and contains the same content. Reading the `DAI_IRPTL_HS.MISCINT4` bit does not affect its contents while reading the `DAI_IRPTL_H.MISCINT4` bit clears it.
25 (R/NW)	MISCINT3	Miscellaneous Interrupt 3. The `DAI_IRPTL_HS.MISCINT3` bit is the shadow of the `DAI_IRPTL_H.MISCINT3` bit and contains the same content. Reading the `DAI_IRPTL_HS.MISCINT3` bit does not affect its contents while reading the `DAI_IRPTL_H.MISCINT3` bit clears it.
24 (R/NW)	MISCINT2	Miscellaneous Interrupt 2. The `DAI_IRPTL_HS.MISCINT2` bit is the shadow of the `DAI_IRPTL_H.MISCINT2` bit and contains the same content. Reading the `DAI_IRPTL_HS.MISCINT2` bit does not affect its contents while reading the `DAI_IRPTL_H.MISCINT2` bit clears it.
23 (R/NW)	MISCINT1	Miscellaneous Interrupt 1. The `DAI_IRPTL_HS.MISCINT1` bit is the shadow of the `DAI_IRPTL_H.MISCINT1` bit and contains the same content. Reading the `DAI_IRPTL_HS.MISCINT1` bit does not affect its contents while reading the `DAI_IRPTL_H.MISCINT1` bit clears it.

Table 33-49: DAI_IRPTL_HS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22 (R/NW)	MISCINT0	Miscellaneous Interrupt 0. The `DAI_IRPTL_HS.MISCINT0` bit is the shadow of the `DAI_IRPTL_H.MISCINT0` bit and contains the same content. Reading the `DAI_IRPTL_HS.MISCINT0` bit does not affect its contents while reading the `DAI_IRPTL_H.MISCINT0` bit clears it.
21 (R/NW)	SRC3MUTE	SRC3 Mute. The `DAI_IRPTL_HS.SRC3MUTE` bit is the shadow of the `DAI_IRPTL_H.SRC3MUTE` bit and contains the same content. Reading the `DAI_IRPTL_HS.SRC3MUTE` bit does not affect its contents while reading the `DAI_IRPTL_H.SRC3MUTE` bit clears it.
20 (R/NW)	SRC2MUTE	SRC2 Mute. The `DAI_IRPTL_HS.SRC2MUTE` bit is the shadow of the `DAI_IRPTL_H.SRC2MUTE` bit and contains the same content. Reading the `DAI_IRPTL_HS.SRC2MUTE` bit does not affect its contents while reading the `DAI_IRPTL_H.SRC2MUTE` bit clears it.
19 (R/NW)	SRC1MUTE	SRC1 Mute. The `DAI_IRPTL_HS.SRC1MUTE` bit is the shadow of the `DAI_IRPTL_H.SRC1MUTE` bit and contains the same content. Reading the `DAI_IRPTL_HS.SRC1MUTE` bit does not affect its contents while reading the `DAI_IRPTL_H.SRC1MUTE` bit clears it.
18 (R/NW)	SRC0MUTE	SRC0 Mute. The `DAI_IRPTL_HS.SRC0MUTE` bit is the shadow of the `DAI_IRPTL_H.SRC0MUTE` bit and contains the same content. Reading the `DAI_IRPTL_HS.SRC0MUTE` bit does not affect its contents while reading the `DAI_IRPTL_H.SRC0MUTE` bit clears it.
4 (R/NW)	RXNONAUDIO	Receive Non Audio. The `DAI_IRPTL_HS.RXNONAUDIO` bit is the shadow of `DAI_IRPTL_H.RXNONAUDIO` bit and contains the same content. Reading this bit does not affect its content.
2 (R/NW)	RXLOSSOFLOCK	Receive Loss of Lock. The `DAI_IRPTL_HS.RXLOSSOFLOCK` bit is the shadow of `DAI_IRPTL_H.RXLOSSOFLOCK` bit and contains the same content. Reading this bit does not affect its content.
1 (R/NW)	RXLOCK	Receive Lock. The `DAI_IRPTL_HS.RXLOCK` bit is the shadow of `DAI_IRPTL_H.RXLOCK` bit and contains the same content. Reading this bit does not affect its content.

Table 33-49: DAI_IRPTL_HS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	RXVALID	Receive Valid. Setting the `DAI_IRPTL_HS.RXVALID` bit is the shadow of `DAI_IRPTL_H.RXVALID` bit and contains the same content. Reading this bit does not affect its content.

Low Priority Interrupt Latch Register

The DAI_IRPTL_L register holds the low priority latched interrupt status for interrupt requests that have been unmasked (enabled) by the DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers. If a bit in DAI_IRPTL_L is already set and the corresponding interrupt is masked in DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers, the latch holds its old value, leaving the interrupt asserted until it is reset by software with a W1C operation.

22 (R/NW)	MISCINT0	Miscellaneous Interrupt 0. The `DAI_IRPTL_LS.MISCINT0` bit is the shadow of the `DAI_IRPTL_L.MISCINT0` bit and contains the same content. Reading the `DAI_IRPTL_LS.MISCINT0` bit does not affect its contents while reading the `DAI_IRPTL_L.MISCINT0` bit clears it.
21 (R/NW)	SRC3MUTE	SRC3 Mute. The `DAI_IRPTL_LS.SRC3MUTE` bit is the shadow of the `DAI_IRPTL_L.SRC3MUTE` bit and contains the same content. Reading the `DAI_IRPTL_LS.SRC3MUTE` bit does not affect its contents while reading the `DAI_IRPTL_L.SRC3MUTE` bit clears it.
20 (R/NW)	SRC2MUTE	SRC2 Mute. The `DAI_IRPTL_LS.SRC2MUTE` bit is the shadow of the `DAI_IRPTL_L.SRC2MUTE` bit and contains the same content. Reading the `DAI_IRPTL_LS.SRC2MUTE` bit does not affect its contents while reading the `DAI_IRPTL_L.SRC2MUTE` bit clears it.
19 (R/NW)	SRC1MUTE	SRC1 Mute. The `DAI_IRPTL_LS.SRC1MUTE` bit is the shadow of the `DAI_IRPTL_L.SRC1MUTE` bit and contains the same content. Reading the `DAI_IRPTL_LS.SRC1MUTE` bit does not affect its contents while reading the `DAI_IRPTL_L.SRC1MUTE` bit clears it.
18 (R/NW)	SRC0MUTE	SRC0 Mute. The `DAI_IRPTL_LS.SRC0MUTE` bit is the shadow of the `DAI_IRPTL_L.SRC0MUTE` bit and contains the same content. Reading the `DAI_IRPTL_LS.SRC0MUTE` bit does not affect its contents while reading the `DAI_IRPTL_L.SRC0MUTE` bit clears it.
4 (R/NW)	RXNONAUDIO	Receiver Non Audio. The `DAI_IRPTL_LS.RXNONAUDIO` bit is the shadow of the `DAI_IRPTL_L.RXNONAUDIO` bit and contains the same content. Reading the `DAI_IRPTL_LS.RXNONAUDIO` bit does not affect its contents while reading the `DAI_IRPTL_L.RXNONAUDIO` bit clears it.
2 (R/NW)	RXLOSSOFLOCK	Receive Emphasis Loss of Lock. The `DAI_IRPTL_LS.RXLOSSOFLOCK` bit is the shadow of `DAI_IRPTL_L.RXLOSSOFLOCK` bit and contains the same content. Reading this bit does not affect its content. Reading the `DAI_IRPTL_L.RXLOSSOFLOCK` bit clears it.
1 (R/NW)	RXLOCK	Receive Error Lock. The `DAI_IRPTL_LS.RXLOCK` bit is the shadow of `DAI_IRPTL_L.RXLOCK` bit and contains the same content. Reading this bit does not affect its content. Reading the `DAI_IRPTL_L.RXLOCK` bit clears it.

Table 33-51: DAI_IRPTL_LS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	RXVALID	Receive Valid. The `DAI_IRPTL_LS.RXVALID` bit is the shadow of `DAI_IRPTL_L.RXVALID` bit and contains the same content. Reading this bit does not affect its content. Reading the `DAI_IRPTL_L.RXVALID` bit clears it.

Miscellaneous Control Register 0

The DAI_MISC0 register allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

Pin Status Register

The DAI_PIN_STAT register bits indicate the status (signal high or low) for each pin. The individual bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

0 (R/NW)	PB01	Pin Buffer 01 Status. The `DAI_PIN_STAT.PB01` bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

34 Serial Port (SPORT)

The programmable serial ports (SPORTs) support various protocols for serial data communication and provide a glueless hardware interface to many industry-standard data converters and codecs. They have high data rates and dual half-duplex datapaths and are ideal for establishing a direct serial connection among two or more processors in a multiprocessor system, as many processors provide compatible serial interfaces.

The SPORT top module consists of two half SPORTs with identical functionality and programming requirements. Each half SPORT can be independently configured as either a transmitter or receiver and can be coupled with the other half SPORT within the same SPORT top module. Further, each half SPORT provides two synchronous half-duplex data lines to double the total supported throughput. As such, a single SPORT top module can be used to provide up to four unidirctional or up to two full-duplex data streams. Further channels are possible as well, but utilization of multiple SPORT top modules is required, thus requiring external connections to provide a common time base.

Features

An individual SPORT top module consists of two independently configurable SPORT halves with identical functionality. These SPORT halves offer the following features:

- Up to two bidirectional data lines - each half SPORT supports up to two transmit or receive channels, thus allowing two unidirectional streams into or out of each half SPORT and providing greater flexibility for serial communications. If full-duplex functionality is desired, two SPORT halves can be combined to enable dual-stream bidirectional communication.
- Six operating modes:
  1. Standard DSP serial mode
  2. I^{2}S mode
  3. Left-Justified mode
  4. Right-Justified mode
  5. Multichannel (TDM) mode
  6. Packed mode

- Supports internally or externally generated clock.
- Support for both even and odd SCLK0_0 to SPORT clock (SPORT_CLK) ratios. If both data lines of a half SPORT are active, the maximum throughput is 2 x SPORT_CLK bps.
- Configurable rising or falling edge of the SPORT_CLK for driving and sampling data and frame syncs.
- Gated clock mode support for internallly or externally generated clocks in DSP serial mode and stereo modes (left-justified and I^2S mode).
- Supports frameless operation.
- Supports internally or externally generated frame sync signals.
- Programmable frame sync polarity.
- Programmable frame sync timing (synchronous to data or 1 SPORT clock in advance of it).
- Detection of prematurely received external frame syncs (with optional interrupt request generation).
- Programmable level-/edge-sensitivity for external frame syncs.
- Programmable (4–32-bit) data length, either in most significant bit (MSB) first or in least significant bit (LSB) first format, with optional sign-extension on received data.
- Optional 16-bit to 32-bit word packing (as receiver) and 32-bit to 16-bit word unpacking (as transmitter).
- Support for A-law and μ-law compression/decompression hardware companding, according to the G.711 specification, on transmitted/received words in all operating modes.
- Transmit underrun and receive overflow detection (with optional interrupt request generation).
- TDM mode transfers data on 128 contiguous channels from a stream of up to 1024 total channels (useful for H.100/H.110 and other telephony interfaces as a network communication scheme for multiple processors).
- Performs interrupt-driven, single word core transfers to and from on-chip or off-chip memory.
- Dedicated DMA channel for each SPORT half supporting autobuffer (for a repeated, identical range of transfers) and numerous descriptor-based (individual or repeated ranges of transfers with differing DMA parameters) modes.
- Master and slave trigger functionality.
- Unique transfer finish interrupt (TFI) signaling when the last transmit word is fully out of the transmit shift register.
- Multiplexer to internally connect critical timing signals between SPORT halves.

Signal Descriptions

Each half SPORT module has five dedicated signals, as described in the ***SPORT Signal Descriptions*** table. The actual pin name varies with different SPORT halves. Individual SPORT halves do not share any of its signals across the pair that comprises the SPORT top module; however, it is possible to connect the clock and frame sync signals between the SPORT half pair, as explained in the Multiplexer Logic section.

All of the SPORT signals are multiplexed on the PORT pins, possibly sharing functionality with other peripherals on the device. By default, the PORT pins are in GPIO mode and must be reconfigured for SPORT functionality by setting the appropriate bits in the `PORT_FER` and `PORT_MUX` registers. Consult the processor datasheet for details regarding which ports the SPORT signals are available on, and be sure to configure the `PORT_MUX` register before the `PORT_FER` register.

Table 34-1: SPORT Signal Descriptions

Internal Node	Direction	Description
SPORTx_CLK	I/O	Transmit or receive serial clock. Data and frame syncs are driven or sampled on this clock's edges. This signal can be either internally or externally generated.
SPORTx_FS	I/O	Transmit or receive frame sync. The frame sync pulse initiates shifting of serial data. This signal is either internally or externally generated.
SPORTx_D0	I/O	Primary transmit or receive data channel. This signal can be configured as an output to transmit serial data or as an input to receive serial data.
SPORTx_D1	I/O	Secondary transmit or receive data channel. This signal can be configured as an output to transmit serial data or as an input to receive serial data.
SPORTx_TDV	O	Multichannel transmit data valid. This signal is only active in multichannel transmit mode and is asserted during enabled slots, as defined by the channel selection registers (`SPORT_CS0_A` through `SPORT_CS3_B`).

The data channel signals are transmit signals when the serial port is configured in transmit mode (`SPORT_CTL_A.SPTRAN` = 1). They are receive signals when the serial port is configured in receive mode (`SPORT_CTL_A.SPTRAN` = 0). The following sections further describe the SPORT signals.

NOTE: These sections refer explicitly to registers associated with half SPORT A, but the same concepts also apply to half SPORT B.

Serial Clock

The serial port clock (`SPORT_ACLK`) is either a receive serial clock or a transmit serial clock, depending on the transfer direction (`SPORT_CTL_A.SPTRAN`), governing when the data bits are serially shifted into or out of the SPORT and when the frame sync signal is driven (in internal frame sync mode) or sampled (in external frame sync mode). It can be internally generated from the processor's system clock (SCLK0_0) or externally provided. If the half SPORT is configured in internal clock mode (`SPORT_CTL_A.ICLK`= 1), then the `SPORT_DIV_A.CLKDIV` field specifies the divisor applied to SCLK0_0 to generate the SPORT clock. As it is a 16-bit divisor, a wide range of serial clock rates is possible. Use the following equation to calculate the serial clock frequency:

`SPORT_ACLK` = [SCLK0_0 ÷ (`SPORT_DIV_A.CLKDIV` + 1)]

From this, the following equation can be used to determine the value of `SPORT_DIV_A.CLKDIV`, given the SCLK0_0 frequency and the desired frequency of the SPORT clock:

`SPORT_DIV_A.CLKDIV`= [(SCLK0_0 ÷ `SPORT_ACLK`) - 1]

The half SPORT also supports a 1:1 `SPORT_ACLK` to SCLK0_0 ratio (per the equations above, program the clock divisor field to zero). In this case, the resulting SPORT clock frequency is equal to SCLK0_0.

NOTE: Be careful not to exceed the maximum `SPORT_ACLK` frequency specified in the processor datasheet.

In certain operating modes, the SPORT can be configured to generate a gated clock, which is active only during valid data. In some applications, a SPORT uses it to generate a general-purpose clock in the system. In this case, enable the SPORT with the appropriate `SPORT_DIV_A.CLKDIV` divisor field in internal clock mode.

If a SPORT is configured in external clock mode (`SPORT_CTL_A.ICLK`= 0), then the serial clock is an input signal, thus making the SPORT operate in slave mode. In this mode, the `SPORT_DIV_A.CLKDIV` is irrelevant and is ignored. The optional loopback capability provided by the internal SPORT multiplexer (SPMUX) block allows the slave SPORT to use the serial clock from the neighboring SPORT half in the same SPORT top module.

An externally-supplied serial clock does not need to be synchronous with the processor clocks. Further, the external clock can be a gated clock, but it must comply with the requirements described in the Gated Clock Mode section.

Refer to the product datasheet for exact AC timing specifications.

Frame Sync

The SPORT frame sync (`SPORT_AFS`) signal is either a receive frame sync or a transmit frame sync, depending on the transfer direction (`SPORT_CTL_A.SPTRAN`), which is used to determine the start of a new word or frame. When this signal goes active, the serial port starts serially shifting data into or out of the SPORT. The frame sync signal can be internally generated based on its serial clock (`SPORT_ACLK`) or externally provided, as configured by the `SPORT_CTL_A.IFS` bit.

If the half SPORT is configured to generate frame syncs (`SPORT_CTL_A.IFS`= 1), then the `SPORT_DIV_A.FSDIV` field specifies the divisor used to generate the periodic `SPORT_AFS` signal from the SPORT clock. As this is a 16-bit divisor, a wide range of frame sync rates to initiate periodic transfers is possible. Whether the serial clock is internally or externally generated, this divisor is a count of SPORT clock cycles between frame sync pulses, the formula for which is:

Number of serial clocks between frame syncs = (`SPORT_DIV_A.FSDIV` + 1)

From this, the following equation can be used to determine the value of `SPORT_DIV_A.FSDIV`, given the serial clock frequency and the desired frame sync frequency:

`SPORT_DIV_A.FSDIV` = [(`SPORT_ACLK` ÷ `SPORT_AFS`) – 1]

The frame sync is continuously active when `SPORT_DIV_A.FSDIV`= 0. The value of `SPORT_DIV_A.FSDIV` cannot be less than the serial word length minus one (the value of the `SPORT_CTL_A.SLEN` bit field). Failure to adhere to this guideline can cause an external device to abort the current operation or cause other unpredictable results.

NOTE: After enabling the SPORT, the first internal frame sync appears after a delay of `SPORT_DIV_A.FSDIV` + 3 SPORT clock cycles.

If a SPORT is configured for external frame syncs (`SPORT_CTL_A.IFS` = 0), then `SPORT_AFS` is an input signal and the `SPORT_DIV_A.FSDIV` field of the `SPORT_DIV_A` register is irrelevant and ignored. By default, this external signal is level-sensitive, but it can be configured as an edge-sensitive signal by setting the `SPORT_CTL_A.FSED` bit. The frame sync is expected to be synchronous with the serial clock. If not, it must meet the timing requirements that appear in the datasheet.

The SPORT can be used as a counter for dividing an external clock to generate periodic pulses or periodic interrupts. To do so, enable the SPORT with the appropriate `SPORT_DIV_A.FSDIV` divisor field with the SPORT configured for an external clock and internal data-independent frame syncs.

In some of the operating modes, the SPORT can be programmed to treat the frame sync signal as an optional signal by clearing the `SPORT_CTL_A.FSR` bit. Even with this bit cleared, the SPORT requires a single frame sync assertion to start the continuous transfers, after which it is ignored (for externally supplied frame syncs) or not generated (for internally-generated frame syncs). Characteristics of the frame sync depend on the settings in the SPORT control registers and the operating mode of the SPORT. For more information, refer to the `SPORT_CTL_A` register.

Data Signals

Each half SPORT has two bidirectional data lines known as the primary (`SPORT_AD0`) and secondary (`SPORT_AD1`) data channels. Both of the data lines can be configured as either transmitters or receivers using the `SPORT_CTL_A.SPTRAN` bit, thus permitting dual unidirectional data streams to increase the data throughput of the SPORT.

NOTE: Configuring one transmit data channel and one receive data channel on a single half SPORT is not supported.

The primary and secondary data lines can be individually enabled or disabled using the `SPORT_CTL_A.SPENPRI` and the `SPORT_CTL_A.SPENSEC` bits, respectively. However, if using both, enable or disable them concurrently. These data lines operate in a synchronous manner (sharing a clock and frame sync) but have separate datapaths with unique data buffers, shift registers and optional companding logic. All of the SPORT control settings are common for both channels, but the single DMA channel per half SPORT serves both the primary and secondary data channels.

When a SPORT is configured in multichannel transmit mode, the data pins three-state during inactive channel slots, thus allowing multiple transmitters to operate on the same bus with different active channels.

See the Architectural Concepts section for more details about data transfer operation.

Transmit Data Valid Signal

The transmit data valid (`SPORT_ATDV`) signal is available only in transmit multichannel modes (including packed mode). It is driven active during enabled multichannel slots, and it is driven inactive during the disabled channels. In other words, the `SPORT_ATDV` signal is active when data is being driven to the data pins and inactive when the data pins are being three-stated. As such, the `SPORT_ATDV` signal can serve as an output-enable signal for the data transmit pin.

SRU Programming

The SPORT uses the SRU (signal routing unit) to connect the SPORT data, serial clock, frame sync, and external sync (if external synchronization is required). Inputs also must be routed through the SRU. Program the corresponding SRU registers to connect the outputs to the required destinations. For details of the routing, see DAI Routing Capabilities in the *Digital Audio Interface (DAI)* chapter.

SRU SPORT Receive Master

If the SPORT is operating as receive master, it must feed its master output clock back to its input clock. This is required to trigger the SPORT's state machine. Using SPORT 0A as an example receive master, programs should route `SPT0_ACLK_O` to `SPT0_ACLK_I`. This is not required if the SPORT is operating as a transmitter in master mode.

Functional Description

The following sections provide general information about the functionality of the processor's serial ports:

- Architectural Concepts
- Data Types and Companding
- Transmit Path
- Receive Path

ADSP-SC58x SPORT Register List

The Serial Port (SPORT) controller, with its range of clock and frame synchronization options, supports a variety of serial communication protocols and provides a glueless hardware interface to many industry-standard data converters and CODECs. Each SPORT has two independent halves (A and B), and each half contains two channels (primary and secondary). A set of registers governs SPORT operations. For more information on SPORT functionality, see the SPORT register descriptions.

Architectural Concepts

Each half SPORT (HSPORT) block has its own set of control registers and data buffers, grouped per SPORT module. The HSPORT A and B blocks can be independently configured as either a transmitter or a receiver, with the option to be coupled together internally within the single SPORT top module. Each HSPORT also supports two synchronous bidirectional datapaths, referred to as the primary (`D0`) and secondary (`D1`) data lines, as shown in the ***Top-Level SPORT Diagram*** figure.

Figure 34-2: Top-Level SPORT Diagram

The `SPORT_CTL_A.SPTRAN` bit controls the direction for both datapaths of the HSPORT. Depending on whether the HSPORT is a transmitter or a receiver, the pair of data signals respectfully transmit or receive data bits synchronously. The dual data signals of each HSPORT cannot transmit and receive the data simultaneously in support of full-duplex operation, however, two HSPORTs can be combined to achieve this.

Serial communications are synchronized to the serial clock signal, where a valid clock pulse must accompany each data bit. Each HSPORT can take its clock from an external source or internally generate it from the processor's system clock using the `SPORT_DIV_A.CLKDIV` clock divisor bit field. Both primary and secondary data channels shift data based on the `SPORT_CLK` rate and the clock polarity defined by the `SPORT_CTL_A.CKRE` bit.

In addition to the serial clock signal, a frame synchronization signal is used to signify the beginning of an individual data word or a multichannel data stream (block of words). Each SPORT can take the frame sync signal from an external source or generate it (`SPORT_FS`), depending on the `SPORT_CTL_A.IFS` bit. An internally generated frame sync is derived from the SPORT clock using the `SPORT_DIV_A.FSDIV` divisor field. Both primary and secondary datapaths start shifting data either synchronous to or one serial clock in advance of detecting/generating a valid frame sync signal, as determined by the `SPORT_CTL_A.LAFS` bit. Various communication protocols for serial data can be emulated according to the frame sync format, and all frame sync options are available whether the signal is generated internally or externally.

NOTE: These SPORTs are not UARTs and cannot communicate with an RS-232 device or any other asynchronous communications protocol.

Multiplexer Logic

The SPORT multiplexing block (SPMUX) is situated between the SPORT hardware block and the processor's pin multiplexing logic. It allows the flexibility to route and share the clock and frame sync signals between the HSPORT A and B halves within each SPORT top module, which can double the data throughput (if both SPORT halves are transmitters or both are receivers) or provide full-duplex capabilities (if one HSPORT is a receiver and the other a transmitter) without the need to allocate pins for the peripheral or make physical connections outside the processor. The `SPORT_CTL2_A` register is used to configure this loopback feature.

NOTE: Throughout this section, HSPORT A is used as a reference, but all concepts also apply to HSPORT B.

The multiplexing depends on the configuration of the `SPORT_CTL_A.IFS` and `SPORT_CTL_A.ICLK` bits, and the `SPORT_CTL2_A.CKMUXSEL` and `SPORT_CTL2_A.FSMUXSEL` bit settings control the multiplexing. The ***Frame Sync Combinations*** and ***Clock Combinations*** tables show the valid combinations for the bit settings.

NOTE: All other settings are illegal. However, hardware does not check or prevent the illegal settings. Ensure that programs use only legal combinations.

The column headers in the ***Frame Sync Combinations*** table are defined as follows:

- FS Combination = Frame sync combination, referenced in the notes that follow the ***Clock Combinations*** table.
- HSA_IFS = the setting of the `SPORT_CTL_A.IFS` configuration bit.
- HSB_IFS = the setting of the `SPORT_CTL_B.IFS` configuration bit.
- FSAMUX = the setting of the `SPORT_CTL2_A.FSMUXSEL` configuration bit.
- FSBMUX = the setting of the `SPORT_CTL2_B.FSMUXSEL` configuration bit.

The Routing column in the ***Frame Sync Combinations*** table defines how the signals are used between the SPORT halves and which pin is used for the frame sync (whether it is an input or an output). Within the column, the inequality characters (≤ and ≥) are used to show the direction of the signal, and the following abbreviations are used (where x = A or B):

- HSx_FI = Frame sync input signal, provided by an external device or the complementing HSPORT.
- HSx_FO = Frame sync output signal.
- SPx_FS = HSPORT's frame sync pin, where the signal is either:
  - provided by an external source and distributed to both HSPORT frame sync signals, or
  - internally generated by one HSPORT and routed to both the pin and to the complementary HSPORT frame sync signal.

Table 34-7: Frame Sync Combinations

FS Combination	HSA_IFS	HSB_IFS	FSAMUX	FSBMUX	Routing
1	0	0	0	0	Native FS Operation
2	0	1	0	0	Native FS Operation
3	1	0	0	0	Native FS Operation
4	1	1	0	0	Native FS Operation

Table 34-7: Frame Sync Combinations (Continued)

FS Combination	HSA_IFS	HSB_IFS	FSAMUX	FSBMUX	Routing
5	0	0	1	0	HSA_FI ≤ SPB_FS; HSB_FI ≤ SPB_FS
6	0	1	1	0	HSA_FI ≤ HSB_FO ≥ SPB_FS
7	0	0	0	1	HSB_FI ≤ SPA_FS; HSA_FI ≤ SPA_FS
8	1	0	0	1	HSB_FI ≤ HSA_FO ≥ SPA_FS

The column headers in the ***Clock Combinations*** table are defined as follows:

- CLK Combination = Clock combination, referenced in the notes that follow the table.
- HSA_ICLK = the setting of the `SPORT_CTL_A.ICLK` configuration bit.
- HSB_ICLK = the setting of the `SPORT_CTL_B.ICLK` configuration bit.
- CKAMUX = the setting of the `SPORT_CTL2_A.CKMUXSEL` configuration bit.
- CKBMUX = the setting of the `SPORT_CTL2_B.CKMUXSEL` configuration bit.

The Routing column in the ***Clock Combinations*** table defines how the signals are used between the SPORT halves and which pin is used for the serial clock (whether it is an input or an output). Within the column, the inequality characters (≤ and ≥) are used to show the direction of the signal, and the following abbreviations are used (x = A or B):

- HSx_CI = Serial clock input signal, provided by an external device or the complementing HSPORT.
- HSx_CO = Serial clock output signal.
- SPx_CLK = HSPORT's serial clock pin, where the signal is either:
  - provided by an external source and distributed to both HSPORT serial clock signals, or
  - internally generated by one HSPORT and routed to both the pin and to the complementary HSPORT serial clock signal.

Table 34-8: Clock Combinations

CLK Combination	HSA_ICLK	HSB_ICLK	CKAMUX	CKBMUX	Routing
9	0	0	0	0	Native CLK Operation
10	0	1	0	0	Native CLK Operation
11	1	0	0	0	Native CLK Operation
12	1	1	0	0	Native CLK Operation

Table 34-8: Clock Combinations (Continued)

CLK Combination	HSA_ICLK	HSB_ICLK	CKAMUX	CKBMUX	Routing
13	0	0	1	0	HSA_CI ≤ SPB_CLK; HSB_CI ≤ SPB_CLK
14	0	1	1	0	HSA_CI ≤ HSB_CO ≥ SPB_CLK
15	0	0	0	1	HSB_CI ≤ SPA_CLK; HSA_CI ≤ SPA_CLK
16	1	0	0	1	HSB_CI ≤ HSA_CO ≥ SPA_CLK

The following is a comprehensive list of the legal combinations for the above described frame sync and clock multiplexing configurations:

- FS Combinations 1–4 are compatible with all CLK Combinations (9–16)
- CLK Combinations 9–12 are compatible with all FS Combinations (1–8)
- FS Combination 5 is only compatible with CLK Combination 13 (and vice versa)
- FS Combination 6 is only compatible with CLK Combination 14 (and vice versa)
- FS Combination 7 is only compatible with CLK Combination 15 (and vice versa)
- FS Combination 8 is only compatible with CLK Combination 16 (and vice versa)

NOTE: Program only the `SPORT_CTL2` register of the HSPORT that is accepting the signal from the other HSPORT. However, be sure to set the `SPORT_CTL_A.CKRE` and `SPORT_CTL_A.LFS` polarity bits to have identical settings between the HSPORTs when making internal connections via the SPMUX block.

Data Types and Companding

The SPORT uses the data type select field `SPORT_CTL_A.DTYPE` bit to specify one of the four data formats supported by serial ports. These formats apply to any of the operating modes of serial port.

Table 34-9: Data Type Bit Field Settings

DTYPE field	SPORT Receiver	SPORT Transmitter
00	Right-justify, zero-fill unused most significant bits	Normal operation
01	Right-justify, sign-extend unused most significant bits	Reserved
10	Expand using μ-law	Compress using μ-law
11	Expand using A-law	Compress using A-law

These formats apply to data words loaded into the SPORT transmit or receive data buffers. The first two data formats (`00` and `01` values of `SPORT_CTL_A.DTYPE`) are applicable only when SPORT is configured as receiver.

When SPORT is configured as transmitter, only the significant bits are transmitted (per the field defined in control register). Therefore, the transmit data buffers are not actually zero-filled or sign-extended.

The other two data formats enable the companding logic on the transmit or receive path. Companding (compressing or expanding) is the process of logarithmically encoding and decoding data to minimize the number of bits sent. The SPORTs of the processor support the two most widely used companding algorithms, A-law, and μ-law. The algorithms are performed according to the CCITT G.711 specification.

If selected, companding applies to both the enabled data channels. When enabled as SPORT transmitter, writes to transmit buffer make the content compressed to 8 bits according to algorithm selected. (The content is zero filled to the width of the transmit word.) Similarly, if configured in receive mode, the 8 bits in the receive data buffers expand in right-justified, zero fill format per the algorithm selected. If companding is enabled in multichannel mode, it applies to all the active channels.

The compression for transmit data requires a minimum word length of 8 for proper function. If `SPORT_CTL_A.SLEN` is less than 7, then expansion does not work correctly. Also, if the data value is greater than 13-bit A-law or 14-bit μ-law maximum, it automatically compresses to the maximum value.

NOTE: The processor companding logic supports in-place companding feature. So, companding can be used for debug without enabling SPORT.

Companding as a Function

Since the values in the transmit and receive buffers are companded in place, the SPORT can use the companding hardware without transmitting or receiving data, which can be useful during testing or debugging. For companding to execute properly, program the SPORT registers prior to loading data values into the SPORT buffers.

To compress data in place without transmitting, use the following procedure:

1. Set the SPORT as a transmitter (`SPORT_CTL_A.SPTRAN` = 1) with both primary and secondary data channels disabled (`SPORT_CTL_A.SPENPRI` = `SPORT_CTL_A.SPENSEC`= 0).
2. Enable companding in the `SPORT_CTL_A.DTYPE` field.
3. Write a 32-bit data word to the transmit buffer.
4. Wait two system clock cycles to allow the SPORT companding hardware to reload the transmit buffer with the companded value. Any instructions that do not access the transmit buffer can be used to cause this delay.
5. Read the 8-bit compressed value from the transmit buffer.

To expand data in place, use the same sequence of operations with the receive buffer instead of the transmit buffer.

Transmit Path

When the `SPORT_CTL_A.SPTRAN` control bit is set, the HSPORT is in transmit mode. Primary and secondary transmit data paths are then enabled using the `SPORT_CTL_A.SPENPRI` and `SPORT_CTL_A.SPENSEC` bits, respectively. The primary and secondary datapaths are unique and identical, each including its own transmit data buffer, optional companding logic, and transmit shift register.

The data buffer on the primary transmit data path is `SPORT_TXPRI_A`, and the data buffer on the secondary transmit data path is `SPORT_TXSEC_A`. The transmit data buffer and output shift register form a FIFO type of structure. When packing is disabled (`SPORT_CTL_A.PACK` = 0), the SPORT can hold as many as three data words. If packing is enabled (`SPORT_CTL_A.PACK` = 1), the serial port can hold two packed data words at any time.

The transmit data for primary and secondary channels is written to the `SPORT_TXPRI_A` and `SPORT_TXSEC_A` transmit data buffers, respectively. The transmit data buffers can be accessed in core mode through the peripheral bus or in DMA mode through the DMA bus. When a SPORT is configured in transmit mode, the receive paths are deactivated and do not respond to serial clock or frame sync signals. Because the receive data buffers and receive shift registers are also deactivated, reading from an empty and inactive receive data buffer can cause the core to hang indefinitely.

> **NOTE:** Be sure to avoid accesses to inactive data buffers. Such accesses can cause unpredictable SPORT behavior or a hang condition and are not reported in any status register.

This data can optionally be compressed in hardware according to the selected algorithm (μ-law or A-law) and then automatically transferred to the transmit shift register. The shift register, clocked by the `SPORT_ACLK` signal, then serially outputs this data on the `SPORT_AD0` and/or `SPORT_AD1` pins (if both are enabled, these output data bits are transmitted synchronously). If the SPORT uses a framing signal, the `SPORT_AFS` signal indicates the start of the serial word transmission.

When using DMA mode, a single DMA feeds the data buffers of the enabled channels (primary and/or secondary). When using both channels, interleave the data of these channels starting with the primary channel in the transmit buffer.

When the SPORT is configured in non-multichannel mode as a transmitter, the enabled SPORT data pins (`SPORT_AD0` and/or `SPORT_AD1`) are always driven. When a SPORT channel is enabled, data from the transmit data buffer is loaded into the transmit shift register. The shift register then immediately latches the first bit of data (either the LSB or MSB, depending on the `SPORT_CTL_A.LSBF` configuration bit) and drives it to the respective data pin such that it is ready when the frame sync signal asserts. Similarly, if the frame sync period exceeds the serial word length, then the data pins are driven with the first bit of the next word for transmission immediately after the active word completes, and the outputs are held during the inactive serial clock cycles (clock cycles between frame sync pulses).

When the SPORT is configured in multichannel mode, the data pins are driven only during active transmit channels and are always three-stated during inactive channel slots.

The SPORT provides status of transmit data buffers and also error detection logic for transmit errors such as an underrun condition. See the Error Detection (Status) Interrupt section for more details.

Receive Path

When the `SPORT_CTL_A.SPTRAN` bit is cleared, the SPORT is in receive mode. Primary and/or secondary receive data paths can be enabled by setting the `SPORT_CTL_A.SPENPRI` and `SPORT_CTL_A.SPENSEC` configuration bits, respectively. These data paths are unique but identical, each with a receive shift register, optional companding logic, and a receive data buffer.

The data buffer on the primary receive path is `SPORT_RXPRI_A`, and the data buffer on the secondary receive path is `SPORT_RXSEC_A`. The receive data paths act like a three-deep (32-bit words) FIFO because they have two data registers plus an input shift register.

Upon enabling the SPORT data channels, the input shift register shifts in data bits on the `SPORT_AD0` and/or `SPORT_AD1` pins, synchronous to the SPORT clock signal. If the SPORT uses a framing signal, the `SPORT_AFS` signal indicates the beginning of the serial word (or frame) to be received. When an entire word is shifted into the primary and secondary channels, the data can be optionally expanded in hardware according to a selected algorithm (μ-law or A-law) and then automatically transferred to the `SPORT_RXPRI_A` and/or `SPORT_RXSEC_A` data buffers.

The receive data buffers can be read in core mode through the peripheral bus or in DMA mode through the DMA bus. When the SPORT uses DMA mode, a single DMA reads the data buffers of the enabled channels (primary and/or secondary) and interleaves them in memory beginning with the primary channel when both channels are enabled. When using both channels, software must de-interleave the data of these channels.

The SPORT provides the status of receive data buffers and also error detection logic for receive errors such as overflow. See the Error Detection (Status) Interrupt section for more details.

When a SPORT is configured in receive mode, the transmit paths are deactivated and do not respond to serial clock or frame sync signals. As the transmit data buffers and transmit shift registers in the data paths are also deactivated, programs must not try to access them.

> **NOTE:** Be sure to avoid accesses to inactive data buffers. Such accesses can cause unpredictable SPORT behavior or a hang condition and are not reported in any status register.

Operating Modes and Options

The SPORT has a number of operating modes:

- Standard DSP Serial mode
- I^{2}S mode
- Left-Justified mode
- Right-Justified mode
- Multichannel (TDM) mode
- Packed I^{2}S mode

The SPORT halves within a SPORT top module can be independently configured in any of these operating modes unless they are coupled together using SPMUX logic, in which case they must be configured identically. Each half SPORT has its own set of control and data registers and is programmed similarly.

The ***Control Bits for SPORT Operating Modes*** table lists all the programmable configuration bits in the `SPORT_CTL_A` control register, which combine to determine the overall function and operating mode of the SPORT. The columns are arranged according to the setting of the `SPORT_CTL_A.OPMODE` bit that selects between standard DSP/multichannel modes and the various I^{2}S modes, and the cell contents are defined as follows:

- Yes – bit is programmable for this mode of operation and may be written
- Reserved – bit is not programmable for this mode of operation and must not be written
- = value – bit must be set to this value to enable this mode of operation
- FUNCTION – indicates alternate function for this bit in this mode

NOTE: When changing operating modes, first clear the `SPORT_CTL_A` register before again writing the register with the new configuration settings.

Table 34-10: Control Bits for SPORT Operating Modes

Table 34-10: Control Bits for SPORT Operating Modes (Continued)

Name (Bit #)	Standard DSP Serial Mode	I^2S and Left-Justified Mode	Right-Justified Mode	Multichannel (TDM) Mode	Packed I^2S Mode
SPENSEC (24)	Valid				
SPTRAN (25)	Valid				

Serial Word Length

The SPORT uses the `SPORT_CTL_A.SLEN` field to determine the word length of the serial data to transmit or receive. Each half SPORT can independently handle word lengths up to 32 bits, and the value that must be programmed to the `SPORT_CTL_A.SLEN` field is obtained from:

SLEN = Desired SPORT word length - 1

The minimal word length depends on the selected operating mode. Words smaller than 32 bits are right-justified in the transmit or receive buffers; however, data can be shifted in or out in MSB or LSB first format, as configured by the `SPORT_CTL_A.LSBF` bit. The received word can also be sign-extended or zero-filled when storing the data to processor memory, as governed by the `SPORT_CTL_A.DTYPE` bit.

The ***Data Lengths for SPORT Operating Modes*** table shows the range of valid word lengths for each of the supported SPORT operating modes.

Table 34-11: Data Lengths for SPORT Operating Modes

Mode	SPORT Word Length (SLEN+1)
Standard DSP Serial	4–32
I^2S	5–32
Left-Justified	5–32
Right-Justified	5–32
Multichannel (TDM)	5–32
Packed I^2S	5–32

NOTE: If the companding feature is enabled on the datapath, it limits the word length settings. See Data Types and Companding for more details about word lengths required for companding. If more than 32 bits per frame sync are required to transmit or receive, use the multichannel mode to spread the data across numerous continuous channels.

Clock Sample and Drive Edges

The SPORT uses two control signals to sample or drive the serial data:

1. Serial clock (`SPORT_ACLK`) - bit clock for the serial data.
2. Frame sync (`SPORT_AFS`) - divides the incoming data stream into frames.

These control signals can be internally generated or externally provided, as determined by the `SPORT_CTL_A.ICLK` and `SPORT_CTL_A.IFS` bit settings, respectively.

Data and frame syncs can be sampled on the rising or falling edges of the SPORT clock signal, as determined by the `SPORT_CTL_A.CKRE` bit. By default, the `SPORT_CTL_A.CKRE` = 0 setting configures the falling edge of the `SPORT_ACLK` signal as the sampling edge for receive data and externally supplied frame syncs. The receive data and frame syncs can be sampled on the rising edges of `SPORT_ACLK` when `SPORT_CTL_A.CKRE` = 1.

NOTE: The SPORT drives transmit data and internal frame sync signals on the opposite serial clock edge of the sampling edge. Be sure to select the same value for `SPORT_CTL_A.CKRE` for transmit and receive functions for any two HSPORTs that are connected together, and always verify the correct polarity for any external device connected to the SPORT.

The ***Frame Sync and Data Driven on Rising Edge*** figure provides an example of the drive and sample edges when two HSPORTs are connected together, each with `SPORT_CTL_A.CKRE` = 0. In this example, the HSPORT that is configured as the transmitter drives the serial clock and frame sync signals, and both HSPORTs are configured for early, active high frame syncs and a word length of eight bits.

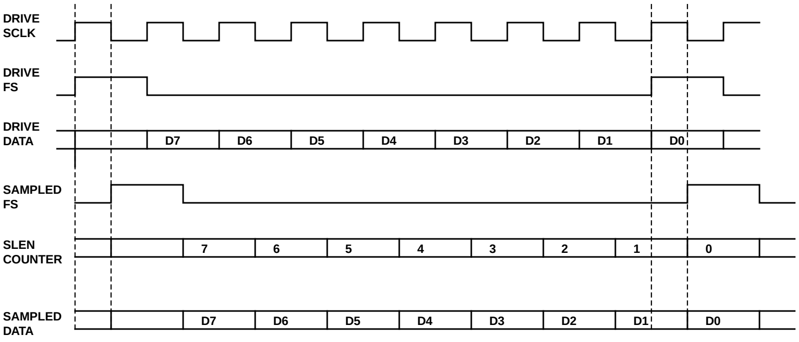

Figure 34-3: Frame Sync and Data Driven on Rising Edge

NOTE: The SCLK in the ***Frame Sync and Data Driven on Rising Edge*** figure is SCLK0_0.

As shown, the transmitting HSPORT provides the clock and generates the frame sync. Because the HSPORTs are configured for early frame mode, the first bit of data is driven one serial clock later, with subsequent bits being driven on the following rising clock edges in the signal train. When the receiving HSPORT samples the frame sync signal (as indicated in the SAMPLED FS waveform), the `SPORT_CTL_A.SLEN` bit counter is loaded with the `SPORT_CTL_A.SLEN` setting, after which each `SPORT_ACLK` decrements the `SPORT_CTL_A.SLEN` counter until the full word is received. In this figure, the DRIVE FS and SAMPLED FS waveforms show the frame sync required for the next word in a continuous data stream. Note that it is legal for this frame sync to be sampled synchronous to the last bit of the previous data being sampled, as the early frame mode means that the data lags the frame sync by one serial clock cycle. If the frame sync were sampled as asserted before the D0 bit is sampled, the frame sync error is logged in the receiver's status register.

Since the transmitter drives the internally-generated frame sync and data on the rising edge of the serial clock, the receiver must use the falling edge to sample the externally-supplied frame sync and data.

Frame Sync Options

The following sections provide details regarding the programmable aspects of the SPORT frame sync signal. See the specific operating mode sections for additional information regarding frame sync requirements and behavior for each specific operating modes.

Data-Dependent versus Data-Independent Frame Syncs

By default, the generation of a frame sync signal is data-dependent:

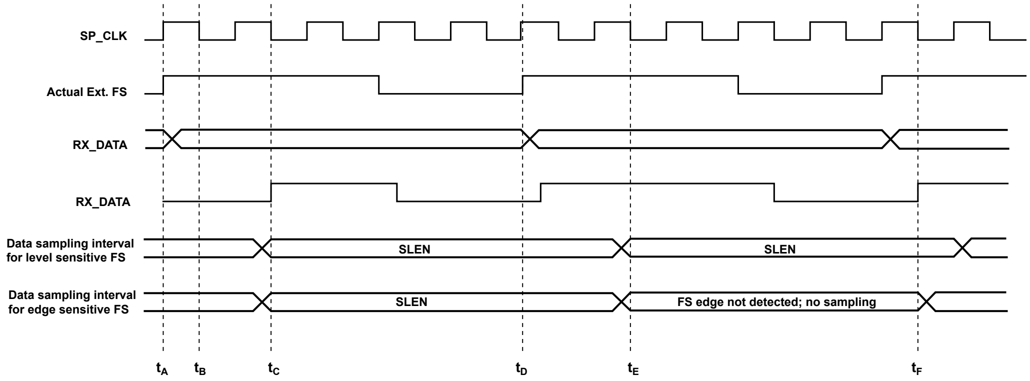
- When the SPORT is configured as a transmitter (`SPORT_CTL_A.SPTRAN` = 1), an internally generated transmit frame sync is output when a new data word has been loaded into the channel transmit buffer of the SPORT (by either the core or the DMA engine).
- When the SPORT is configured as a receiver (`SPORT_CTL_A.SPTRAN` = 0), an internally-generated receive frame sync is output only when the receive data buffer is not full.

The data-independent frame sync option, enabled by setting the `SPORT_CTL_A.DIFS` bit, allows for the generation of a periodic framing signal, regardless of the status of the data buffers. When this bit is set, the frame sync output will be continuous and periodic, according to the setting of the `SPORT_DIV_A.FSDIV` field.

Support for Edge-Detected and Level-Sensitive Frame Syncs

The level-sensitive nature of frame sync signals operates well in a noise-free environment. However, if noise corrupts the signals coming into the SPORT, the internal logic can lose synchronization. For example, excessive noise on the frame sync signal may cause the frame sync to be sampled as inactive on the clock edge that it is intended to be synchronous to, but then be sampled at the correct active level one cycle later. Similarly, a noisy clock signal can cause an unintended clock edge, resulting in potential premature sampling of the frame sync signal being applied to the pin.

The ***Level-Sensitive Frame Sync versus Edge Sensitive Frame Sync*** figure describes a scenario where an external frame sync signal is corrupted due to noise, causing the receiving SPORT module to incorrectly sample the signal. If the frame sync is driven on the rising edge of the serial clock at t_A, the SPORT would normally sample the signal on the falling edge of the serial clock at t_B. Due to the noise, however, the SPORT misses the first edge of the frame sync and instead samples it at t_C.



SP_CLK

t_C
t_D
t_E
t_F

Figure 34-4: Level-Sensitive Frame Sync versus Edge Sensitive Frame Sync

NOTE: SCLK in the ***Level-Sensitive Frame Sync versus Edge Sensitive Frame Sync*** figure is SCLK0_0.

When the above occurs, the internal word length counter runs for a period equal to the `SPORT_CTL_A.SLEN` field of the control register, but it erroneously expires at t_E rather than at the appropriate point at t_D, thus receiving incorrect data. Further, if a new level-sensitive frame sync edge arrives at time t_D, the SPORT samples this framing signal again at t_E. As such, the frame sync sampling continues to be misaligned with the external data.

To help address this, the SPORT module provides an option to configure the frame sync signal to instead be edge-sensitive via the `SPORT_CTL_A.FSED` configuration bit. When this bit is set with active high frame syncs enabled (`SPORT_CTL_A.LFS` = 0), the rising edge of the frame sync is valid. Conversely, when the frame sync is active low (`SPORT_CTL_A.LFS`= 1), the falling edge is defined to be valid.

NOTE: `SPORT_CTL_A.FSED` is valid only in external frame sync mode. In internal frame sync mode, the setting of this bit is irrelevant and ignored.

In the above example, an edge-sensitive frame sync signal is not detected at t_E because the edge of the framing signal already occurred in the previous cycle (t_D) and there is no new edge to detect at t_E. As a result, the internal word length counter remains idle for this frame, thus ignoring the incorrect data, and the counter correctly resumes operation at t_F when a new frame sync edge is detected.

This activity sets the `SPORT_ERR_A.FSERRSTAT` bit and optionally generates a premature frame sync error interrupt.

Frame sync edge detection is used by default for stereo modes. MCM mode and DSP serial mode choose between edge detection and normal mode of FS detection.

NOTE: When the SPORT is first enabled, an already active externally applied frame sync will not commence operation. The SPORT will wait for a valid change in the frame sync's state from inactive to active before operation begins.

Early versus Late Frame Syncs

Frame sync signals can occur in the same serial clock cycle as the first bit of the data word (late) or one serial clock cycle before the first bit (early), as controlled by the `SPORT_CTL_A.LAFS` bit.

By default, the frame sync signal is configured to be early (`SPORT_CTL_A.LAFS` = 0). The first bit of the transmit data word will be driven one serial clock cycle after the frame sync is asserted (whether sensed externally or internally provided), and the first bit of the receive data word is expected to lag the frame sync by one serial clock cycle. The frame sync is not checked again until the entire word has been transferred.

If data transmission is continuous in early framing mode, then an internally-generated frame sync signal will be asserted (pulsed active for one serial clock cycle) synchronous to the last data bit of the current transfer, as the first bit of the next transfer will be immediately driven in the next serial clock cycle (no clocks are wasted). This event is not a premature frame sync error, so the `SPORT_ERR_A.FSERRSTAT` bit is not set.

The frame sync can alternatively be configured as late (`SPORT_CTL_A.LAFS` = 1), in which case the first bit of the transmit data word is available in the same serial clock cycle that the frame sync is asserted (whether sensed externally or internally provided), and the first bit of the receive data word is also latched in the same cycle. Serial clock edges latch the receive data bits, but the frame sync signal is checked only during the first bit of each word. Internally generated frame syncs remain asserted for the entire length of the data word in late framing mode.

The ***Normal Framing (Early Frame Sync) Versus Alternate Framing (Late Frame Sync)*** figure illustrates these concepts.

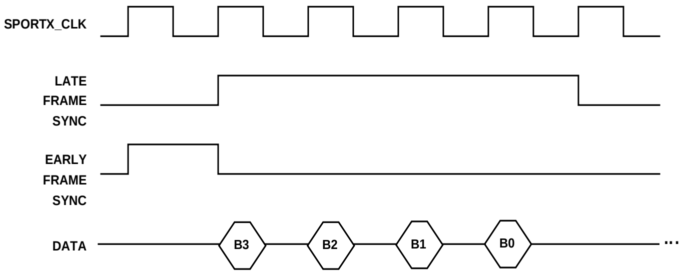

Figure 34-5: Normal Framing (Early Frame Sync) Versus Alternate Framing (Late Frame Sync)

Framed versus Unframed Frame Syncs

The use of a frame sync signal is optional for SPORT operation, as controlled by the `SPORT_CTL_A.FSR` bit. When the frame sync is configured to be required (`SPORT_CTL_A.FSR` = 1), the data is defined to be framed (a frame sync signal must accompany every data word). To allow continuous transmission from the processor, ensure that a new data word is loaded into the transmit buffer before the ongoing transfer is completed (this is automatically cared for when DMA is used to transmit blocks of data).

Data words can be transferred continuously in what is referred to as unframed data mode, which is appropriate for continuous reception, by setting `SPORT_CTL_A.FSR` = 0. In this configuration, a single frame sync is still required to initiate communication, but it is subsequently unrequired once the communication begins. From that point onward, externally provided frame syncs are ignored and internally generated frame syncs are not driven. The ***Framed versus Unframed Data Stream*** figure shows the differences in SPORT operation between framed and unframed data modes with the frame sync configured to be early (`SPORT_CTL_A.LAFS` = 0).

NOTE: When DMA is enabled in a mode where frame syncs are not required, chaining can delay DMA requests. DMA requests are not always serviced frequently enough to guarantee continuous unframed data flow. Monitor status bits or check for a SPORT error interrupt to detect underflow or overflow of data.

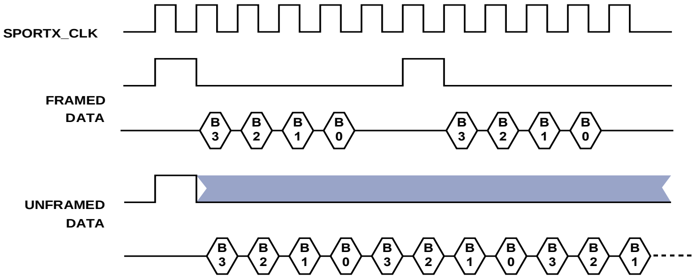

Figure 34-6: Framed versus Unframed Data Stream

Frame Sync Polarity

The framing signals can be active high or active low, as governed by the `SPORT_CTL_A.LFS` bit:

- When `SPORT_CTL_A.LFS` = 0, the corresponding frame sync signal is active high.
- When `SPORT_CTL_A.LFS` = 1, the corresponding frame sync signal is active low.

Active high is the default polarity of the frame sync signal.

Premature Frame Sync Error Detection

A SPORT framing signal is used to synchronize transmit or receive data. In external frame sync mode, any frame sync received during an active frame is premature and invalid. When this occurs, the `SPORT_ERR_A.FSERRSTAT` bit is set to indicate the framing error, and an optional error interrupt request can be generated for this event by setting the `SPORT_ERR_A.FSERRMSK` bit.

NOTE: The `SPORT_ERR_A.FSERRSTAT` bit is not set in the presence of uncleared underflow or overflow errors.

Refer to the ***Frame Sync Error Detection*** figure. The frame sync error bit gets set when an unexpected frame sync occurs during the ongoing data transfer (transmission or reception).

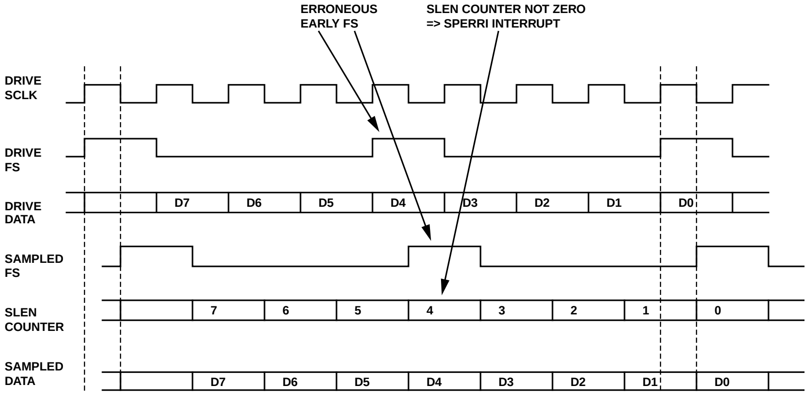

Figure 34-7: Frame Sync Error Detection

NOTE: SCLK in the ***Frame Sync Error Detection*** figure is SCLK0_0.

Whether a SPORT is receiving or transmitting, its bit count is set to the programmed serial word length when the frame sync is sampled, which is then decremented every subsequent serial clock cycle until the transfer has completed. At this point, the bit count reaches zero and will be reset to the programmed serial length when the next frame sync is sampled. As such, the bit count value is non-zero during an active transfer, and the frame sync error is asserted if a frame sync is sampled when this count is non-zero.

Mode Selection

The SPORT's operating mode is configured in the `SPORT_CTL_A` and `SPORT_MCTL_A` registers. The *SPORT Operating Modes* table provides specific guidance to properly program these SPORT control registers for the desired mode of operation.

Table 34-12: SPORT Operating Modes

Operating Modes	SPORT_CTL_A.OPMODE	SPORT_CTL_A.LAFS	SPORT_CTL_A.RJUST	SPORT_MCTL_A.MCE
Standard DSP Serial	0	Programmable	Reserved	0
I^2S	1	0	Reserved	0
Left-Justified	1	1	Reserved	0
Right-Justified	1	1	1	0
Multichannel	0	Reserved	Reserved	1
Packed I^2S mode	1	Reserved	Reserved	1

The following sections provide detailed information for each of the supported SPORT modes of operation.

Standard DSP Serial Mode

The SPORT can be configured in standard DSP serial mode by clearing the `SPORT_CTL_A.OPMODE` and `SPORT_MCTL_A.MCE` bits. This mode provides great flexibility in terms of programmable options to configure the SPORTs to communicate with various serial devices such as serial data converters and audio codecs. In order to properly connect to such devices, various clocking, framing, and data formatting options are available.

Timing Control Bits

Several bits in the `SPORT_CTL_A` control register define the configuration of the SPORT in standard DSP serial mode:

- SLEN: serial word length (4–32 bits)
- LSBF: shift LSB or MSB first
- ICLK: internally generated or externally provided serial clock
- CKRE: sample on rising or falling edge of the serial clock
- IFS: internally generated or externally provided frame sync
- FSR: framed or continuous operation
- DIFS: data-dependent or data-independent frame sync
- LFS: active high or active low frame sync
- LAFS: frame sync synchronous to data or one clock cycle before it
- PACK: 16-bit to 32-bit packing option

- GCLKEN: free-running or gated clock

Clocking Options

In standard DSP serial mode, the SPORTs can either accept an external serial clock or generate one internally, as controlled by the `SPORT_CTL_A.ICLK` bit. For internally generated serial clocks (`SPORT_CTL_A.ICLK` = 1), the `SPORT_DIV_A.CLKDIV` field configures the serial clock rate from the system clock.

The SPORT clock can also be gated, where it is only valid during an active transfer, as controlled by the `SPORT_CTL_A.GCLKEN` bit.

The SPORT clock edge used for driving and sampling of serial data and frame syncs is configured using the `SPORT_CTL_A.CKRE` bit:

- If `SPORT_CTL_A.CKRE` = 0, input data and frame sync signals are sampled on the falling edge of the serial clock, and output data and frame sync signals are driven on the rising edge.
- If `SPORT_CTL_A.CKRE` = 1, input data and frame sync signals are sampled on the rising edge of the serial clock, and output data and frame sync signals are driven on the falling edge.

Stereo Modes

The SPORTs support three widely used stereo modes of operation:

- I^2S mode
- Left-Justified mode
- Right-Justified mode

In these modes, the serial data stream consists of left and right channels. The following sections describe these modes in more detail.

Channel Order

The active low frame sync (`SPORT_CTL_A.LFS`) bit is used to determine the polarity of the frame sync signal in the non-stereo modes of operation. For the stereo modes of operation, it instead controls whether the right or left channel is first in the data transfer. The ***Channel Order Bit Settings*** table shows which word is transmitted or received first, based on the setting of the `SPORT_CTL_A.LFS` bit.

Table 34-13: Channel Order Bit Settings

Mode	**`SPORT_CTL_A.LFS`**=0	**`SPORT_CTL_A.LFS`**=1
Left-Justified or Right-Justified	Left channel first	Right channel first
I^2S or Packed I^2S	Right channel first	Left channel first

I^{2}S Mode

I^{2}S mode is a commonly used stereo mode, where left and right channel data words are interleaved in the serial data stream and each transition of the frame sync signal is associated with one of the channels. The left channel data is transferred during the low segment of the frame sync signal, and the right channel data is transferred during the high segment of the frame sync signal. As such, the frame sync signal is considered to be a left-right (L/R) clock in this mode.

To set the SPORT up in I^{2}S mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 1
- `SPORT_CTL_A.LFS` = 0
- `SPORT_MCTL_A.MCE` = 0

Protocol Configuration Options

Several bits in the `SPORT_CTL_A` control register must be configured to be compliant with the I^{2}S standard, but they can be otherwise configured to support non-standard operation as well:

- SLEN: programmable (allowable word lengths are 5–32 bits)
- LSBF: set to 0 (MSB first)
- ICLK: programmable (serial bit clock can be internally generated or externally provided)
- IFS: programmable (serial L/R clock source must match serial bit clock source)
- LFS: set to 1 (left channel first)
- CKRE: set to 1 (sample L/R clock and data on rising edge of bit clock)

Serial Bit Clock and L/R Clock Rates

If the SPORT is configured to generate the bit clock and the L/R clock (`SPORT_CTL_A.ICLK` = `SPORT_CTL_A.IFS` = 1), set the serial bit clock rate using the `SPORT_DIV_A.CLKDIV` bit field and the L/R clock rate using the `SPORT_DIV_A.FSDIV` bit field.

The *Word Select Timing in I^{2}S Mode* figure shows the SPORT timing in I^{2}S mode. The data lags the L/R clock transition by one SCLK0_0 cycle, and the transfer begins with the left channel data word first.

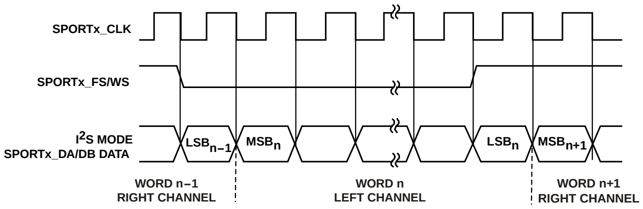

Figure 34-8: Word Select Timing in I^{2}S Mode

Left-Justified Mode

Left-justified mode is a stereo mode subset of the I^{2}S standard. As in I^{2}S mode, the frame sync signal acts as a left-right clock (L/R clock), where left and right data samples are transferred each L/R clock period. The left channel is associated with the high segment of the frame sync, and the right channel aligns with the low segment of the frame sync. The difference between left-justified mode and standard I^{2}S mode is that the channel data is driven in the same bit clock cycle as the L/R clock transition (rather than one bit clock cycle later), such that the MSB is synchronous with the leading edge of the frame sync transition.

To set the SPORT up in left-justified mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 1
- `SPORT_CTL_A.LAFS` = 1
- `SPORT_MCTL_A.MCE` = 0

Protocol Configuration Options

Several bits in the `SPORT_CTL_A` control register must be configured to operate the SPORT in left-justified mode, but they can be otherwise configured as well:

- SLEN: programmable (allowable word lengths are 5–32 bits)
- LSBF: set to 0 (MSB first)
- ICLK: programmable (serial bit clock can be internally generated or externally provided)
- IFS: programmable (serial L/R clock source must match serial bit clock source)
- LFS: set to 0 (left channel first)
- CKRE: set to 1 (sample L/R clock and data on rising edge of bit clock)

Serial Bit Clock and L/R Clock Rates

If the SPORT is configured to generate the bit clock and the L/R clock (`SPORT_CTL_A.ICLK` = `SPORT_CTL_A.IFS` = 1), set the serial bit clock rate using the `SPORT_DIV_A.CLKDIV` bit field and the L/R clock rate using the `SPORT_DIV_A.FSDIV` bit field.

The ***Word Select Timing in Left-Justified Mode*** figure shows the SPORT timing in left-justified mode. The start of a data sample is synchronous to the L/R clock transition, and the transfer begins with the left channel data word first.

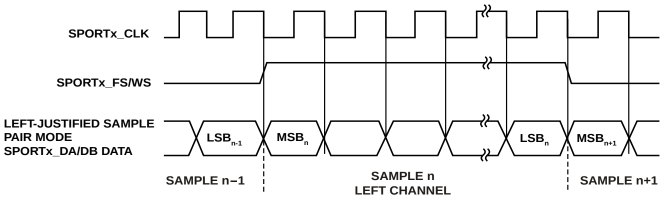

Figure 34-9: Word Select Timing in Left-Justified Mode

Right-Justified Mode

Right-justified mode is a stereo mode subset of the I^2S standard. As in I^2S mode and left-justified mode, the frame sync signal acts as a left-right clock (L/R clock), where left and right data samples are transferred each L/R clock period. The left channel is associated with the high segment of the frame sync, and the right channel aligns with the low segment of the frame sync. The difference between right-justified mode and standard I^2S mode is that the LSB of the channel data ends at the point that the L/R clock transitions to frame the next sample (rather than one bit clock cycle after the L/R clock transition).

To set the SPORT up in right-justified mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 1
- `SPORT_CTL_A.RJUST` = 1
- `SPORT_MCTL_A.MCE` = 0

Timing Control Bits

Several bits in the `SPORT_CTL_A` control register must be configured to operate the SPORT in right-justified mode, but they can be otherwise configured as well:

- SLEN: programmable (allowable word lengths are 5–32 bits)
- LSBF: set to 0 (MSB first)
- ICLK: programmable (serial bit clock can be internally generated or externally provided)
- IFS: programmable (serial L/R clock source must match serial bit clock source)
- LFS: set to 0 (left channel first)
- CKRE: set to 1 (sample L/R clock and data on rising edge of bit clock)

Serial Bit Clock and L/R Clock Rates

If the SPORT is configured to generate the bit clock and the L/R clock (`SPORT_CTL_A.ICLK` = `SPORT_CTL_A.IFS` = 1), set the serial bit clock rate using the `SPORT_DIV_A.CLKDIV` bit field and the L/R clock rate using the `SPORT_DIV_A.FSDIV` bit field.

The *Word Select Timing in Right-Justified Mode* figure shows the SPORT timing in right-justified mode. The transmitter aligns the transmit data such that the last bit of the serial word is sent in the last clock cycle of the L/R clock (frame sync) signal marking the channels.

Figure 34-10: Word Select Timing in Right-Justified Mode

NOTE: For some SPORT-compatible ADCs or DACs such as the AD1871, right-justified mode is limited to commonly used ratios such as 64 FS and 128 FS. FS is the sampling frequency of ADCs and DACs, referrd to as the SPORT's L/R clock (frame sync) signal.

Consider the SPORT timing for right-justified mode, as shown in the ***Timing Comparison Between Different Stereo Modes*** figure. The frame sync width is limited to 32 SPORT clock periods (or 32 bits per channel) if:

- the SPORT's frame sync (L/R clock) runs at the FS rate, and
- the SPORT's serial bit clock runs at the 64 FS rate

The limitation applies to the frame sync width of either channel. If the data is confined to 24 bits, the SPORT introduces a 32–24=8-bit clock delay before it starts to transmit or capture data.

Figure 34-11: Timing Comparison Between Different Stereo Modes

Similarly, to support the 128 FS bit clock frequency, the frame sync width becomes 64 serial bit clock periods per channel. In this case, the delay can be a maximum of 59 bit clocks (64 – 5, which is the minimum serial data length in right-justified mode).

The starting point of the first bit is delayed so that the LSB of the serial data aligns properly with the end of the channel. A 6-bit counter is added for this purpose in the stereo mode counter, which is programmed by writing the least significant six bits of the `SPORT_MCTL_A.WOFFSET` field. Though this is a multichannel mode configuration register, the SPORT uses these bits in right-justified mode to configure the offset from the transition of the L/R clock to where the first data bit must be driven in order to have the end of the last bit align properly with the next L/R clock transition. Software must program this register with the appropriate delay.

Multichannel (TDM) Mode

The multichannel mode of SPORT operation allows the SPORT to communicate as part of a time division multiplexed (TDM) serial system. In TDM communications, a large frame of streamed serial data words is defined to be a particular length. It consists of a specific number of channels, and each channel contains one serial data word of the defined data length. For example, a 24-word block of 24-bit data can be defined to be a window within a frame, having a duration of 576 bit clocks and comprised of 24 continuous channels. The SPORT is configured to transfer on specific channels within a defined window in this frame.

To set the SPORT up in multichannel mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 0
- `SPORT_MCTL_A.MCE` = 1

In multichannel mode, the SPORT can selectively transfer data on up to a maximum window size of 128 continuous channels out of a maximum 1024-channel frame while ignoring all the disabled channels within the window and all the channels outside the window. The SPORT can do any of the following on each channel:

- Transmit data (`SPORT_CTL_A.SPTRAN` = 1)
- Receive data (`SPORT_CTL_A.SPTRAN` = 0)
- Do nothing (during inactive channels)

Channel selection is configured in the half SPORT multichannel select registers (`SPORT_CS0_A` - `SPORT_CS3_A`) before enabling SPORT operation for multichannel mode. Programming of these registers is especially important in DMA data unpacked mode, since the SPORT data buffers begin operation immediately after the SPORT data lines are enabled. Be sure to enable multichannel operation (set the `SPORT_MCTL_A.MCE` bit) prior to enabling the SPORT itself.

Clocking Options

In multichannel mode, the SPORTs can either accept an external serial clock or generate one internally, as governed by the `SPORT_CTL_A.ICLK` bit. For an internally-generated serial clock (`SPORT_CTL_A.ICLK` = 1), the `SPORT_DIV_A.CLKDIV` bit field is used to configure the serial clock rate, as derived from the system clock.

The serial clock edges used to drive and sample data and frame syncs are also configurable using the `SPORT_CTL_A.CKRE` bit:

- If `SPORT_CTL_A.CKRE`= 0, input data and frame sync signals are sampled on the falling edge of the serial clock, and output data and frame sync signals are driven on the rising edge.
- If `SPORT_CTL_A.CKRE` = 1, input data and frame sync signals are sampled on the rising edge of the serial clock, and output data and frame sync signals are driven on the falling edge.

Frame Sync Options

The frame sync signal synchronizes the channels and restarts each multichannel sequence, starting with the channel 0 data word. For internally-generated frame syncs (`SPORT_CTL_A.IFS` = 1), the frame sync period in multichannel mode is defined as:

FS period = [(`SPORT_CTL_A.SLEN` + 1) × number of channels] - 1

The active level for the frame sync signal is also configurable by programming the `SPORT_CTL_A.LFS` bit. Set this bit to make the frame sync an active low signal, and clear it to make it active high.

In multichannel mode, frame sync timing resembles late framing mode (although the `SPORT_CTL_A.LAFS` bit is reserved in this mode). The first bit of the transmit data word is driven and the first bit of the receive data word is sampled in the same serial clock cycle as the frame sync, provided there is no programmed frame delay (`SPORT_MCTL_A.MFD` = 0).

Once the frame sync signal is asserted, word transfers are performed continuously for the duration of the active window, and no further frame syncs are required for different channels within the window. As such, internally-generated frame syncs are always data-independent, and the `SPORT_CTL_A.DIFS` bit is reserved.

Transmit Data Valid (TDV)

Each SPORT features a transmit data valid signal (`SPORT_ATDV`), which is driven high during enabled transmit channels. Because the SPORT output data signals are three-stated during inactive channels, the `SPORT_ATDV` signal signifies when the processor is actively driving the SPORT data outputs, thus serving as an output-enable signal for the data transmit pin(s).

Active Channel Selection Registers

In multichannel mode, the SPORT supports a window size of up to 128 channels for transmitting or receiving data, where it can selectively receive or transmit data in any of these 128 channels. Each channel can be individually enabled or disabled using the multichannel selection registers (`SPORT_CS0_A` to `SPORT_CS3_A`) to select the channels in which to transfer data during a multichannel communication stream. Data words associated with enabled channels are transmitted or received in the respective channels, while disabled channels cause a transmit SPORT to three-state the data output pins and a receive SPORT to ignore the data.

The four 32-bit multichannel selection registers combine to form up to a 128-bit meta-register to accommodate the maximum window size of 128 channels. Setting any bit within these registers enables the associated channel. The 128 channels are sequentially numbered from bit 0 in the `SPORT_CS0_A` register (corresponding to channel 0 of the window) to bit 31 of the `SPORT_CS3_A` register (corresponding to channel 127 of the window). For example, setting bit 13 of the `SPORT_CS1_A` register enables channel number 45 (add 32 for the channels in the `SPORT_CS0_A`). Likewise, setting bit 5 of the `SPORT_CS3_A` register enables channel number 101 (add 96 for the 32 channels in each of the `SPORT_CS0_A`, `SPORT_CS1_A`, and `SPORT_CS2_A` registers).

Multichannel Frame Delay (MFD)

The multichannel frame delay (`SPORT_MCTL_A.MFD`) field specifies the delay in serial bit clocks between the frame sync pulse and the first data bit in the frame. This configurability allows the processor to work with different types of telephony interface devices.

As `SPORT_MCTL_A.MFD` is a 4-bit field, the maximum value allowed for the frame delay is 15 serial clock cycles. When set to 0, the frame sync is concurrent with the first data bit. If `SPORT_MCTL_A.MFD`>0, a new frame sync can occur during the last channel(s) of a previous frame and still be valid (does not cause a frame sync error).

NOTE: If the required frame delay exceeds 15 serial clocks, use the window offset field (`SPORT_MCTL_A.WOFFSET`) to delay the start of channel 0 in increments of the serial word length, and then adjust `SPORT_MCTL_A.MFD`accordingly. For example, if the serial word length is 12 bits and the desired frame delay is 16 serial clock cycles, set the `SPORT_MCTL_A.WOFFSET` to 1 to insert a 12-bit delay after the frame sync to where the channel 0 data begins, and then program `SPORT_MCTL_A.MFD` to 4 (i.e., 16 - 12).

Window Size (WSIZE)

Select the number of channels used in multichannel operation by programming the 7-bit `SPORT_MCTL_A.WSIZE` field. This field must be set to the actual number of channels minus one (`SPORT_MCTL_A.WSIZE` = Number of channels -1).

The 10-bit `SPORT_MSTAT_A.CURCHAN` field holds the channel number currently being serviced during multichannel operation.

Window Offset (WOFFSET)

The window offset (`SPORT_MCTL_A.WOFFSET`) field specifies where in the 1024-channel frame to place the start of the active window (up to 128 channels long). A value of 0 specifies no channel offset from the frame sync (channel 0 immediately follows it). Any non-zero value indicates the number of channels that come between the frame sync and the start of channel 0 of the active frame, with 896 (for example, 1024–128) being the largest value that permits using all 128 channels.

As an example, a program could define an active window comprised of eight channels (`SPORT_MCTL_A.WSIZE` = 7) with a window offset of 93 (`SPORT_MCTL_A.WOFFSET` = 93). If configured in this fashion, the 8-channel window that the SPORT will transfer within resides in the channel range from 93 to 100 in the up-to-1024-channel frame.

Do not change the window offset or the number of multichannel slots (`SPORT_MCTL_A.WSIZE`) while the SPORT is enabled. If the combination of the window size and offset place any portion of the window out-of-range relative to the channel counter, none of the channels are enabled.

Companding Selection

Like the other operating modes, companding logic can optionally be applied to serial data (compression logic for transmit mode or expansion logic for receive mode). The two widely used companding algorithms, A-law and μ-law, are selectable using the `SPORT_CTL_A.DTYPE` field.

If companding is enabled, the companding algorithm is applied to both the primary and secondary datapaths. In multichannel mode, companding can be applied to either all or none of the enabled channels (companding cannot be selected on a per-channel basis).

Multichannel DMA Data Packing (MCPDE)

Multichannel DMA data packing and unpacking are enabled using the `SPORT_MCTL_A.MCPDE` bit.

When set, data is packed, and the SPORT expects the data in the DMA buffer to correspond only with enabled SPORT channels. For example, if only channels 1 and 9 are enabled in a 10-channel window (`SPORT_MCTL_A.WSIZE` = 9), the SPORT expects the buffer to be exactly two words in length, where channel 1 is associated with the first element in the buffer and channel 9 is associated with the second.

When cleared, data is unpacked, and the SPORT expects the DMA buffer to have a word for each of the channels in the active window, whether the channel is enabled or not. As such, the DMA buffer size must be exactly the size of the window. Using the same example as the packed case above, if only channels 1 and 9 are enabled in a 10-channel window (`SPORT_MCTL_A.WSIZE` = 9), then the DMA buffer size is ten words. The data at offsets 1 and 9 within the buffer are associated with the data transfers of channels 1 and 9, respectively. The rest of the words in the buffer are unused.

Packed I^{2}S Mode

The SPORT supports a packed I^{2}S mode, which can be used for audio codec communications using multiple channels. This mode allows applications to send more than the standard 32 bits per channel available through standard I^{2}S mode. Packed mode is implemented using standard multichannel mode (and is therefore programmed similarly to multichannel mode).

To set the SPORT up in packed I^{2}S mode, the following configuration is required:

- `SPORT_CTL_A.OPMODE` = 1
- `SPORT_MCTL_A.MCE` = 1

Like multichannel mode, packed I^{2}S mode also supports a maximum of 128 channels, where up to 128 channels of data can be transferred for every transition of the frame sync signal acting as an L/R clock (for example, up to 128 left-channel words transfer during the high portion of the L/R clock, and up to 128 right-channel words transfer during the low portion).

As shown in the ***Packed I^{2}S Mode 128 Operation*** figure, the packed waveforms are the same as those waveforms used in multichannel mode, except the frame sync is toggled for every frame and emulates I^{2}S mode.

Serial Bit Clock Options

In packed I^{2}S mode, the SPORTs can either accept an external serial bit clock or generate one internally, as governed by the `SPORT_CTL_A.ICLK` configuration bit. For an internally-generated serial bit clock (`SPORT_CTL_A.ICLK` = 1), use the `SPORT_DIV_A.CLKDIV` bit field to configure the serial bit clock rate from the system clock.

The serial bit clock edge that is used for sampling or driving data and frame syncs is programmable using the `SPORT_CTL_A.CKRE` bit.

L/R Clock (Frame Sync) Options

The frame sync period in packed I^{2}S mode is defined as:

FS period = [(`SPORT_CTL_A.SLEN` + 1) × number of channels] - 1.

The L/R clock can be supplied externally or internally generated depending on the `SPORT_CTL_A.IFS` bit setting. The logic level of the L/R clock associated with the left and right channel data can be changed using the `SPORT_CTL_A.LFS` configuration bit.

Gated Clock Mode

Some system components such as ADCs and DACs utilize a SPI-compatible protocol for the interface. To communicate with such devices, the SPORT must support a gated clock, where the data valid information is embedded in the clock (for example, the clock only toggles when data is valid). This gated clock feature is enabled using the `SPORT_CTL_A.GCLKEN` bit.

To enable the gated clock mode of operation, program the SPORT to comply with the following requirements.

- Do not enable gated clock functionality in right-justified or multichannel mode
- Gated clock mode has the following requirements for other control bits:

  - The serial clock and frame sync signals must have the same source (SPORT_CTL_A.ICLK = SPORT_CTL_A.IFS)
  - Unframed mode is not supported (SPORT_CTL_A.FSR must be set)
  - Clear the SPORT_CTL_A.DIFS bit in transmit mode; set it in receive mode
- Satisfy the following necessary conditions when gated clock mode is enabled:
  - Seven serial clock cycles are required between enabling the SPORT and the first frame sync. If this requirement is not met, the SPORT can drop the first data (for subsequent data, this requirement is not applicable)
  - For externally-provided clock and frame sync, the frame sync must be inactive during clock synchronization after the SPORT has been enabled
  - For an edge-detected frame sync (SPORT_CTL_A.FSED = 1), the frame sync must transition back to the inactive state before the current word transfer is complete (or when the clock is still running). If this requirement is not met, the SPORT does not recognize the next valid frame sync and skips the channel. The SPORT continues to skip the frame syncs until the frame sync transitions back to an inactive state while the clock is active.

Data Transfers and Interrupts

SPORT data can be transferred to or from internal or external memory by two methods:

- Core-driven, single-word transfers
- DMA-driven, multiple-word transfers (optionally with multiple work units)

Core-driven transfers use SPORT interrupts to signal the processor core to perform MMR-based single-word transfers to or from the SPORT data buffers. DMA can be set up to automatically transfer a configurable number of serial words between the SPORT transmit/receive data buffers and memory, and then generate a data completion interrupt request when a work unit or a series of work units completes, thus signaling by the SEC to the processor core that a block of data has been transferred.

The following sections provide information on core-driven and DMA-driven data transfers.

Data Buffers

When programming the serial port data channels (primary or secondary) as a transmitter by setting SPORT_CTL_A.SPTRAN =1, only the corresponding transmit data buffers (SPORT_TXPRI_A and SPORT_TXSEC_A) become active. The receive data buffers (SPORT_RXPRI_A and SPORT_RXSEC_A) remain inactive. Similarly, when the SPORT data channels are programmed for receive operation (SPORT_CTL_A.SPTRAN =0), then only corresponding receive data buffers (SPORT_RXPRI_A and SPORT_RXSEC_A) are active. Do not attempt to read or write inactive data buffers. If the processor operates on the inactive transmit or receive buffers while the SPORT is enabled, unpredictable results can occur.

Each of these buffers is 32-bit wide (corresponds to maximum serial data word length). When using word lengths less than 32 bits for SPORT operation, the data in these buffers is automatically right-justified. (The LSB bit of data is at the bit 0 location of the buffer). The upper unused bits can be zero-filled or sign-extended depending on `SPORT_CTL_A.DTYPE` field.

Transmit Data Buffers (`SPORT_TXPRI_A` and `SPORT_TXSEC_A`)

When enabled as a transmitter (`SPORT_CTL_A.SPTRAN` =1), each SPORT half has its own set of transmit data buffers. The primary (0) and secondary (1) datapaths of each SPORT half have separate data buffers, referred to as `SPORT_TXPRI_A` and `SPORT_TXSEC_A` respectively.

These transmit data buffers are 32 bits wide. Load these buffers with the data for transmission on the primary and secondary data channels. The DMA controller loads the data automatically. Or, the program running on the processor core loads the data manually.

Together with the output shift register, transmit data buffers act like a two-location FIFO. If data packing is disabled (`SPORT_CTL_A.PACK` =0), the transmit path can hold as many as three data words. If data packing is enabled (`SPORT_CTL_A.PACK` =1), it can hold two packed data words at any given time.

When the transmit shift register becomes empty (transfer out all the bits of previous word), data in the transmit data buffer is automatically loaded into it. An interrupt occurs when the output transmit shift register has been loaded, signifying that the transmit data buffer is empty and ready to accept the next word. This interrupt does not occur when serial port is operating in DMA mode or when the corresponding interrupt enable mask bit is set.

If only the primary datapath of a SPORT half is enabled, programs must not write to the inactive secondary transmit data buffer and conversely. If the core keeps writing to the inactive buffer, the status of that transmit buffer becomes full. This state can cause the core to hang indefinitely, since data is never transmitted to the output shift register.

Receive Data Buffers (`SPORT_RXPRI_A` and `SPORT_RXSEC_A`)

When enabled as receiver (`SPORT_CTL_A.SPTRAN` =0), each SPORT half has its own set of receive data buffers. The primary (0) and secondary (1) datapaths of each SPORT half have separate data buffers, referred as `SPORT_RXPRI_A` and `SPORT_RXSEC_A` respectively. Together with input shift register, the receive data buffers act like a three-location FIFO, as the receive path has two data registers.

These receive data buffers are the 32 bits wide. These buffers are automatically loaded from the receive shift register when a complete word has been received into it. An interrupt occurs when the receive data buffer is loaded, signifying that new data is available in the receive data buffer and is ready to read. This interrupt does not occur when the serial port is operating in DMA mode or when the corresponding interrupt enable mask bit is set.

If only the primary datapath of a SPORT half is enabled, programs must not read from the inactive secondary receive data buffer and conversely. If the core keeps reading from the inactive buffer, the status of that receive buffer becomes empty. This state can cause the core to hang indefinitely since new data is never received through the input shift register.

Data Buffer Status

The SPORT provides status information about its primary and secondary data buffers through the `SPORT_CTL_A.DXSPRI` and `SPORT_CTL_A.DXSSEC` bits, respectively. It also provides error status information through the corresponding `SPORT_CTL_A.DERRPRI` and `SPORT_CTL_A.DERRSEC` bits, respectively. Depending on the `SPORT_CTL_A.SPTRAN` bit setting, these bits reflect the status of either the pair of transmit (`SPORT_TXPRI_A` and `SPORT_TXSEC_A`) or receive (`SPORT_RXPRI_A` and `SPORT_RXSEC_A`) buffers, indicating whether the buffer is full, partially full, or empty.

When attempting to read from an empty receive buffer or write to a full transmit buffer, the SPORT delays access until the buffer is ready, potentially resulting in excessive MMR bus response times. To avoid this when doing core-driven transfers, always check the buffer status to determine if the access can be made. The SPORT updates the status bits in the `SPORT_CTL_A` register during reads and writes by the core processor.

NOTE: These status bits are updated during reads and writes from the core processor even when the SPORT is disabled.

Two complete 32-bit words can be stored in the receive buffer while a third word shifts in. Therefore, almost three complete words can be received without the receive buffer being read before an overflow occurs. After receiving the third word completely, the shift register contents overwrite the second word, which will occur if the first word has not yet been read by the processor core or the DMA controller. This receive overflow condition is flagged through the error status bits of the `SPORT_CTL_A` register on the last bit of the third word.

Data Buffer Packing

When the SPORT is configured as a receiver with a serial data word length of 16 or less, the received data words can be packed into a 32-bit word. Similarly, if the SPORT is configured as a transmitter with a serial data word length of 16 or less, then 32-bit words being transmitted can be unpacked into 16-bit words. The `SPORT_CTL_A.PACK` bit is used to select this packing or unpacking feature.

When `SPORT_CTL_A.PACK` = 1, two consecutive received words are packed into a single 32-bit word, or each 32-bit word is unpacked and transmitted as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15–0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31–16. This packing method applies to both receive (packing) and transmit (unpacking) operations. In this case, the transmit and receive interrupt requests are generated for the 32-bit packed words, not for each 16-bit word.

NOTE: When 16-bit received data is packed into 32-bit words and stored in normal word space in the processor's internal memory, the 16-bit words can be read or written using short word space addressing.

Single-Word (Core) Transfers

The SPORTs can transmit or receive individual data words with interrupt requests occurring as each data word is transferred. When a SPORT is enabled with the corresponding DMA channel disabled, interrupt requests are generated when:

- a complete word has been received in the receive data buffer or

- the transmit data buffer is not full

When performing core transfers, be sure to access only those buffers that are associated with enabled datapaths, as governed by the transfer direction (`SPORT_CTL_A.SPTRAN`) bit and the primary/secondary (`SPORT_CTL_A.SPENPRI`/`SPORT_CTL_A.SPENSEC`) data enable bits. If inactive SPORT data buffers are read from or written to by the core while the SPORT is enabled, the core can hang. For example, if a half SPORT is programmed to be a transmitter and the core reads from one of the receive buffers associated with that half SPORT, the core can hang as if it were reading an empty buffer that is active and awaiting new data to arrive. Because this is a transmitting HSPORT, that data will never arrive, thus locking the core up until the SPORT is reset. To avoid such a situation, be sure to check the status of the appropriate data buffer before attempting a core access to it by interrogating the `SPORT_CTL_A.DXSPRI` or `SPORT_CTL_A.DXSSEC` status bits.

DMA Transfers

Direct memory access (DMA) provides a mechanism for transferring an entire block of serial data before an interrupt is generated. The processor's on-chip DMA controller automatically handles the DMA transfer, thus allowing the processor core to run in parallel until the entire block of data is transferred. When the interrupt request occurs, a service routine can then process the entire block of data (rather than react to single words), thus significantly reducing overhead.

Each half SPORT has a dedicated DMA channel that serves both the primary and secondary datapaths. When configured as a transmitter (`SPORT_CTL_A.SPTRAN` = 1) with both the primary and secondary datapaths enabled (`SPORT_CTL_A.SPENPRI` = `SPORT_CTL_A.SPENSEC` = 1), the DMA channel requires that the source DMA buffer interleave the data beginning with the primary channel, as it will alternately load to the primary and secondary transmit data buffers once it is enabled. The complementary operation is true in receive mode (`SPORT_CTL_A.SPTRAN` = 0) when both datapaths are enabled, as the DMA channel alternately reads from the primary and secondary receive data buffers and interleaves them in the destination DMA buffer. As such, software must de-interleave the data corresponding to the primary and secondary channels from the receive DMA buffer.

If the SPORT is configured in stereo mode, the same DMA channel handles both the left and right channels of both datapaths (primary and/or secondary). Therefore, for a transmit DMA with only one datapath enabled, the source buffer must be populated such that the left- and right-channel data is interleaved. If both datapaths are enabled, the DMA channel alternately loads to the primary and secondary transmit data buffers once it is enabled. As such, the interleaving requirement is for the primary left-channel data to be followed by the secondary left-channel data, then the primary right-channel data, and finally the secondary right-channel data. The complementary operation is true in receive mode, where the DMA channel alternately reads from the primary and secondary receive data buffers and interleave them in the destination DMA buffer. For the stereo modes of operation, the destination DMA buffer is interleaved as left-right data for a single data input. If both datapaths are enabled, the destination DMA buffer is written with the primary and secondary left-channel data followed by the primary and secondary right-channel data. As such, software must de-interleave the primary and secondary left- and right-channel data from the receive DMA buffer, as defined by this scheme.

Since both the primary and secondary datapaths share the single DMA channel, each half SPORT has a single interrupt request for data completion, as well as an error interrupt request. The DMA controller can generate an interrupt request at the end of a chain of DMA work units (when using multiple descriptors) or at the end of individual DMA work unit.

The SPORT DMA channels are assigned a higher priority than all the other DMA channels (for example, the SPI port). Having higher priority causes the SPORT DMA transfers to execute first when multiple DMA requests occur in the same cycle. The SPORT DMA channels are numbered and prioritized in the DMA channel list table in the DMA chapter.

Although the most efficient DMA transfers execute with 32-bit words, the SPORTs can handle word sizes from 4 to 32 bits (as defined by `SPORT_CTL_A.SLEN` field). If the serial data length is 16 bits or smaller, two pieces of data can be packed into 32-bit words for each DMA transfer, as selected by setting the `SPORT_CTL_A.PACK` bit. When this bit is set, the SPORT generates the transmit and receive interrupts for the 32-bit packed words, not for each 16-bit word. For more information, see the Data Buffer Status section.

NOTE: The SPORT DMA channel can access both internal memory and external memory of the processor without any core overhead.

Data Transfer Interrupt

Each half SPORT features a data transfer interrupt request that is shared by both the primary and secondary data channels in both transmit and receive modes. To determine the source of the data transfer interrupt request, applications can check the primary and secondary data buffer status bits (`SPORT_CTL_A.DXSPRI` and , `SPORT_CTL_A.DXSSEC` , respectively).

When using core-driven transfers, this interrupt's meaning depends on the direction of the SPORT:

- As transmitter (`SPORT_CTL_A.SPTRAN` = 1) - the transmit data buffer is empty
- As receiver (`SPORT_CTL_A.SPTRAN` = 0) - new data is available in the receive data buffer

NOTE: When data packing is enabled (`SPORT_CTL_A.PACK` = 1), the core-driven transmit and receive interrupt requests are generated for 32-bit packed words, not for each 16-bit word.

In both cases, the interrupt request can be used to signal the core that an individual transfer has completed. For transmit operations, it indicates that the transmit data buffer can be safely loaded (either the buffer is already empty or the last data has moved from the data buffer to the shift register). For receive operations, it indicates that new data has arrived and can be read (or must be read before a subsequent word overwrites it).

When the SPORT is configured to use DMA to move data between memory and the peripheral (the most generic way to use dedicated DMA for sport data transfers), the same data transfer interrupt request instead indicates the completion of the transfer of a block of serial data (rather than a single word). When DMA is used, the DMA count register must be initialized to specify the number of words to transfer. This count decrements after each DMA transfer on the channel, and the data transfer interrupt request signal is asserted when the word count reaches zero (for example, a DMA work unit has finished).

For transmit DMA, the interrupt request is raised when the last word in the DMA work unit is loaded from the source memory to the HSPORT FIFO. This interrupt request can signal to the core that a new DMA work unit can be configured or that other software threads can now run. The transmit interrupt request can optionally be deferred until the last word of the work unit has fully shifted out of the shift register (see the Transfer Finish Interrupt (TFI) section for details).

For receive DMA, the interrupt request is raised when the last word is loaded to the destination memory. In addition to that described for transmit DMA, this interrupt request also serves as an indication to the core that there is a buffer of newly acquired data that is ready to be processed.

See the DMA chapter for further details regarding enabling of the DMA interrupt requests associated with the various modes of DMA operation.

NOTE: As a single DMA channel services both the primary and secondary datapaths associated with the SPORT, there is a single DMA completion interrupt request.

Transfer Finish Interrupt (TFI)

When configured for transmit DMA (`SPORT_CTL_A.SPTRAN` =1), the data transfer interrupt request gets generated by the DMA engine itself when it decrements its count register upon loading the last element from memory to the HSPORT hardware. Alternately, the SPORT can use a Transmit Finish Interrupt (TFI) to signal the actual end of the transmission (for example, when the last bit of the last data word of the buffer has shifted out of the SPORT to the system) by setting the `SPORT_CTL_A.TFIEN` bit. When this bit is set, then DMA signal that would normally assert the data transfer interrupt request instead signals the SPORT that the DMA work unit is complete. The SPORT then waits until all the data in the FIFO is shifted out (including the transmit shift register) and asserts the TFI interrupt request upon completion.

NOTE: To enable this functionality in the DMA engine, be sure to configure the interrupt type field in the DMA configuration register for Peripheral interrupt. See the DMA chapter for further details.

Error Detection (Status) Interrupt

In addition to the dedicated data transfer interrupt request, each half SPORT also features an optional error status interrupt request that can be triggered when error conditions occur relative to data or frame syncs associated with the half SPORT.

Data-related errors depend on the direction of the SPORT and reflect overflow or underflow conditions, which are depicted in the `SPORT_CTL_A` control register as read-only sticky bits `SPORT_CTL_A.DERRPRI` and `SPORT_CTL_A.DERRSEC` (for the primary and secondary channels, respectively).

- When the SPORT is configured as a transmitter, these bits provide transmit data buffer underflow status. When the frame sync signal occurs when the transmit data buffer is empty, the underflow bit corresponding with the offending transmit data buffer is set, as the SPORT will transmit data whenever it detects a valid frame sync signal, whether new data is present or not.
- When the SPORT is configured as a receiver, these bits provide receive overflow status. When a channel receives new data while the receive buffer is already full, the new data overwrites the existing data, thus causing

an overflow. When this occurs, the overflow bit corresponding with the offending receive data buffer is set, as the SPORT receives data whenever it detects a valid frame sync signal, whether there is room in the receive buffer or not.

Each half SPORT also features an error register (SPORT_ERR_A), which is the source for the assertion of the described data-related error status bits. When a data-related error occurs on the primary or secondary datapaths, the error is logged in the SPORT_ERR_A.DERRPSTAT or SPORT_ERR_A.DERRSSTAT bits, respectively. To enable these status bits to generate the HSPORT status interrupt request in the SEC, the corresponding SPORT_ERR_A.DERRPMSK and SPORT_ERR_A.DERRSMSK bits must be set (for the primary and secondary datapaths, respectively).

The SPORT_CTL_A.DERRPRI and SPORT_CTL_A.DERRSEC channel error status bits are sticky read-only bits that can be cleared in two ways:

- Reset the error detection logic by disabling the channel associated with the error condition (clear the SPORT_CTL_A.SPENPRI or SPORT_CTL_A.SPENSEC control bit).
- Clear the source of the interrupt by writing-1-to-clear the SPORT_ERR_A.FSERRSTAT, SPORT_ERR_A.DERRPSTAT, or SPORT_ERR_A.DERRSSTAT status bits.

In addition to data-related errors, SPORT_ERR_A also tracks frame sync errors in the SPORT_ERR_A.FSERRSTAT status bit. Similar to the data-related errors, the frame sync error can be enabled as a source for raising the error status interrupt request via the SEC by setting the SPORT_ERR_A.FSERRMSK bit. A frame sync error occurs when the frame sync is detected prematurely, as explained in the Premature Frame Sync Error Detection section.

A frame sync error is not detected in the following cases:

- When there is no active transmit or receive data, and the frame sync pulse occurs due to noise on the input signal – if there is no active transfer, a noise-induced frame sync pulse is valid.
- If there is an active underflow or overflow error – frame sync errors cannot be detected because the SPORT error logic does not run after one of the data errors has occurred and remains unserviced.
- When the frame sync pulse doesn't meet minimum timing requirements – if the frame sync pulse is shorter than a SPORT clock period, there is no guarantee that it gets sampled at all and may go unnoticed.

SPORT Programming Model

The following sections provide programming guidance for setting up the SPORTs for use in an application:

- Initializing Core-Driven (Non-MCM) Transfers
- Initializing Multichannel Transfers
- Using DMA for SPORT Transfers
- Using Companding as a Function

Initializing Core-Driven (Non-MCM) Transfers

The following programming model applies to all of Standard DSP Serial Mode, I^{2}S Mode, Left-Justified Mode, and Right-Justified Mode for core-driven transfers. More steps are required to properly initialize the SEC to service the SPORT interrupts (see the SEC chapter for details).

NOTE: This example uses half SPORT A registers. With appropriate changes to register names, this example also applies to half SPORT B.

1. Clear the `SPORT_CTL_A` and `SPORT_MCTL_A` configuration registers.

   ADDITIONAL INFORMATION: Clearing these registers ensures that the SPORT logic (including the multichannel logic) is fully reset before attempting to reprogram it.

2. Optionally program the `SPORT_DIV_A` clock divisor register.

   ADDITIONAL INFORMATION: This step is only required for internally-generated timing signals. Configure the serial bit clock and/or frame sync (or L/R clock, for stereo modes) rates according to the guidance in the Serial Clock and Frame Sync sections.

3. Program the `SPORT_CTL_A` primary configuration register.

   ADDITIONAL INFORMATION: Set the SPORT operating mode along with the configurable clock, frame sync, word length, direction, and data format options (see the Operating Modes and Options section for details). Do not set the `SPORT_CTL_A.SPENPRI` and/or `SPORT_CTL_A.SPENSEC` buffer enable bits in this step.

4. Optionally program the `SPORT_CTL2_A` secondary configuration register.

   ADDITIONAL INFORMATION: This step is required only if internal multiplexing logic must be enabled to share clock and frame sync signals between a top SPORT module's A and B halves (see the Multiplexer Logic section for details).

5. Optionally program the `SPORT_ERR_A` error register.

   ADDITIONAL INFORMATION: This step is required only if a separate SPORT error interrupt is desired (see the Error Detection (Status) Interrupt section for details).

6. For Right-Justified mode only, program the `SPORT_MCTL_A.WOFFSET` field.

   ADDITIONAL INFORMATION: In Right-Justified mode, this field serves as the delay count (`DCNT`) required to align the LSB of each stereo channel with the L/R clock transition and must be programmed manually (see the Right-Justified Mode section for details).

7. Enable the primary/secondary datapath(s) in the `SPORT_CTL_A` register.

   ADDITIONAL INFORMATION: This should be performed in a read-modify-write operation setting the `SPORT_CTL_A.SPENPRI` and/or `SPORT_CTL_A.SPENSEC` bits, as appropriate.

8. Write data to be transmitted to the transmit buffer (`SPORT_TXPRI_A` and/or `SPORT_TXSEC_A`) *or* read data that has been received from the receive buffer (`SPORT_RXPRI_A` and/or `SPORT_RXSEC_A`).

   ADDITIONAL INFORMATION: These accesses are typically performed in the context of an interrupt service routine. See the SEC chapter for further information. Do not attempt to read or write inactive data buffers. If the core attempts to access inactive transmit or receive buffers while the SPORT is enabled, unpredictable results may occur.

Initializing Multichannel Transfers

When in Multichannel (TDM) Mode or Packed I^{2}S Mode, the SPORT is in a multichannel operational mode. Follow the steps below to properly initialize the SPORT for multichannel modes of operation. More steps are required to properly initialize the SEC to service the SPORT interrupts (see the SEC chapter for details).

NOTE: This example uses half SPORT A registers. With appropriate register changes, this example also applies to half SPORT B.

1. Clear the `SPORT_CTL_A` and `SPORT_MCTL_A` registers.

   ADDITIONAL INFORMATION: Clearing these registers ensures that the SPORT logic (including the multichannel logic) is fully reset before attempting to reprogram it.

2. Optionally program the `SPORT_DIV_A` clock divisor register.

   ADDITIONAL INFORMATION: This step is only required for internally-generated timing signals. Configure the serial bit clock and/or frame sync (or L/R clock, for stereo modes) rates according to the guidance in the Serial Clock and `SPORT_CTL2_A` sections.

3. Program the `SPORT_CS0_A` - `SPORT_CS3_A` channel select registers.

4. Program the `SPORT_MCTL_A` multichannel configuration register.

   ADDITIONAL INFORMATION: The SPORT supports many multichannel options. For more information, see the Multichannel (TDM) Mode section. Do not set the `SPORT_MCTL_A.MCE` enable bit in this step.

5. Program the `SPORT_CTL_A` primary configuration register.

   ADDITIONAL INFORMATION: Set the SPORT operating mode along with the configurable clock, frame sync, word length, direction, and data format options (see the Operating Modes and Options section for details). Do not set the `SPORT_CTL_A.SPENPRI` and/or `SPORT_CTL_A.SPENSEC` buffer enable bits in this step.

6. Optionally program the `SPORT_CTL2_A` secondary configuration register.

   ADDITIONAL INFORMATION: This step is required only if internal multiplexing logic must be enabled to share clock and frame sync signals between a top SPORT module's A and B halves (see the Multiplexer Logic section for details).

7. Optionally program the `SPORT_ERR_A` error register.

ADDITIONAL INFORMATION: This step is required only if a separate SPORT error interrupt request is desired (see the Error Detection (Status) Interrupt section for details).

8. Set the `SPORT_MCTL_A.MCE` bit to enable multichannel mode.
9. Enable the primary/secondary datapath(s) in the `SPORT_CTL_A` register.

   ADDITIONAL INFORMATION: This should be performed in a read-modify-write operation setting the `SPORT_CTL_A.SPENPRI` and/or `SPORT_CTL_A.SPENSEC` bits, as appropriate. DMA mode is recommended for multichannel modes of operation. For more information, see the Using DMA for SPORT Transfers programming model.

Using DMA for SPORT Transfers

DMA is supported in all SPORT operating modes (Standard DSP Serial Mode, I^{2}S Mode, Left-Justified Mode, Right-Justified Mode, Multichannel (TDM) Mode or Packed I^{2}S Mode). To enable DMA operation with the SPORT, execute the steps described in this section after initializing and enabling the SPORT. Instead of using the single word read or write operations described in the referenced programming models, the DMA engine automates accesses to the enabled SPORT data buffers.

NOTE: This example uses half SPORT A registers. With appropriate changes to register names, it also applies to half SPORT B.

1. Follow the guidance in the multichannel (Initializing Multichannel Transfers) or non-multichannel (Initializing Core-Driven (Non-MCM) Transfers) programming models to properly initialize and enable the SPORT hardware.
2. Prepare the data buffers in memory.

   ADDITIONAL INFORMATION: Ensure that the DMA buffer is defined according to the DMA Transfers section. For the multichannel modes of operation, be sure to also consider the setting of the `SPORT_MCTL_A.MCPDE` bit, as described in the Multichannel DMA Data Packing (MCPDE) section.
3. Initialize and enable the DMA channel allocated for the SPORT, as described in the Direct Memory Access (DMA) chapter.

Using Companding as a Function

The data in the transmit and receive buffers are actually companded in place. As such, the following programming model can be used to exercise the companding hardware without transferring data, which is useful for test/debug purposes.

NOTE: This example uses half SPORT A registers. With appropriate changes to register names, this example also applies to half SPORT B.

1. Configure the SPORT as a transmitter (`SPORT_CTL_A.SPTRAN`=1) with both the primary and secondary data channels disabled (`SPORT_CTL_A.SPENPRI`=0 and `SPORT_CTL_A.SPENSEC`=0).

2. Enable the desired companding scheme in the `SPORT_CTL_A.DTYPE` field.
3. Write a 32-bit word to one of the transmit buffers.
4. Wait two system clock cycles.

   ADDITIONAL INFORMATION: This delay is required to allow the SPORT companding hardware to reload the transmit buffer with the companded result. Any instructions that do not access the transmit buffer can be used to cause this delay.
5. Read the 8-bit compressed value from the transmit buffer written above.

To expand data in place, use the same sequence of operations with the receive buffer instead of the transmit buffer. When expanding data in this way, set the appropriate serial word length (`SPORT_CTL_A.SLEN`).

ADSP-SC58x SPORT Register Descriptions

Serial Port (SPORT) contains the following registers.

Table 34-14: ADSP-SC58x SPORT Register List

Name	Description
SPORT_CS0_A	Half SPORT 'A' Multichannel 0-31 Select Register
SPORT_CS0_B	Half SPORT 'B' Multichannel 0-31 Select Register
SPORT_CS1_A	Half SPORT 'A' Multichannel 32-63 Select Register
SPORT_CS1_B	Half SPORT 'B' Multichannel 32-63 Select Register
SPORT_CS2_A	Half SPORT 'A' Multichannel 64-95 Select Register
SPORT_CS2_B	Half SPORT 'B' Multichannel 64-95 Select Register
SPORT_CS3_A	Half SPORT 'A' Multichannel 96-127 Select Register
SPORT_CS3_B	Half SPORT 'B' Multichannel 96-127 Select Register
SPORT_CTL2_A	Half SPORT 'A' Control 2 Register
SPORT_CTL2_B	Half SPORT 'B' Control 2 Register
SPORT_CTL_A	Half SPORT 'A' Control Register
SPORT_CTL_B	Half SPORT 'B' Control Register

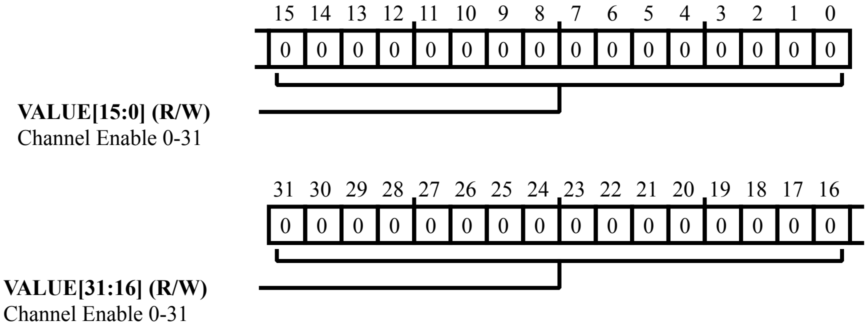
SPORT_DIV_B	Half SPORT 'B' Divisor Register
SPORT_ERR_A	Half SPORT 'A' Error Register
SPORT_ERR_B	Half SPORT 'B' Error Register
SPORT_MCTL_A	Half SPORT 'A' Multichannel Control Register
SPORT_MCTL_B	Half SPORT 'B' Multichannel Control Register
SPORT_MSTAT_A	Half SPORT 'A' Multichannel Status Register

Table 34-14: ADSP-SC58x SPORT Register List (Continued)

Name	Description
`SPORT_MSTAT_B`	Half SPORT 'B' Multichannel Status Register
`SPORT_RXPRI_A`	Half SPORT 'A' Rx Buffer (Primary) Register
`SPORT_RXPRI_B`	Half SPORT 'B' Rx Buffer (Primary) Register
`SPORT_RXSEC_A`	Half SPORT 'A' Rx Buffer (Secondary) Register
`SPORT_RXSEC_B`	Half SPORT 'B' Rx Buffer (Secondary) Register
`SPORT_TXPRI_A`	Half SPORT 'A' Tx Buffer (Primary) Register
`SPORT_TXPRI_B`	Half SPORT 'B' Tx Buffer (Primary) Register
`SPORT_TXSEC_A`	Half SPORT 'A' Tx Buffer (Secondary) Register
`SPORT_TXSEC_B`	Half SPORT 'B' Tx Buffer (Secondary) Register

Half SPORT 'A' Multichannel 0-31 Select Register

Each of the bits (when set, =1) of the `SPORT_CS0_A` register correspond to an active channel for the half SPORT in multichannel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register deactivates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Channel Enable 0-31.

Half SPORT 'B' Multichannel 0-31 Select Register

Each of the bits (when set, =1) of the `SPORT_CS0_B` register correspond to an active channel for the half SPORT in multichannel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register deactivates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).

1 (R/W)	CKMUXSEL	Clock Multiplexer Select. The SPORT_CTL2_B.CKMUXSEL bit enables multiplexing of the half SPORT' serial clock. In this mode, the serial clock of the related half SPORT is used instead of the half SPORT's own serial clock. For example, if the SPORT_CTL2_B.CKMUXSEL bit is enabled, half SPORT 'B' uses SPORT_ACLK instead of SPORT_BCLK.	
		0	Disable serial clock multiplexing
		1	Enable serial clock multiplexing
0 (R/W)	FSMUXSEL	Frame Sync Multiplexer Select. The SPORT_CTL2_B.FSMUXSEL bit enables multiplexing of the half SPORT' frame sync. In this mode, the frame sync of the related half SPORT is used instead of the half SPORT's own frame sync. For example, if the SPORT_CTL2_B.FSMUXSEL bit is enabled, half SPORT 'B' uses SPORT_AFS instead of SPORT_BFS.	
		0	Disable frame sync multiplexing
		1	Enable frame sync multiplexing

Half SPORT 'A' Control Register

The `SPORT_CTL_A` register contains transmit and receive control bits for SPORT half 'A', including serial port mode selection for the half SPORT's primary and secondary channels. The function of some bits in the `SPORT_CTL_A` register vary depending on the SPORT's operating mode. For more information, see the SPORT operating modes description. If reading reserved bits, the read value is the last written value to these bits or is the reset value of these bits.

Figure 34-23: SPORT_CTL_A Register Diagram

Table 34-25: SPORT_CTL_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:30 (R/NW)	DXSPRI	Data Transfer Buffer Status (Primary). The `SPORT_CTL_A.DXSPRI` bit field indicates the status of the half SPORT's primary channel data buffer.	
		0	Empty
		1	Reserved
		2	Partially full
		3	Full
29 (R/NW)	DERRPRI	Data Error Status (Primary). The `SPORT_CTL_A.DERRPRI` bit reports the half SPORT's primary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction. If the `SPORT_CTL_A.FSR` bit =1, the `SPORT_CTL_A.DERRPRI` bit indicates whether the `SPORT_AFS` signal (from an internal or external source) occurred while the `SPORT_TXPRI_A` data buffer was empty (during transmit) or the `SPORT_RXPRI_A` data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the `SPORT_AFS` signal. It is important to note that, as a receiver, the `SPORT_CTL_A.DERRPRI` bit indicates when the channel has received new data while the `SPORT_RXPRI_A` receive buffer is full. This new data overwrites existing data. If the `SPORT_CTL_A.FSR` bit =0, the `SPORT_CTL_A.DERRPRI` bit is set whenever the SPORT is required to transmit while the `SPORT_TXPRI_A` transmit buffer is empty. It is also set whenever the SPORT is required to receive while the `SPORT_RXPRI_A` receive buffer is full. The SPORT clears the `SPORT_CTL_A.DERRPRI` bit if the `SPORT_ERR_A.DERRPSTAT` bit is cleared.	
		0	No error
		1	Error (Tx underflow or Rx overflow)
28:27 (R/NW)	DXSSEC	Data Transfer Buffer Status (Secondary). The `SPORT_CTL_A.DXSSEC` bit field indicates the status of the half SPORT's secondary channel data buffer.	
		0	Empty
		1	Reserved
		2	Partially full
		3	Full

Table 34-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/NW)	DERRSEC	Data Error Status (Secondary). The `SPORT_CTL_A.DERRSEC` bit reports the half SPORT's secondary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction. If the `SPORT_CTL_A.FSR` bit =1, the `SPORT_CTL_A.DERRSEC` bit indicates whether the `SPORT_AFS` signal (from an internal or external source) occurred while the `SPORT_TXSEC_A` data buffer was empty (during transmit) or the `SPORT_RXSEC_A` data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the `SPORT_AFS` signal. It is important to note that, as a receiver, the `SPORT_CTL_A.DERRSEC` bit indicates when the channel has received new data while the `SPORT_RXSEC_A` receive buffer is full. This new data overwrites existing data. If the `SPORT_CTL_A.FSR` bit =0, the `SPORT_CTL_A.DERRSEC` bit is set whenever the SPORT is required to transmit while the `SPORT_TXSEC_A` transmit buffer is empty. It is also set whenever the SPORT is required to receive while the `SPORT_RXSEC_A` receive buffer is full. The SPORT clears the `SPORT_CTL_A.DERRSEC` bit if the `SPORT_ERR_A.DERRSSTAT` bit is cleared. 0 — No error 1 — Error (Tx underflow or Rx overflow)
25 (R/W)	SPTRAN	Serial Port Transfer Direction. The `SPORT_CTL_A.SPTRAN` bit selects the transfer direction (receive or transmit) for the half SPORT's primary and secondary channels. When the direction is receive, the half SPORT activates the receive buffers, and the `SPORT_ACLK` and `SPORT_AFS` pins control the receive buffers. The transmit buffers are inactive when the half SPORT's transfer direction is receive. When the direction is transmit, the half SPORT activates the transmit buffers, and the `SPORT_ACLK` and `SPORT_AFS` pins control the transmit shift registers. The receive buffers are inactive when the half SPORT's transfer direction is transmit. 0 — Receive 1 — Transmit
24 (R/W)	SPENSEC	Serial Port Enable (Secondary). The `SPORT_CTL_A.SPENSEC` bit enables the half SPORT's secondary channel. When this bit is cleared (changes from =1 to =0), the half SPORT automatically flushes the channel's data buffers. 0 — Disable 1 — Enable

Table 34-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	GCLKEN	Gated Clock Enable. The `SPORT_CTL_A.GCLKEN` bit enables gated clock operation for the half SPORT when in DSP serial mode or left-justified stereo modes (`SPORT_CTL_A.OPMODE` = 0 or 1). This bit is ignored when the half SPORT is in right-justified mode (`SPORT_CTL_A.RJUST` =1) or multichannel mode (`SPORT_MCTL_A.MCE` =1). When the `SPORT_CTL_A.GCLKEN` bit is enabled, the SPORT clock is active when the SPORT is transferring data or when the frame sync changes (transitions to active state).	
		0	Disable
		1	Enable
20 (R/W)	TFIEN	Transmit Finish Interrupt Enable. The `SPORT_CTL_A.TFIEN` bit selects when the half SPORT issues its transmission complete interrupt request, if a DMA complete interrupt request is enabled by the `DMA_CFG.INT` configuration. When enabled (`SPORT_CTL_A.TFIEN` =1), the DMA complete peripheral interrupt request is generated when the last bit of last word in the DMA is shifted out. When disabled (`SPORT_CTL_A.TFIEN` =0), the DMA interrupt request is generated when the DMA counter expires (the last word goes to the transmit buffer).	
		0	Last word sent (DMA count done) interrupt
		1	Last bit sent (Tx buffer done) interrupt
19 (R/W)	FSED	Frame Sync Edge Detect. The `SPORT_CTL_A.FSED` bit enables the half SPORT to start transmitting or receiving after detecting an active edge of an external frame sync. The `SPORT_CTL_A.FSED` bit may be enabled even during an active frame sync, and the half SPORT starts the transfer on the next valid rising or falling edge of external frame sync. If disabled (`SPORT_CTL_A.FSED` =0), the half SPORT operates in the standard level-sensitive detection mode for external frame sync.	
		0	Level detect frame sync
		1	Edge detect frame sync

Table 34-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	RJUST	Right-Justified Operation Mode. The `SPORT_CTL_A.RJUST` bit enables the half SPORT (if `SPORT_CTL_A.OPMODE` =1) to transfer data in right-justified operation mode. In this mode, the half SPORT aligns data to the end of the frame sync, rather than the start of the frame sync. When using right-justified mode, systems should program an appropriate delay count to introduce a clock delay before the half SPORT state machine starts to capture data. This value is set in the DCNT field (right-justified mode usage of the `SPORT_MCTL_A.WOFFSET` field). For information about appropriate delay selections, see the SPORT operating modes section.	
		0	Disable
		1	Enable
17 (R/W)	LAFS	Late Frame Sync / OPMODE2. When the half SPORT is in DSP standard mode (`SPORT_CTL_A.OPMODE` =0) or in right-justified mode (`SPORT_CTL_A.RJUST` =1), the `SPORT_CTL_A.LAFS` bit selects whether the half SPORT generates a late frame sync (`SPORT_AFS` during first data bit) or generates an early frame sync signal (`SPORT_AFS` during serial clock cycle before first data bit). When the half SPORT is in I^{2}S / left-justified mode (`SPORT_CTL_A.OPMODE` =1), the `SPORT_CTL_A.LAFS` bit acts as OPMODE2, selecting whether the half SPORT is in left-justified mode or I^{2}S mode. When the half SPORT is in multichannel mode (`SPORT_MCTL_A.MCE` =1), the `SPORT_CTL_A.LAFS` bit is reserved.	
		0	Early frame sync (or I^{2}S mode)
		1	Late frame sync (or left-justified mode)
16 (R/W)	LFS	Active-Low Frame Sync / L_FIRST / PLFS. When the half SPORT is in DSP standard mode and multichannel mode (`SPORT_CTL_A.OPMODE` =0), the `SPORT_CTL_A.LFS` bit selects whether the half SPORT uses active low or active high frame sync. When the half SPORT is in I^{2}S / packed / left-justified mode (`SPORT_CTL_A.OPMODE` =1), the `SPORT_CTL_A.LFS` bit acts as L_FIRST, selecting whether the half SPORT transfers data first for the left or right channel.	
		0	Active high frame sync (DSP standard mode) or rising edge frame sync (multichannel mode) or right channel first (I^{2}S/packed mode) or left channel first (left-justified mode)
		1	Active low frame sync (DSP standard mode) or falling edge frame sync (multichannel mode) or left channel first (I^{2}S/packed mode) or right channel first (left-justified mode)

Table 34-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	DIFS	Data-Independent Frame Sync. The `SPORT_CTL_A.DIFS` bit selects whether the half SPORT uses a data-independent or data-dependent frame sync. When using a data-independent frame sync, the half SPORT generates the sync at the interval selected by the `SPORT_DIV_A.FSDIV` bit. When using a data-dependent frame sync, the half SPORT generates the sync on the selected interval when the transmit buffer is not empty or when the receive buffer is not full. Note that the `SPORT_CTL_A.DIFS` bit is automatically set when the half SPORT is in packed or multichannel modes.	
		0	Data-dependent frame sync
		1	Data-independent frame sync
14 (R/W)	IFS	Internal Frame Sync. The `SPORT_CTL_A.IFS` bit selects whether the half SPORT uses an internal frame sync or uses an external frame sync. Note that the externally-generated frame sync does not need to be synchronous with the processor's system clock.	
		0	External frame sync
		1	Internal frame sync
13 (R/W)	FSR	Frame Sync Required. The `SPORT_CTL_A.FSR` bit selects whether or not the half SPORT requires frame sync for data transfer. This bit is automatically set when the half SPORT is in I^{2}S / packed / left-justified mode (`SPORT_CTL_A.OPMODE` =1) or is in multichannel mode (`SPORT_MCTL_A.MCE` =1).	
		0	No frame sync required
		1	Frame sync required
12 (R/W)	CKRE	Clock Rising Edge. The `SPORT_CTL_A.CKRE` bit selects the rising or falling edge of the `SPORT_ACLK` clock for the half SPORT to sample receive data and frame sync. Note that the half SPORT changes the state of transmit data and frame sync signals on the non-selected edge of the `SPORT_ACLK`. Also, note that the transmit and receive related SPORT halves (A and B) should be programmed with the same value for the `SPORT_CTL_A.CKRE` bit. This programming drives the internally-generated signals on one edge of `SPORT_ACLK` and samples the received signals on the opposite edge.	
		0	Clock falling edge
		1	Clock rising edge

Table 34-25: SPORT_CTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	OPMODE	Operation mode. The `SPORT_CTL_A.OPMODE` bit selects whether the half SPORT operates in DSP standard/multichannel mode or operates in I^{2}S/packed/left-justified mode. The mode selection affects the operation of the `SPORT_CTL_A.LAFS` and `SPORT_CTL_A.LFS` bits. Also, the `SPORT_CTL_A.OPMODE` bit enables or disables operation of the `SPORT_CTL_A.GCLKEN`, `SPORT_CTL_A.FSED`, `SPORT_CTL_A.RJUST`, `SPORT_CTL_A.DIFS`, `SPORT_CTL_A.FSR`, and `SPORT_CTL_A.CKRE` bits.	
		0	DSP standard/multichannel mode
		1	I^{2}S/packed/left-justified mode
10 (R/W)	ICLK	Internal Clock. When the half SPORT is in DSP standard mode (`SPORT_CTL_A.OPMODE` =0), the `SPORT_CTL_A.ICLK` bit selects whether the half SPORT uses an internal or external clock. For internal clock enabled, the half SPORT generates the `SPORT_ACLK` clock signal, and `SPORT_ACLK` is an output. The `SPORT_DIV_A.CLKDIV` serial clock divisor value determines the clock frequency. For internal clock disabled, the `SPORT_ACLK` clock signal is an input, and the serial clock divisor is ignored. Note that the externally-generated serial clock does not need to be synchronous with the processor's system clock.	
		0	External clock
		1	Internal clock
9 (R/W)	PACK	Packing Enable. The `SPORT_CTL_A.PACK` bit enables the half SPORT to perform 16- to 32-bit packing on received data and to perform 32- to 16-bit unpacking on transmitted data. The receive packing operation packs two successive received words into a single 32-bit word. The transmit unpacking operation unpacks each 32-bit word and transmits it as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15:0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31:16. This format applies to both receive (packing) and transmit (unpacking) operations. Companding may be used with word packing or unpacking. The half SPORT generates data transfer related interrupts when packing is enabled. The transmit and receive interrupts are generated for the 32-bit packed words, not for each 16-bit word.	
		0	Disable
		1	Enable

Half SPORT 'B' Control Register

The `SPORT_CTL_B` register contains transmit and receive control bits for SPORT half 'B', including serial port mode selection for the half SPORT's primary and secondary channels. The function of some bits in the `SPORT_CTL_B` register vary, depending on the SPORT's operating mode. For more information, see the SPORT operating modes description. If reading reserved bits, the read value is the last written value to these bits or is the reset value of these bits.

Figure 34-24: SPORT_CTL_B Register Diagram

Table 34-26: SPORT_CTL_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:30 (R/NW)	DXSPRI	Data Transfer Buffer Status (Primary). The `SPORT_CTL_B.DXSPRI` bit field indicates the status of the half SPORT's primary channel data buffer.	
		0	Empty
		1	Reserved
		2	Partially full
		3	Full
29 (R/NW)	DERRPRI	Data Error Status (Primary). The `SPORT_CTL_B.DERRPRI` bit reports the half SPORT's primary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction. If the `SPORT_CTL_B.FSR` bit =1, the `SPORT_CTL_B.DERRPRI` bit indicates whether the `SPORT_BFS` signal (from an internal or external source) occurred while the `SPORT_TXPRI_B` data buffer was empty (during transmit) or the `SPORT_RXPRI_B` data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the `SPORT_BFS` signal. It is important to note that, as a receiver, the `SPORT_CTL_B.DERRPRI` bit indicates when the channel has received new data while the `SPORT_RXPRI_B` receive buffer is full. This new data overwrites existing data. If the `SPORT_CTL_B.FSR` bit =0, the `SPORT_CTL_B.DERRPRI` bit is set whenever the SPORT is required to transmit while the `SPORT_TXPRI_B` transmit buffer is empty and is set whenever the SPORT is required to receive while the `SPORT_RXPRI_B` receive buffer is full. The SPORT clears the `SPORT_CTL_B.DERRPRI` bit if the `SPORT_ERR_B.DERRPSTAT` bit is cleared.	
		0	No error
		1	Error (Tx underflow or Rx overflow)
28:27 (R/NW)	DXSSEC	Data Transfer Buffer Status (Secondary). The `SPORT_CTL_B.DXSSEC` bit field indicates the status of the half SPORT's secondary channel data buffer.	
		0	Empty
		1	Reserved
		2	Partially full
		3	Full

Table 34-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/NW)	DERRSEC	Data Error Status (Secondary). The `SPORT_CTL_B.DERRSEC` bit reports the half SPORT's secondary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction. If the `SPORT_CTL_B.FSR` bit =1, the `SPORT_CTL_B.DERRSEC` bit indicates whether the `SPORT_BFS` signal (from an internal or external source) occurred while the `SPORT_TXSEC_B` data buffer was empty (during transmit) or the `SPORT_RXSEC_B` data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the `SPORT_BFS` signal. It is important to note that, as a receiver, the `SPORT_CTL_B.DERRSEC` bit indicates when the channel has received new data while the `SPORT_RXSEC_B` receive buffer is full. This new data overwrites existing data. If the `SPORT_CTL_B.FSR` bit =0, the `SPORT_CTL_B.DERRSEC` bit is set whenever the SPORT is required to transmit while the `SPORT_TXSEC_B` transmit buffer is empty. It is also set whenever the SPORT is required to receive while the `SPORT_RXSEC_B` receive buffer is full. The SPORT clears the `SPORT_CTL_B.DERRSEC` bit if the `SPORT_ERR_B.DERRSSTAT` bit is cleared. 0 No error 1 Error (Tx underflow or Rx overflow)
25 (R/W)	SPTRAN	Serial Port Transfer Direction. The `SPORT_CTL_B.SPTRAN` bit selects the transfer direction (receive or transmit) for the half SPORT's primary and secondary channels. When the direction is receive, the half SPORT activates the receive buffers, and the `SPORT_BCLK` and `SPORT_BFS` pins control the receive buffers. The transmit buffers are inactive when the half SPORT's transfer direction is receive. When the direction is transmit, the half SPORT activates the transmit buffers, and the `SPORT_BCLK` and `SPORT_BFS` pins control the transmit shift registers. The receive buffers are inactive when the half SPORT's transfer direction is transmit. 0 Receive 1 Transmit
24 (R/W)	SPENSEC	Serial Port Enable (Secondary). The `SPORT_CTL_B.SPENSEC` bit enables the half SPORT's secondary channel. When this bit is cleared (changes from =1 to =0), the half SPORT automatically flushes the channel's data buffers. 0 Disable 1 Enable

Table 34-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	GCLKEN	Gated Clock Enable. The `SPORT_CTL_B.GCLKEN` bit enables gated clock operation for the half SPORT when in DSP serial mode or left-justified stereo modes (`SPORT_CTL_B.OPMODE` = 0 or 1). This bit is ignored when the half SPORT is in right-justified mode (`SPORT_CTL_B.RJUST` =1) or multichannel mode (`SPORT_MCTL_B.MCE` =1). When `SPORT_CTL_B.GCLKEN` is enabled, the SPORT clock is active when the SPORT is transferring data or when the frame sync changes (transitions to active state).	
		0	Disable
		1	Enable
20 (R/W)	TFIEN	Transmit Finish Interrupt Enable. The `SPORT_CTL_B.TFIEN` bit selects when the half SPORT issues its transmission complete interrupt request, if a DMA complete interrupt request is enabled by the `DMA_CFG.INT` configuration. When enabled (`SPORT_CTL_B.TFIEN` =1), the DMA complete peripheral interrupt request is generated when the last bit of last word in the DMA is shifted out. When disabled (`SPORT_CTL_B.TFIEN` =0), the DMA interrupt request is generated when the DMA counter expires (the last word goes to the transmit buffer).	
		0	Last word sent (DMA count done) interrupt
		1	Last bit sent (Tx buffer done) interrupt
19 (R/W)	FSED	Frame Sync Edge Detect. The `SPORT_CTL_B.FSED` bit enables the half SPORT to start transmitting or receiving after detecting an active edge of an external frame sync. The `SPORT_CTL_B.FSED` may be enabled even during an active frame sync, and the half SPORT starts the transfer on the next valid rising or falling edge of external frame sync. If disabled (`SPORT_CTL_B.FSED` =0), the half SPORT operates in the standard level-sensitive detection mode for external frame sync.	
		0	Level detect frame sync
		1	Edge detect frame sync

Table 34-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	RJUST	Right-Justified Operation Mode. The `SPORT_CTL_B.RJUST` bit enables the half SPORT (if `SPORT_CTL_B.OPMODE` =1) to transfer data in right-justified operation mode. In this mode, the half SPORT aligns data to the end of the frame sync, rather than the start of the frame sync. When using right-justified mode, systems should program an appropriate delay count to introduce a clock delay before the half SPORT state machine starts to capture data. This value is set in the DCNT field (right-justified mode usage of the `SPORT_MCTL_B.WOFFSET` field). For information about appropriate delay selections, see the SPORT operating modes section.	
		0	Disable
		1	Enable
17 (R/W)	LAFS	Late Frame Sync / OPMODE2. When the half SPORT is in DSP standard mode (`SPORT_CTL_B.OPMODE` =0) or in right-justified mode (`SPORT_CTL_B.RJUST` =1), the `SPORT_CTL_B.LAFS` bit selects whether the half SPORT generates a late frame sync (`SPORT_BFS` during first data bit) or generates an early frame sync signal (`SPORT_BFS` during serial clock cycle before first data bit). When the half SPORT is in I^{2}S / left-justified mode (`SPORT_CTL_B.OPMODE` =1), the `SPORT_CTL_B.LAFS` bit acts as OPMODE2, selecting whether the half SPORT is in left-justified mode or I^{2}S mode. When the half SPORT is in multichannel mode (`SPORT_MCTL_B.MCE` =1), the `SPORT_CTL_B.LAFS` bit is reserved.	
		0	Early frame sync (or I^{2}S mode)
		1	Late frame sync (or left-justified mode)

Table 34-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	LFS	Active-Low Frame Sync / L_FIRST / PLFS. When the half SPORT is in DSP standard mode and multichannel mode (`SPORT_CTL_B.OPMODE` =0), the `SPORT_CTL_B.LFS` bit selects whether the half SPORT uses active low or active high frame sync. When the half SPORT is in I^{2}S / packed / left-justified mode (`SPORT_CTL_B.OPMODE` =1), the `SPORT_CTL_B.LFS` bit acts as L_FIRST, selecting whether the half SPORT transfers data first for the left or right channel.	
		0	Active high frame sync (DSP standard mode) or rising edge frame sync (multichannel mode) or right channel first (I^{2}S/packed mode) or left channel first (left-justified mode)
		1	Active low frame sync (DSP standard mode) or falling edge frame sync (multichannel mode) or left channel first (I^{2}S/packed mode) or right channel first (left-justified mode)
15 (R/W)	DIFS	Data-Independent Frame Sync. The `SPORT_CTL_B.DIFS` bit selects whether the half SPORT uses a data-independent or data-dependent frame sync. When using a data-independent frame sync, the half SPORT generates the sync at the interval selected by `SPORT_DIV_B.FSDIV`. When using a data-dependent frame sync, the half SPORT generates the sync on the selected interval when the transmit buffer is not empty or when the receive buffer is not full. Note that the `SPORT_CTL_B.DIFS` bit is automatically set when the half SPORT is in packed or multichannel modes.	
		0	Data-dependent frame sync
		1	Data-independent frame sync
14 (R/W)	IFS	Internal Frame Sync. The `SPORT_CTL_B.IFS` bit selects whether the half SPORT uses an internal frame sync or uses an external frame sync. Note that the externally-generated frame sync does not need to be synchronous with the processor's system clock.	
		0	External frame sync
		1	Internal frame sync

Table 34-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	FSR	Frame Sync Required. The `SPORT_CTL_B.FSR` selects whether or not the half SPORT requires frame sync for data transfer. This bit is automatically set when the half SPORT is in I^{2}S / packed / left-justified mode (`SPORT_CTL_B.OPMODE` =1) or is in multichannel mode (`SPORT_MCTL_B.MCE` =1).	
		0	No frame sync required
		1	Frame sync required
12 (R/W)	CKRE	Clock Rising Edge. The `SPORT_CTL_B.CKRE` selects the rising or falling edge of the `SPORT_BCLK` clock for the half SPORT to sample receive data and frame sync. Note that the half SPORT changes the state of transmit data and frame sync signals on the non-selected edge of the `SPORT_BCLK`. Also note that the transmit and receive related SPORT halves (A and B) should be programmed with the same value for `SPORT_CTL_B.CKRE`. This programming drives the internally-generated signals on one edge of `SPORT_BCLK` and samples the received signals on the opposite edge.	
		0	Clock falling edge
		1	Clock rising edge
11 (R/W)	OPMODE	Operation Mode. The `SPORT_CTL_B.OPMODE` bit selects whether the half SPORT operates in DSP standard / multichannel mode or operates in I^{2}S / packed / left-justified mode. The mode selection affects the operation of the `SPORT_CTL_B.LAFS` and `SPORT_CTL_B.LFS` bits. Also, the `SPORT_CTL_B.OPMODE` bit enables or disables operation of the `SPORT_CTL_B.GCLKEN`, `SPORT_CTL_B.FSED`, `SPORT_CTL_B.RJUST`, `SPORT_CTL_B.DIFS`, `SPORT_CTL_B.FSR`, and `SPORT_CTL_B.CKRE` bits.	
		0	DSP standard/multichannel mode
		1	I^{2}S/packed/left-justified mode
10 (R/W)	ICLK	Internal Clock. When the half SPORT is in DSP standard mode (`SPORT_CTL_B.OPMODE` =0), the `SPORT_CTL_B.ICLK` bit selects whether the half SPORT uses an internal or external clock. For internal clock enabled, the half SPORT generates the `SPORT_BCLK` clock signal, and the `SPORT_BCLK` is an output. The `SPORT_DIV_B.CLKDIV` serial clock divisor value determines the clock frequency. For internal clock disabled, the `SPORT_BCLK` clock signal is an input, and the serial clock divisor is ignored. Note that the externally-generated serial clock does not need to be synchronous with the processor's system clock.	
		0	External clock
		1	Internal clock

Table 34-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	PACK	Packing Enable. The `SPORT_CTL_B.PACK` bit enables the half SPORT to perform 16- to 32-bit packing on received data and to perform 32- to 16-bit unpacking on transmitted data. The receive packing operation packs two successive received words into a single 32-bit word. The transmit unpacking operation unpacks each 32-bit word and transmits it as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15:0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31:16. This format applies to both receive (packing) and transmit (unpacking) operations. Companding may be used with word packing or unpacking. The half SPORT generates data transfer related interrupts when packing is enabled. The transmit and receive interrupts are generated for the 32-bit packed words, not for each 16-bit word.	
		0	Disable
		1	Enable
8:4 (R/W)	SLEN	Serial Word Length. The `SPORT_CTL_B.SLEN` bits selects word length in bits for the half SPORT's data transfers. Word may be from 4- to 32-bits in length. The formula for selecting the word length in bits is: `SPORT_CTL_B.SLEN` = (serial word length in bits) - 1 For DSP standard mode (`SPORT_CTL_B.OPMODE` =0), use `SPORT_CTL_B.SLEN` of 3 to 31 bits. For I^{2}S / packed / left-justified mode (`SPORT_CTL_B.OPMODE` =1), use `SPORT_CTL_B.SLEN` of 4 to 31 bits.	
3 (R/W)	LSBF	Least-Significant Bit First. The `SPORT_CTL_B.LSBF` bit selects whether the half SPORT transmits or receives data LSB first or MSB first.	
		0	MSB first sent/received (big endian)
		1	LSB first sent/received (little endian)
2:1 (R/W)	DTYPE	Data Type. The `SPORT_CTL_B.DTYPE` bits selects the data type formatting for the half SPORT's data transfers in DSP standard mode (`SPORT_CTL_B.OPMODE` =0).	
		0	Right-justify data, zero-fill unused MSBs
		1	Right-justify data, sign-extend unused MSBs
		2	u-law compand data
		3	A-law compand data

Table 34-26: SPORT_CTL_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	SPENPRI	Serial Port Enable (Primary). The `SPORT_CTL_B.SPENPRI` bit enables the half SPORT's primary channel. When this bit is cleared (changes from =1 to =0), the half SPORT automatically flushes the channel's data buffers.	
		0	Disable
		1	Enable

Half SPORT 'A' Divisor Register

The SPORT_DIV_A register contains divisor values that determine frequencies of internally-generated clocks and frame syncs for half SPORT 'A'.

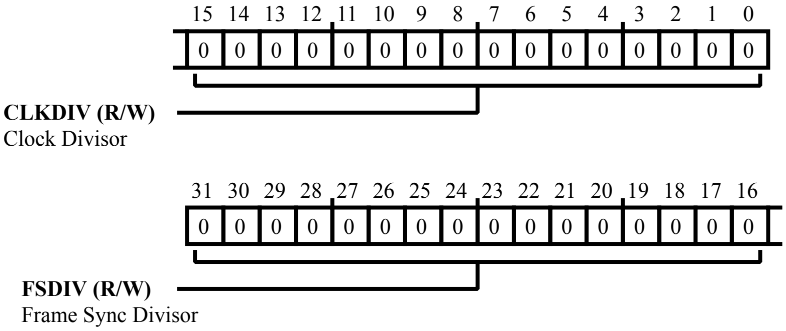

Figure 34-25: SPORT_DIV_A Register Diagram

Table 34-27: SPORT_DIV_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	FSDIV	Frame Sync Divisor. The `SPORT_DIV_A.FSDIV` bits select the number of transmit or receive clock cycles that the half SPORT counts before generating a frame sync pulse. The half SPORT counts serial clock cycles whether these are from an internally- or an externally-generated serial clock. The formula relating `SPORT_DIV_A.FSDIV` to the number of cycles between frame sync pulses is: `SPORT_DIV_A.FSDIV` = (number of serial clocks between frame syncs) - 1 Use the following equation to determine the value of `SPORT_DIV_A.FSDIV`, given the serial clock frequency and desired frame sync frequency: FSDIV = (`SPORT_ACLK` / `SPORT_AFS`) - 1 Note that the frame sync is continuously active when `SPORT_DIV_A.FSDIV` = 0. The value of `SPORT_DIV_A.FSDIV` should not be less than the serial word length (`SPORT_CTL_A.SLEN`), as this may cause an external device to abort the current operation or cause other unpredictable results.
15:0 (R/W)	CLKDIV	Clock Divisor. The `SPORT_DIV_A.CLKDIV` bits select the divisor that the half SPORT uses to calculate the serial clock (`SPORT_ACLK`) from the processor system clock (SCLK0_0). The divisor is a 16-bit value, allowing a wide range of serial clock rates. When configured for internal clock (`SPORT_CTL_A.ICLK` =1), legal `SPORT_DIV_A.CLKDIV` values are 0 to 65535. Given the processor system clock frequency and desired serial clock frequency, use the following formula to calculate the value of `SPORT_DIV_A.CLKDIV`: CLKDIV = (SCLK0_0 / `SPORT_ACLK`) - 1 For the maximum serial clock frequency, see the processor data sheet.

Half SPORT 'B' Divisor Register

The `SPORT_DIV_B` contains divisor values that determine frequencies of internally-generated clocks and frame syncs for SPORT half 'B'.

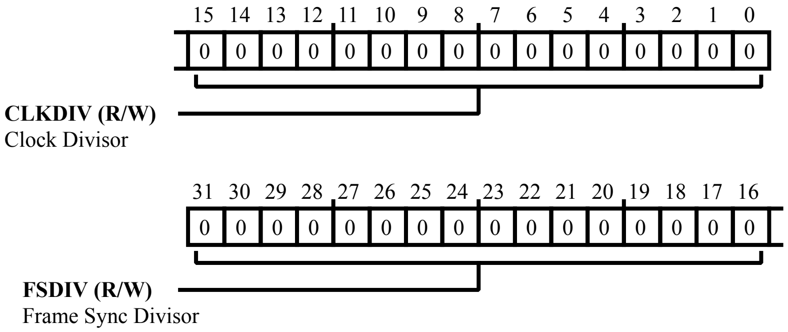

Figure 34-26: SPORT_DIV_B Register Diagram

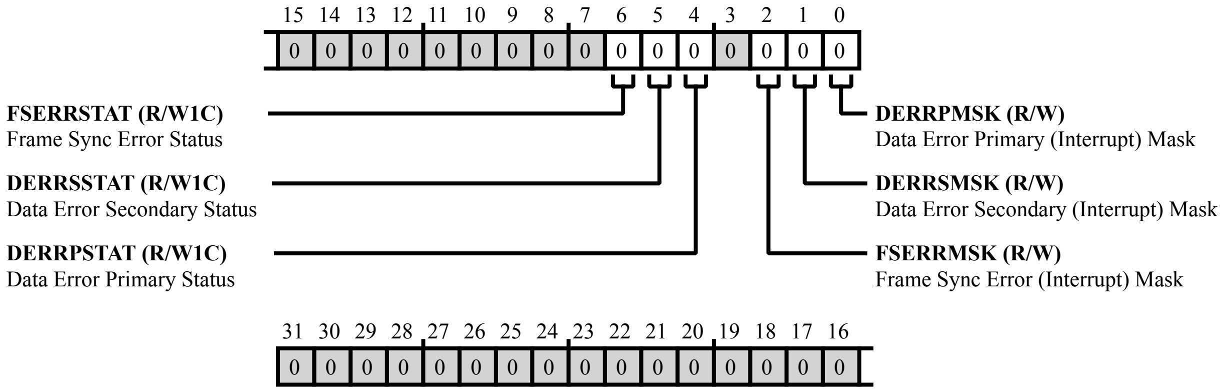
Table 34-28: SPORT_DIV_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	FSDIV	Frame Sync Divisor. The `SPORT_DIV_B.FSDIV` bits select the number of transmit or receive clock cycles that the half SPORT counts before generating a frame sync pulse. The half SPORT counts serial clock cycles whether these are from an internally- or an externally-generated serial clock. The formula relating `SPORT_DIV_B.FSDIV` to the number of cycles between frame sync pulses is: `SPORT_DIV_B.FSDIV` = (number of serial clocks between frame syncs) - 1 Use the following equation to determine the value of `SPORT_DIV_B.FSDIV`, given the serial clock frequency and desired frame sync frequency: FSDIV = (`SPORT_BCLK` / `SPORT_BFS`) - 1 Note that the frame sync is continuously active when `SPORT_DIV_B.FSDIV` = 0. The value of `SPORT_DIV_B.FSDIV` should not be less than the serial word length (`SPORT_CTL_B.SLEN`), as this may cause an external device to abort the current operation or cause other unpredictable results.
15:0 (R/W)	CLKDIV	Clock Divisor. The `SPORT_DIV_B.CLKDIV` bits select the divisor that the half SPORT uses to calculate the serial clock (`SPORT_BCLK`) from the processor system clock (SCLK0_0). The divisor is a 16-bit value, allowing a wide range of serial clock rates. When configured for internal clock (`SPORT_CTL_B.ICLK` =1), legal `SPORT_DIV_B.CLKDIV` values are 0 to 65535. Given the processor system clock frequency and desired serial clock frequency, use the following formula to calculate the value of `SPORT_DIV_B.CLKDIV`: CLKDIV = (SCLK0_0 `SPORT_BCLK`) - 1 For the maximum serial clock frequency, see the processor data sheet.

Half SPORT 'A' Error Register

The SPORT_ERR_A register contains error status and error interrupt mask bits for SPORT half 'A', including error handling bits for the half SPORT's primary and secondary channels and frame sync. Detected errors are frame sync violations or buffer over/underflow conditions.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 34-27: SPORT_ERR_A Register Diagram

Table 34-29: SPORT_ERR_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	FSERRSTAT	Frame Sync Error Status. The SPORT_ERR_A.FSERRSTAT bit indicates that the half SPORT has detected a frame sync when the bit count (bits remaining in the frame) is non-zero. When a half SPORT is receiving or transmitting, its bit count is set to a word length (for example, SPORT_CTL_A.SLEN = 31). After each serial clock edge, the half SPORT decrements the transfer's bit count. After the word is received or transmitted, the transfer's bit count reaches zero, and the half SPORT resets it (for example, to 32) on next frame sync. Normal SPORT data transfers always have a non-zero bit count value when active transmission or reception is occurring. Normal SPORT frame syncs occur after the bit count becomes zero.	
		0	No error
		1	Error (non-zero bit count at frame sync)

Table 34-29: SPORT_ERR_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1C)	DERRSSTAT	Data Error Secondary Status. The `SPORT_ERR_A.DERRSSTAT` bit indicates the error status for the half SPORT's secondary channel data buffers. During transmit (`SPORT_CTL_A.SPTRAN` =1), the `SPORT_ERR_A.DERRSSTAT` bit indicates the transmit underflow status. During receive (`SPORT_CTL_A.SPTRAN` =0), the `SPORT_ERR_A.DERRSSTAT` bit indicates the receive overflow status. This bit is used to clear the latch of SPORT status interrupt request when triggered by a secondary data error. This bit can also be used to clear the read-only `SPORT_CTL_A.DERRSEC` status bit.	
		0	No error
		1	Error (transmit underflow or receive overflow)
4 (R/W1C)	DERRPSTAT	Data Error Primary Status. The `SPORT_ERR_A.DERRPSTAT` bit indicates the error status for the half SPORT's primary channel data buffers. During transmit (`SPORT_CTL_A.SPTRAN` =1), the `SPORT_ERR_A.DERRPSTAT` bit indicates the transmit underflow status. During receive (`SPORT_CTL_A.SPTRAN` =0), the `SPORT_ERR_A.DERRPSTAT` bit indicates the receive overflow status. This bit is used to clear the latch of SPORT status interrupt request when triggered by a primary data error. This bit can also be used to clear the read-only `SPORT_CTL_A.DERRPRI` status bit.	
		0	No error
		1	Error (transmit underflow or receive overflow)
2 (R/W)	FSERRMSK	Frame Sync Error (Interrupt) Mask. The `SPORT_ERR_A.FSERRMSK` unmasks (enables) the half SPORT to generate the frame sync error interrupt request.	
		0	Mask (disable)
		1	Unmask (enable)
1 (R/W)	DERRSMSK	Data Error Secondary (Interrupt) Mask. The `SPORT_ERR_A.DERRSMSK` unmasks (enables) the half SPORT to generate the data error interrupt request for the secondary channel.	
		0	Mask (disable)
		1	Unmask (enable)
0 (R/W)	DERRPMSK	Data Error Primary (Interrupt) Mask. The `SPORT_ERR_A.DERRPMSK` unmasks (enables) the half SPORT to generate the data error interrupt request for the primary channel.	
		0	Mask (disable)
		1	Unmask (enable)

Half SPORT 'B' Error Register

The `SPORT_ERR_B` register contains error status and error interrupt mask bits for SPORT half 'B', including error handling bits for the half SPORT's primary and secondary channels and frame sync. Detected errors are frame sync violations or buffer over/underflow conditions.

Figure 34-28: SPORT_ERR_B Register Diagram

Table 34-30: SPORT_ERR_B Register Fields

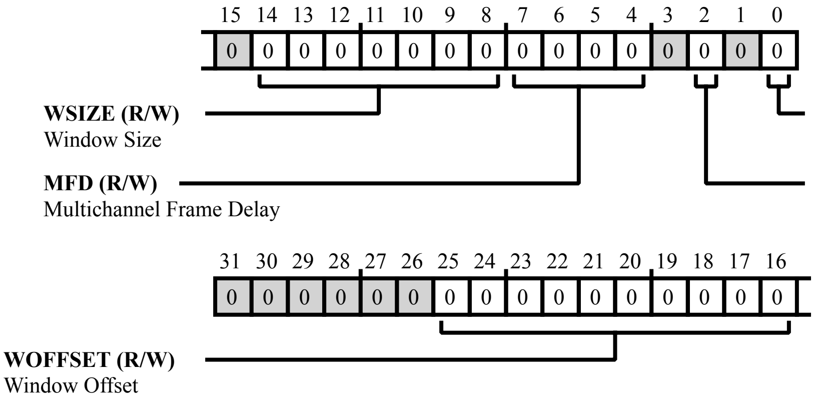
Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	FSERRSTAT	Frame Sync Error Status. The `SPORT_ERR_B.FSERRSTAT` bit indicates that the half SPORT has detected a frame sync when the bit count (bits remaining in the frame) is non-zero. When a half SPORT is receiving or transmitting, its bit count is set to a word length (for example, `SPORT_CTL_B.SLEN` = 31). After each serial clock edge, the half SPORT decrements the transfer's bit count. After the word is received or transmitted, the transfer's bit count reaches zero, and the half SPORT resets it (for example, to 32) on next frame sync. Normal SPORT data transfers always have a non-zero bit count value when active transmission or reception is occurring. Normal SPORT frame syncs occur after the bit count becomes zero.	
		0	No error
		1	Error (non-zero bit count at frame sync)

Table 34-30: SPORT_ERR_B Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1C)	DERRSSTAT	Data Error Secondary Status. The `SPORT_ERR_B.DERRSSTAT` bit indicates the error status for the half SPORT's secondary channel data buffers. During transmit (`SPORT_CTL_B.SPTRAN` =1), `SPORT_ERR_B.DERRSSTAT` indicates the transmit underflow status. During receive (`SPORT_CTL_B.SPTRAN` =0), `SPORT_ERR_B.DERRSSTAT` indicates the receive overflow status. This bit is used to clear the latch of SPORT status interrupt request when triggered by a secondary data error. This bit can also be used to clear the read-only `SPORT_CTL_B.DERRSEC` status bit.	
		0	No error
		1	Error (transmit underflow or receive overflow)
4 (R/W1C)	DERRPSTAT	Data Error Primary Status. The `SPORT_ERR_B.DERRPSTAT` bit indicates the error status for the half SPORT's primary channel data buffers. During transmit (`SPORT_CTL_B.SPTRAN` =1), the `SPORT_ERR_B.DERRPSTAT` bit indicates the transmit underflow status. During receive (`SPORT_CTL_B.SPTRAN` =0), the `SPORT_ERR_B.DERRPSTAT` bit indicates the receive overflow status. This bit is used to clear the latch of SPORT status interrupt request when triggered by a primary data error. This bit can also be used to clear the read-only `SPORT_CTL_B.DERRPRI` status bit.	
		0	No error
		1	Error (transmit underflow or receive overflow)
2 (R/W)	FSERRMSK	Frame Sync Error (Interrupt) Mask. The `SPORT_ERR_B.FSERRMSK` unmasks (enables) the half SPORT to generate the frame sync error interrupt request.	
		0	Mask (disable)
		1	Unmask (enable)
1 (R/W)	DERRSMSK	Data Error Secondary (Interrupt) Mask. The `SPORT_ERR_B.DERRSMSK` unmasks (enables) the half SPORT to generate the data error interrupt request for the secondary channel.	
		0	Mask (disable)
		1	Unmask (enable)
0 (R/W)	DERRPMSK	Data Error Primary (Interrupt) Mask. The `SPORT_ERR_B.DERRPMSK` unmasks (enables) the half SPORT to generate the data error interrupt request for the primary channel.	
		0	Mask (disable)
		1	Unmask (enable)

Half SPORT 'A' Multichannel Control Register

The `SPORT_MCTL_A` register controls the half SPORT's multichannel operations. This register enables multichannel operation, enables multichannel data packing, selects the multichannel frame delay, selects the number of multichannel slots, and selects the multichannel window offset size.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

MCE (R/W)
Multichannel enable
MCPDE (R/W)
Multichannel Packing DMA Enable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
WOFFSET (R/W)
Window Offset

Figure 34-29: SPORT_MCTL_A Register Diagram

Table 34-31: SPORT_MCTL_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/W)	WOFFSET	Window Offset. The `SPORT_MCTL_A.WOFFSET` bits select the start location for the half SPORT's active window of channels within the 1024-channel range. A value of 0 specifies no offset and 896 is the largest value that permits using all 128 channels. When multichannel mode is disabled (`SPORT_MCTL_A.MCE` =0) and the right-justified mode is enabled (`SPORT_CTL_A.RJUST` =1), the least significant 6 bits of `SPORT_MCTL_A.WOFFSET` serve as the delay count (DCNT) field. These bits introduce a clock delay before the half SPORT state machine starts to capture data. For information about appropriate delay selections, see the SPORT operating modes section.
14:8 (R/W)	WSIZE	Window Size. The `SPORT_MCTL_A.WSIZE` bits select the window size for the half SPORT's active window of channels. Use the following formula to calculate the window size value: `SPORT_MCTL_A.WSIZE` = (number of channel slots) -1
7:4 (R/W)	MFD	Multichannel Frame Delay. The `SPORT_MCTL_A.MFD` bits select the delay (in serial clock cycles) between the half SPORT's multichannel frame sync pulse and channel 0. The 4-bit field allows selecting multichannel frame delay of 0-15 serial clocks.

Table 34-31: SPORT_MCTL_A Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	MCPDE	Multichannel Packing DMA Enable. The `SPORT_MCTL_A.MCPDE` bit enables DMA data packing for transmit and enables DMA data unpacking for the half SPORT's multichannel data transfers.	
		0	Disable
		1	Enable
0 (R/W)	MCE	Multichannel enable. The `SPORT_MCTL_A.MCE` bit enables multichannel operations for the half SPORT. The half SPORT is configured in normal multichannel mode if `SPORT_CTL_A.OPMODE`=0; while it is configured in packed mode if `SPORT_CTL_A.OPMODE`=1. When configuring in these modes, the multichannel enable bit (`SPORT_MCTL_A.MCE`) should be set before enabling the SPORT data channel enable bits (`SPORT_CTL_A.SPENPRI` and/or `SPORT_CTL_A.SPENSEC`). When these channel bits transition from 1 to 0, note that the half SPORT's data transfer buffers are cleared, and the `SPORT_CTL_A.DERRPRI` and `SPORT_CTL_A.DERRSEC` bits are cleared.	
		0	Disable
		1	Enable

Half SPORT 'B' Multichannel Control Register

The `SPORT_MCTL_B` register controls the half SPORT's multichannel operations. This register enables multichannel operation, enables multichannel data packing, selects the multichannel frame delay, selects the number of multichannel slots, and selects the multichannel window offset size.

		0	Disable
		1	Enable
0 (R/W)	MCE	Multichannel Enable. The `SPORT_MCTL_B.MCE` bit enables multichannel operations for the half SPORT. The half SPORT is configured in normal multichannel mode if `SPORT_CTL_B.OPMODE`=0; while it is configured in packed mode if `SPORT_CTL_B.OPMODE`=1. When configuring in these modes, the multichannel enable bit (`SPORT_MCTL_B.MCE`) should be set before enabling SPORT data channel enable bits (`SPORT_CTL_B.SPENPRI` and/or `SPORT_CTL_B.SPENSEC`). When these channel bits transition from 1 to 0, note that the half SPORT's data transfer buffers are cleared, and the `SPORT_CTL_B.DERRPRI` and `SPORT_CTL_B.DERRSEC` bits are cleared.	
		0	Disable
		1	Enable

Half SPORT 'A' Multichannel Status Register

The `SPORT_MSTAT_A` register indicates the current multichannel being serviced among the half SPORT's active channels in multichannel mode. The half SPORT increments the value by one in this register as each channel is serviced. The value in the `SPORT_MSTAT_A` register restarts at 0 at each frame sync.

Half SPORT 'A' Rx Buffer (Primary) Register

The `SPORT_RXPRI_A` register buffers the half SPORT's primary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the primary channel. After a complete word has been received in the receive shifter, it is placed into the `SPORT_RXPRI_A` register. This data can be read in core mode (in interrupt-based or polling-based mechanism) or directly transferred into processor memory using the DMA controller. With a data buffer and an input shift register, the `SPORT_RXPRI_A` register acts as a two-location buffer. So, the SPORT can keep a maximum of two 32-bit received words at any given time (independent of the `SPORT_CTL_A.PACK` bit setting).

Note that changes to the half SPORT operation mode (for example, toggling the `SPORT_MCTL_A.MCE`) empty the contents of this data buffer. For more information, see the `SPORT_CTL_A` and `SPORT_MCTL_A` register descriptions.

Half SPORT 'B' Rx Buffer (Primary) Register

The SPORT_RXPRI_B register buffers the half SPORT's primary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the primary channel. After a complete word has been received in the receive shifter, it is placed into the SPORT_RXPRI_B register. This data can be read in core mode (in interrupt-based or polling-based mechanism) or directly transferred into processor memory using the DMA controller. With a data buffer and an input shift register, the SPORT_RXPRI_B register acts as a two-location buffer. So, the SPORT can keep a maximum of two 32-bit received words at any given time (independent of the SPORT_CTL_A.PACK bit setting).

Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_B.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_B and SPORT_MCTL_B register descriptions.

Half SPORT 'A' Rx Buffer (Secondary) Register

The SPORT_RXSEC_A register buffers the half SPORT's secondary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the secondary channel. After a complete word has been received in the receive shifter, it is placed into the SPORT_RXSEC_A register. This data can be read in core mode (in interrupt-based or polling-based mechanism) or directly transferred into processor memory using the DMA controller. With a data buffer and an input shift register, the SPORT_RXSEC_A register acts as a two-location buffer. So, the SPORT can keep a maximum of two 32-bit received words at any given time (independent of the SPORT_CTL_A.PACK bit setting).

For more information, see the SPORT_CTL_A and SPORT_MCTL_A register descriptions.

Half SPORT 'B' Rx Buffer (Secondary) Register

The `SPORT_RXSEC_B` register buffers the half SPORT's secondary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the secondary channel. After a complete word has been received in the receive shifter, it is placed into the `SPORT_RXSEC_B` register. This data can be read in core mode (in interrupt-based or polling-based mechanism) or directly transferred into processor memory using the DMA controller. With a data buffer and an input shift register, the `SPORT_RXSEC_B` register acts as a two-location buffer. So, the SPORT can keep a maximum of two 32-bit received words at any given time (independent of the `SPORT_CTL_A.PACK` bit setting).

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Receive Buffer (Secondary). The `SPORT_RXSEC_B.VALUE` bits hold the half SPORT's secondary channel receive data. Note that changes to the half SPORT operation mode (for example, toggling the `SPORT_MCTL_B.MCE`) empty the contents of this data buffer. For more information, see the `SPORT_CTL_B` and `SPORT_MCTL_B` register descriptions.

Half SPORT 'A' Tx Buffer (Primary) Register

The `SPORT_TXPRI_A` register buffers the half SPORT's primary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the primary channel. Either a program running on the processor core loads the data into the buffer (word-by-word process) or the DMA controller automatically loads the data into the buffer (DMA process).

The `SPORT_TXPRI_A` register acts as a three-location buffer if SPORT data packing is disabled (`SPORT_CTL_A.PACK` =0); while it acts as a two-location buffer when packing is enabled (`SPORT_CTL_A.PACK` =1). So, depending on the PACK bit setting, two 32-bit words or three 32-bit words can be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the `SPORT_TXPRI_A` register contents are automatically loaded into the output shifter. The half SPORT can issue an interrupt request (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt request does not occur when the half SPORT is executing a DMA-based transfer.

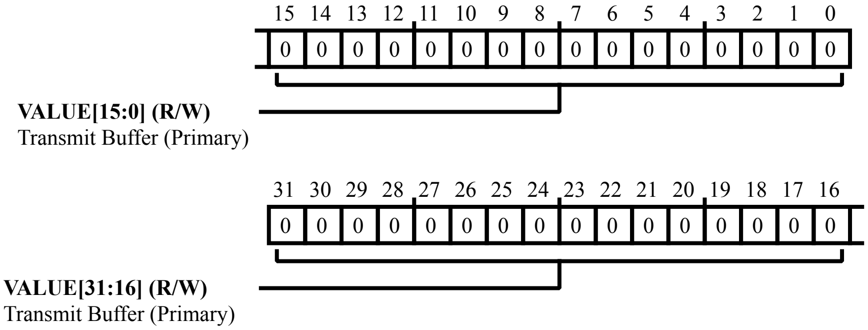

Figure 34-37: SPORT_TXPRI_A Register Diagram

Table 34-39: SPORT_TXPRI_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Transmit Buffer (Primary). The `SPORT_TXPRI_A.VALUE` bits hold the half SPORT's primary channel transmit data. Note that changes to the half SPORT operation mode (for example, toggling the `SPORT_MCTL_A.MCE`) empty the contents of this data buffer. For more information, see the `SPORT_CTL_A` and `SPORT_MCTL_A` register descriptions.

Half SPORT 'B' Tx Buffer (Primary) Register

The `SPORT_TXPRI_B` register buffers the half SPORT's primary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the primary channel. Either a program running on the processor core loads the data into the buffer (word-by-word process) or the DMA controller automatically loads the data into the buffer (DMA process).

The `SPORT_TXPRI_B` register acts as a three-location buffer if SPORT data packing is disabled (`SPORT_CTL_B.PACK` =0); while it acts as a two-location buffer when packing is enabled (`SPORT_CTL_B.PACK` =1). So, depending on the PACK bit setting, two 32-bit words or three 32-bit words can be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the `SPORT_TXPRI_B` register contents are automatically loaded into the output shifter. The half SPORT can issue an interrupt request (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt request does not occur when the half SPORT is executing a DMA-based transfer.

Table 34-40: SPORT_TXPRI_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Transmit Buffer (Primary). The `SPORT_TXPRI_B.VALUE` bits hold the half SPORT's primary channel transmit data. Note that changes to the half SPORT operation mode (for example, toggling the `SPORT_MCTL_B.MCE`) empty the contents of this data buffer. For more information, see the `SPORT_CTL_B` and `SPORT_MCTL_B` register descriptions.

Half SPORT 'A' Tx Buffer (Secondary) Register

The `SPORT_TXSEC_A` register buffers the half SPORT's secondary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the secondary channel. Either a program running on the processor core loads the data into the buffer (word-by-word process) or the DMA controller automatically loads the data into the buffer (DMA process).

The `SPORT_TXSEC_A` register acts as a three-location buffer if SPORT data packing is disabled (`SPORT_CTL_A.PACK` =0); while it acts as a two-location buffer when packing is enabled (`SPORT_CTL_A.PACK` =1). So, depending on the PACK bit setting, two 32-bit words or three 32-bit words can be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the `SPORT_TXSEC_A` register contents are automatically loaded into the output shifter. The half SPORT can issue an interrupt request (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt request does not occur when the half SPORT is executing a DMA-based transfer.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Transmit Buffer (Secondary). The `SPORT_TXSEC_B.VALUE` bits hold the half SPORT's secondary channel transmit data. Note that changes to the half SPORT operation mode (for example, toggling the `SPORT_MCTL_B.MCE`) empty the contents of this data buffer. For more information, see the SPORT_CTL_B and SPORT_MCTL_B register descriptions.

35 Precision Clock Generators (PCG)

The precision clock generators are used to produce a pair of signals from a clock input signal. The two signals generated are normally used as a serial bit clock and frame sync pair. The PCG is part of the DAI. There are two PCG signals in each DAI: *PCGA* and *PCGB* belong to DAI0, *PCGC* and *PCGD* belong to DAI1.

Features

The following list describes the features of the precision clock generators.

- SRU allows the routing of all of the PCG signals in one DAI (four PCG signals in DAI0 or DAI1)
- Input clock selection: SYS_CLKIN0 for PCG DAI0; SYS_CLKIN1 for PCG DAI1; SCLK0 for external DAI pins
- Provides four different clock dividers for serial clock, frame sync, phase (20-bit), and pulse width (16-bit)
- Phase shift allows adjustment of the frame sync relative to the serial clock and can be shifted the full period and wrapped around
- Provides pulse width control for arbitrary frame sync signal generation
- Bypass mode for external frame sync manipulation
- External trigger mode starts PCG operation
- No additional jitter is introduced when using off-chip clocks

Functional Description

The ***PCG Block Diagram*** shows the blocks within the module and its connection to the DAI. The following sections provide information on the function of these blocks.

PCG_SYNC2	Precision Clock Frame Sync Synchronization 2 Register

Internal Interface

The fundamental clock of the PCG is *SCLK0*. The clock to this module can be shut off for power savings.

Serial Clock

Each of the four units (A, B, C, and D) produces a clock output. Serial clock generation from a unit is independently enabled and controlled. Sources for the serial clock generation can be either from the *CLKIN*, *SCLK0*, or a DAI pin source. When CLKIN is chosen as input clock in PCG, the PCGs in DAI0 use `SYS_CLKIN0` and the PCGs in DAI1 use `SYS_CLKIN1`. The clock output is derived from the input to the PCG with a 20-bit divisor.

Note that the divider is working in normal mode for `PCG0_CTLx1.CLKDIV` > 1. For `PCG_CTLA1.CLKDIV`/`PCG_CTLB1.CLKDIV` = 0 or 1, the divider operates in bypass mode (input clock is fed directly to its output). In bypass mode, the clock at the output can theoretically run at up to the SCLK0 frequency. Check the data sheet for the specified maximum operation speed of the DAI pin buffers.

Note that the clock output is always set (as closely as possible) to a 50% duty cycle. If the clock divisor is even, the duty cycle of the clock output is exactly 50%. If the clock divisor is odd, then the duty cycle is slightly less than 50%. The low period of the output clock is one input clock period more than the high period of the output clock. For higher values of an odd divisor, the duty cycle is close to 50%.

NOTE: A PCG clock output cannot be fed to its own input.

Frame Sync

The following sections describe the use of frame syncs in the PCGs.

Frame Sync Output

Each of the four units (A through D) produces a synchronization signal for framing serial data. The frame sync outputs are much more flexible since they must accommodate the wide variety of serial protocols used by peripherals.

Frame sync generation from a unit is independently enabled and controlled. Sources for the frame sync generation can be either from the crystal buffer output, SCLK0, or an external pin source. There is only one external source pin for both frame sync and clock output for a unit.

If an external source is selected for both frame sync and clock output for a unit, then they operate on the same input signal. Apart from enable and source select control bits, a 20-bit divisor controls frame sync generation.

Divider Mode Selection

If a frame sync divisor is greater than 1, the PCG frame sync output frequency is equal to the input clock frequency, divided by a 20-bit integer. This integer is specified in the `PCG_CTLA0.FSDIV`/`PCG_CTLB0.FSDIV` bit field (bits 19:0).

However, if the frame sync divisor is 0 or 1, the PCG's frame sync clock generation unit is bypassed, and the frame sync input is connected directly to the frame sync output. For `PCG_CTLB0.FSDIV` =0, 1 the `PCG_PW1`/`PCG_PW2` registers function differently than in normal mode.

Phase Shift

Phase shift is a frame sync parameter that defines the phase shift of the frame sync relative to the input clock of the same unit. This feature allows the shifting of the frame sync signal in time relative to the clock input signal. Frame sync phase shifting is often required by peripherals that need a frame sync signal to lead or lag a clock signal.

For example, the I^2S protocol specifies that the frame sync transition from high-to-low occurs one clock cycle before the beginning of a frame. Since an I^2S frame is 64 clock cycles long, delaying the frame sync by 63 cycles produces the required framing.

Phase shifting is represented as a full 20-bit value. Even when the frame sync is divided by the maximum amount, the phase can be shifted to the full range, from zero to one input clock short of the period.

NOTE: Phase shifting is specified as a 2 x 10-bit divider value in the `PCG_CTLA0.FSPHASEHI` bit field (bits 29:20) and in the `PCG_CTLA1.FSPHASELO` bit field (bits 29:20).

A single 20-bit value spans these two-bit fields. The upper half of the word (bits 19:10) is in the `PCG_CTLA0` register, and the lower half (bits 9:0) is in the `PCG_CTLA1` register.

The phase shift between clock and frame sync outputs can be programmed using the `PCG_PW1`/`PCG_PW2` registers and all of the control registers under these conditions:

- The input clock source for the clock generator output and the frame sync generator output is the same.
- The clock and frame sync are enabled at the same time using a single atomic instruction.
- The frame sync divisor is an integral multiple of the clock divisor.

NOTE: When using a clock and frame sync as a synchronous pair, the units must be enabled in a single atomic instruction before their parameters are modified. Both units must also be disabled in a single atomic instruction.

NOTE: If the phase shift is 0 (see the ***Phase and Pulse Width Settings*** figure), the clock and frame sync outputs rise at the same time.

If the phase shift is 1, the frame sync output transitions one input clock period ahead of the clock transition.

If the phase shift is *divisor* – 1, the frame sync transitions *divisor* – 1 input clock periods ahead of the clock transitions.

Figure 35-2: Phase and Pulse Width Settings

NOTE: When generating single frame sync pulses (the length of one SPORT clock cycle), take care with respect to the drive and sampling edges. If the rules are violated, for example if the SPORT is not driving data, the module cannot detect a valid sample edge.

Pulse Width

Pulse width is the number of input clock periods for which the frame sync output is high.

A 16-bit value determines the width of the framing pulse. Settings for pulse width can range from zero to `DIV` - 1. The pulse width should be less than the divisor of the frame sync. The pulse width of frame sync is specified in the `PCG_PW1.FSA`, `PCG_PW1.FSB`, `PCG_PW2.FSC`, and `PCG_PW2.FSD` bits (15-0) and (31-16).

Default Pulse Width

If the pulse width count is equal to 0 and if the `PCG_CTLA0.FSDIV`/`PCG_CTLB0.FSDIV` bit field is even, then the actual pulse width of the frame sync output is equal to:

For even divisors: frame sync divisor/2

If the pulse width count is equal to 0 and if the `PCG_CTLA0.FSDIV`/`PCG_CTLB0.FSDIV` bit field is odd, then the actual pulse width of the frame sync output is equal to:

For odd divisors: frame sync divisor – 1/2

Input Clock Source Considerations

The core Phase-Locked Loop (PLL) has been designed to provide clocking for the processor core. The performance specifications of this PLL are appropriate for the core. But, they have not been optimized or specified for precision data converters where jitter directly translates into time quantization errors and distortion.

Therefore, the PCG allows the routing of external clock sources which are independent of the core PLL.

Timing Example for I^2S Mode

For I^2S mode, the frame sync should be driven at the falling edge of SPORT clock. In other words, the frame sync edge must coincide with the falling edge of the SPORT clock. To satisfy this requirement, program the phase of the frame sync accordingly in the PCG control registers.

For example, assume that the input clock source for both clock and frame sync are the same and both the clock and frame sync are enabled at the same time. Also, assume that the clock divisor value for generating the required SPORT clock is `PCG_CTLA1.CLKDIV` = 4. Then, for a 32-bit word length, the frame sync divisor value is:

`PCG_CTLA0.FSDIV` = 64, `PCG_CTLA1.CLKDIV` = 256.

By default, for phase = 0, the rising edge of both SPORT clock and frame sync coincide. To make sure that the frame sync edges coincide with the falling edge of the SPORT clock, program the phase value as:

`PCG_CTLA1.CLKDIV`/2 = 2.

Cross Mode Connections

The symmetric dual DAI architecture allows cross connections between both PCGs (A,B) and (C,D) to the other DAI. Each PCG (A through D) supports an alternative input clock (PCG0_EXTx_I) (see Figure 35-1 PCG Block Diagram) which can be sourced via a DAI pin buffer from the other DAI. Note however if routing a source (clock or FS) only DAI pin buffer 2 to 20 can be used (DAI pin buffer 1 is no longer available and is replaced by the DAI CRS buffer for the other DAI). See DAI Routing Capabilities for more information.

Operating Modes

The following sections provide information on the operating modes of the precision clock generator.

Normal Mode

When the frame sync divisor is set to any value other than zero or one, the PCGs operate in normal mode. In normal mode, the divisor determines the frequency of the frame sync output where:

Frequency of Frame Sync Output = Input Frequency/Divisor

The value of the pulse width control determines the high period of the frame sync output. The value of the pulse width control must be less than the value of the divisor.

The value of the phase control determines the phase of the frame sync output. If the phase is zero, then the positive edges of the clock and frame sync coincide when:

- the clock and frame sync dividers are enabled at the same time using an atomic instruction
- the divisors of the clock and frame sync are the same
- the source for the clock and frame sync is the same

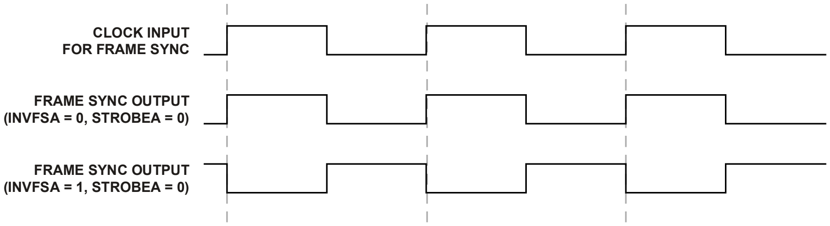
The number of input clock cycles that have already elapsed before the frame sync is enabled is equal to the difference between the divisor and the phase values. If the phase is a small fraction of the divisor, then the frame sync appears to lead the clock. If the phase is only slightly less than the frame sync divisor, then the frame sync appears to lag the clock. The frame sync phase must not be greater than the divisor.

Bypass Mode

When the frame sync divisor for the frame sync has a value of zero or one, the frame sync is in bypass mode, and the `PCG_PW1`/`PCG_PW2` registers have different functionality than in normal mode.

NOTE: In normal mode, bits 15:0 and 31:18 of the `PCG_PW1`/`PCG_PW2` registers are used to program the pulse width count. In bypass mode, bits 15:2 and 31:18 are ignored. Bits 1:0 and 17:16 are renamed to `PCG_PW1.STROBEA` and `PCG_PW1.INVFSA`, respectively. This functionality is described in more detail as follows.

If the `PCG_PW1.STROBEA` register is cleared, then the input is directly passed (see the ***Bypass and Inverted Bypass*** figure) to the frame sync output either inverted or not inverted, depending on the `PCG_PW1.INVFSA` bits.

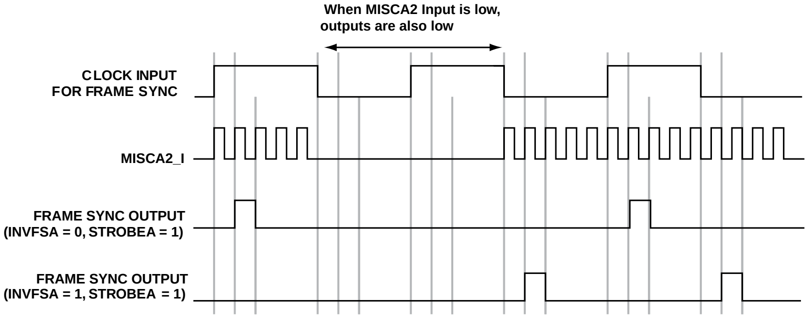


CLOCK INPUT
FOR FRAME SYNC
FRAME SYNC OUTPUT
(INVFSA = 0, STROBEA = 0)
FRAME SYNC OUTPUT
(INVFSA = 1, STROBEA = 0)

Figure 35-3: Bypass and Inverted Bypass

One-Shot Mode

In the one-shot mode operation shown in the ***One Shot Mode PCG A (MISCA2_I Input)*** figure, the PCG produces a series of periods but does not run continuously.



When MISCA2 Input is low,
outputs are also low
CLOCK INPUT

MISCA2_I
FRAME SYNC OUTPUT
(INVFSA = 0, STROBEA = 1)
FRAME SYNC OUTPUT
(INVFSA = 1, STROBEA = 1)

Figure 35-4: One Shot Mode PCG A (MISCA2_I Input)

Bypass mode also enables the generation of a strobe pulse (one-shot frame sync). Strobe usage ignores the divider counters and looks to the SRU to provide the input signal. Two-bit fields determine the operation in this mode.

In the bypass mode, if the `PCG_PW1.STROBEA` bit =1, then a one-shot pulse is generated. This one-shot pulse has the duration equal to the period of `DAI_MISCAx_I` for the PCGx unit. This pulse is generated either at the falling or rising edge of the input clock, depending on the value of the `PCG_PW1.INVFSA` bit. The output pulse width is equal to the period of the SRU source signal `DAI_MISCAx_I`. The pulse begins at the second rising edge of `MISCAx_I` following a rising edge of the clock input. When the `PCG_PW1.INVFSA` bit is set, the pulse begins at the second rising edge of `DAI_MISCAx_I` coinciding with or following a falling edge of the clock input.

NOTE: A strobe period is defined to be the period of the FS input clock signal as specified by the `PCG_CTLA1.FSSRC` bit.

PCG Event Control

The following sections describe the generation and control of PCG events.

External Event Trigger

The trigger with the external clock is enabled by setting bits 0 and 16 of the `PCG_SYNC1`/`PCG_SYNC2` registers .

Refer to the ***FS Output Synchronization With External Trigger Input*** figure. Since the rising edge of the external clock is used to synchronize with the frame sync, the frame sync output is not generated until a rising edge of the external clock is sensed.

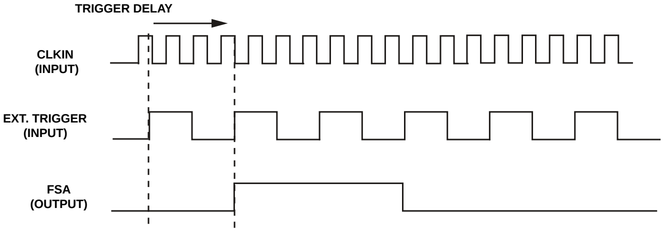

Figure 35-5: FS Output Synchronization With External Trigger Input

External Event Trigger Delay

The time delay between the rising trigger edge and the start of serial clock and frame sync varies between 2.5 to 3.5 input clock periods. If the input clock and the trigger signal are synchronous, the delay is 3 input clock periods. Consider the following cases:

- SCLK0 is the input source. In this case, if the given trigger event is synchronous to SCLK0, the delay is 3 SCLK0 periods. If the trigger signal is asynchronous with SCLK0, the delay varies from 2.5 SCLK0 periods to 3.5 SCLK0 periods. (It depends on whether the trigger edge occurs in the positive half cycle or negative half cycle of SCLK0.)
- The `SYS_CLKIN0` signal is the input source for PCG AB. The `SYS_CLKIN1` signal is the input source for PCG CD. In this case if the given trigger signal is synchronous to CLKIN, the delay is 3 CLKIN periods. But if they are asynchronous to CLKIN, the delay can vary between 2.5 CLKIN periods to 3.5 CLKIN periods.
- SRU DAI0 is the input source for PCG AB. SRU DAI1 is the input source for PCG CD. If the input clock and trigger signal are synchronous, the delay is exactly 3 input clock periods. If asynchronous, it varies between 2.5 to 3.5 input clock periods depending on the phase difference between the input clock and trigger signal.

Audio System Example

The *PCG Setup for I2S or Left-Justified DAI* figure shows an example of the interconnections between the S/PDIF receiver, ASRC, and the PCGs. The interconnections are made by programming the signal routing unit. It shows how to set up two precision clock generators using the S/PDIF receiver and an asynchronous sample rate converter (ASRC) to interface to an external audio DAC. The PCG is configured to provide a fixed ASRC/DAC output sample rate of 65.098 kHz. The input to the S/PDIF receiver is typically 44.1 kHz if supplied by a CD player, but can also be from other source at any nominal sample rates.

Similarly, the phase shift for frame syncs B, C, and D is specified in the corresponding control registers (`PCG_CTLA0` through `PCG_CTLB1`).

Figure 35-6: PCG Setup for I^2S or Left-Justified DAI

Three synchronous clocks are required in audio systems:

1. Frame sync (FS)
2. Serial bit clock (64 FS)
3. Master DAC clock (256 FS)

Since each PCG has only two outputs, this example requires two PCGs. Furthermore, because the digital audio interface requires a fixed-phase relation between serial clock and FS, these two outputs should come from one PCG (PCG A). The master clock comes from the second (PCG B).

The combined PCGs can provide a selection of synchronous clock frequencies to support alternate sample rates for the ASRCs and external DACs. However, the range of choices is limited by CLKIN and the ratio of `PCG_CLKx_O`: serial clock:*FS*. The ratio is normally fixed at 256:64:1 to support digital audio left-justified, I^2S and right-justified interface modes.

Many DACs also support 384, 512, and 786x FS for `PCG_CLKx_O`, which allows some additional flexibility in choosing serial clock.

Note that the falling edge of serial clock must always be synchronous with both edges of FS. This condition requires that the phase of the serial clock and FS signals for a common PCG (PCG A) be adjustable.

While the frequency of the master DAC clock (`PCG_CLKx_O`) must be synchronous with the sample rate supplied to the external DAC, there is no fixed-phase requirement.

Set the clock divisor and source and low-phase word first, followed by the control register enable bits, which are set together. When the `PCG_PW1`/`PCG_PW2` registers are set to zero (default), the FS pulse width is (divisor 2) for even divisors and (divisor - 1) 2 for odd divisors. Alternatively, the `PCG_PW1`/`PCG_PW2` registers can be set high for exactly one-half the period of CLKIN cycles for a 50% duty cycle, provided the FS divisor is an even number.

Clock Configuration Examples

For a CLKIN = 33.330 MHz, the two PCGs provide the three synchronous clocks PCGx_CLK, serial clock and *FS* for the SRCs and external DAC. These divisors are stored in the `PCG_CTLA1.CLKDIV`/`PCG_CTLB1.CLKDIV` bit fields.

The integer divisors for several possible sample rates based on 33.330 MHz *CLKIN* are shown in the ***Precision Clock Generator Division Ratios (33.330 CLKIN)*** table.

Table 35-2: Precision Clock Generator Division Ratios (33.330 CLKIN)

	PCG Divisors		FSDIV A[*1]
Sample Rate kHz)	CLKDIV B	CLKDIV A	
130.195	1	4	256
65.098	*2*	*8*	*512*
43.398	3	12	768
32.549	4	16	1024
26.039	5	20	1280
21.699	6	24	1536
18.599	7	28	1792

[*1] The frame sync divisor should be an even integer in order to produce a 50% duty cycle waveform. See Frame Sync

Programming Model

This section describes the sequence of software steps required for successful PCG operation.

If the PCG is disabled to reprogram a parameter, use a delay after writing to the disable bit. This delay in core clock (*CCLK*) cycles = (PCG source clock period/*CCLK* period). In summary, use the following general procedure:

1. Clear the PCG enable bits without modifying any other settings.
2. Wait for N *CCLK* cycles (N = PCG source clock period/processor clock period).
3. Program all new parameters without setting the PCG enable bit.
4. Enable the PCG.

Frame Sync Phase Setting

The phase unit requires that the clock and FS are enabled simultaneously in an atomic instruction.

1. Write the clock divider/low 10-bit phase divider to the `PCG_CTLA1`/`PCG_CTLB1` registers.
2. Program the FS divider/high 10-bit phase divider, enabling both the `PCG_CTLA0.CLKEN`/`PCG_CTLA0.FSEN` and the `PCG_CTLB0.CLKEN`/`PCG_CTLB0.FSEN` bits.

Note that both units must be disabled in the same way.

External Event Trigger

The trigger with the external clock is is enabled by setting bits 0 and 16 of the `PCG_SYNC` register. Program the phase to 3, so that the rising edge of the external clock is in-sync with the frame sync (***FS Output Synchronization With External Trigger Input***).

Use the following steps.

1. Program the `PCG_SYNC1`/`PCG_SYNC2` registers and the `PCG_CTLA0` through `PCG_CTLB1` registers appropriately.
2. Enable the clock or frame sync, or both.

Since the rising edge of the external clock is used to synchronize with the frame sync, the frame sync output is not generated until a rising edge of the external clock is sensed.

Debug Features

Take care in cases where any input to the phase unit is modified. Any individual change of the `PCG_CTLA1.CLKDIV` or `PCG_CTLA0.FSDIV` dividers can cause a failure in the PCG sync operation between the serial clock and the frame sync. Only the programming model ensures a correct setup for phase settings.

ADSP-SC58x PCG Register Descriptions

Precision Clock Generator (PCG) contains the following registers.

		1	Frame sync enabled

36 Asynchronous Sample Rate Converter (ASRC)

Sample rate converters (SRC) are frequently used in digital signal processing audio applications. The most frequently used sample rate conversions are off-loaded into hardware modules that are dedicated for filter processing and reduce the instruction processing load on the core, freeing it up for other tasks.

Features

The ASRC has these features and capabilities.

- 4 asynchronous stereo SRCs operating in slave mode are available in each DAI
- Simple programming model
- Controllable muting options (hardware, software and automatic)
- Automatically senses input and output sample frequencies
- Supports left-justified, I^2S, right-justified (16-,18-, 20-, 24-bits), and TDM serial port modes
- Daisy-chain configuration in TDM modes (including between DAI0 and DAI1) for input and output ports to create a serial frame
- Different protocols on input/output port allow format conversions
- De-emphasis filter for 32, 44.1 and 48 kHz sampling frequencies
- Up to 192 kHz sample rate input/output continuous sample ratios from 7.5:1 to 1:8
- Group delay (latency of interpolation filter) is 16 samples
- SNR from 128 to 140 dB (depending on processor model)
- Matched phase mode available to compensate for group delays
- Can be used to de-jitter clocks in systems

Functional Description

Conceptually, the sample rate converter interpolates the serial input data at a rate of 220 and samples the interpolated data stream by the output sample rate. In practice, a 64-tap FIR filter with 220 polyphases, a FIFO, a digital servo loop that measures the time difference between the input and output samples within 5 ps, and a digital circuit to track the sample rate ratio are used to perform the interpolation and output sampling.

ADSP-SC58x ASRC Register List

Sample Rate Converter Module

Table 36-1: ADSP-SC58x ASRC Register List

Name	Description
ASRC_CTL01	Control Register for ASRC 0 and 1
ASRC_CTL23	Control Register for ASRC 2 and 3
ASRC_MUTE	Mute Register
ASRC_RAT01	Ratio Register for ASRC 0 and 1
ASRC_RAT23	Ratio Register for ASRC 2 and 3

ASRC Interrupt List

The ASRC interrupts are controlled through the DAI.

Table 36-2: ASRC Interrupt List

Interrupt Name	Interrupt Condition	Return DAI Register	Return SEC Register	SEC ID
DAI0_IRQH	ASRC initialization	DAIx_IRPTL	SEC_ID	24
DAI1_IRQH	ASRC Sample rate change			25
DAI0_IRQL				145
DAI1_IRQL			146

SRU Programming

The SRU (signal routing unit) needs to be programmed in order to connect the ASRCs to the output pins or any other peripherals. For more information, see the Digital Audio Interface (DAI) chapter.

Clocking

The ASRC module is in the SCLK0 clock domain. An internal divided version of the SCLK0 clock is generated and used as the fundamental clock for the ASRC module.

I/O Ports

The I/O ports provide the interface through which data is transferred asynchronously into and out of the SRC modules. The SRC has a 3-wire interface for the serial input and output ports that supports left-justified, I^2S, and right-justified (16-, 18-, 20-, 24-bit) modes. Additionally, the serial interfaces support TDM mode for daisy-chaining multiple SRCs to form a frame. The serial output data is dithered down to 20, 18, or 16 bits when 20-, 18-, or 16-bit output data is selected.

NOTE: The SRC converts the data from the serial input port to the sample rate of the serial output port. The sample rate at the serial input port can be asynchronous with respect to the output sample rate of the output serial port.

De-Emphasis Filter

The de-emphasis filter is used to de-emphasize audio data that has been emphasized.

Mute Control

When either the SRC starts up (or there is a change in sample ratio), the mute out signal (`SRCx_MUTEOUT`) is asserted (=1). The mute out signal stays high until the SRC settles on the new sample rates. While mute out is asserted high, the mute in signal should be asserted high as well. The mute in signal performs a soft mute of the audio input data when asserted and un-mutes the input audio data softly when deasserted.

Note that it takes 4096 input port FS samples until the audio input data is completely muted and 4096 FS samples until the audio input data is completely unmuted.

SRC Core

As shown in the ***ASRC Core Architecture*** figure, the sample rate converter's RAM FIFO block adjusts the left and right input samples and stores them for the FIR filter's convolution cycle. The `ASRCx_FS_IP` counter provides the write address (for scaling) to the FIFO block and the ramp input to the digital-servo loop. The ROM stores the coefficients for the FIR filter convolution and performs a high-order interpolation between the stored coefficients. The sample rate ratio block measures the sample rate by dynamically altering the ROM coefficients and scaling the FIR filter length and input data. The digital-servo loop automatically tracks the `SRCx_FS_IP` and `SRCx_FS_OP` sample rates and provides the RAM and ROM start addresses for the start of the FIR filter convolution.

NOTE: Unlike other peripherals, the sample rate converters own local memories (RAM and ROM) which are dedicated for the purpose of sample rate conversion only.

The sample rate converter only operates asynchronously and is always a slave to the input and output ports.

RAM FIFO

The RAM FIFO receives the left and right input data and adjusts the amplitude of the data for both the soft muting of the SRC and the scaling of the input data by the sample rate ratio before storing the samples in RAM. The input data is scaled by the sample rate ratio because as the FIR filter length of the convolution increases, so does the amplitude of the convolution output. To keep the output of the FIR filter from saturating, the input data is scaled down by multiplying it by (`SRCx_FS_OP`)/(`SRCx_FS_IP`) when `SRCx_FS_OP<SRCx_FS_IP`. The FIFO also scales the input data to mute and stop muting the SRC.

Digital Servo Loop

The digital-servo loop is essentially a ramp filter that provides the initial pointer to the address in RAM and ROM for the start of the FIR convolution. The RAM pointer is the integer output of the ramp filter while the ROM pointer is the fractional part. The digital-servo loop must be able to provide excellent rejection of jitter on the `SRCx_FS_IP` and `SRCx_FS_OP` clocks as well as measure the arrival of the `SRCx_FS_OP` clock within 5 ps. The digital-servo loop also divides the fractional part of the ramp output by the ratio of (`SRCx_FS_IP`)/(`SRCx_FS_OP`) for the case when `SRCx_FS_IP`> `SRCx_FS_OP`, to dynamically alter the ROM coefficients.

The digital-servo loop is implemented with a multi-rate filter. To settle the digital-servo loop filter quickly at startup or at a change in the sample rate, a fast mode has been added to the filter. When the digital-servo loop starts up or the sample rate is changed, the digital-servo loop kicks into fast mode to adjust and settle on the new sample rate. Upon sensing the digital-servo loop settling down to some reasonable value, the digital-servo loop kicks into normal or slow mode. During fast mode, the `SRCx_MUTE_OUT` bit of the ASRC is asserted to mute the ASRC input which avoids clicks and pops.

FIR Filter

The FIR filter is a 64-tap filter in the case of `SRCx_FS_OP<SRCx_FS_IP` and is (`SRCx_FS_IP`)/(`SRCx_FS_OP`) × 64 taps for the case when `SRCx_FS_IP>SRCx_FS_OP`. The FIR filter performs its convolution by loading in the starting address of the RAM address pointer and the ROM address pointer from the digital-servo loop at the start of the `SRCx_FS_OP` period. The FIR filter then steps through the RAM by decrementing its address by 1 for each tap, and the ROM pointer increments its address by the (`SRCx_FS_OP/SRCx_FS_IP`) × 2^{20} ratio for `SRCx_FS_IP>SRCx_FS_OP` or 2^{20} for `SRCx_FS_OP <SRCx_FS_IP`. Once the ROM address rolls over, the convolution is complete. The convolution is performed for both the left and right channels, and the multiply/accumulate circuit used for the convolution is shared between the channels.

Sample Rate Sensing

The (`SRCx_FS_IP`)/(`SRCx_FS_OP`) sample rate ratio circuit is used to dynamically alter the coefficients in the ROM for the case when `SRCx_FS_IP>SRCx_FS_OP`. The ratio is calculated by comparing the output of an `SRCx_FS_OP` counter to the output of an `SRCx_FS_IP` counter. If `ASRCx_FS_OP>SRCx_FS_IP`, the ratio is held at one. If `SRCx_FS_IP>SRCx_FS_OP`, the sample rate ratio is updated if it is different by more than two `SRCx_FS_OP` periods from the previous `SRCx_FS_OP` to `SRCx_FS_IP` comparison. This is done to provide some hysteresis to prevent the filter length from oscillating and causing distortion.

Digital Filter Group Delay

The RAM in the FIFO is 512 words deep for both left and right channels. An offset of 16 samples to the write address, provided by the `SRCx_FS_IP` counter, is added to prevent the RAM read pointer from overlapping the write address. The maximum decimation rate can be calculated from the RAM word: depth = (512 – 16) ÷ 64 taps = 7.5:1.

The 64 samples effect latency in the interpolation filter. This latency (group delay) depends on interpolation or decimation ratio and is determined as follows:

Interpolation or Decimation Ratio (1): GDL = $16/f_{S\_IN} + 32/f_{S\_IN}$ seconds for `SRC_FS_OP` > `SRC_FS_IP`

Interpolation or Decimation Ratio (2): GDL = $16/f_{S\_IN} + 32/f_{S\_IN} \times f_{S\_IN}/f_{S\_OUT}$ seconds for `SRC_FS_OP` < `SRC_FS_IP`

Data Format

The ***ASRC Data Frame Format by Protocol*** figure shows the data input format for a frame (stereo data). The frame format is valid for all protocols. For models which do not support matched phase mode the 8-bit data field is ignored.

Figure 36-3: ASRC Data Frame Format by Protocol

Operating Modes

The ASRC can operate in TDM, I^2S, left-justified, right-justified, and bypass modes. The serial ports of the processor can be used for moving the ASRC data to/from the internal memory.

In I^2S, left-justified and right-justified modes, the ASRCs operate individually. The serial data provided in the input port is converted to the sample rate of the output port.

TDM Input Mode

In TDM input port, several ASRCs can be daisy-chained together and connected to the serial input port of a SHARC processor or other processor (see the ***TDM Input/Output Modes*** figure). The ASRC IP contains a 64-bit parallel load shift register. When the `SRCx_FS_IP_I` pulse arrives, each ASRC parallel loads its left and right data into the 64-bit shift register. The input to the shift register is connected to `SRCx_DATA_IP_I`, while the output is connected to `SRCx_TDM_IP_O`. By connecting the `SRCx_TDM_IP_O` to the `SRCx_DATA_IP_I` of the next ASRC, a large shift register is created, which is clocked by `SRCx_CLK_IP_I`.

NOTE: The number of ASRCs that can be daisy-chained together is limited by the maximum frequency of `SRCx_CLK_xx_I`, refer to the data sheet for exact values. For example, if the maximum frequency of `SRCx_CLK_xx_I` is *x* MHz, and the output sample rate is *fS*, then number of ASRCs (n) that can be connected in daisy chained fashion is: n 64 FS $\leq x$ MHz.

TDM Output Mode

As shown in the ***TDM Input/Output Modes*** figure, using the TDM output port several ASRCs can be daisy-chained together and connected to the SPORT of this or another processor. The ASRC OP contains a 64-bit parallel load shift register. When the `SRCx_FS_OP_I` pulse arrives, each ASRC loads its left and right data into the 64-bit shift register. The input to the shift register is connected to `SRCx_TDM_OP_I`, and the output is connected to

`SRCx_DAT_OP_O`. By connecting the `SRCx_DAT_OP_O` to the `SRCx_TDM_OP_I` of the next ASRC, a large shift register is created, which is clocked by `SRCx_CLK_OP_I`.

As shown in ***TDM Input/Output Modes***, with three ASRCs in a daisy-chain connection, the serial clock for input/or output port is defined as: SCLK = 3 × 64 FS = 192 FS.

Matched-Phase Mode

The matched-phase mode of the sample rate converter, shown in ***Typical Configuration for Matched-Phase Mode Operation***, is enabled by the `ASRC_CTL01.MPHASE0`, `ASRC_CTL01.MPHASE1`, `ASRC_CTL23.MPHASE2` and `ASRC_CTL23.MPHASE3` bits. This mode is used to match the phase (group delay) between two or more adjacent sample rate converters that are operating with the same input and output clocks.

Figure 36-5: Typical Configuration for Matched-Phase Mode Operation

Hysteresis of the (`SRCx_FS_OP`)/(`SRCx_FS_IP`) ratio circuit can cause phase mismatching between two ASRCs operating with the same input and output clocks. Since the hysteresis requires a difference of more than two `SRCx_FS_OP` periods to update the `SRCx_FS_OP` and `SRCx_FS_IP` ratios, two ASRCs may have differences in their ratios from 0 to 4 `SRCx_FS_OP` period counts. The (`SRCx_FS_OP`)/(`SRCx_FS_IP`) ratio adjusts the filter length of the ASRC, which corresponds directly with the group delay. Thus, the magnitude in the phase difference depends upon the resolution of the `SRCx_FS_OP` and `SRCx_FS_IP` counters. The greater the resolution of the counters, the smaller the phase difference error.

When the slave SRC matched-phase mode bit is set (=1), it accepts the sample rate ratio transmitted by another SRC, (the matched-phase master) which has its matched-phase mode bit cleared (=0), through its serial output.

The phase master ASRC device transmits its `SRCx_FS_OP`/`SRCx_FS_IP` ratio through the data output pin (`SRCx_DAT_OP_O`) to the slave's ASRC's data input pins (`SRCx_TDM_OP_I`). The transmitted data (32-bit subframe) contains 24-bit data and 8-bits matched phase (see the ***ASRC Data Frame Format by Protocol*** figure).

The slave SRCs receive the 8-bit matched phase bits (instead of their own internally-derived ratio) if their `SRCx_MPHASE` bits are set to 1, respectively. The `SRCx_FS_IP` and `SRCx_FS_OP` signals may be asynchronous with respect to each other in this mode. Note that there must be 64 `SRCx_CLK_OP` cycles per frame in matched-phase mode (two 24-bits data and two 8-bits phase match).

NOTE: By default, matched phased data is sent on the `SRCx_DAT_OP_O` pin, but only if the `SRCx_TDM_OP_I` pin is tied low. The slaves simply ignore the matched phased data if their `ASRC_CTL01.MPHASE1` through `ASRC_CTL23.MPHASE3` bits are cleared (= 0).

Bypass Mode

When the `ASRC_CTL01.BYP0`, `ASRC_CTL01.BYP1`, `ASRC_CTL23.BYP2` and `ASRC_CTL23.BYP3` bits are set (=1), the input data bypasses the sample rate converter and is sent directly to the serial output port. Dithering is disabled. This mode is ideal when the input and output sample rates are the same and the `SRCx_FS_IP_I` and `SRCx_FS_OP_I` signals are synchronous with respect to each other. In matched phase bypass mode, the `SRCx_FS_OP_I` signal should come at least one `SRCx_CLK_xx_I` period before `SRCx_FS_IP_I`. Cases where this is not met could result in data loss. For example, if internal SPORTS are used then the `SRCx_FS_OP_I` and `SRCx_FS_IP_I` signals could be driven by different SPORTs so that the timing of these signals can be controlled by enabling them at different times. This mode can also be used for passing through non-audio data since no processing is performed on the input data.

De-Emphasis Mode

The `ASRC_CTL01.DEEMPHASIS0`, `ASRC_CTL01.DEEMPHASIS1`, `ASRC_CTL23.DEEMPHASIS2` and `ASRC_CTL23.DEEMPHASIS3` bits choose the type of de-emphasis filter based on the input sample rate for 32, 44.1 or 48 kHz sampling rates.

Dithering Mode

The `ASRC_CTL01.DITHER0`, `ASRC_CTL01.DITHER1`, `ASRC_CTL23.DITHER2`, and `ASRC_CTL23.DITHER3` control this mode of operation. Serial output data is dithered down to 20, 18, or 16 bits when 20-, 18-, or 16-bit output data is selected. In the case of 20-, 18- and 16-bit word lengths, the least significant bits of the 24-bit word coming from the SRC into the serial output port are truncated. The `DITHER_EN` signal (not user configurable) automatically adds dithering to the 24-bit word before truncating to the appropriate output word length. The `21BIT_DITHER` signal is used for the consumer version of the SRC to reduce the dynamic range performance to approximately 128 dB.

NOTE: The ASRC can be programmed to add the triangular Probability Distribution Function (PDF) dither to the digital audio samples. It is advisable to add dither when the input word width exceeds the output word width, for example the input word is 20 bits and the output word is 16 bits. Triangular PDF is generally considered to create the most favorable noise shaping of the residual quantization noise.

Muting Modes

The mute feature of the ASRC can be controlled automatically in hardware using the `MUTE_IN` signal by connecting it to the `MUTE_OUT` signal. Automatic muting can be disabled by setting (=1) the `ASRC_MUTE.MUTE0` through `ASRC_MUTE.MUTE3` bits.

NOTE: Note that by default, the `ASRC_MUTE` register connects the `MUTE_IN` signal to the `MUTE_OUT` signal, but not conversely.

Soft Mute

When the `ASRC_CTL01.SOFTMUTE0`, `ASRC_CTL01.SOFTMUTE1`, `ASRC_CTL23.SOFTMUTE2` and `ASRC_CTL23.SOFTMUTE3` bits are set, the `MUTE_IN` signal is asserted, and the ASRC performs a soft mute by linearly decreasing the input data to the ASRC FIFO to zero, (-144 dB) attenuation as described for automatic hardware muting.

A 12-bit counter, clocked by `SRCx_FS_IP_I`, is used to control the mute attenuation. Therefore, the time it takes from the assertion of the `MUTE_IN` signal to -144 dB, full mute attenuation is 4096 FS cycles. Likewise, the time it takes to reach 0 dB mute attenuation from the deassertion of the `MUTE_IN` signal is 4096 FS cycles.

Hard Mute

When the `ASRC_CTL01.HARDMUTE0`, `ASRC_CTL01.HARDMUTE1`, `ASRC_CTL23.HARDMUTE2` and `ASRC_CTL23.HARDMUTE3` bits are set, the ASRC immediately mutes the input data to the ASRC FIFO to zero, (-144 dB) attenuation.

Auto Mute

When the `ASRC_CTL01.AUTOMUTE0`, `ASRC_CTL01.AUTOMUTE1`, `ASRC_CTL23.AUTOMUTE2` and `ASRC_CTL23.AUTOMUTE3` bits are set, the ASRC communicates with the S/PDIF receiver peripheral to determine when the input should mute.

This mode is useful for automatic detection of non-PCM audio data received from the S/PDIF receiver.

Interrupts

The following sections provide information about interrupt sources, masking and servicing.

Sources

Each ASRC module drives one interrupt signal (mute out asserted). All these signals are connected into the DAI_IRPTL_H or DAI_IRPTL_L latch registers. The ASRC ports generate interrupts as described below.

SRC Mute Out

The SRC mute out signal can be used to generate interrupts on their rising edge, falling edge, or both, depending on how the DAI interrupt mask registers (DAI_IMSK_RE/DAI_IMSK_FE) are programmed. This programming allows the generation of DAI_IRPTL_H/DAI_IRPTL_L interrupts either entering mute, exiting muting or both. The SRCx_MUTE_OUT interrupt is generated only once when the SRC is locked (after 4096 FS input samples) and after changes to the sample ratio. Hard mute, soft mute, and auto mute only control the muting of the input data to the SRC.

Masking

The DAI_IMSK_FE, DAI_IMSK_RE, and DAI_IMSK_PRI registers must be unmasked accordingly. The DAI_IRQH and DAI_IRQL signals are routed to the system event controller (SEC) and general interrupt controller (GIC).

Service

The ISR reads the DAI_IRPTL_H and DAI_IRPTL_L registers to clear the interrupt request.

Programming Model

The following is basic information on programming the ASRC module.

1. Program the ASRC_CTL01 and ASRC_CTL23 registers and keep the ASRC_CTL01.EN0 through ASRC_CTL23.EN3 bits cleared.
2. Set the ASRC_CTL01.EN0 through ASRC_CTL23.EN3 bits. After 4096 input port FS cycles the ASRC has un-muted.

Debug Features

The asynchronous sample rate converter allow the bypass mode. When the ASRC_CTL01.BYP0 through ASRC_CTL23.BYP3 bits are set (=1), the input data bypasses the sample rate converter and is sent directly to the serial output port. This mode can be used for testing both ports when the input and output sample rates are at the same frequency, therefore both input and output ports can be routed to the same serial clock and frame sync.

ADSP-SC58x ASRC Register Descriptions

Sample Rate Converter Module (ASRC) contains the following registers.

Table 36-3: ADSP-SC58x ASRC Register List

Name	Description
ASRC_CTL01	Control Register for ASRC 0 and 1
ASRC_CTL23	Control Register for ASRC 2 and 3

Table 36-4: ASRC_CTL01 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EN1	Enable SRC 1. The `ASRC_CTL01.EN1` bit enables SRC 1. When (set = 1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (144 dB). Note that SRC power-up completion is finished by clearing the `ASRC_RAT01.MUTEOUT1` bit. Writes to the `ASRC_CTL01` register should be at least one cycle before setting the `ASRC_CTL01.EN1` bit. When setting and clearing this bit, it should be held low for a minimum of 5 SCLK0_0 cycles.	
30 (R/W)	MPHASE1	Matched-phase Mode 1. The `ASRC_CTL01.MPHASE1` bit configures SRC1 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase slave disabled
		1	Matched phase slave enabled
29:28 (R/W)	LENOUT1	Length Output 1. The `ASRC_CTL01.LENOUT1` bit field selects the serial output word length on SRC1.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
27:26 (R/W)	SMODEOUT1	Serial Mode Output 1. The `ASRC_CTL01.SMODEOUT1` bit field selects the serial output format on SRC1.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
25 (R/W)	DITHER1	Dither Enable 1. The `ASRC_CTL01.DITHER1` bit enables dithering before truncation on SRC1 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 36-4: ASRC_CTL01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	SOFTMUTE1	Soft Mute 1. The `ASRC_CTL01.SOFTMUTE1` bit enables soft mute on SRC1.	
		0	Unmute
		1	Mute
23:22 (R/W)	DEEMPHASIS1	De-emphasize Audio 1. The `ASRC_CTL01.DEEMPHASIS1` bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
21 (R/W)	BYP1	Bypass 1. The `ASRC_CTL01.BYP1` bit makes the output of SRC1 the same as the input.	
20:18 (R/W)	SMODEIN1	Serial Mode Input 1. The `ASRC_CTL01.SMODEIN1` bit field selects the serial input format for SRC1.

Figure 36-7: ASRC_CTL23 Register Diagram

Table 36-5: ASRC_CTL23 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EN3	Enable SRC 3. The `ASRC_CTL23.EN3` bit enables SRC 3. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (144 dB). Note that SRC power-up completion is finished by clearing the `ASRC_RAT23.MUTEOUT3` bit. Writes to the `ASRC_CTL23` register should be at least one cycle before setting the `ASRC_CTL23.EN3` bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
30 (R/W)	MPHASE3	Matched-phase Mode 3. The `ASRC_CTL23.MPHASE3` bit configures SRC3 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase slave disabled
		1	Matched phase slave enabled
29:28 (R/W)	LENOUT3	Length Output 3. The `ASRC_CTL23.LENOUT3` bit field selects the serial output word length on SRC3.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
27:26 (R/W)	SMODEOUT3	Serial Mode Output 3. The `ASRC_CTL23.SMODEOUT3` bit field selects the serial output format on SRC3.

Mute Register

This register connects an ASRCx mute input and output when the mute bit is cleared (=0). This allows ASRCx to automatically mute input while the ASRC is initializing (0 = automatic muting and 1 = manual muting). Bit 0 controls ASRC0, bit 1 controls ASRC1, bit 2 controls ASRC2, and bit 3 controls ASRC3.

Figure 36-9: ASRC_RAT01 Register Diagram

Table 36-7: ASRC_RAT01 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MUTEOUT1	Mute Status for ASRC1. The `ASRC_RAT01.MUTEOUT1` bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC1 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loops internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.
30:16 (R/NW)	RATIO1	Sampling Ratio of Frame Syncs for ASRC1. The `ASRC_RAT01.RATIO1` bit field is read to find the ratio of output to input sampling frequency for ASRC1 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.
15 (R/NW)	MUTEOUT0	Mute Status for ASRC0. The `ASRC_RAT01.MUTEOUT0` bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC0 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loops internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/NW)	RATIO2	Sampling Ratio of Frame Syncs for ASRC2. The `ASRC_RAT23.RATIO2` bit field is read to find the ratio of output to input sampling frequency for ASRC2 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.

37 Sony/Philips Digital Interface (S/PDIF)

The Sony/Philips Digital Interface (S/PDIF) is a standard audio data transfer format that allows the transfer of digital audio signals from one device to another without having to convert them to an analog signal. The digital audio interface carries three types of information; audio data, non audio data (compressed data) and timing information.

Features

The S/PDIF interface has the following features.

- Supports one stereo channel or compressed audio streams.
- AES3-compatible S/PDIF transmitter and receiver.
- Transmitting a biphase mark encoded signal that may contain any number of audio channels (compressed or linear pulse code modulation) or non-audio data.
- S/PDIF receiver managing clock recovery with separate S/PDIF on-chip PLL.
- S/PDIF receiver supports the detection of DTS frames of 256, 512, 1024, 2048, and 4096.
- Manage user status information and provide error-handling capabilities in both the transmitter and receiver.
- DAI allows interactions over DAI by serial ports and the external DAI pins to interface to other S/PDIF devices. This includes using the receiver to decode incoming biphase encoded audio streams and passing them via the SPORTs to internal memory for processing-or using the transmitter to encode audio or digital data and transfer it to another S/PDIF receiver in the audio system.

It is important to be familiar with serial digital audio interface standards IEC-60958, EIAJ CP-340, AES3 and AES11.

ADSP-SC58x SPDIF Register List

The S/PDIF module is a standard audio data transfer format that allows the transfer of digital audio signals from one device to another without having to convert them to an analog signal. A set of registers govern S/PDIF operations. For more information on S/PDIF functionality, see the S/PDIF register descriptions.

Table 37-1: ADSP-SC58x SPDIF Register List

Name	Description

Table 37-1: ADSP-SC58x SPDIF Register List (Continued)

Name	Description
SPDIF_TX_USRUPDT	User Bit Update Register

SRU Programming

The SRU (signal routing unit) is used to connect the S/PDIF transmitter biphase data out to the output pins or to the S/PDIF receiver. The serial clock, frame sync, data, and external sync (if external synchronization is required) inputs also need to be routed through the SRU. For details of the routing, see the DAI Routing Capabilities section in the *Digital Audio Interface (DAI)* chapter.

The SRU needs to be programmed in order to connect the S/PDIF receiver to the output pins or any other peripherals and also for the connection to the input biphase stream.

Program the corresponding SRU registers to connect the outputs to the required destinations (see the DAI Routing Capabilities section). The biphase encoded data and the external PLL clock inputs to the receiver are routed through the SRU. The extracted clock, frame sync, and data are also routed through the SRU.

S/PDIF Interrupt List

Table 37-2: S/PDIF Interrupt List

Interrupt Name	Interrupt Condition	Return DAI Register	Return SEC Register	SEC ID
DAI0_IRQH	Block Start	DAIx_IRPTL	SEC_ID	24
DAI1_IRQH	Validity			25
DAI0_IRQL	Non Audio			145
DAI1_IRQL	Locked/Loss of Lock			146

Clocking

The module clock of the S/PDIF transceiver is SCLK0_0. The clock source for the S/PDIF receiver reference clock is CLKO5 from the CDU. When CLKO5 is configured, it supports sampling frequencies of 24 kHz to 192 kHz. The clock to this module may be shut off for power savings.

Sample rates of 24 kHz to 96 kHz are supported using a 170 MHz to 180 MHz setting on CLKO5.

Sample rates of 32 kHz to 192 kHz are supported using a 225.0 MHz setting on CLKO5.

For information on clock programming, see CDU Programming Model.

S/PDIF Transmitter

The following sections provide information on the S/PDIF transmitter.

Functional Description

The S/PDIF transmitter, shown in the ***S/PDIF Transmitter Block Diagram***, resides within the DAI, and its inputs and outputs can be routed via the SRU. It receives audio data in serial format, encloses the specified user status information, and converts it into the biphase encoded signal. The serial data input to the transmitter can be formatted as left-justified, I^{2}S, or right-justified with word widths of 16, 18, 20 or 24 bits. ***AES3 Output Block*** shows the detail of the AES block.

The serial data, clock, and frame sync inputs to the S/PDIF transmitter are routed through the signal routing unit (SRU).

The S/PDIF transmitter output may be routed to an output pin via the SRU and then routed to another S/PDIF receiver or to components for off-board connections to other S/PDIF receivers. The output is also available to the S/PDIF receiver for loop-back testing through SRU.

In addition to encoding the audio data in the bi-phase format, the transmitter also provides a way to easily add the channel status information to the outgoing bi-phase stream. There are status/user registers for a frame (192-bits/24 bytes) in the transmitter that correspond to each channel or subframe.

Figure 37-1: S/PDIF Transmitter Block Diagram

Validity bits for both channels may also be controlled by the transmitter control register. Optionally, the user bit, validity bit, and channel status bit are sent to the transmitter with each left/right sample. For each subframe the parity bit is automatically generated and inserted into the bi-phase encoded data.

A mute control and support for double-frequency single-channel mode are also provided. The serial data input format may be selected as left-justified, I^{2}S, or right-justified with 16-, 18-, 20- or 24-bit word widths. The over sampling clock is also selected by the transmitter control register.

Operating Modes

The S/PDIF transmitter can operate in standalone and full serial modes. The following sections describe these modes in detail.

Full Serial Mode

This mode is selected by clearing the `SPDIF_TX_CTL.AUTO` bit. In this mode all the status bits, audio data and the block start bit (indicating start of a frame), come through the serial data stream (`SPDIF_TX_DATA_I`) pin. The transmitter should be enabled after or at the same time as all of the other control bits.

Standalone Mode

This mode is selected by setting the `SPDIF_TX_CTL.AUTO` bit. In this mode, the block start bit (indicating the start of a frame) is generated internally. The channel status bits come from the channel status buffer registers. The user status bits come from the user bits buffers as shown in the ***AES3 Output Block*** figure.

The validity bits are the `SPDIF_TX_CTL.VALIDR` and `SPDIF_TX_CTL.VALIDL`. In this mode only audio data comes from the `SPDIF_TX_DATA_I` pin. All other data, including the status bit and block start bit is either generated internally or taken from the internal register.

Once the user bits buffer registers (`SPDIF_TX_UBUFF_A0` - `SPDIF_TX_UBUFF_B5`) are programmed, they are used only for the next block of data. This allows programs to change the user bit information in every block of data.

To allow user bit updates, write a 0x1 to the `SPDIF_TX_USRUPDT` register that is used for further processing. If the `SPDIF_TX_CTL.AUTO` bit is set:

- and if `SPDIF_TX_USRUPDT` =1, at every 192nd frame end the user status bits are taken from user bits buffers and transmitted. Simultaneously, the `SPDIF_TX_USRUPDT` register is cleared automatically by hardware.
- and if `SPDIF_TX_USRUPDT` =0, at every 192nd frame end the user status bits are updated as zeros and transmitted. The `SPDIF_TX_USRUPDT` register remains low.

In general, for the next block, programs can update user bits buffers at any time during the transfer of the current block (1 block = 192 frames). There are internal buffers to store the user status bits of the current block of transfer. In other words, at the beginning of every new block, the user status bit (`SPDIF_TX_CTL.USRPEND` bit) from user bits buffers are copied to internal buffers and transmitted in each frame during the transfer.

Note that since a frame contains 192 bits/8 = 24 bytes, six status/user registers are required to store each four bytes.

Data Output Mode

Two output data formats are supported by the transmitter; *two channel mode* and *single-channel double-frequency* (SCDF) mode. The output format is determined by the transmitter control register (`SPDIF_TX_CTL`).

In two channel mode, the left channel (channel A) is transmitted when the `SPDIF_TX_FS_I` is high and the right channel (channel B) is transmitted when the `SPDIF_TX_FS_I` is low.

In SCDF mode, the transmitter sends successive audio samples of the same signal across both sub frames, instead of channel A and B. The transmitter will transmit at half the sample rate of the input bit stream. The `SPDIF_TX_CTL.SCDF` bit selects SCDF mode. When in SCDF mode, the `SPDIF_TX_CTL.SCDFLR` bit determines whether left or right channel data is transmitted.

S/PDIF Receiver

The S/PDIF receiver (***S/PDIF Receiver Block Diagram***) is compliant with all common serial digital audio interface standards including IEC-60958, IEC-61937, AES3, and AES11. For the IEC-60958 standard, all the user-data and channel-status bits (as outlined in this document) are not decoded by the S/PDIF receiver. The interface does make all 192 user-data and channel-status pairs available as an output of the block, for post-decoding.

For the IEC-61937 standard, the S/PDIF only detects compressed AC-3 and DTS formats. No decompression is performed.

Figure 37-5: S/PDIF Receiver Block Diagram

Functional Description

If the receiver is used, programs need to enable it using the `SPDIF_RX_CTL` register. After the SRU programming is complete, write to the register with control values. At this point, the receiver attempts to lock.

NOTE: The S/PDIF receiver is disabled at default. If the receiver is used in an application, programs should enable the receiver.

The input to the receiver (SPDIFn_RX_I) is a biphase encoded signal that may contain two audio channels (compressed or linear PCM) or non-audio data. The receiver decodes the single biphase encoded stream, producing an I^{2}S compatible serial data output that consists of a serial clock, a left-right frame sync, and data (channel A/B). It provides the programmer with several methods of managing the incoming status bit information.

The S/PDIF receiver receives any S/PDIF stream with a sampling frequency range of 24 kHz to 192 kHz. Refer to Clocking for more details.

The channel status bits are collected into memory-mapped registers, while other channel status and user bytes must be handled manually. The block start bit, which replaces the parity bit in the serial I^{2}S stream, indicates the reception of the Z preamble and the start of a new block of channel status and data bits.

Clock Recovery

The S/PDIF receiver recovers the clock that generated the AES3/SPDIF biphase encoded stream from the incoming S/PDIF stream.

This clock is used by the receiver to clock in the biphase encoded data stream and also to provide clocks for either the SPORTs, sample rate converter, or the AES3 and S/PDIF transmitter. The recovered clock may also be used externally to the chip for clocking D/A and A/D converters.

In order to maintain performance, jitter on the clock is sourced to several peripherals.

To be AES11 compliant, the recovered left/right clock must be aligned with the preambles within a + or - 5% of the frame period. Since the PLL clock generates a clock 512 times the frame rate clock (512 f_{SCLK}), this clock can be used and divided down to create the phase aligned jitter-free left/right clock.

Output Data Format

The extracted 24-bit audio data, V, U, C and block start bits are sent on the `SPDIF_RX_DAT` pin in 32-bit I^2S format as shown in ***I2S and Left-Justified Formats***. The frame sync is transmitted on the `SPDIF_RX_FS` pin and serial clock is transmitted on the `SPDIF_RX_CLK` pin. All three pins are routed through the SRU.

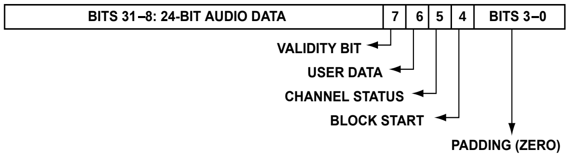

Figure 37-6: I2S Format

Channel Status

The channel status for the first bytes 4-0 (consumer mode) are collected into memory-mapped registers (`SPDIF_RX_STAT0_A`, `SPDIF_RX_STAT0_B`, `SPDIF_RX_STAT1_A` and `SPDIF_RX_STAT1_B`). All other channel status bytes 23-5 (professional mode) must be manually extracted from the receiver data stream.

NOTE: Only the first 5 channel status bytes (40-bit) for consumer mode of a frame are stored into the S/PDIF receiver status registers.

Operating Modes

This section describes the receiver channel status for the different modes.

Compressed or Non-linear Audio Data

The S/PDIF receiver processes compressed as well as non-linear audio data according to the supported standards. The following sections describe how this peripheral handles different data.

MPEG-2, AC-3, DTS, and AAC compressed data may be transmitted without setting either the `SPDIF_RX_STAT.VALID` bit or bit 1 of byte 0. To detect this data, the IEC61937 and SPMTE 337M standards dictate that there be a 96-bit sync code in the 16-, 20- or 24-bit audio data stream. This sync code consists of four words of zeros followed by a word consisting of 0xF872 and another word consisting of 0x4E1F. When this sync code is detected, the `SPDIF_RX_STAT.COMPMODE` bits hold the information regarding type of compression.

The last two words of the sync code, 0xF872 and 0x4E1F, are called the preamble-A and preamble-B of the burst preamble. Preamble-C of the burst preamble contains burst information and is captured and stored by the receiver. Preamble-D of the burst preamble contains the length code and is captured by the receiver. Even if the validity bit or bit 1 of byte 0 has been set, the receiver still looks for the sync code in order to record the preamble-C and D values. Once the sync code has not been detected in 4096 frames, the preamble-C and D registers are set to zero.

Emphasized Audio Data

Determination as to whether the received audio data is emphasized or not is done in software using the channel status bits as detailed below.

- In professional mode, (bit 0 of byte 0 = 1), channel status bits 2-4 of byte 0 indicate the audio data is emphasized if they are equal to 110 or 111.
- In consumer mode, (bit 0 of byte 0 = 0), channel status bits 3-5 indicate the audio data is emphasized if they are equal to 100, 010 or 110.

Single-Channel Double-Frequency Mode

Unlike previous processors, support for single-channel, double-frequency mode (SCDF) is not supported through specific bits within the `SPDIF_RX_CTL` register, but rather have to be implemented in software using the information provided by the CS (channel status) bits.

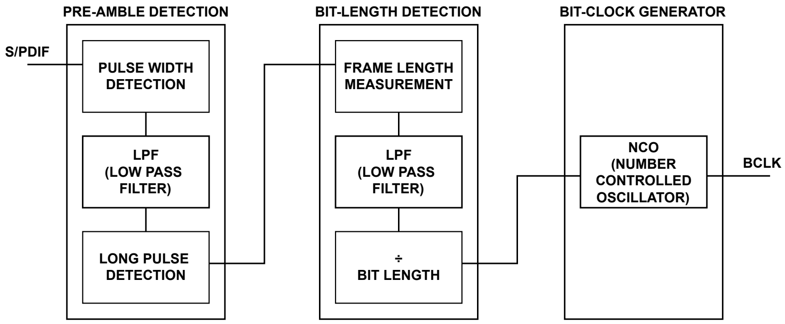
- 0111 = single channel double frequency mode
- 1000 = single channel double frequency mode-stereo left
- 1001 = single channel double frequency mode-stereo right

Clock Recovery Modes

The S/PDIF receiver extracts audio data, channel status, and user bits from the biphase encoded AES3 and S/PDIF stream. In addition, a 50% duty cycle reference clock running at the sampling rate of the audio input data is generated for the receiver to recover the oversampling clock.

Number Controlled Oscillator

The receiver can recover the clock from the biphase encoded stream using an on-chip NCO shown in the following figure. Note the dedicated NCO is separate from the PLL that supplies the clock to the processor core and which is the default operation of the receiver.



PRE-AMBLE DETECTION
BIT-LENGTH DETECTION
BIT-CLOCK GENERATOR
S/PDIF
PULSE WIDTH DETECTION

LONG PULSE DETECTION
FRAME LENGTH MEASUREMENT
LPF (LOW PASS FILTER)
÷ BIT LENGTH
NCO (NUMBER CONTROLLED OSCILLATOR)
BCLK

Figure 37-7: S/PDIF Clock Recovery Mechanism

The left/right frame reference clock for the NCO is generated using the preambles. The recovered low jitter left/right frame clock from the NCO attempts to align with the reference clock. However, this recovered left/right clock, like the reference clock, is not phase aligned with the preambles.

Interrupts

The following sections provide information about interrupt sources, masking and servicing.

Sources

The S/PDIF module of each DAI drives five interrupt signals. Four are status signals driven from SPDIFn_RX and one signal is driven from SPDIFn_TX (block start). These signals are connected into the `DAI_IRPTL_L`/`DAI_IRPTL_H` latch register.

Transmit Block Start

The SPDIFn_TX_BLKSTART output signal, if routed to any miscellaneous interrupt bits (DAIn_INT_31-22 in the `DAI_MISC0`/`DAI_MISC1` registers), triggers a block start interrupt during the last frame of current block.

Receiver Status

The following receiver status bits generate an interrupt.

- Validity (`SPDIF_RX_STAT.VALID`)
- Receiver locked (`SPDIF_RX_STAT.LOCK`)
- No audio (`SPDIF_RX_STAT.AUDIOTYPE`)

Receiver Error

The loss of lock (`SPDIF_RX_STAT.LOCKLOSS`) bit generates an interrupt.

Masking

For the S/PDIF receiver the `DAI_IMSK_RE` register must be unmasked accordingly. For the S/PDIF transmit the DAIn_IMASK_x register must be unmasked accordingly.

The `INTR_DAI_IRQH` and `INTR_DAI_IRQL` signals are routed to the SEC and GIC.

Service

The ISR reads the `DAI_IRPTL_H` and `DAI_IRPTL_L` registers to clear the interrupt request.

Programming Model

The following sections provide information on programming the transmitter and receiver.

Programming the Transmitter

Since the S/PDIF transmitter data input is not available to the core, programming the transmitter is as simple as: 1) connecting the SRU to the on-chip (serial ports or input data port) or off-chip (DAI pins) serial devices that provide the clock and data to be encoded, and 2) selecting the desired mode in the transmitter control register. This setup can be accomplished in three steps.

1. Connect the transmitter's four required input signals and one biphase encoded output in the SRU. The four input signals are the serial clock (`SPDIF_TX_CLK_I`), the serial frame sync (`SPDIF_TX_FS_I`), the serial data (`SPDIF_TX_DAT_I`), and the high frequency clock (`SPDIF_TX_HFCLK_I`) used for the encoding. The only output of the transmitter is `SPDIF_TX_O`.
2. If user bits are required, write 0x1 to the `SPDIF_TX_USRUPDT` register for the first block of transfer. Also route the `SPDIF_TX_BLK_START_O` signal to the `DAI_INT_31-22` (`DAI_IRPTLx` register). This generates interrupts during the last frame of the block (192), allowing changes of user bits for the next block.
3. Initialize the `SPDIF_TX_CTL` register to enable the data encoding.
4. Manually set the block start bit in the data stream once per block (every 384 words). This is necessary if automatic generation of block start information is not enabled using the `SPDIF_TX_CTL.AUTO` bit = 0.

NOTE: For more information, see the "DAI Routing Capabilities" section of the *Digital Audio Interface (DAI)* chapter.

Programming the Receiver

Since the S/PDIF receiver data output is not available to the core, programming the peripheral is as simple as connecting the SRU to the on-chip (serial ports) or off-chip (DAI pins) serial devices that provide the clock and data to be decoded, and selecting the desired mode in the receiver control register. This setup can be accomplished in two steps.

1. Connect the input signal and three output signals in the SRU. The only input of the receiver is the biphase encoded stream, `SPDIFn_RX_I`. The three required output signals are the serial clock (`SPDIFn_RX_CLK`), the serial frame sync (`SPDIFn_RX_FS`), and the serial data (`SPDIFn_RX_DAT`). The high frequency clock (`SPDIFn_RX_TDMCLK`) derived from the encoded stream is also available if the system requires it.

2. Initialize the `SPDIF_RX_CTL` register to enable the data decoding. Note that this peripheral is disabled by default.

NOTE: For more information, see the "DAI Routing Capabilities" section of the *Digital Audio Interface (DAI)* chapter.

Interrupted Data Streams on the Receiver

When using the S/PDIF receiver with data streams that are likely to be interrupted, (in other words unplugged and reconnected), it is necessary to take some extra steps to ensure that the S/PDIF receiver's digital PLL will relock to the stream. The steps to accomplish this are described below.

1. Set up interrupts within the DAI so that the S/PDIF receiver can generate an interrupt when the stream is reconnected.
2. Within the interrupt service routine (ISR), stop and restart the NCO. This is accomplished by setting and then clearing the `SPDIF_RX_CTL.RST` bit.
3. Return from the ISR and continue normal operation.

This method of resetting the NCO has been shown to provide extremely reliable performance when the S/PDIF inputs are interrupted or unplugged momentarily.

Debug Features

The following feature supports S/PDIF debugging.

Loopback Routing

The S/PDIF supports an internal loopback mode by using the SRU. For more information about loopback, see "Loopback Routing" in the the *Digital Audio Interface (DAI)* chapter.

ADSP-SC58x SPDIF Register Descriptions

The S/PDIF module (SPDIF) contains the following registers.

Table 37-3: ADSP-SC58x SPDIF Register List

Name	Description
`SPDIF_RX_CTL`	Receive Control

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 37-8: SPDIF_RX_CTL Register Diagram

Table 37-4: SPDIF_RX_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	RST	Reset SPDIF Receiver. The `SPDIF_RX_CTL.RST` bit resets the receiver.	
		0	Takes the receiver out of reset
		1	Resets the SPDIF receiver
3 (R/W)	RSTRTAUDIO	Restart Audio. The `SPDIF_RX_CTL.RSTRTAUDIO` bit restarts the audio once a re-lock has occurred. When the S/PDIF receiver loses lock the audio output is set to 0. This bit determines the behavior of the audio once lock is re-established. Audio can be manually restarted by toggling this bit high and then low.	
		0	Manually restart audio
		1	Automatically restart audio
2 (R/W)	FASTLOCK	Fast Lock Select. The `SPDIF_RX_CTL.FASTLOCK` bit allows the lock mechanism to lock at normal speed or at faster speed. This has the advantage of recovering very quickly whenever the S/PDIF receiver looses lock due to glitches in the signal. In normal mode the S/PDIF receiver locks after 64 consecutive valid samples, in fast mode the S/PDIF receiver locks after 8 consecutive valid samples	
		0	Enable normal mode
		1	Enable fast mode

Table 37-4: SPDIF_RX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	STRENGTH	FS strength Control. The `SPDIF_RX_CTL.STRENGTH` bit controls the strength of the bit clock and Frame sync outputs from the SPDIF receiver. In strong mode these output signals are continued (as best possible) when the receiver notices a loss-of-lock condition. Note that 'as best possible' refers to the fact that this recovered signal may not be accurate, given the loss-of-lock condition. In weak mode these output signals are interrupted as soon as the receiver notices a loss-of-lock condition.	
		0	Enable strong mode
		1	Enable weak mode
0 (R/W)	EN	SPDIF Receiver Enable. When the `SPDIF_RX_CTL.EN` bit =0 the clock to SPDIF is switched off for power savings.	
		0	Disable receiver
		1	Enable receiver

Receive Status Register

The `SPDIF_RX_STAT` register consists of bits that indicate the status of various functions supported by S/PDIF receiver.

Table 37-5: SPDIF_RX_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	LOCKLOSS	Loss of Lock (sticky). The `SPDIF_RX_STAT.LOCKLOSS` bit indicates that the system has lost lock. This is different to the lock register, as it is sticky it goes high when system looses lock, but returns to low once `SPDIF_RX_CTL.RSTRTAUDIO` bit is toggled. This is to allow the programs to poll the lock status.	
		0	SPDIF receiver locked
		1	SPDIF Receiver lost lock
3 (R/NW)	LOCK	Lock Receiver. The `SPDIF_RX_STAT.LOCK` bit indicates the S/PDIF receiver has successfully locked to the S/PDIF stream and is outputting valid data.	
		0	Receiver not locked
		1	Receiver locked
2 (R/NW)	VALID	Validity Bit. The `SPDIF_RX_STAT.VALID` bit indicates the ORed bits of channel A and B.	
		0	Linear PCM data
		1	Non-linear audio data
1 (R/NW)	COMPTYPE	Compression Type. The `SPDIF_RX_STAT.COMPTYPE` bit indicates AC3 or DTS compression. Valid only if `SPDIF_RX_STAT.AUDIOTYPE` indicates compressed data.	
		0	AC3 compressed data
		1	DTS compressed data
0 (R/NW)	AUDIOTYPE	Audio Type. The `SPDIF_RX_STAT.AUDIOTYPE` bit indicates PCM or compressed data.	
		0	PCM data
		1	Compressed Data

Receive Status A0 Register

The `SPDIF_RX_STAT0_A` register holds the receive channel 0 status for bytes 0-3 for sub frame A.

Bit No. (Access)	Bit Name	Description/Enumeration
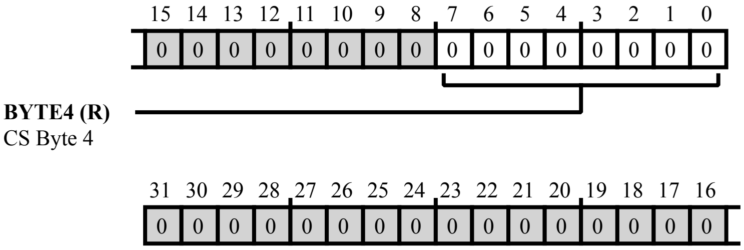
31:24 (R/NW)	BYTE3	CS Byte 3. The `SPDIF_RX_STAT0_B.BYTE3` bit field contains byte 3 of received channel B status.
23:16 (R/NW)	BYTE2	CS Byte 2. The `SPDIF_RX_STAT0_B.BYTE2` bit field contains byte 2 of received channel B status.
15:8 (R/NW)	BYTE1	CS Byte 1. The `SPDIF_RX_STAT0_B.BYTE1` bit field contains byte 1 of received channel B status.
7:0 (R/NW)	BYTE0	CS Byte 0. The `SPDIF_RX_STAT0_B.BYTE0` bit field contains byte 0 of received channel B status.

Receive Status A1 Register

The `SPDIF_RX_STAT1_A` register holds the receive channel 1 status for byte 4 for sub frame A.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
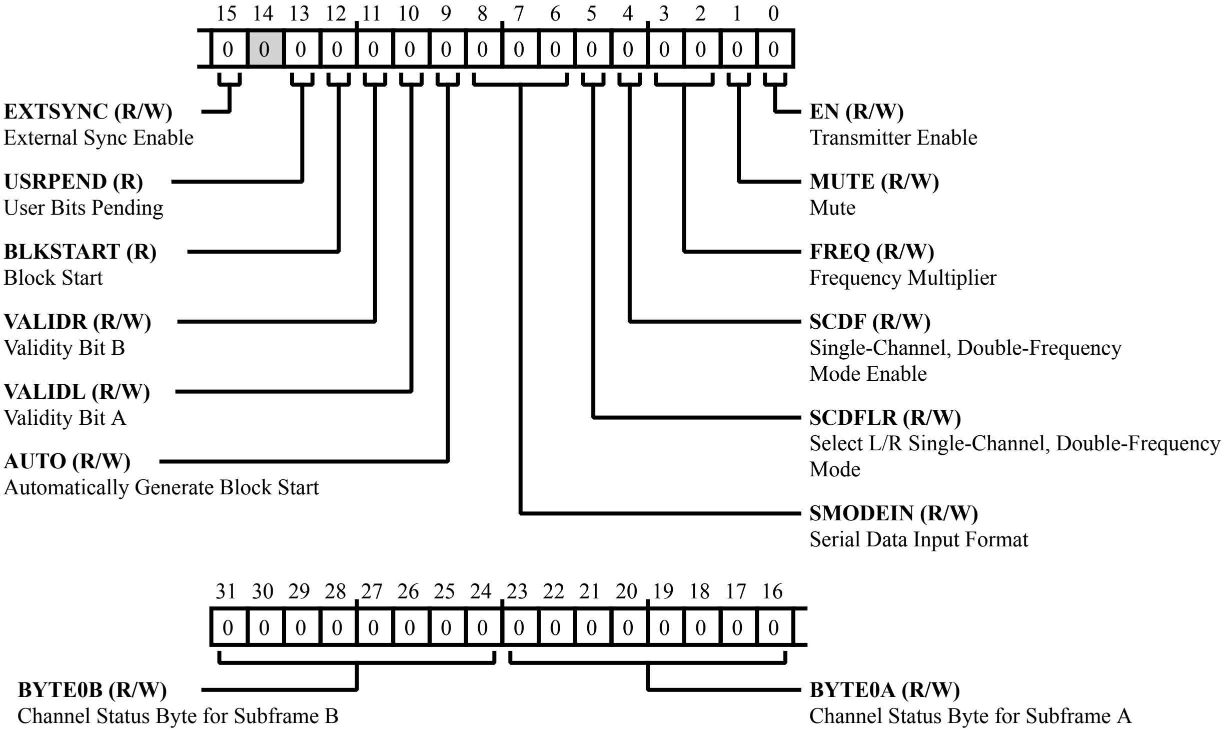
7:0 (R/NW)	BYTE4	CS Byte 4. The `SPDIF_RX_STAT1_B.BYTE4` bit field contains byte 4 of received channel B status.

Transmit Control Register

The `SPDIF_TX_CTL` register provides bits the enable/disable the transmitter and configure several options related to data transmission.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
EXTSYNC (R/W)
External Sync Enable
USRPEND (R)
User Bits Pending
BLKSTART (R)
Block Start
VALIDR (R/W)
Validity Bit B
VALIDL (R/W)
Validity Bit A
AUTO (R/W)
Automatically Generate Block Start
EN (R/W)
Transmitter Enable
MUTE (R/W)
Mute
FREQ (R/W)
Frequency Multiplier
SCDF (R/W)
Single-Channel, Double-Frequency Mode Enable
SCDFLR (R/W)
Select L/R Single-Channel, Double-Frequency Mode
SMODEIN (R/W)
Serial Data Input Format
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BYTE0B (R/W)
Channel Status Byte for Subframe B
BYTE0A (R/W)
Channel Status Byte for Subframe A

Figure 37-14: SPDIF_TX_CTL Register Diagram

Table 37-10: SPDIF_TX_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE0B	Channel Status Byte for Subframe B. The `SPDIF_TX_CTL.BYTE0B` bit field contains the channel status for the second bytes 95.
23:16 (R/W)	BYTE0A	Channel Status Byte for Subframe A. The `SPDIF_TX_CTL.BYTE0A` bit field contains the channel status for the first bytes 40.
15 (R/W)	EXTSYNC	External Sync Enable. When the `SPDIF_TX_CTL.EXTSYNC` bit is set (regardless of the `SPDIF_TX_CTL.AUTO` bit setting) the internal frame counter is set to zero at an internal LRCLK rising edge followed by an EXTSYNC_I rising edge.

Table 37-10: SPDIF_TX_CTL Register Fields (Continued)

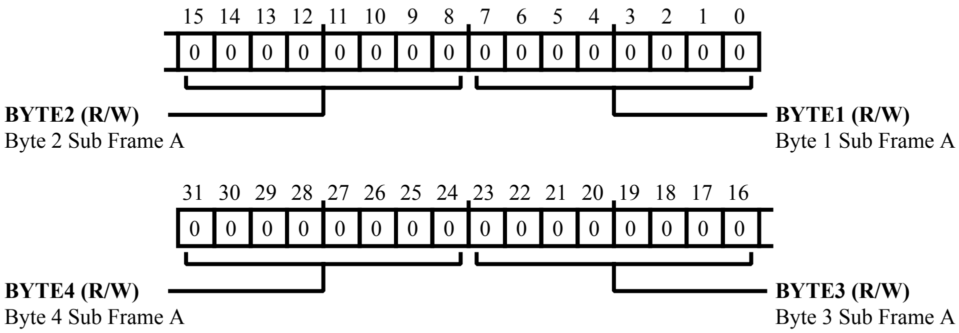
Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/NW)	USRPEND	User Bits Pending. The `SPDIF_TX_CTL.USRPEND` bit is set if the update of the internal buffer from the Transmit User Bits Buffer registers has not yet completed.	
12 (R/NW)	BLKSTART	Block Start. The `SPDIF_TX_CTL.BLKSTART` bit is a status bit that indicates block start (when the `SPDIF_TX_CTL.AUTO` bit = 1).	
		0	Current word is not block start
		1	Current word is block start
11 (R/W)	VALIDR	Validity Bit B. Use the `SPDIF_TX_CTL.VALIDR` bit with the channel status buffer.	
10 (R/W)	VALIDL	Validity Bit A. The `SPDIF_TX_CTL.VALIDL` bit either manually start block transfer according to input stream status bits or automatically start block transfer. Use the `SPDIF_TX_CTL.VALIDL` bit with the channel status buffer.	
		0	Manually start block transfer
		1	Automatically start block transfer
9 (R/W)	AUTO	Automatically Generate Block Start. When enabled, the transmitter is in standalone mode where it inserts block start, channel status, and validity bits on its own. If the channel status or validity buffer needs to be enabled (after the DAI programming is complete), first write to the buffers with the required data and then enable the buffers by setting the `SPDIF_TX_CTL.AUTO` bit.	
8:6 (R/W)	SMODEIN	Serial Data Input Format. The `SPDIF_TX_CTL.SMODEIN` bit selects the data input format.	
		0	Left-justified
		1	I2S
		2	Reserved
		3	Reserved
		4	Right-justified, 24 bits
		5	Right-justified, 20 bits
		6	Right-justified, 18 bits
		7	Right-justified, 16 bits

Table 37-10: SPDIF_TX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SCDFLR	Select L/R Single-Channel, Double-Frequency Mode. The `SPDIF_TX_CTL.SCDFLR` bit selects the left or right channel in SCDF mode.	
		0	Left channel
		1	Right channel
4 (R/W)	SCDF	Single-Channel, Double-Frequency Mode Enable. The `SPDIF_TX_CTL.SCDF` bit enables single-channel, double-frequency mode.	
		0	Two-channel mode
		1	SCDF mode
3:2 (R/W)	FREQ	Frequency Multiplier. The `SPDIF_TX_CTL.FREQ` bit field sets the oversampling ratio.	
		0	256 x frame sync oversampling
		1	384 x frame sync oversampling
		2-3	Reserved
1 (R/W)	MUTE	Mute. The `SPDIF_TX_CTL.MUTE` bit mutes the serial data output.	
		0	Disable Mute
		1	Enable Mute
0 (R/W)	EN	Transmitter Enable. The `SPDIF_TX_CTL.EN` bit enables the transmitter and resets the control registers to their defaults.	
		0	Transmitter disabled
		1	Transmitter enabled

Transmit Status A0 Register

The `SPDIF_TX_STAT_A0` register holds the transmit channel 0 status for bytes 1-4 for sub frame A.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 37-39: SPDIF_TX_USRUPDT Register Diagram

Table 37-35: SPDIF_TX_USRUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	EN	Enable. After writing to the transmit user buffer registers, a value of 0x1 must be written into the `SPDIF_TX_USRUPDT` register to enable the use of these `SPDIF_TX_USRUPDT.EN` bits in the next transfer block.

38 Direct Memory Access (DMA)

The processor architecture distributes the DMA channels throughout the infrastructure. Often, the channels cluster together through system crossbars (SCB), sharing a single interface with the main system crossbar.

The DMA channels can perform transfers between memory and a peripheral or between one memory and another memory. Memory-to-memory DMA transfers (MDMA) require two DMA channels. One channel is the source channel, and the second, the destination channel.

All DMA channels can transport data to and from virtually all on-chip and off-chip memories.

DMA transfers on the processor use either a descriptor-based method or register-based method. Register-based DMA allows the processor directly to program DMA controller registers to initiate a DMA transfer. On completion, the controller registers can automatically update with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. Descriptor-based transfers allow the chaining together of multiple DMA sequences. In descriptor-based DMA operations, DMA channel programming can automatically set up and start another DMA transfer after the current sequence completes.

The DMA channel does not connect external memories and devices directly. Rather, data passes through an external-memory interface port. DMA operations can access any device the external memory interface supports. These interfaces typically include:

- Flash memory
- SRAM
- FIFOs
- Memory-mapped peripheral devices
- Dynamic Memory (if present)

DMA Channel Features

The processor uses Direct Memory Access (DMA) to transfer data within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA channel carries out the data transfers independent of processor activity. The DMA channels are dispersed throughout the infrastructure and interface with the system crossbar unit (SCB).

The following is a list of DMA interface features.

- Supports integer byte strides including byte strides of 0 and negative byte strides
- Register-based configuration
    - Core writes DMA configuration
    - Supports automatic reloading for continuous operation
- Flexible descriptor-based configuration
    - DMA descriptors are fetched from memory
    - Support for variable descriptor sizes
- Flexible flow control – Transitions between the various descriptor-based modes and for DMA termination
- Orthogonal transfers
    - Support for three transfer dimensions
    - 1D and 2D transfers supported per descriptor set
    - 3D support provided by chained descriptor sets
- Configurable memory and peripheral-transfer word sizes
    - Memory interface supports 8-bit, 16-bit, 32-bit, 64-bit, 128-bit, and 256-bit transfers
    - Peripheral interface supports for 8-bit, 16-bit, and 32-bit transfers
- Interrupt notification
    - Row or work unit completion
    - Error conditions
- Incoming and outgoing trigger support
    - Trigger generation for row or work unit completion
    - Work unit can wait for incoming trigger
- MMR access bus – Provides access to memory-mapped registers for configuration, monitoring, and debug
- SCB crossbar interface connects the DMA channel to the system crossbar
- Peripheral DMA bus – Interfaces the DMA channel to a peripheral or another DMA channel
- Peripheral data-request interrupt support
- Bandwidth monitoring and limiting for MDMA channels

DMA Channel Functional Description

This section provides a functional description of the DMA channel interface.

NOTE: There are two types of peripherals that use DMA. The first have dedicated DMA channels controlled by the Dedicated DMA Engine (DDE) and are described in this chapter. The second type is not controlled by the DDE. These peripherals have their own operating modes and programming models (see the peripheral chapter for this information). The complete list of DMA supported peripherals are shown in Table 54-4 DMA Channel Peripherals Controlled by SCBs.

ADSP-SC58x DMA Register List

The DMA channel controller (DMA) supports data transfers within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA channel carries out the data transfers independent of processor activity. The DMA channels are dispersed throughout the infrastructure, as DMAn's. A set of registers governs DMA operations. For more information on DMA functionality, see the DMA register descriptions.

Table 38-1: ADSP-SC58x DMA Register List

Name	Description
DMA_ADDRSTART	Start Address of Current Buffer Register
DMA_ADDR_CUR	Current Address Register
DMA_BWLCNT	Bandwidth Limit Count Register
DMA_BWLCNT_CUR	Bandwidth Limit Count Current Register
DMA_BWMCNT	Bandwidth Monitor Count Register
DMA_BWMCNT_CUR	Bandwidth Monitor Count Current Register
DMA_CFG	Configuration Register
DMA_DSCPTR_CUR	Current Descriptor Pointer Register
DMA_DSCPTR_NXT	Pointer to Next Initial Descriptor Register
DMA_DSCPTR_PRV	Previous Initial Descriptor Pointer Register
DMA_STAT	Status Register
DMA_XCNT	Inner Loop Count Start Value Register
DMA_XCNT_CUR	Current Count (1D) or Intra-row XCNT (2D) Register
DMA_XMOD	Inner Loop Address Increment Register
DMA_YCNT	Outer Loop Count Start Value (2D only) Register
DMA_YCNT_CUR	Current Row Count (2D only) Register
DMA_YMOD	Outer Loop Address Increment (2D only) Register

ADSP-SC58x DMA Channel List

Table 38-2: ADSP-SC58x DMA Channel List

DMA ID	DMA Channel Name	Description
DMA0	SPORT0_A_DMA	SPORT0 Channel A DMA

DMA43	MDMA3_SRC	Memory DMA Stream n Source Channel
DMA44	MDMA3_DST	Memory DMA Stream n Destination Channel

DMA Definitions

To make the best use of the DMA controller, it is useful to understand the following terms.

Descriptor

An individual configuration fetched from memory that maps to a single register within a DMA channel.

Descriptor Fetch

The action of retrieving descriptors from memory through memory read operations and loading then into the DMA channel registers upon their read return.

Descriptor Set

A group of descriptors associated with a single work unit.

Disabled State

The channel is disabled because the enable bit = 0 or as a result of an error.

DMAC

An acronym used for a DMA cluster.

DMA Channel

A single DMA engine that has all the capabilities and registers as defined for a given processor. A DMA channel or engine is connected to a single peripheral.

DMA Cluster

A grouping of multiple DMA channels with a shared SCB crossbar interface, controller, and arbiter. Also known as a DMAC.

Initial Descriptor

The first descriptor in the descriptor set.

MDMA

Memory-to-Memory DMA data transfer. Two DMA channels are paired to perform a memory read from one address location and a memory write of that data to another address location.

Stop State

A time where the channel is enabled but not currently programmed to perform a data transfer. Programming the flow to STOP causes the channel to enter the stop state at the end of the work unit.

User

Any person, debug, emulator, software routine, or action taken by the core that accesses the MMR registers of the DMA channel or peripherals, or sets up data and descriptors in memory.

Wait State

If instructed to wait for a trigger, the channel enters this state once it has completed a work unit. The channel remains in this state until a trigger occurs. If a trigger came in before reaching the wait state, the channel skips over the wait state upon completion of the work unit.

Work Unit

A single data transaction or series of data transactions performed based on the configuration of the DMA channel. For autobuffer mode, a new work unit is defined at the time all current count registers are initialized to start values. Once all the current count registers count down to zero, the work unit has completed.

Work Unit Chain

A single work unit or a series or work units separated by a `STOP` or disabled state. The work units in the chain are programmed to another descriptor flow. The last work unit in the chain is programmed to a flow of `STOP` or `AUTO`. `STOP` terminates the state at the end of that work unit. `AUTO` must be be terminated by disabling the DMA channel. A work unit chain is also known as a descriptor chain.

Architectural Concepts

The DMA channel provides a method to transfer data between memory spaces or between memory and a peripheral using a number of system interfaces. The DMA channel provides an efficient method of distributing data throughout the system, freeing up the processor core for other operations. Each peripheral that supports DMA transfers has its own dedicated DMA channel or channels with its own register set. The register set configures and controls the operating modes of the DMA transfers.

DMA Channel SCB Interface

The SCB interface connects the DMA channel to the SCB crossbar allowing for transfers to and from the processors internal memory and other suitable system resources.

The DMA channel connects to the system interconnect through the SCB interface. This connection lets the DMA channel perform work-unit data transfers with memories such as L1, L2 (internal), and L3 (external). In addition to work unit data transfers, the SCB interface also is used for fetching descriptor sets for all the descriptor-based transfer modes.

The DMA channel can support data bus widths of 16, 32, 64, or 128 bits. The data bus widths for a given DMA channel on a specific processor can vary and are not configurable. Read the `DMA_STAT.MBWID` field to determine the assigned bus widths.

SCB Interface Signals

The DMA channel operates at one of the *SCLKn* frequencies, as does the SCB interface. SCLK0 clocks all but four DMA channels which are clocked by SCLK1. The SCB crossbar handles the internal arbitration of the transfer requests of all the masters interfaced to the SCB crossbar instance as shown in the ***SCB Interface Signals*** table.

Table 38-3: SCB Interface Signals

Signal	Width (bits)	Description
SCB_WRITE_DATA	16, 32, 64, or 128	Data bus used for write operations. The width of the bus can be determined from `DMA_STAT.MBWID`.
SCB_WRITE_ADDRESS	32	Write address bus. Provides the address of the first transfer in a burst transaction.
SCB_READ_DATA	16, 32, 64, or 128	Data bus used for read operations. The width of the bus can be determined from `DMA_STAT.MBWID`.
SCB_READ_ADDRESS	32	Read address bus. Provides the address of the first transfer in a burst transaction.

SCB Burst Transfers

The SCB interface supports burst transfers for memory read and write operations. The burst length is a function of the configurable memory size of the DMA channel for the work unit and the fixed bus width of the SCB data bus of the DMA channel.

- If the DMA channel configuration selects a memory transfer size less than or equal to the DMA channels bus width, the burst length is always 1.
- If the configured memory size is greater than the SCB interface bus width, the burst length is sufficient to transfer a transaction as specified by the configured memory size.

Table 38-4: DMA Channel SCB Burst Lengths

Configured Memory Size	Burst Length			
	16-bit Bus	*32-bit Bus*	*64-Bit Bus*	*128-bit Bus*

Table 38-4: DMA Channel SCB Burst Lengths (Continued)

Configured Memory Size	Burst Length			
1 Byte	1	1	1	1
2 Bytes	1	1	1	1
4 Bytes	2	1	1	1
8 Bytes	4	2	1	1
16 Bytes	8	4	2	1
32 Bytes	16	8	4	2

Data Address Alignment

To prevent addressing errors and to maximize bandwidth of the SCB interface to the DMA channel, data addresses align with a multiple of the programmable memory size of the DMA channels configuration. These configuration options appear in the Descriptor Set Address Alignment table.

There are situations in which entire work units may not transfer at the maximum configurable memory size. In this case, the entire work unit can transfer by reducing the configured memory size at the expense of bus bandwidth using descriptor sets as follows:

- The first descriptor set can be configured to transfer data until the larger memory size alignments are met.
- A second descriptor set with a larger memory size configuration then can be used to transfer the bulk of the data in the work unit.
- Finally, a third descriptor set can be used with a smaller memory size to complete any final data transfers that cannot meet the alignment requirements of the previous descriptor set configuration.

Table 38-5: DMA Channel Address Alignment Requirements

Configured Memory Size	Address Restriction
1 Byte	No restriction
2 Bytes	ADDR[0] == 0
4 Bytes	ADDR[1:0] == 0
8 Bytes	ADDR[2:0] == 0
16 Bytes	ADDR[3:0] == 0
32 Bytes	ADDR[4:0] == 0

Descriptor Set Address Alignment

All descriptor set addresses and descriptors within a descriptor set must align to a 32-bit address. For descriptor set fetches, the DMA engine ignores the memory-size configuration of the DMA channel. This feature avoids the need to align descriptor sets based on the memory width configuration of the previous descriptor set.

For descriptor sets containing only a single descriptor, the transfer takes place as a single 32-bit transfer. For descriptor sets containing multiple descriptors, the DMA engine fetches each 32-bit descriptor individually and treats it as multiple 32-bit transfers.

DMA Channel Peripheral DMA Bus

The DMA channel connects to peripherals or other DMA channels through the peripheral DMA bus. This bus is a dedicated point-to-point interface supporting data bus widths of 8, 16, 32, or 64 bits. The data bus widths for a given DMA channel on a particular processor can vary and are not configurable. Reading the `DMA_STAT.PBWID` field permits determining the assigned bus width.

The DMA channel operates at one of the *SCLKn* frequencies, as does the peripheral DMA bus. The ***Peripheral DMA Bus Signals*** table provides descriptions of the peripheral DMA bus signals.

Table 38-6: Peripheral DMA Bus Signals

Signal	Width (bits)	Description
PDMA_WRITE_DATA	8, 16, 32, or 64	Data bus used for write operations. The width of the bus can be determined from `DMA_STAT.PBWID`.
PDMA_READ_DATA	8, 16, 32, or 64	Data bus used for read operations. The width of the bus can be determined from `DMA_STAT.PBWID`.
PDMA_DMA_GRANT		Control signals to indicate that data is valid for DMA channel read operations (peripheral transmit). These signals indicate that the DMA channel is ready to receive data for write operations (peripheral receive).
PDMA_CMD	3	The peripheral uses the signal for issuing DMA channel control commands.
PDMA_CTRL		The peripheral uses the control signals to send various commands to the DMA channel and control the direction of flow.

Peripheral Control Commands

The peripheral DMA bus of the DMA channel provides a means for peripherals on the processor to issue commands to the DMA channel. These commands provide greater control over the DMA channel operation. This control improves real-time performance and relieves control and interrupt demands on the core. Peripherals can send commands to the DMA controller over the 3-bit PERI_CMD bus. The DMA control commands extend the set of operations available to the peripheral beyond the simple “request data” command used by peripherals in general. Refer to the appropriate peripheral chapter for a description on how that peripheral uses DMA control commands.

These DMA control commands (see the ***PDMA_CMD Peripheral DMA Control Commands*** table) are not visible to or controlled by the program. But, their use by a peripheral has implications for the structure of the DMA transfers that the peripheral can support. It is important to write application software such that it complies with certain restrictions, regarding work units and descriptor chains. Complying with this guideline makes the peripheral operate properly whenever it issues DMA control commands.

The ***PDMA_CMD Peripheral DMA Control Commands*** table describes the commands the DMA controller issues. The following sections describe these commands in more detail.

Table 38-7: PDMA_CMD Peripheral DMA Control Commands

Command	Name	Description
b#000	NOP	No operation
b#001	Restart	Restarts the current work unit from the beginning
b#010	Finish	Finishes the current work unit and starts the next
b#011	Interrupt	Immediately sets the DMA completion interrupt in the DMA channel
b#100	Request Data	Typical DMA data request
b#101	Request Data Urgent	Urgent DMA data request
b#110	Reserved	Reserved
b#111	Reserved	Reserved

Idle Command

The DMA channel drives this command when the enabled peripheral has no data requests required.

Restart Command

This command causes the current work unit to interrupt processing and start again, using the addresses and count values from the `DMA_ADDRSTART`, `DMA_XCNT`, and `DMA_YCNT` registers. The DMA controller does not signal an interrupt request when the work unit terminates.

If a channel programmed to transmit (memory read) receives a restart command, the channel momentarily pauses, permitting any pending memory reads initiated before the restart command to complete. During this period, the channel does not grant DMA requests. After all pending reads flush from the pipelines of the channel, the channel resets its counters and FIFO, and then starts pre-fetch reads from memory. The DMA controller grants data requests from the peripheral as soon as new prefetched data is available in the DMA FIFO. In this case, the peripheral can use the restart command to reattempt a failed transmission of a work unit.

If a channel programmed to receive (memory write) receives a restart command, the channel stops writing to memory, discards any data held in its DMA FIFO, and resets its counters and FIFO. As soon as this initialization is complete, the channel again grants DMA write requests from the peripheral. In this case, the peripheral can use the restart command to abort the transfer of received data into a work unit, and reuse the memory buffer for a later data transfer.

The request from the restart control command is not granted or acknowledged. The DMA controller always accepts the request.

Finish Command

The finish command causes the current work unit to terminate processing and move on to the next work unit. If enabled within the `DMA_CFG` register, the DMA channel signals an interrupt or a trigger event. The peripheral can then use the finish command to partition the DMA stream into work units on its own. This partitioning occurs---perhaps as a result of parsing the data currently passing though its supported communication channel---without direct real-time control by the processor.

When a DMA channel programmed to transmit (memory read) then receives a finish command, the channel momentarily pauses for the completion of any pending memory reads, which were initiated prior to the finish command. During this time, the channel does not grant DMA requests. After the flush of all pending reads from the pipelines of the channel, the channel signals an interrupt request or a trigger (if enabled) and begins fetching the next descriptor (if any). DMA data requests from the peripheral are granted as soon as new prefetched data is available in the DMA FIFO.

If a channel programmed to receive (memory write) then receives a finish command, the channel stops granting new DMA requests while it drains its FIFO. The channel writes to memory any DMA data received by the DMA channel prior to the finish command. When the FIFO reaches an empty state, the channel signals an interrupt or a trigger (if enabled) and begins fetching the next descriptor (if any). After fetching the next descriptor, the channel initializes its FIFO, then resumes granting DMA requests from the peripheral.

The finish command request is not granted or acknowledged. The request is always accepted by the DMA channel.

Interrupt Command

The interrupt command causes the DMA channel to generate an interrupt request. When programming the channel to support this command, configure the `DMA_CFG.INT` bit field to PIRQ mode. This configuration directs the channel not to generate interrupt requests based on the work unit state. Instead, the channel generates interrupts only when it receives the interrupt command from the peripheral. When the channel receives an interrupt request command, the `DMA_STAT.PIRQ` bit indicates the event under the following conditions:

- The `DMA_CFG.EN` bit enables the DMA channel.
- The DMA channel is in the stop state.
- The interrupt in `DMA_CFG.INT` is configured for PIRQ mode.

The peripheral only issues the interrupt command in response to receiving the last grant command from the DMA channel, indicating that the transfer is the last transfer in the work unit.

Request-Data Command

The request data command is a request for data transfers between the DMA channel and the peripheral. The request is held by the peripheral until granted or acknowledged by the DMA channel.

Request-Data Urgent Command

The request-data urgent command behaves identically to the request data command, except that---during the commands assertion---the DMA channel performs its memory accesses with urgent priority. This priority includes both data and descriptor fetch memory accesses. For example, a DMA management capable peripheral can use this control command if an internal FIFO approaches a critical condition.

The request is held by the peripheral until granted or acknowledged by the DMA channel.

Peripheral-Control Command Restrictions

The proper operation of the DMA channel FIFO leads to certain restrictions in the sequence of DMA peripheral control commands issued by a peripheral. The following sections describe these restrictions.

Transmit-Restart or Transmit-Finish Command

A peripheral only can issue a restart or finish control command to a channel configured for memory read under the following conditions:

- The peripheral has already performed at least one DMA transfer in the current work unit.
- The current work unit has (`FIFO_SIZE/DMA_CFG.MSIZE`) + 1 memory transfers remaining.

The first item ensures that the work unit has started. The second item ensures that the work unit has not completed. The second item is sufficiently large that it is always at least five more than the maximum data count before any restart or finish command. If using restart or finish commands to manage a work unit, this requirement implies that the work unit must have `DMA_XCNT_CUR` and `DMA_YCNT_CUR` register values representing at least five data items.

To satisfy the second item, ensure that the number of memory transfers described by the descriptor is (`FIFO_SIZE/DMA_CFG.MSIZE`) + 1 larger than the maximum number of memory transfers expected.

Receive-Restart or Receive-Finish Commands

A peripheral only can issue a restart or finish control command to a channel configured for memory write under the following conditions:

- The number of peripheral transfers completed is less than (`DMA_CFG.MSIZE/DMA_CFG.PSIZE`) × (transfers described by descriptor).
- In addition to the previous condition, one of the following conditions also must apply:
  - A finish command terminated the previous work unit, *and* the peripheral has done at least one transfer in the current work unit.
  - The peripheral has done (`FIFO_SIZE/DMA_CFG.PSIZE`) + 1 transfers in the current work unit.

The first condition ensures that the descriptor is still active. The second set of conditions ensures that data from the previous descriptor has left the FIFO and that the current descriptor has started.

Memory DMA and Triggering

A memory DMA (MDMA) channel provides a means of doing memory-to-memory DMA transfers among the various memory spaces that have DMA support.

The DMA controller implements memory DMA (MDMA) channels by interfacing two DMA channels through the peripheral DMA bus interface. One DMA channel serves for memory read operations, and the second channel servers for memory writes. Depending on the processor, a memory DMA channel can have an additional peripheral, such as a CRC peripheral. The additional peripheral is inserted into the peripheral DMA bus that optionally can be enabled.

MDMA channel configurations that do not involve an additional peripheral impose no restrictions on which of the DMA channels is used for the read operation or the write operation. But, the configuration of both channels cannot have the same transfer direction. For MDMA channel configurations that enable a peripheral between the read and write channels, be aware of possible restrictions imposed on which channel can be used for a given transfer direction.

Figure 38-3: MDMA Channel Pair with Peripheral

A memory-to-memory transfer always requires enabled source and destination channels. Because the channels interface through the peripheral DMA bus and can have an additional peripheral inserted into the peripheral DMA bus, programs must make sure to set the same values in the `DMA_CFG.PSIZE` of both the source and destination channels.

The memory DMA channels support the full range of the `DMA_CFG.MSIZE` options for the DMA transfers to and from the memories.

Because the MDMA channel consists of two DMA channels, the entire MDMA channel has two sets of FIFOs, one in the read channel and one in the write channel. This FIFO usage allows for more efficient bursting of both read and write transactions using the available bandwidth. While the `DMA_CFG.PSIZE` configuration must be identical for both source and destination DMA channels, this restriction does not apply for the `DMA_CFG.MSIZE` configuration.

Configure the `DMA_CFG.PSIZE` bits to a value no larger than the supported bus width of the peripheral DMA bus.

NOTE: This is applicable for all of the DMA channels, except the enhanced and high-speed MDMA channels. For the enhanced and high-speed MDMAs, the minimum *PSIZE* and *MSIZE* is 4 bytes (32 bits).

The independent source and destination DMA channels also have their own dedicated interrupt and trigger events. While it is normal practice to have only event generation performed at destination DMA completion, programs also can use other means of interrupt generation.

Configuration of an MDMA transfer is done in a similar manner to peripheral DMA transfers, except for writing two DMA channel registers instead of one.

To control the pace of data transfers, use triggers on either the memory read or the memory write channel pair used in an MDMA operation. Setting the `DMA_CFG.TWAIT` bit in the memory read channel prevents both channels from transferring data before the system is ready. However, only configuring the memory write channel to wait for a trigger allows for data fetch from the memory in anticipation of the memory write operation.

The processor supports these categories of MDMA channels:

Standard Bandwidth MDMA. The channels run in the SCLK0 domain and support 32-bit memory and peripheral bus width. The maximum theoretical bandwidth of these MDMA streams is up to 4 × 112.5 = 450 MB/s. This MDMA optionally supports CRC.

Enhanced Bandwidth MDMA. The channels run in SYSCLK domain and support 32-bit memory and peripheral bus width. The maximum theoretical bandwidth of this MDMA stream is up to 4 × 225 = 900 MB/s.

Maximum Bandwidth MDMA. The channels run in SYSCLK domain and support 64-bit memory and peripheral bus width. The maximum theoretical bandwidth of these MDMA streams is up to 8 × 125 = 1800 MB/s. However, the practical maximum throughput for these MDMA streams is only up to 1500 MB/s.

NOTE: One MDMA channel is shared with the FFTA.

Medium Band Width DMA Channel MMR Access Bus

The MMR access bus provides access to all the DMA channels memory-mapped registers for DMA channel configuration, monitoring, and debug. The interface has a fixed 32-bit data bus for read and write accesses.

The ***MMR Access Bus Signals*** table provides descriptions of the MMR access bus signals.

Table 38-8: MMR Access Bus Signals

Signal	Width (bits)	Description
MMR_WRITE_DATA	32	Data bus used for write operations to the MMRs from the core
MMR_READ_DATA	32	Data bus used to return read data from the MMRs
MMR_READ_ADDR	7	Address used to select the MMR to access

DMA Channel Operation Flow

A detailed description of the flow of operation of the DMA channel appears in the following topics:

- Startup Flow
- Refresh Flow
- DMA Operating Modes
- Stop Mode
- DMA Channel Errors

Startup Flow

Enabling a DMA operation on a given channel first requires directly writing some or all of the DMA parameter registers. The minimum set of register required to be initialized depends on the desired mode of operation as described in the following sections.

Startup Minimum-Enable Requirements

To start a DMA operation on a given channel, some or all of the DMA parameter registers must first be initialized and configured to the desired DMA channels operating mode.

- For descriptor-array-based flow modes, at minimum, write the `DMA_DSCPTR_CUR` register prior to writing to the `DMA_CFG` register, which is the special action required to start the DMA channel.
- For descriptor-list-based flow modes, at minimum, write the `DMA_DSCPTR_NXT` register prior to writing to the `DMA_CFG` register, which is the special action required to start the DMA channel.
- For non-descriptor-based flow modes, write the `DMA_ADDRSTART`, `DMA_XCNT`, and `DMA_XMOD` registers prior to writing the `DMA_CFG` register.

Programs can write other registers that can remain static throughout the course of the DMA activity. The write to the `DMA_CFG` register begins the DMA operation.

ATTENTION: When software directly writes the `DMA_CFG` register, the DMA controller recognizes this action as the special startup condition. This condition occurs when starting the DMA controller for the first time on this channel or occurs after the DMA channel stops. It is possible for the channel to flag a DMA error condition regardless of the `DMA_CFG.EN` bit setting.

Startup Operation

The startup operation is initiated by software directly writing the `DMA_CFG` register when starting DMA for the first time on a channel or after the channel has entered to the stop state.

When the descriptor fetch is complete and the DMA channel is enabled, the `DMA_CFG` descriptor element in the `DMA_CFG` register assumes control. Before this point, the direct write to the `DMA_CFG` register had control.

At startup, the selected flow mode and the descriptor size determine the course of the DMA initialization process. The `DMA_CFG.FLOW` field determines whether to load more current registers from descriptor sets in memory. The

DMA_CFG.NDSIZE field details how many descriptor elements to fetch before starting the DMA operation. This process does not affect DMA registers that are not in the descriptor; no modifications are made to their prior values.

For descriptor-list flow modes, the channel copies the DMA_DSCPTR_NXT register value into the DMA_DSCPTR_CUR register. Then, the channel fetches new descriptor elements from memory. The DMA_DSCPTR_CUR register indexes each fetch, and the channel increments the index after each fetch. After completion of the descriptor fetch, the DMA_DSCPTR_CUR register points to the next 32-bit word in memory past the end of the descriptor.

If the descriptor fetch is for a descriptor-array mode transfer, the channel does *not* copy the DMA_DSCPTR_NXT register into the DMA_DSCPTR_CUR register. *Instead*, the descriptor fetch indexing begins with the value in the DMA_DSCPTR_CUR register.

If DMA_CFG is not part of the fetched descriptor set, the previous value (originally as written on startup) controls the work unit operation. If the DMA_CFG register is part of the fetched descriptor set, the value programmed by the MMR access controls only the loading of the first descriptor fetched from memory. The configuration of the DMA_CFG register controls the subsequent DMA work units of the fetched descriptor set.

After the descriptor fetch is complete or if the flow configuration was originally for one of the register-based flow modes, the DMA operation begins. The DMA channel immediately fills its FIFO. For a memory-write operation, the DMA channel begins accepting data from the peripheral. For a memory-read operation, the DMA channel begins memory reads when the SCB bus grants access to the DMA channel.

When the DMA channel performs its first data-memory access, its address and count computations take their input operands from the start registers. These registers can include DMA_ADDRSTART, DMA_XCNT, and DMA_YCNT, if necessary. The channel writes results back to the current registers. These registers include DMA_ADDR_CUR, DMA_XCNT_CUR, and DMA_YCNT_CUR. Note that the current registers are not valid until the channel performs the first memory access, which can be some time after the write to the DMA_CFG register starts the channel. Once started, the channel automatically loads the current registers from the appropriate descriptor elements, overwriting their previous contents. These automatic-load operations include:

- The channel copies the DMA_ADDRSTART value to DMA_ADDR_CUR.
- The channel copies the DMA_XCNT value to DMA_XCNT_CUR.
- The channel copies the DMA_YCNT to DMA_YCNT_CUR.

Refresh Flow

When the channel completes processing of a work unit, the DMA channel performs the following operations:

- Completes the transfer of all data between memory and the DMA channel.
- Performs a synchronized transition (if the DMA channel configuration is a memory read operation with the DMA_CFG.SYNC bit enabled) *and* transfers all data to the peripheral before continuing.
- Forwards the signals from the DMA channel (if interrupts or triggers are enabled) *and* updates the DMA_STAT register to indicate the interrupt request or trigger events.

- Clears the DMA_STAT.RUN bit field to stop DMA operation (if the flow was set to stop mode) *and* transfers any remaining data in the FIFO of the DMA channel to the peripheral.
- Loads a new descriptor from memory into the DMA registers by way of the contents of the DMA_DSCPTR_CUR register (for descriptor-array mode) *and* increments the DMA_DSCPTR_CUR register

  The channel takes the descriptor size from the DMA_CFG.NDSIZE value before the fetch.
- Copies the DMA_DSCPTR_NXT register into the DMA_DSCPTR_CUR register (for descriptor-list mode), fetches the descriptor from the new contents of the DMA_DSCPTR_CUR register, *and* places these contents into the DMA registers while incrementing the DMA_DSCPTR_CUR register.
- Checks for detection of an incoming trigger event (for descriptor-on-demand array mode):
  - If the channel detects a trigger event, the DMA channel loads a new descriptor from memory into the DMA registers from the contents of the DMA_DSCPTR_CUR register, while incrementing the DMA_DSCPTR_CUR register. The channel takes the descriptor size from the DMA_CFG.NDSIZE value before the fetch.
  - If the channel detects no trigger event, the DMA channel begins the next work unit by reloading the current registers.
- Checks for detection of an incoming trigger event (for descriptor-on-demand list mode):
  - If the channel detects a trigger event, the DMA channel copies the DMA_DSCPTR_NXT register value to the DMA_DSCPTR_CUR register, fetches the descriptor memory from the DMA_DSCPTR_CUR register, *and* places the contents into the DMA registers while incrementing the DMA_DSCPTR_CUR register.
  - If the channel detects no trigger event, the DMA channel begins the next work unit by reloading the current registers as described in the next step.
- Begins the next work unit (if flow configuration is anything other than stop mode) by reloading the current registers (DMA_ADDR_CUR, DMA_XCNT_CUR, and DMA_YCNT_CUR) from their descriptor registers (DMA_ADDRSTART, DMA_XCNT, and DMA_YCNT)

Work Unit Transition Flow

The DMA_CFG.SYNC bit controls transitions from one work unit to the next work unit. In general, continuous transitions have lower latency at the cost of restrictions on changes of data format or addressed memory space in the two work units. These latency gains and data restrictions arise from the way the channel handles the DMA FIFO while fetching the next descriptor.

In continuous transitions, with disabled synchronization, the DMA FIFO pipeline continues to transfer data to and from the peripheral or destination memory. These transfers continue during the descriptor fetch and during the DMA channel pause between descriptor chains. By comparison, synchronized transitions provide better real-time synchronization of interrupts and triggers with a given peripheral state. Synchronized transitions also provide greater flexibility in the data formats and memory spaces of the two work units. This flexibility comes at the cost of higher latency in the transition. In synchronized transitions, the DMA FIFO pipeline drains to the destination or flushes (received data discarded) between work units.

NOTE: The `DMA_CFG.SYNC` bit of the MDMA source channel controls work unit transitions for MDMA streams. Clear this reserved bit of the MDMA destination channel, placing it in the disabled state. In transmit (memory read) channels, the `DMA_CFG.SYNC` bit of the last descriptor before the transition controls the transition behavior. In contrast, in receive channels, the `DMA_CFG.SYNC` bit of the first descriptor of the next descriptor chain controls the transition.

Work Unit Transmit and MDMA Source Transitions

In DMA transmit (memory read) and MDMA source channels, the `DMA_CFG.SYNC` bit controls the interrupt timing at the end of the work unit. This bit also controls the handling of the DMA FIFO between the current and the next work unit.

If the `DMA_CFG.SYNC` bit configuration disables synchronization, the DMA channel operates in continuous transition. In a continuous transition, just after reading the last data item from memory, the DMA channel starts all of the following operations parallel:

- Signals the interrupt request or trigger
- Updates the `DMA_STAT` register to indicate DMA completion status
- Begins fetching the next descriptor
- Delivers the final data items from the DMA FIFO to the destination memory or peripheral

This process lets the DMA channel provide data from the FIFO to the peripheral continuously during the descriptor fetch latency period.

If the configuration disables synchronization, the final interrupt request or trigger (if enabled) occurs when the channel reads the last data from memory. This event occurs at the earliest time that the channel safely can modify the output memory buffer without affecting the previous data transmission. There can be a number of data items remaining in the FIFO and not yet at the peripheral. This number depends on the FIFO depth of the DMA channel. In this configuration, do not use the DMA interrupt request as the sole means of synchronizing the shutdown or reconfiguration of the peripheral following a transmission.

NOTE: If the configuration selects continuous transition on a transmit (memory read) descriptor, the next descriptor must have the same:

- Peripheral transfer size (`DMA_CFG.PSIZE`)
- Read or write direction
- Source memory (internal versus external) as the current descriptor

It is possible to disable synchronization by selecting continuous transition on a work unit with configuration for stop-flow mode and with enabled interrupts or triggers. This approach can result in the execution of the event service routine while draining of the final data is ongoing from the FIFO to the peripheral. If data transfers are in-progress, the FIFO is not yet empty. The `DMA_STAT.RUN` bits of the DMA channels indicate this status. Do not start a new work unit with a different peripheral transfer size or direction while data transfers are in-progress.

CAUTION: Disabling the channel with the `DMA_CFG.EN` bit while data transfers are in-progress causes the loss of the data in the FIFO.

A synchronized transition configuration directs the channel to drain the DMA FIFO to the destination memory or peripheral. This FIFO operation occurs before the channel signals any interrupt and before the channel fetches any subsequent descriptor or data. This operation incurs greater latency, but provides direct synchronization between the DMA interrupt and the state of the data at the peripheral.

If the configuration enables synchronization and enables interrupts, on the last descriptor in a work unit, the interrupt occurs when the channel transfers the final data to the peripheral. This event allows the service routine to switch properly to non-DMA transmit operation. When the event vectors to the interrupt service routine, the DMA channel FIFO is empty, and the DMA channel is no longer running (indicated by the `DMA_STAT.RUN` bits).

A synchronized transition also allows greater flexibility in the format of the DMA descriptor chain. When enabled, the next descriptor can have any `DMA_CFG.PSIZE` configuration or read/write direction supported by the peripheral and can come from either memory space (internal or external). This feature can be useful in managing MDMA work unit queues, since it is no longer necessary to interrupt the queue between dissimilar work units.

Work Unit Receive and MDMA Destination Transitions

In DMA receive channels (memory write operations), the `DMA_CFG.SYNC` bit controls the handling of the DMA FIFO between descriptor chains (not individual descriptor sets), during the DMA channel pause. The DMA channel pauses after the descriptor sets configured with stop flow mode are complete. Restart the channel (for example, after an interrupt) by writing the `DMA_CFG` register of the channel with a value that enables the DMA channel. If the configuration disables synchronization in the `DMA_CFG` value of the new work unit, the configuration selects a continuous transition. In this mode, the DMA FIFO retains any data items received during the channel pause, and they are the first items written to memory in the new work unit. This mode of operation provides lower latency at work unit transitions and ensures no dropping of data items during a DMA pause. The channel provides this operation at the cost of certain restrictions on the DMA descriptors.

NOTE: If the `DMA_CFG.SYNC` bit disables synchronization on the first descriptor of a chain after a DMA pause, do not change the configuration of the `DMA_CFG.PSIZE` field of the new chain from the previous descriptor chain (active before the pause). This restriction applies unless the DMA channel is reset between chains by disabling and then re-enabling the DMA channel.

If the `DMA_CFG.SYNC` bit configuration enables synchronization, the channel uses a synchronized transition. In this mode, only the data that the DMA channel receives from the peripheral after the write to the `DMA_CFG` register gets to memory. The channel discards any prior data items transferred from the peripheral to the DMA FIFO before this register write occurs. This operation provides direct synchronization between the data stream received from the peripheral and the timing of the channel restart, which occurs on the write to the `DMA_CFG` register.

For receive DMA operations, the synchronization has no effect in transitions between work units in the same descriptor chain. When the flow mode of previous descriptor was not stopped, the DMA channel did not pause.

If a descriptor chain begins with synchronization enabled, there is no restriction on the `DMA_CFG.PSIZE` of the new chain in comparison with the previous chain.

NOTE: The peripheral transfer size (`DMA_CFG.PSIZE`) must not change between one descriptor and the next in any DMA receive (memory write) channel within a single descriptor chain, regardless of the `DMA_CFG.SYNC` bit setting. In other words, all memory write descriptor sets in a descriptor chain must have the same `DMA_CFG.PSIZE` value. For any DMA receive channel (memory write operation), there is no restriction on changes of peripheral transfer size (internal versus external) between descriptors or descriptor chains.

Transfer Termination and Shutdown Flow

This section describes channel transfer termination and shutdown in stop flow mode and in autobuffer flow mode.

Stop Flow Mode

In stop flow mode, the DMA channel stops automatically after the work unit is complete. If using a list or array of descriptors to control DMA transfers and if every descriptor contains a `DMA_CFG` descriptor element, configure the flow of the final `DMA_CFG` descriptor element to stop mode, stopping the channel gracefully. After completion, the DMA channel remains in the stop state. Do not confuse this state with the disabled state, which either occurs due to a DMA error or occurs through disabling the DMA channel by configuring the `DMA_CFG.EN` bit.

The intention of disabling the DMA channel through a write to the `DMA_CFG.EN` bit is to shut down the DMA channel and to enter the disabled state. All memory and peripheral data transfers cease, and only peripheral interrupts pass through the DMA channels interrupt signals. However, the DMA channel maintains the `DMA_STAT.RUN` bits. For a write to memory, the outstanding memory-transaction counter tracks returning memory write acknowledgments and updates as required.

For memory reads, the outstanding memory-transaction count also tracks returning memory reads. The channel does not write the memory reads into the FIFO. The channel updates the counter to reflect the completion of the transaction, but the channel ignores the data. The `DMA_STAT.RUN` bits remain in the *waiting for write ACK or FIFO drain to peripheral* state and do not change to *stop or idle state* until the return of all outstanding transactions.

When the `DMA_CFG.EN` bit again enables the DMA channel, the channel performs a full reset and clears all counters. If an outstanding memory transaction returns an acknowledgment or read data after this event, a memory transaction error occurred, which generates an error event. Programs must ensure that all outstanding memory transactions complete before reconfiguring the DMA channel. For example, programs can poll the `DMA_STAT.RUN` bits to return to the stop or idle state before proceeding.

Autobuffer Flow Mode

In this mode, the flow does not use any descriptors in stored memory. Instead, the channel performs DMA in a continuous circular buffer fashion, based on user-programmed DMA register settings. On completion of the work unit, the channel reloads the parameter registers into the current registers, and the DMA controller resumes immediately with zero overhead. Consider this mode as a succession of automatically restarted work units.

For autobuffer-flow modes, the only way to cease operations is to disable the DMA channel through the `DMA_CFG.EN` bit. One method of changing to a new work unit is:

- Disable the DMA channel
- Set up all the registers (and descriptors in memory, if used) except for `DMA_CFG`

- Poll `DMA_STAT.RUN` to wait for the status to reflect stop or idle state, and
- Write `DMA_CFG` to the new configuration to begin the next work unit

In autobuffer-flow mode or for a list or array of descriptor sets without `DMA_CFG` descriptors, use an MMR write to the `DMA_CFG` register to terminate the DMA transfer process. Configure the value of the `DMA_CFG.EN` bit in this register to disable the DMA channel.

CAUTION: When the configuration disables a DMA channel, the DMA controller disables interrupt logic that is based on work unit transitions. Be aware of the system environment and current actions, so that additional interrupts are not required from the DMA channel.

CAUTION: If disabled through `DMA_CFG.EN` in the middle of a transaction, the DMA channel completes any transactions that have begun and avoids generating bus errors. However, the channel considers the action of re-enabling the DMA as a hard reset for all internal DMA channel components. Therefore, pay attention to that particular action to avoid unexpected results.

DMA Channel Errors

When an error occurs, the DMA channel maintains all the state and register values that allow programs to diagnose error causes more thoroughly. The greatest benefit to the programmer is to know exactly what operational state the DMA channel was in at the exact moment the error occurred.

Take care to address the root cause of the error, whether or not the problem originated in the DMA channel. If not properly resolved, the error can result in an additional error shortly after operations resume. The problem can cause other errors elsewhere in the DMA channel or associated modules and circuitry. So, take care also to address those potential problems. Ensure that all outstanding memory reads and writes are complete or cleared before resuming DMA channel operation.

After addressing all issues and neutralizing all side effects of any errors, clear the `DMA_STAT.ERRC` status field and restart the DMA channel by disabling then re-enabling the DMA channel through the `DMA_CFG.EN` bit.

The following sections describe the error types.

Status and Debug Errors

DMA channel error conditions can cause the DMA process to end abnormally. The DMA channel provides error detection as a tool for system development and debug, helping to identify DMA-related programming errors. When the DMA channel detects an error, the channel immediately stops and discards any returned memory-read transactions. The `DMA_STAT.RUN` field of the DMA channel indicates the idle state after acknowledging all outstanding memory transactions. In addition, the channel asserts an error interrupt request and updates the `DMA_STAT.IRQERR` field. Also, the channel updates the `DMA_STAT.ERRC` field, indicating the error cause of the first detected error. Unless the error occurs at the exact moment that modification of register values occurs, the registers contain the error values.

All the DMA error interrupt requests are combined into a single shared interrupt request output. Combined error signals require reading the `DMA_STAT` register of each DMA channel associated with a combined error interrupt request to determine the DMA channel responsible for the generation of the interrupt.

The DMA channel error interrupt handler performs the following actions:

- Read the `DMA_STAT` register of each DMA channel, seeking a channel with the `DMA_STAT.IRQERR` set to indicate an error.
- Read the `DMA_STAT.ERRC` field of each DMA channel, determining the cause of the error.
- Clear the problem with the DMA channel. For example, fix the register values.
- Clear the error in the DMA channel through a write-1-to-clear operation to the `DMA_STAT.IRQERR` bit.

If the channel flags any uncleared error other than a bandwidth monitor error, the channel reports no other error. If the channel reports an uncleared bandwidth monitor error, the channel reports any newly detected error through updating the `DMA_STAT.ERRC` field.

DMA Configuration Register Errors

The channel only flags these configuration errors when the `DMA_CFG.EN` bit enables the DMA channel. Error flagging occurs when the configuration:

- Uses a reserved setting
- Enables `DMA_CFG.TWAIT` in descriptor on-demand flow mode
- Uses an illegal `DMA_CFG.NDSIZE`
- Uses an illegal `DMA_CFG.MSIZE`
- Configures `DMA_XCNT` = 0 or, when `DMA_YCNT` = 0 in 2D DMA mode
- Uses non-zero value in `DMA_CFG.NDSIZE` when DMA is configured in stop mode or auto mode
- Enables interrupt or outgoing triggers on `DMA_YCNT` when DMA is configured in 1D mode
- Use a `DMA_CFG.MSIZE` that exceeds the FIFO size of the DMA channel
- Uses an illegal `DMA_CFG.PSIZE`
- Uses a `DMA_CFG.PSIZE` that exceeds the FIFO size
- Uses a `DMA_CFG.PSIZE` that exceeds the bus width
- Attempts to change from a transmit operation (memory read) to a receive operation without properly synching in the previous work unit or when it is the first work unit in a new chain
- Attempts to change `DMA_CFG.PSIZE` of a transmit operation (memory read) without properly synching in previous work unit or when it is the first work unit in a new chain
- Attempts to change from receive operation (memory write) to a transmit operation during a descriptor chain.

  The channel only can change from receive to transmit if the new transmit is synchronized and is the first work unit.

- Attempts to change `DMA_CFG.PSIZE` of a receive operation (memory write) when the operation was not the first work unit (with `DMA_CFG.SYNC` enabled)

Illegal Register Write During Run

The channel generates an error when a write occurs to writable registers of an enabled, running DMA channel. The channel blocks the write. The `DMA_STAT`, `DMA_BWLCNT`, and `DMA_BWMCNT` registers are exempt from this behavior. The `DMA_STAT` register is exempt from this behavior.

Address Alignment Error

The channel generates an address alignment error when any of the following apply:

- Alignment of a descriptor address is not on a 32-bit boundary.
- The current `DMA_CFG.MSIZE` configuration contains an unaligned transfer address. The `DMA_ADDRSTART` register is not aligned according to the `DMA_CFG.MSIZE` field.

Memory Access Error

The channel generates a memory access error when the DMA process:

- attempts to access an unpopulated address,
- attempts to access an address defined as cache, or
- attempts to access a location that provokes a security violation

The error returned from the memory triggers the memory access error.

Trigger Overrun Error

A trigger overrun error is generated when a new trigger input occurred while an outstanding trigger is waiting. This error is only generated if `DMA_CFG.TOVEN` is enabled.

Bandwidth-Monitor Error

The channel generates this error when the bandwidth-monitor count expires. This error is not fatal, and the DMA channel continues operation.

Control Interface Error

The channel reports control-interface errors as bus errors to the bus master. This error can result from:

- An address error
- A register write error (write to a read-only register)

DMA Operating Modes

The DMA channel supports a number of different flow modes that control how the DMA channel progresses from one work unit to the next.

The flow mode of a DMA channel is not a global setting. A DMA descriptor set can include the descriptor responsible for configuring the flow of the work unit. There is no restriction, limiting the flow configuration to be the same for the entire descriptor chain. If the descriptor chain is not endless, the last descriptor set configures the flow to stop mode, which results in termination of the descriptor chain after the work unit completes. Another example for mixing flow modes is to create an endless descriptor-array. The configuration of the last descriptor set in the array selects the descriptor-list mode. The next descriptor pointer in this set of descriptors points to the first descriptor in the array.

Register-Based Flow Modes

Register-based DMA operations require configuration by directly writing to the memory-mapped registers of the DMA channel.

Register-based DMA is the traditional method of DMA operation. Software writes all of the configuration of the DMA channel into the memory-mapped registers. This configuration includes information such as the source or destination address and length of the data in the transfer. The DMA controller then starts channel operation. The DMA channel supports the following register-based flow modes.

- Stop Mode
- Autobuffer Mode

The DMA channel supports variable descriptor set sizes within the configuration. The size of a descriptor set can contain as little as a single descriptor. The supported descriptor set sizes can differ between the various descriptor-based flow modes. In addition to the descriptor set size being configurable, descriptor-based DMA also allows altering the flow mode of the next descriptor set. This feature allows for the transition from descriptor-array mode to descriptor-list mode and permits configuring the flow to stop or autobuffer mode.

Stop Mode

In stop mode, the DMA operation executes only once. If started, the DMA channel transfers the desired number of data words and stops itself again when finished. If the DMA channel is no longer used, software configures the enable bit to disable a paused channel. The channel also can generate interrupts and triggers for each row or work unit completion, depending on the desired operation.

Autobuffer Mode

In autobuffer mode, the DMA operates repeatedly in a circular manner. If the transfer of all data words completes, the channel reloads the address pointer (`DMA_ADDR_CUR`) automatically with the `DMA_ADDRSTART` value. The channel also can generate an interrupt.

The `DMA_CFG.FLOW` field enables autobuffer mode. The configuration must load the `DMA_CFG.NDSIZE` field value, such that the next descriptor size is zero.

Descriptor-Based Flow Modes

Descriptor-based DMA operations fetch descriptor sets from memory allowing for autonomous loading of work units on other work units. Software does not need to set up the DMA sequences directly by writing into the DMA controller registers. Rather, software keeps DMA descriptor sets in memory.

Descriptor-based DMA operations have the following additional attributes.

- The DMA controller autonomously loads the descriptor set from memory to the affected DMA controller registers on demand.
- The channel can fetch descriptor sets from any memory space that supports DMA read operations.
- The descriptor set describes the next operation that the DMA controller performs.
- The descriptor set can include information such as the DMA configuration word as well as data source or destination address, transfer count, and address modify values.

A descriptor set describes a single work unit. The next work unit can reuse some values from the previous one descriptor set. But, this reusage is possible only if they are not overwritten in the subsequent descriptor set fetches and only if the work unit requires the use of this descriptor.

The DMA channel supports the following flow modes with descriptor-based operations.

- Descriptor-Array Mode
- Descriptor-List Mode
- Descriptor-On-Demand Modes

The DMA channel supports variable descriptor set sizes within the configuration. The size of a descriptor set can contain as little as a single descriptor and the supported descriptor set sizes can differ between the various descriptor-based flow modes. In addition to configurable descriptor set size, descriptor-based DMA also allows for altering of the flow mode of the next descriptor set. Programs can transition from one descriptor-based mode to another descriptor-based mode and can also transition to any of the register-based flow modes.

Descriptor-Array Mode

When configured in this mode, the descriptor sets do not contain further descriptor pointers. Software writes the initial descriptor-pointer value, which points to an array of descriptors. This operation assumes that the individual descriptors reside next to each other and assumes that their addresses are known.

The *Offsets for Descriptor-Array Mode Parameters and Descriptors* table illustrates how to structure a descriptor set in memory. The descriptor sets must reside in a contiguous block or memory in the format shown in the table. Locate the first descriptor of the next descriptor set in the memory location immediately following the last descriptor of the current descriptor set. The values have the same order as the corresponding offset addresses of the memory-mapped register.

Table 38-9: Offsets for Descriptor -Array Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_ADDRSTART
0x04	DMA_CFG
0x08	DMA_XCNT
0x0C	DMA_XMOD
0x10	DMA_YCNT

Table 38-9: Offsets for Descriptor -Array Mode Parameters and Descriptors (Continued)

Descriptor Offset	Parameter Register
0x14	DMA_YMOD

All other DMA channel registers not loaded as a result of the descriptor set fetch retain their previous values. The channel reloads all of the current registers between the descriptor set fetch and the start of the DMA operation for the work unit.

NOTE: At a minimum, write the `DMA_DSCPTR_CUR` register prior to writing to the `DMA_CFG` register, which is the special action required to start the DMA channel.

Descriptor-List Mode

In this flow mode, multiple descriptors form a chained list in which each descriptor set contains a pointer to the next descriptor set, allowing greater flexibility in memory layout options. When the channel fetches the descriptor set, the operation loads this pointer value into the next descriptor pointer register of the DMA channel.

Descriptor Sets

The ***Offsets for Descriptor-List Mode Parameters and Descriptors*** table shows how to structure a descriptor set in memory. Disperse the placement of the descriptor sets throughout memory, having sets reside in different memory blocks. But, each descriptor of the descriptor set must reside in a contiguous section of memory in the format shown in the table. The values have the same order as the corresponding offset addresses of the memory-mapped registers.

Table 38-10: Offsets for Descriptor-List Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_DSCPTR_NXT
0x04	DMA_ADDRSTART
0x08	DMA_CFG
0x0C	DMA_XCNT
0x10	DMA_XMOD
0x14	DMA_YCNT
0x18	DMA_YMOD

All other DMA channel registers not loaded as a result of the descriptor set fetch retain their previous values. The channel reloads all of the current values of the registers between the descriptor set fetch and the start of the DMA operation for the work unit.

Minimum Startup Requirements

At a minimum, write the `DMA_DSCPTR_NXT` register prior to write to the `DMA_CFG` register, which is the special action required to start the DMA channel.

Descriptor-On-Demand Modes

The Descriptor-Array Mode and Descriptor-List Mode each have an on-demand mode of operation.

In on-demand mode, at the end of the work unit, if the DMA channel has not detected an incoming trigger event, the channel repeats the current work unit. If the DMA channel receives an incoming trigger before completion of the work unit, the channel fetches a new descriptor set.

The *Offsets for Descriptor-Array Mode Parameters and Descriptors* and *Offsets for Descriptor-List Mode Parameters and Descriptors* tables illustrate how to structure each descriptor set in memory.

Table 38-11: Offsets for Descriptor-Array Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_ADDRSTART
0x04	DMA_CFG
0x08	DMA_XCNT
0x0C	DMA_XMOD
0x10	DMA_YCNT
0x14	DMA_YMOD

NOTE: For descriptor-array mode, at a minimum, write the `DMA_DSCPTR_CUR` register prior to writing to the `DMA_CFG` register, which is the special action required to start the DMA channel.

Table 38-12: Offsets for Descriptor-List Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_DSCPTR_NXT
0x04	DMA_ADDRSTART
0x08	DMA_CFG
0x0C	DMA_XCNT
0x10	DMA_XMOD
0x14	DMA_YCNT
0x18	DMA_YMOD

NOTE: For descriptor-list mode, at a minimum, write the `DMA_DSCPTR_NXT` register prior to write to the `DMA_CFG` register, which is the special action required to start the DMA channel.

Data Transfer Modes

In addition to supporting basic one-dimensional DMA transfers, the DMA channel also supports two-dimensional functionality.

Two-Dimensional DMA

Register-based flow modes and descriptor-based flow modes support two-dimensional data transfers.

In two-dimensional (2D) mode, the X-direction count (DMA_XCNT), the X-direction modifier (DMA_XMOD), the Y-direction count (DMA_YCNT), and the Y-direction modifier (DMA_YMOD) support arbitrary row and column sizes. Also, the modify values can be negative, allowing implementation of interleaved data streams. The DMA_XCNT value specifies the row size, and the DMA_YCNT value specifies the column size; where the DMA_XCNT value must be 2 or greater.

The DMA start address (DMA_ADDRSTART), the X-direction modifier (DMA_XMOD), and theY-direction modifier (DMA_YMOD) specifications all are in bytes. The alignment must be a multiple of the DMA transfer word size; configured using the DMA_CFG.MSIZE bit. Misalignment results in a DMA channel error.

The DMA_XMOD register value is the byte-address increment that the channel applies after each transfer, decrementing the DMA_XCNT register. The channel does not apply the DMA_XCNT when the inner loop count ends with the DMA_XCNT_CUR register decrementing to 0 from 1. Except, the channel does apply the DMA_XCNT on the final transfer, when the DMA_YCNT register is 1 and the DMA_XCNT register decrements from 1 to 0.

The DMA_YMOD register value is the byte-address increment that the channel applies after each decrement of the value in DMA_YCNT_CUR. However, the channel does not apply the DMA_YMOD value to the last item in the array on which the outer loop count (DMA_YCNT_CUR) also expires by decrementing from 1 to 0.

After the last transfer completes, DMA_YCNT_CUR is 1 and the DMA_XCNT_CUR register is 0. The DMA channels current address points to the last items address plus the DMA_XMOD register value. If the DMA channel programming selects automatic refresh (such as in autobuffer mode), the channel reloads the DMA_XCNT_CUR, DMA_YCNT_CUR, and DMA_ADDR_CUR for the first data transfer of the next work unit.

Interrupt notification is configurable for end-of-row or end-of-work unit completion.

For example, two-dimensional DMA can be used to extract interleaved data (such as RGB values for a video frame) by modifying both of the DMA_XMOD and DMA_YMOD values. The ***Capturing a Video Data Stream 2D DMA Example*** depicts the process of receiving a stream of the R, G, B values from an N*M frame. The inner loop of the 2D DMA configuration has three values (DMA_XCNT = 3) and a stride (DMA_XMOD) of N*M, chosen such that successive elements in each row are 1-2-3, 4-5-6 and so forth. The outer loop of the 2D DMA configuration has N*M values (DMA_YCNT = N*M) and a negative stride (DMA_YMOD) of 1-2*N*M chosen to instruct the DMA controller to jump from element 3 to 4, 6 to 7 and so forth at the end of each inner loop.

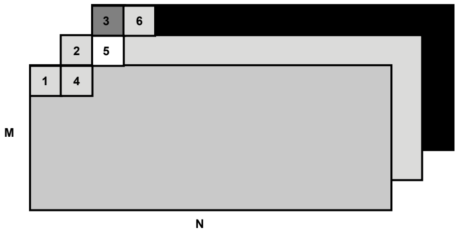

Figure 38-4: Capturing a Video Data Stream 2D DMA Example

DMA Channel Event Control

The DMA channel supports a number of events that provide notification of work unit state, peripheral data request, peripheral interrupt request and completion events, and DMA channel error conditions. In addition to flexible interrupt configuration, the DMA channel also supports incoming and outgoing triggers which are useful in synchronizing the DMA channel with other system resources.

The DMA channel has two interrupt signals for support of a number of events such as work-unit state events, peripheral interrupt request (PIRQ) events, peripheral data request (PDR) events, and DMA channel errors. The channel reports DMA channel errors on a dedicated interrupt signal. All other interrupt sources share an interrupt signal. In addition to flexible interrupt configuration, the DMA channel also supports incoming and outgoing triggers which are useful in synchronizing the DMA channel with other system resources.

The channel can signal the processor on DMA channel events using status information and optional interrupt requests. Programs can use these events to update the progress of data transfers and to request intervention from the processor core. Configure most DMA channel interrupts using bits in the `DMA_CFG` register. Dedicated bits in the `DMA_STAT` register report the occurrence of various events. Use write-one-to-clear (W1C) operations to clear interrupt requests from the status register.

> **NOTE:** Hardware does not clear the interrupt status bits automatically, even when programs disable then reenable the DMA channel. In this situation, the channel deasserts the interrupt signal, after the program disables the DMA channel. But, the status bit remains set until software either re-enables the DMA channel or clears the status bit.

The DMA channel supports the following categories of events on the interrupt signals:

- Work-unit state events generate interrupts on row or on work unit DMA completion.
- A peripheral uses peripheral interrupt request (PIRQ) events to signal when it has completed the transfer of all data.
- A peripheral uses peripheral data request (PDR) events to request data from a disabled or idle DMA channel.
- Error events signal a failure in the work unit.

> **ATTENTION:** While in an error state, the DMA channel does not generate an interrupt to the processor for a work-unit state event or a PIRQ event, nor does the channel forward a PDR event.

Event Signals

The *Event Signals* table provides descriptions of DMA channel events.

Table 38-13: Event Signals

Signal	Width (bits)	Description
DMA_ERROR	1	Used to signal an error condition in the DMA channel. The source of the error can be determined by reading the `DMA_STAT.ERRC` bit.

Table 38-13: Event Signals (Continued)

Signal	Width (bits)	Description
DONE_PIRQ_INT	1	Signal used to indicate DMA completions events, PIRQ events and also for forwarding PDR events based on configuration. Read the corresponding fields in `DMA_STAT` to determine the source of the event.
DMA_TRIG_OUT	1	Trigger output that gets routed to the TRU and can be configured to provide notification on row or work unit completion.
DMA_TRIG_IN	1	Trigger input from the TRU that can be used to control the start of a work unit.

Work Unit State Events

Completing a row or a work unit generates a work-unit state event. For either of these events to generate an interrupt request, the configuration of the interrupt of the DMA channel must select one of the available work-unit completion modes.

- Current X count reaching 0 for row completion or 1D DMA work unit completion
- Current Y count reaching 0 for work unit completion of 2D DMA

NOTE: For 1D DMA, a DMA channel configuration error results if the configuration generates the interrupt request when the current Y counter reaches 0.

The DMA channel issues the last memory read or write transaction for the row or work unit, then pauses until the return of the read or write acknowledge. After successful acknowledge of the transfer, the DMA channel issues the interrupt request and continues to process the next row or work unit.

Waiting for acknowledgement of the memory access results in a delay. However, programs can read or modify data in the memory without adversely affecting or being affected by the DMA transfer.

NOTE: While the DMA channel pauses waiting for acknowledgement of the memory transfer, the DMA channel is still capable of fetching the next descriptor set. This fetch gets the channel ready to process the next work unit as soon as the memory access completes.

The channel configuration of the synchronization feature also affects interrupt timing. For memory-read operations with synchronization enabled, the channel delays the interrupt request until the completion of the last transfer from the DMA channel FIFO to the peripheral. The synchronization feature does not affect interrupt timing for memory write operations.

Peripheral Interrupt Request Events

For peripheral-transmit operations, a peripheral connected to the DMA channel can use peripheral interrupt request (PIRQ) events to indicate that data has left the channel FIFO and to indicate transfer completion.

In order to support PIRQ interrupts, correctly configure the interrupt of the DMA channel. This configuration disables the generation of interrupt requests based on the work unit state and, instead, results in generating an interrupt request when the DMA channel receives the command from the peripheral.

The channel only generates the interrupt request under the following conditions:

- The configuration enables the DMA channel
- The DMA channel is in the stop state
- The configuration of the DMA channel interrupt selects PIRQ operation

Peripheral Data Request Events

Peripheral data request (PDR) events occur when an interfaced peripheral requests data from the DMA channel and the DMA channel (either disabled or enabled) is in the stop state.

When a peripheral sends a data request command to a disabled DMA channel, the DMA channel generates an interrupt to the System Event Controller (SEC). There is no status information reported about this event in the status register of the DMA channel. Instead, the channel identifies the PDR event from the fact that the DMA channel generated an interrupt while disabled. It is possible to further confirm event status by verifying the status of the peripheral interfaced to the DMA channel.

This operation forwards data requests as interrupts when the DMA channel is in the disabled state. Also, the DMA channel is able to forward PDR events as an interrupt request when the DMA channel is in the stop state after the completion of a work unit. The forwarding of this interrupt when the DMA channel is in the stop state is optional and configured by the program during DMA channel configuration.

DMA Channel Triggers

DMA channel triggers are useful for synchronizing the DMA channel with other events in the system. One usage is to combine channel triggers with each other to create ping-pong buffers. Another usage is to combine the triggers with interrupt requests to notify the processor on reaching a particular milestone that requires service. The channel also can use triggers to enforce a handshake DMA operation in which the trigger acts as a signal for a DMA request.

> **NOTE:** Using the trigger to control the pace of data transfers, such as for handshake DMA, requires that all the data for the entire work unit is ready for transfer.

The DMA channel has a single incoming trigger that can control the pace of the data transfers performed by the DMA channel. The configuration can direct the DMA channel to wait for the incoming trigger before starting the work unit transfer or fetching a descriptor set from memory.

The DMA channel also has a single outgoing trigger signal. This configuration can direct this trigger to signal the end of row or an entire work unit. The DMA channel issues the last memory read or memory write transaction for the row or work unit, then pauses until return of the transfer acknowledge. After acknowledgement of the transfer, the DMA channel issues the trigger before processing the next row or work unit.

Issuing Triggers

The DMA channel configuration can direct the channel to generate an outgoing trigger signal at the end of row or the end of a work unit. The DMA channel issues the last memory read or memory write transaction for the row or work unit, then pauses until the return of the transfer acknowledge. After acknowledgement of the transfer, the DMA channel issues the trigger before processing the next row or work unit.

NOTE: While the DMA channel pauses waiting for acknowledgement of the memory transfer, the DMA channel is still capable of fetching the next descriptor set. This fetch gets the channel ready to process the next work unit as soon as the memory access completes.

Waiting For Triggers

Programs can use triggering to control the pace of data transfers performed by the DMA channel. The DMA channel enters a wait state before beginning the next work unit if the configuration enables `DMA_CFG.TWAIT` and either of the following apply:

- The channel receives a trigger since the last time the DMA channel left the wait state.
- The channel receives a trigger since its transition from disable to enable.

In the wait state, the DMA channel also does not perform a descriptor fetch. After receiving a trigger, the DMA channel leaves the wait state and begins the next work unit or fetches the next descriptor if configured for a descriptor-based mode of operation.

If a memory-mapped register write operation programs the channel with stop flow mode enabled (`DMA_CFG.TWAIT` bit) and the channel has not already received a trigger, the DMA channel enters a wait state before performing the data transfer. On receiving the trigger, the DMA channel begins the data transfer portion of the work unit. Once the data transfer is complete, the DMA channel enters the stop state.

If a memory-mapped register write operation programs the DMA channel with the flow mode configured to one of the descriptor-based modes, the DMA channel enters the wait state before performing the descriptor fetch. After completing the descriptor fetch, the DMA channel immediately proceeds to the data transfer, regardless of the value of the `DMA_CFG.TWAIT` bit. If another (next) descriptor fetch follows the descriptor fetch, the DMA channel enters a wait state before fetching the next descriptor.

If the descriptor fetch returns a descriptor with stop flow mode, the `DMA_CFG.TWAIT` value for that descriptor does not affect the DMA as the channel enters the stop state after completing the data transfer. The DMA channel only enters the wait state based on `DMA_CFG.TWAIT` before the next work unit or descriptor fetch.

If the descriptor fetch returns a descriptor configured for autobuffer flow mode, the `DMA_CFG.TWAIT` for that descriptor does not affect the DMA for the first work unit of the autobuffer transfer. After completing the first work unit and not receiving another trigger, the DMA channel enters the wait state before reinitializing its counters and address registers (if not configured for current addressing). The channel performs the next work unit after receiving the trigger.

The incoming trigger can occur when the DMA channel has not entered the wait state. The trigger can occur while the DMA channel is executing a work unit, is performing descriptor fetch, or is in the stop state. The trigger is held internally. After the work unit is complete, the DMA channel skips the wait state and proceeds directly to executing the following work unit. If the `DMA_CFG.TWAIT` bit is not enabled, the DMA channel also skips the wait state. However, the trigger is held internally and is used the next time the configuration enables `DMA_CFG.TWAIT`. This trigger retention allows programs to enable the `DMA_CFG.TWAIT` functionality several work units apart without concern for losing a trigger. The DMA channels trigger-overrun enable functionality can be enabled in all work units to ensure that multiple triggers do not occur between the work units with the `DMA_CFG.TWAIT` bit enabled.

DMA Channel Programming Model

Several synchronization and control methods are available for use in development of software tasks which manage peripheral DMA and memory DMA. Software must accept requests for new DMA transfers from other software tasks, integrate these transfers into existing transfer queues, and reliably notify other tasks when the transfers are complete.

In the processor, it is possible to manage each peripheral DMA and memory DMA stream with a separate task or to manage them together with any other stream. Each DMA channel has independent, orthogonal control registers, resources, and interrupts. So, the selection of the control scheme for one channel does not affect the choice of control scheme on other channels. For example, one peripheral can use a linked-descriptor-list, interrupt-driven scheme while another peripheral can simultaneously use a demand-driven, buffer-at-a-time scheme synchronized by polling DMA events.

The topics that follow describe the steps required to configure the DMA channel for the various modes in addition to the programming concepts required for software synchronization.

Mode Configuration

Use the step-by-step directions that follow to set up the DMA channel for operating modes.

Register-Based Linear-Buffer Stop Flow Mode

This procedure configures the DMA channel of a peripheral to read data from internal memory and to send it to the peripheral for transmission.

Assume that the peripheral is in a state where it is ready to transmit data received from the DMA channel.

The task involves writing to a number of DMA channel MMR registers to configure a DMA channel to:

- Read data from internal memory, and
- Send it to a peripheral connected to the peripheral DMA bus.

On DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the `DMA_ADDRSTART` register.

   ADDITIONAL INFORMATION: Software can use the address to calculate the most optimum possible `DMA_CFG.MSIZE`.

2. Calculate the optimum `DMA_CFG.MSIZE` based on the `DMA_ADDRSTART` register and number of bytes in work unit.

ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected `DMA_CFG.MSIZE`, and the calculation also must consider the start address alignment.

3. Write the `DMA_XCNT` register based on the calculated `DMA_CFG.MSIZE`.

   ADDITIONAL INFORMATION: The `DMA_XCNT` value is the number of `DMA_CFG.MSIZE` transfers to make up the entire work unit.

4. Write the `DMA_XMOD` register.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in `DMA_XMOD` from the selected `DMA_CFG.MSIZE`. Always specify this register as a number of bytes.

5. Write the `DMA_CFG` register with `DMA_CFG.EN` configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the `DMA_CFG.FLOW` bit for STOP mode. Configure the `DMA_CFG.WNR` bit for memory read operation. Configure the `DMA_CFG.PSIZE` bits to a value no larger than the supported bus width of the peripheral DMA bus.

   - The `DMA_CFG.SYNC` bit can be configured to control DMA completion notification timing.
   - Interrupts and triggers also can be configured at this step depending on requirements.

Now, the DMA channel is enabled, and the buffer is transferred. The DMA channel enters the IDLE state upon completion of the work unit.

Register-Based Autobuffer Flow Mode

This procedure configures the DMA channel of a peripheral to read data from internal memory and send it to the peripheral for transmission. The transmission of the buffer repeats endlessly.

Assume the peripheral is in a state where it is ready to transmit data received from the DMA channel.

The task involves writing to a number of DMA channel MMR registers to configure a DMA channel to:

- Read data from internal memory, and
- Send it to a peripheral connected to the peripheral DMA bus.

On DMA completion, the DMA channel restarts the DMA operation, creating an endless circular buffer transfer.

1. Write the `DMA_ADDRSTART` register.

   ADDITIONAL INFORMATION: Use the address to calculate the optimum possible `DMA_CFG.MSIZE`.

2. Calculate the optimum `DMA_CFG.MSIZE` based on the `DMA_ADDRSTART` register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected `DMA_CFG.MSIZE`, and the calculation must consider the start address alignment.

3. Write the `DMA_XCNT` register based on calculated `DMA_CFG.MSIZE`.

   ADDITIONAL INFORMATION: The `DMA_XCNT` register value is the number of `DMA_CFG.MSIZE` transfers to make up the entire work unit.

4. Write the `DMA_XMOD` register.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in `DMA_XMOD` from the selected `DMA_CFG.MSIZE`. Always specify this register as a number of bytes.

5. Write the `DMA_CFG` register with the `DMA_CFG.EN` bit configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the `DMA_CFG.FLOW` bit for autobuffer mode. Configure the `DMA_CFG.WNR` bit for memory read operation. Configure the `DMA_CFG.PSIZE` bit to a value no larger than the supported bus width of the peripheral DMA bus.

   - The `DMA_CFG.SYNC` bit can be configured to control DMA completion notification timing.
   - Interrupts and triggers also can be configured at this step depending on requirements.

Now, the DMA channel is enabled, and the buffer transfers until the DMA channel is disabled.

Descriptor-Array Flow Mode

This procedure configures the DMA channel of a peripheral to:

- Read data from memory as described by the descriptor sets in the array, and
- Send the data to the peripheral for transmission.

Descriptor sets are read from an array in memory to configure the individual work units.

Assume the peripheral is in a state where it is ready to transmit data received from the DMA channel. Assume that the array of descriptors is to be initialized with the last descriptor set configured for STOP flow mode.

The task involves writing to a number of DMA channel MMR registers to:

- Configure a DMA channel to read the array in memory, containing the first descriptor set that configured the DMA channel to retrieve, and
- Send the data to a peripheral connected to the peripheral DMA bus.

On DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the `DMA_DSCPTR_CUR` register with the address of the array in which the descriptor sets are stored.

   ADDITIONAL INFORMATION: The array address must meet any processor alignments restrictions imposed by descriptor fetches.

2. Write the `DMA_CFG` register with the `DMA_CFG.EN` bit configured to enable the DMA channel.

ADDITIONAL INFORMATION: Set the `DMA_CFG.FLOW` bit for descriptor-array mode. Configure the `DMA_CFG.NDSIZE` bits to describe the number of descriptor elements contained within the first descriptor set. Configure the `DMA_CFG.WNR` bit for memory read operation. Configure the `DMA_CFG.PSIZE` bits to a value no larger than the supported bus width of the peripheral DMA bus.

- The descriptor set that is fetched controls the `DMA_CFG.SYNC` configuration and the interrupt or trigger configurations.

The first descriptor set is fetched from memory location provided by the `DMA_DSCPTR_CUR` register and loaded to the MMR registers of the DMA channel.

Now, the DMA channel is processing all the work units provided in the descriptor array. The DMA channel enters the IDLE state on completion of the final work unit that was configured for STOP flow mode.

Descriptor-List Flow Mode

This procedure configures the DMA channel of a peripheral to:

- Read data from memory as described by the descriptor sets in the list, and
- Send it to the peripheral for transmission.

The DMA controller reads the descriptor sets from a list of descriptors. With the list, each descriptor set has a descriptor that points to the next descriptor set location in memory.

Assume the peripheral must be in a state where it is ready to transmit data received from the DMA channel. Assume that the list of descriptors must be initialized with the last descriptor set in the list configured for Stop flow mode.

The task involves writing to a number of DMA channel MMR registers to:

- Configure a DMA channel to read the list in memory, containing the first descriptor set that configured the DMA channel to retrieve, and
- Send the data to a peripheral connected to the peripheral DMA bus.

On DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the `DMA_DSCPTR_NXT` register with the address of the first descriptor in the list to be processed.

   ADDITIONAL INFORMATION: The array address must meet any processor alignments restrictions imposed by descriptor fetches.

2. Write the `DMA_CFG` register with the `DMA_CFG.EN` configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the `DMA_CFG.FLOW` for descriptor-list mode. Configure the `DMA_CFG.NDSIZE` bit to describe the number of descriptor elements contained within the first descriptor set. Configure the `DMA_CFG.WNR` bit for memory read operation. Configure the `DMA_CFG.PSIZE` bit to a value no larger than the supported bus width of the peripheral DMA bus.

- The descriptor set that is fetched controls the `DMA_CFG.SYNC` configuration and controls the interrupt or trigger configurations.

The first descriptor set is fetched from the memory location provided by `DMA_DSCPTR_NXT` and is loaded to the MMR registers of the DMA channel.

Now, the DMA channel is processing all the work units provided in the descriptor list. The DMA channel enters the idle state when the final work unit that was configured for stop-flow mode is complete.

Register-Based Memory-to-Memory Transfer in Stop Flow Mode

This procedure configures a memory DMA channel pair in stop flow mode. One DMA channel is configured for memory read operations, while the other DMA channel is configured for memory write.

The task involves writing to a number of DMA channels on two DMA channels that create a memory DMA pair. On DMA completion, the DMA channel enters the idle state, until either the DMA channel is disabled or is reconfigured for a new transfer.

1. Write the `DMA_ADDRSTART` register of the source DMA channel.

   ADDITIONAL INFORMATION: The address can be used to calculate the optimum `DMA_CFG.MSIZE` possible.

2. Calculate the optimum `DMA_CFG.MSIZE` based on the `DMA_ADDRSTART` register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected `DMA_CFG.MSIZE` and the start address alignment must also be considered.

3. Write the `DMA_XCNT` register of the source DMA channel based on calculated `DMA_CFG.MSIZE`.

   ADDITIONAL INFORMATION: `DMA_XCNT` is the number of `DMA_CFG.MSIZE` transfers to make up the entire work unit.

4. Write the `DMA_XMOD` register of the source DMA channel.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in `DMA_XMOD` from the selected `DMA_CFG.MSIZE`. This register is always specified in the number of bytes.

5. Write the `DMA_ADDRSTART` register of the destination DMA channel.

   ADDITIONAL INFORMATION: The address can be used to calculate the most optimum `DMA_CFG.MSIZE` possible.

6. Calculate the optimum `DMA_CFG.MSIZE` based on the `DMA_ADDRSTART` register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected `DMA_CFG.MSIZE` and the start address alignment must also be considered.

7. Write the `DMA_XCNT` register of the destination DMA channel based on the calculated `DMA_CFG.MSIZE`.

   ADDITIONAL INFORMATION: `DMA_XCNT` is the number of `DMA_CFG.MSIZE` transfers to make up the entire work unit.

8. Write the `DMA_XMOD` register of the destination DMA channel.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in `DMA_XMOD` from the selected `DMA_CFG.MSIZE`. This register is always specified in the number of bytes.

9. Write the `DMA_CFG` register of the source DMA channel with `DMA_CFG.EN` configured to enable the DMA channel.

   ADDITIONAL INFORMATION: The `DMA_CFG.FLOW` bit must be set for stop mode. The `DMA_CFG.WNR` bit must be configured for memory read operation. The `DMA_CFG.PSIZE` bits must be configured to a value no larger than the supported bus width of the peripheral DMA bus.

   - The `DMA_CFG.SYNC` bit can be configured to control DMA completion notification timing.
   - Interrupts and triggers also can be configured at this step, depending on requirements. The interrupts and triggers are enabled within the destination DMA channel configuration.

   The memory read DMA transfer begins.

10. Write the `DMA_CFG` register of the destination DMA channel with `DMA_CFG.EN` configured to enable the DMA channel.

    ADDITIONAL INFORMATION: The `DMA_CFG.FLOW` bit must be set for stop mode. The `DMA_CFG.WNR` bit must be configured for memory write operation. The `DMA_CFG.PSIZE` bits must be configured to a value no larger than the supported bus width of the peripheral DMA bus. This value must also match the value written for the source DMA channel configuration.

    - Interrupts and triggers also can be configured at this step depending on requirements.

    The memory write DMA transfer begins.

Both memory DMA channels are now running and the data is transferred from the source address to the destination address. The DMA channel enters the IDLE state upon completion of the work unit.

Programming Concepts

Using the features, operating modes, and event control for the DMA channel to their greatest potential requires an understanding of some DMA channel-related concepts.

Synchronization of Software and DMA

A critical element of software DMA management is the synchronization of DMA work unit completion with software. This synchronization can be achieved using DMA channel interrupt request and trigger events and using a poll of the status bits of these events within the DMA channel registers, or combining these techniques. Processor polling of DMA address/count/status for completion is not a recommended programming practice. The requirements and limitations of processor polling place significant responsibility onto the code developer to be deeply aware of the underlying hardware. The interrupt requests and triggers are designed for efficient code development and reuse.

Interrupt and Trigger Event-Based Synchronization

Interrupt and trigger based synchronization methods must avoid overrun. An overrun occurs when some events fail to invoke the event handler of a DMA channel for every event due to excessive latency in processing of events. The system design must ensure to either:

- Schedule only one event per channel (for example, at the end of a descriptor list), or
- Space the generated events sufficiently far apart in time that system processing budgets can guarantee service of every event.

The DMA channel issues status information through an interrupt request or trigger event or changes event status bits in the `DMA_STAT` register. This status guarantees that the last memory operation of the work unit is complete. For memory read DMA transactions, this status means that the FIFO of the DMA channel safely receives the final memory read data. For DMA transactions writing to memory, this status indicates that the DMA channel received an acknowledge of completion of the last write transfer of the work unit.

Register Polling Based Synchronization

Do not poll the DMA channel registers (`DMA_ADDR_CUR`, `DMA_DSCPTR_CUR`, `DMA_XCNT_CUR`, or `DMA_YCNT_CUR`) as a method of precisely synchronizing DMA with data processing. This approach is inaccurate due to the operation of the DMA channel FIFOs and DMA or memory pipelining. The current address, pointer, and count registers change several cycles in advance of the completion of the corresponding memory operation. This timing is measurable from the time at which the results of the operation are first visible to the core by memory read or write instructions.

For example, in a DMA channel memory write operation to external memory, assume DMA channel *A* initiates a DMA channel write operation. For memories with access latency, this operation requires many system-clock cycles. Meanwhile, DMA channel *B* (which does not in itself incur latency) initiates a transfer, which stalls behind the slow operation of channel *A*. Software monitoring channel *B* could not safely conclude whether the memory location pointed to by the `DMA_ADDR_CUR` of channel *B*. Also, the software cannot conclude whether the register has been written based solely on the contents of this register.

Polling of the current address, pointer, and count registers can permit loose synchronization of DMA with software. But, the software must allow for the lengths of the DMA or memory pipeline. Also, software must consider the length of the DMA FIFO for a particular peripheral. If the FIFOs are filled with incomplete work, the DMA channel does not advance current address, pointer, or count registers. The incomplete work includes reads that have been started but have not yet finished.

Additionally, software must consider the length of the pipelines to the destination memory. If the DMA FIFO length and channel memory-pipeline length are added, software can estimate the maximum number of incomplete memory operations in progress.

NOTE: The estimate would be a maximum, as the DMA or memory pipeline can include traffic from other DMA channels.

Descriptor Queues

A system designer may want to write a DMA manager facility which accepts DMA requests from other software. The DMA manager software does not know in advance when new work requests are received or what these requests contain. The software could manage these transfers using a circular linked list of DMA descriptors. In such a list, each descriptor sets the `DMA_DSCPTR_NXT` descriptor, which points to the next descriptor set. And, the last descriptor set in the list points to the first descriptor set.

The code that writes into this descriptor list could use the circular addressing modes of the processor. This approach does not need to use comparison and conditional instructions to manage the circular structure. In this case, the `DMA_DSCPTR_NXT` descriptor of each descriptor set can be written once at startup, and skipped over as new contents are written for each descriptor.

The recommended method for synchronization of a descriptor queue is to use an interrupt or trigger. The descriptor queue is structured, such that (at least) the final valid descriptor set is always programmed to generate an interrupt or trigger event upon completion. More detail is provided in the following sections.

- Queues Using Event Generation for Every Descriptor Set
- Queues Using Minimal Events

Queues Using Event Generation for Every Descriptor Set

In this system, the DMA manager software synchronizes with the DMA channel by enabling an interrupt request or trigger on every descriptor set. Only use this method if the system design can guarantee that each work unit completion event is serviced separately (no interrupt or trigger overrun).

To maintain synchronization of the descriptor set queue, the non-interrupt software maintains a count of descriptor sets added to the queue. The event handler (either interrupt or trigger) maintains a count of completed descriptor sets removed from the queue. The counts are equal only when the DMA channel is paused after having processed all the descriptor sets.

When each new work unit event is received, the DMA manager software initializes a new descriptor set, taking care to set the flow to stop mode. Next, the software compares the descriptor set counts to determine whether the DMA channel is running. If the DMA channel is paused (counts equal), the software increments its count. Then, the software starts the DMA channel by writing the `DMA_CFG` of the new descriptor set.

If the counts are unequal, the software instead modifies the `DMA_CFG` of the next-to-last descriptor set, such that it now describes the newly queued descriptor set. This operation does not disrupt the DMA channel provided the rest of the descriptors of the set are initialized in advance. It is necessary to synchronize the software to the DMA to determine whether the DMA channel read the new or the old `DMA_CFG` value.

The event handler performs the synchronization operation. When an event is detected, the handler reads the `DMA_STAT` register of the DMA channel. If the `DMA_STAT.RUN` bit indicates that the DMA channel is running, the channel has moved on to processing another descriptor. The event handler can increment its count and exit. If the `DMA_STAT.RUN` bit indicates that the channel is not running, the channel is paused because either:

- There are no more descriptor sets to process, or
- The last descriptor set was queued too late

Where *too late* means that the modification of the `DMA_CFG` of the next-to-last descriptor set occurred *after* that descriptor was read into the DMA channel. In this case, the event handler does the following:

- Writes the `DMA_CFG` value appropriate for the last descriptor set to `DMA_CFG` register of the DMA channel,
- Increments the completed descriptor count, and
- Exits

If the event latencies of the system are large enough to cause any of the events to be dropped, this system can fail. An event handler capable of safely synchronizing multiple descriptor set interrupt requests is complex, performing several MMR accesses to ensure robust operation. In such a system environment, a minimal event synchronization method is preferred.

Queues Using Minimal Events

In this system, only one DMA interrupt request or trigger event is generated in the queue at any time. The DMA event handler for this system can also be extremely short. Here, the descriptor queue is organized into an *active* and a *waiting* portion, where events are enabled only on the last descriptor set in each portion.

When each new DMA request is processed, the software fills in the content of a new descriptor set and adds it to the waiting portion of the queue. The `DMA_CFG` descriptor of the descriptor set must have the flow set to stop mode. If more than one request is received before the DMA queue completion event occurs, the non-interrupt code queues later descriptor sets. It forms a waiting portion of the queue separate from the active portion of the queue that the DMA channel is processing. In other words, all but the last active descriptor sets contain flow values for a descriptor-based mode and have no event enable set.

The last active descriptor set has the stop flow mode and an event generation enabled. Also, all but the last waiting descriptor sets are configured for descriptor-based flow modes with no event generation. Only the last waiting descriptor set is configured for stop flow mode and event generation enabled. This configuration ensures that the DMA channel can automatically process the whole active queue before then issuing one event. Also, this arrangement makes it easy to start the waiting queue within the event handler by a single `DMA_CFG` register write.

After queuing a new waiting descriptor, the non-interrupt software leaves a message for its interrupt handler in a memory mailbox location. The location contains the desired `DMA_CFG` value for starting the first waiting descriptor set in the waiting queue (or 0, indicating no waiting descriptors).

The software must not modify the contents of the active descriptor set queue directly once processing by the DMA channel has started, unless careful synchronization measures are taken. In the most straightforward implementation of a descriptor set queue, the DMA manager software never modifies descriptors on the active queue. Instead, the DMA manager waits until the DMA queue completion event indicates that the processing of the entire active queue is complete.

When a DMA queue completion event is received, the event handler reads the mailbox from the non-interrupt software and writes the value to the `DMA_CFG` register of the DMA channel. This write to a register restarts the queue, effectively transforming the waiting queue to an active queue. The event handler then passes a message back to the non-interrupt software indicating the location of the last descriptor set accepted into the active queue.

However, the event handler can read its mailbox and find a DMA_CFG value of zero, indicating there is no more work to perform. It then passes an appropriate message back to the non-interrupt software indicating that the queue has stopped.

The non-interrupt software which accepts new DMA work unit requests must synchronize the activation of a new work unit with the interrupt handler. If the queue has stopped (the mailbox from the event handler is zero), the non-interrupt software must start the queue. (The queue starts by writing the first descriptor sets DMA_CFG value to the DMA_CFG register of the channel). If the queue is not stopped, the non-interrupt software must not write the DMA_CFG register. (This write causes a DMA error). Instead, it must queue the descriptor onto the waiting queue and update its mailbox directed to the event handler.

ADSP-SC58x DMA Register Descriptions

The Direct Memory Access module (DMA) contains the following registers.

Table 38-14: ADSP-SC58x DMA Register List

Name	Description
DMA_ADDRSTART	Start Address of Current Buffer Register
DMA_ADDR_CUR	Current Address Register
DMA_BWLCNT	Bandwidth Limit Count Register
DMA_BWLCNT_CUR	Bandwidth Limit Count Current Register
DMA_BWMCNT	Bandwidth Monitor Count Register
DMA_BWMCNT_CUR	Bandwidth Monitor Count Current Register
DMA_CFG	Configuration Register
DMA_DSCPTR_CUR	Current Descriptor Pointer Register
DMA_DSCPTR_NXT	Pointer to Next Initial Descriptor Register
DMA_DSCPTR_PRV	Previous Initial Descriptor Pointer Register
DMA_STAT	Status Register
DMA_XCNT	Inner Loop Count Start Value Register
DMA_XCNT_CUR	Current Count (1D) or Intra-row XCNT (2D) Register
DMA_XMOD	Inner Loop Address Increment Register
DMA_YCNT	Outer Loop Count Start Value (2D only) Register
DMA_YCNT_CUR	Current Row Count (2D only) Register
DMA_YMOD	Outer Loop Address Increment (2D only) Register

Start Address of Current Buffer Register

The `DMA_ADDRSTART` register contains the start address of the work unit currently targeted for DMA. This register is read/write prior to enabling the channel, but is read-only after enabling channel.

Table 38-15: DMA_ADDRSTART Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Address Start Value. The `DMA_ADDRSTART.VALUE` bit field contains the start address of the work unit currently targeted for DMA.

Current Address Register

The DMA_ADDR_CUR register contains the present memory transfer address for a given work unit. At the start of a work unit, the DMA_ADDR_CUR register is loaded from the DMA_ADDRSTART register, and the DMA_ADDR_CUR register is incremented as each transfer occurs. The DMA_ADDR_CUR register is read/write prior to enabling the channel, but is read-only after enabling the channel.

31:0 (R/W)	VALUE	Work Unit Current Address Value. The `DMA_ADDR_CUR.VALUE` bit field contains the present memory transfer address for a given work unit.

Bandwidth Limit Count Register

The DMA_BWLCNT register contains a count that determines how often the DMA issues memory transactions. The DMA loads the value from the DMA_BWLCNT register into the DMA_BWLCNT_CUR register and decrements the current value each SCLK cycle. When DMA_BWLCNT_CUR reaches 0x0000, the next request is issued, and the DMA reloads DMA_BWLCNT_CUR. This bandwidth limit functionality is not applied to descriptor fetch requests. Programming 0x0000 allows the DMA to request as often as possible. 0xFFFF is a special case and causes requests to stop.

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Bandwidth Limit Count Current. The `DMA_BWLCNT_CUR.VALUE` bit field contains the number of SCLK count cycles remaining before the next request is issued.

Bandwidth Monitor Count Register

The `DMA_BWMCNT` register contains the maximum number of SCLK cycles allowed for a work unit to complete. Each time the `DMA_CFG` register is written (MMR access only), a work unit ends or an autobuffer wraps. The DMA loads the value in this register into the `DMA_BWMCNT_CUR` register.

The DMA decrements `DMA_BWMCNT_CUR` every SCLK a work unit is active. If the `DMA_BWMCNT_CUR` register reaches 0x0000_0000, the `DMA_STAT.IRQERR` bit is set, and the `DMA_STAT.ERRC` bit field is set to 0x6. The `DMA_BWMCNT_CUR` remains at 0x0000_0000 until it is reloaded when the work unit completes.

Unlike other errors, a bandwidth monitor error does not stop work unit processing. Programming 0x0000_0000 disables bandwidth monitor functionality.

Configuration Register

The `DMA_CFG` register sets up DMA parameters and operation modes. Writing to the `DMA_CFG` register while a DMA process is already running causes a DMA error (except when clearing the `DMA_CFG.EN` bit).

Figure 38-11: DMA_CFG Register Diagram

Table 38-21: DMA_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	PDRF	Peripheral Data Request Forward. The `DMA_CFG.PDRF` bit defines how the DMA handles data requests from the peripheral while in idle state after a stop mode or memory read work unit. If set, the DMA forwards the peripheral data request as an interrupt. This bit applies only to the `DMA_CFG.FLOW` bits configured for stop and `DMA_CFG.WNR` bits configured for memory read.	
		0	Peripheral Data Request Not Forwarded
		1	Peripheral Data Request Forwarded

Table 38-21: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	TWOD	Two Dimension Addressing Enable. The `DMA_CFG.TWOD` bit selects whether the DMA addressing involves only `DMA_XCNT` and `DMA_XMOD` (one-dimensional DMA) or also involves `DMA_YCNT` and `DMA_YMOD` (two-dimensional DMA).	
		0	One-Dimensional Addressing
		1	Two-Dimensional Addressing
25 (R/W)	DESCIDCPY	Descriptor ID Copy Control. The `DMA_CFG.DESCIDCPY` bit specifies when to copy the initial descriptor pointer to the `DMA_DSCPTR_PRV` register. A bus write to the `DMA_CFG` register to clear the `DMA_CFG.EN` bit causes the DMA to immediately use the new value of the `DMA_CFG.DESCIDCPY` bit. To preserve consistency (if required by application), match the new value of this bit to the previous value.	
		0	Never Copy
		1	Copy on Work Unit Complete
24 (R/W)	TOVEN	Trigger Overrun Error Enable. A trigger overrun occurs if more than one trigger was received before the DMA reached the trigger wait state. If `DMA_CFG.TOVEN` is set, a trigger overrun causes the DMA to flag an error. In cases where a trigger overrun is not a problem, clearing `DMA_CFG.TOVEN` prevents the overrun from causing an error and halting the DMA. The `DMA_CFG.TOVEN` operates independently of the `DMA_CFG.TWAIT` bit selection.	
		0	Ignore Trigger Overrun
		1	Error on Trigger Overrun

Table 38-21: DMA_CFG Register Fields (Continued)

<table>
<tr><th>Bit No.
(Access)</th><th>Bit Name</th><th colspan="2">Description/Enumeration</th></tr>
<tr><td rowspan="5">23:22
(R/W)</td><td rowspan="5">TRIG</td><td colspan="2">Generate Outgoing Trigger.
The DMA_CFG.TRIG selects whether the DMA issues an outgoing trigger, based on the work unit counter values. In one-dimensional mode, the only options are to trigger at the end of the whole work unit (trigger when DMA_XCNT_CUR reaches 0) or not to trigger at all. If in one-dimensional addressing mode, programming the DMA_CFG.TRIG bit field to trigger when DMA_YCNT_CUR reaches 0 (or to reserved) causes the DMA to flag a configuration error.
In two-dimensional addressing mode, the trigger options are: at the end of each row of the inner loop (when DMA_XCNT_CUR reaches 0), only after completing the whole work unit (when DMA_YCNT_CUR reaches 0), or no trigger. If in two-dimensional mode and set to trigger when DMA_XCNT_CUR reaches 0, the DMA also issues a trigger at the end of the work unit. If in two-dimensional addressing mode, programming DMA_CFG.TRIG to reserved causes the DMA to flag a configuration error.
If DMA_CFG.TRIG is non-zero and the peripheral issues a finish command, the DMA issues a trigger after the finish procedure is complete.
For more information about trigger generation timing, see the trigger section of the DMA functional description.</td></tr>
<tr><td>0</td><td>Never Assert Trigger</td></tr>

<tr><td>2</td><td>Trigger When YCNTCUR Reaches 0</td></tr>
<tr><td>3</td><td>Reserved</td></tr>
</table>

Table 38-21: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	INT	Generate Interrupt Request. The `DMA_CFG.INT` bit field selects whether an interrupt request goes to the core based on work unit status or a peripheral interrupt request. For one-dimensional mode, setting the `DMA_CFG.INT` bits to generate an interrupt request when the `DMA_YCNT_CUR` register reaches 0 causes the DMA to flag a configuration error. The peripheral interrupt setting lets the DMA generate the last grant indication and to accept and or forward the peripheral interrupt command. The peripheral interrupt selection applies only to the `DMA_CFG.FLOW` bits set for stop and the `DMA_CFG.WNR` bits set for memory read. If the `DMA_CFG.INT` is set for interrupt request on count completion (`DMA_XCNT_CUR` or `DMA_YCNT_CUR` reach 0) and the peripheral issues a finish command, the DMA issues an interrupt request after the finish procedure is complete. For more information, see the sections on interrupt generation and peripheral control in the DMA functional description.	
		0	Never Assert Interrupt
		1	Interrupt When X Count Expires
		2	Interrupt When Y Count Expires
		3	Peripheral Interrupt request
18:16 (R/W)	NDSIZE	Next Descriptor Set Size. The `DMA_CFG.NDSIZE` bit field specifies the number of descriptor elements in memory to load during the next descriptor fetch. The DMA loads the descriptors in a specific order. The descriptor set contains the next descriptor pointer when it is a descriptor list. The descriptor set does not contain the next descriptor pointer when it is a descriptor array.	
		0	Fetch One Descriptor Element
		1	Fetch Two Descriptor Elements
		2	Fetch Three Descriptor Elements
		3	Fetch Four Descriptor Elements
		4	Fetch Five Descriptor Elements
		5	Fetch Six Descriptor Elements
		6	Fetch Seven Descriptor Elements
		7	Reserved

Table 38-21: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	TWAIT	Wait for Trigger. The `DMA_CFG.TWAIT` bit controls whether the DMA waits for an incoming trigger from another channel or user. If the `DMA_CFG.TWAIT` bit is set, the DMA enters the wait state before starting the next work unit, including descriptor fetch when in descriptor mode. Do not use the wait for trigger control for descriptor-on-demand mode which causes an error. For more information, see the trigger section of the DMA functional description.	
		0	Begin Work Unit Automatically (No Wait)
		1	Wait for Trigger (Halt before Work Unit)
14:12 (R/W)	FLOW	Next Operation. The `DMA_CFG.FLOW` bit field selects the descriptor handling options.	
		0	STOP. See the Stop Flow Mode section.
		1	AUTO. See the Autobuffer Flow Mode section.
		2	Reserved
		3	Reserved
		4	DSCL. See the Descriptor List Mode section.
		5	DSCA. See the Descriptor Array Mode section.
		6	Descriptor On-Demand List. See the Descriptor List Mode section.
		7	Descriptor On Demand Array. See the Descriptor On Demand section.
10:8 (R/W)	MSIZE	Memory Transfer Word Size. The `DMA_CFG.MSIZE` bits select memory transfer sizes of 8-, 16-, 32-, 64-, 128-, or 256-bit words. The transfer start address (`DMA_ADDRSTART`) and transfer increment values (`DMA_XMOD`, and, if needed, `DMA_YMOD`) must be a multiple of the memory transfer unit size.	
		2	4 Bytes
		3	8 Bytes
		4	16 Bytes
		5	32 Bytes

Table 38-21: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:4 (R/W)	PSIZE	Peripheral Transfer Word Size. The `DMA_CFG.PSIZE` bits select peripheral transfer sizes as 8, 16, 32, or 64 bits wide. Each request and grant results in a single peripheral access. There are no bursts on the peripheral bus, so the `DMA_CFG.PSIZE` selection must be less than or equal to the width of the bus. If the selection is greater than the bus width, a configuration error occurs. The peripheral bus of the processor is dedicated to DMA and peripheral accesses.	
		2	4 Bytes
		3	8 Bytes
3 (R/W)	CADDR	Use Current Address. When the `DMA_CFG.CADDR` bit is cleared, the DMA loads the `DMA_ADDRSTART` register on the first access of the work unit. When the `DMA_CFG.CADDR` bit is set, the DMA uses the `DMA_ADDR_CUR` register value for the starting address for the work unit and writes the same value to the `DMA_ADDRSTART` register. This operation permits continuation of a previous work unit. When DMA uses this mode, the fetched start address value (as part of the descriptor set at the end of a descriptor list or array) is ignored.	
		0	Load Starting Address
		1	Use Current Address

Table 38-21: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	SYNC	Synchronize Work Unit Transitions. Setting the `DMA_CFG.SYNC` bit clears the DMA FIFO and pointers before starting the first work unit of a work unit chain. When the transfer direction is memory read/transmit (`DMA_CFG.WNR` =0), the DMA waits until all data transmits to a peripheral before moving on to the next work unit, clearing the FIFO and pointers. When the transfer direction is memory write/receive (`DMA_CFG.WNR` =1), the DMA ignores the `DMA_CFG.SYNC` bit value after processing the first work unit of a work unit chain. As a channel can receive data when turned on but idle, data from the peripheral can still be in the FIFO even though the channel was not programmed. When the `DMA_CFG.SYNC` bit field is set at the beginning of a work unit chain (during the first work unit), the DMA clears the FIFO, erasing the data put into the FIFO while the channel was idle. Syncing lets programs change the `DMA_CFG.PSIZE` between individual work units and (in some cases) work unit chains. The sync resets the pointers in the FIFO, preventing misaligned FIFO access. Programs can change the `DMA_CFG.MSIZE` field between consecutive work units, independent of the `DMA_CFG.SYNC` bit setting. Syncing also permits changes to transfer direction. Because the data in the FIFO is eliminated, the data that went into the FIFO from one direction (transmit or receive) is not sent back in the other direction after the direction change.	
		0	No Synchronization
		1	Synchronize Channel
1 (R/NW)	WNR	Write/Read Channel Direction. The `DMA_CFG.WNR` selects receive (write to memory) or transmit (read from memory) channel direction.	
		0	Transmit (Read from memory)
		1	Receive (Write to memory)

Table 38-21: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	DMA Channel Enable. The `DMA_CFG.EN` bit enables the selected DMA channel. When a peripheral DMA channel is enabled, data requests from the peripheral denote DMA requests. When a channel is disabled, the DMA unit ignores the peripheral data request and passes it directly to the system event controller. To avoid unexpected results, enable the DMA channel before enabling the peripheral, and disable the peripheral before disabling the DMA channel. A transition of the `DMA_CFG.EN` bit from 0 to 1 creates a hard reset of all internal counters and states, including the `DMA_STAT` register. (All other register values remain unaffected.) A transition from 1 to 0 maintains all counters and registers for reading and analysis. Note that if a descriptor loads when this bit is cleared (see the `DMA_CFG.FLOW` field), the DMA transitions to the off or idle state after the descriptor load is complete.	
		0	Disable
		1	Enable

Current Descriptor Pointer Register

The DMA_DSCPTR_CUR register contains the memory address for the next descriptor to be loaded. The DMA_DSCPTR_CUR register is read/write prior to enabling the channel, but is read-only after enabling the channel. For DMA_CFG.FLOW mode settings that involve descriptor fetches, this register is used to read descriptors into appropriate MMRs before a work unit begins. For descriptor list mode, the DMA_DSCPTR_CUR register is initialized from the DMA_DSCPTR_NXT register before fetching each descriptor set. Then, the address in the DMA_DSCPTR_CUR register increments as each descriptor is read.

When the entire descriptor set has been read, the DMA_DSCPTR_CUR register contains this value:

DMA_DSCPTR_CUR = Descriptor Start Address + Descriptor Size (# of elements)

For descriptor array mode, the DMA_DSCPTR_CUR register, and not the DMA_DSCPTR_NXT register, must be programmed by a MMR access before starting DMA operation.

31:0 (R/W)	VALUE	Pointer for Current Descriptor Element. The DMA_DSCPTR_CUR.VALUE bit field contains the memory address for the next descriptor to be loaded.

Pointer to Next Initial Descriptor Register

The DMA_DSCPTR_NXT register specifies the start location of the next descriptor set, which begins when the DMA activity specified by the current descriptor set completes. This register is read/write prior to enabling the channel, but is read-only after enabling channel.

The DMA_DSCPTR_NXT register is only used in descriptor list mode. At the start of a descriptor fetch in this mode, the DMA_DSCPTR_NXT register is copied into the DMA_DSCPTR_CUR register. During descriptor fetch, the DMA increments the DMA_DSCPTR_CUR register value after reading each element of the descriptor set.

In descriptor list mode, the DMA_DSCPTR_NXT register (not the DMA_DSCPTR_CUR register) must be programmed directly through MMR access, before the DMA operation is started. In descriptor array mode, the DMA disregards the DMA_DSCPTR_NXT register and uses the DMA_DSCPTR_CUR register to control descriptor fetch.

Table 38-23: DMA_DSCPTR_NXT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Pointer to Next Descriptor Set. The DMA_DSCPTR_NXT.VALUE bit field specifies the start location of the next descriptor set.

Previous Initial Descriptor Pointer Register

The `DMA_DSCPTR_PRV` register contains the initial descriptor pointer for the previous work unit. If `DMA_CFG.DESCIDCPY`is set, the DMA copies the initial descriptor pointer to `DMA_DSCPTR_PRV` after the work unit completes. Otherwise, the value is not updated.

To indicate an overrun, bit 0 of the `DMA_DSCPTR_PRV` register is used as a previous descriptor pointer overrun (PDPO) status bit. Due to aligned addressing combined with all descriptors being 32 bits in width, bits 0 and 1 of all descriptor pointers must be zero. Otherwise, an alignment error occurs when used for descriptor fetches. As a result, bit 1 and 0 of the `DMA_DSCPTR_PRV` register can be used for status. For more information, see the section on descriptor pointer capture in the DMA functional description.

20 (R/NW)	TWAIT	Trigger Wait Status. The `DMA_STAT.TWAIT` bit indicates whether the DMA has or has not received a trigger. This bit is set until it reaches the next wait state. At that point, the bit is cleared, the DMA stops processing that work unit, and the following work unit processes. The DMA does not distinguish between one or more triggers received.	
		0	No Trigger Received
		1	Trigger Received
18:16 (R/NW)	FIFOFILL	FIFO Fill Status. The `DMA_STAT.FIFOFILL` bit field reports the quantity of data in the FIFO relative to available space.	
		0	Empty
		1	Empty < FIFO = 1/4 Full
		2	1/4 Full < FIFO = 1/2 Full
		3	1/2 Full < FIFO = 3/4 Full
		4	3/4 Full < FIFO = Full
		5	Reserved

Table 38-25: DMA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	Reserved
		7	Full
15:14 (R/NW)	MBWID	Memory Bus Width. The `DMA_STAT.MBWID` bit field indicates the width of the memory bus connected to this DMA.	
		0	2 Bytes
		1	4 Bytes
		2	8 Bytes
		3	16 Bytes
13:12 (R/NW)	PBWID	Peripheral Bus Width. The `DMA_STAT.PBWID` bit field indicates the width of the peripheral bus connected to this DMA.	
		0	1 Byte
		1	2 Bytes
		2	4 Bytes
		3	8 Bytes
10:8 (R/NW)	RUN	Run Status. The `DMA_STAT.RUN` bit field reports the DMA's current operational state. If the DMA is in idle or stop state, the `DMA_CFG.EN` bit is either 0 or 1. This bit field does not clear when a transition of the `DMA_CFG.EN` bit from 0 to 1 occurs. The `DMA_STAT.RUN` clears automatically when the DMA completes.	
		0	Idle/Stop State
		1	Descriptor Fetch
		2	Data Transfer
		3	Waiting for Trigger
		4	Waiting for Write ACK/FIFO Drain to Peripheral
		5	Reserved
		6	Reserved
		7	Reserved
6:4 (R/NW)	ERRC	Error Cause. When an interrupt request error occurs (`DMA_STAT.IRQERR`), the DMA updates the `DMA_STAT.ERRC` bit field to identify the type of error. For more information, see the errors section of the DMA functional description.	

Table 38-25: DMA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Configuration Error
		1	Illegal Write Occurred While Channel Running
		2	Address Alignment Error
		3	Memory Access or Fabric Error
		4	Reserved
		5	Trigger Overrun
		6	Bandwidth Monitor Error
		7	Reserved
2 (R/W1C)	PIRQ	Peripheral Interrupt Request. The `DMA_STAT.PIRQ` bit indicates a peripheral interrupt request. Programs can use the `DMA_STAT.PIRQ` bit status to help determine which DMA asserted the interrupt request. This bit also helps to distinguish between an interrupt request caused by the state of the work unit and an interrupt request caused by the peripheral.	
		0	No Interrupt request
		1	Interrupt Request signaled by peripheral
1 (R/W1C)	IRQERR	Error Interrupt Request. The `DMA_STAT.IRQERR` bit indicates that the DMA has detected a documented rule violation during DMA programming or operation. The DMA cannot, however, flag all possible programming or operation issues to indicate errors. Programmers can use the `DMA_STAT.IRQERR` bit to help determine which DMA issued the error interrupt request. The `DMA_STAT.IRQERR` does not clear a transition of the `DMA_CFG.EN` bit from 0 to 1. Clear the `DMA_STAT.IRQERR` bit with a write-1-to-clear operation prior to the `DMA_CFG.EN` transition for the fields to be reset.	
		0	No Error
		1	Error Occurred
0 (R/W1C)	IRQDONE	Work Unit/Row Done Interrupt. The `DMA_STAT.IRQDONE` bit indicates that the DMA has detected the completion of a work unit or row (inner loop count) and has issued an interrupt request. Programs can use the `DMA_STAT.IRQDONE` status to help determine which DMA asserted the interrupt request. Programs can also use these bits to help distinguish between an interrupt request based on the state of the work unit and an interrupt request made by the peripheral. For more information, see the interrupts section of the DMA functional description.	
		0	Inactive
		1	Active

Inner Loop Count Start Value Register

For 2D DMA, the `DMA_XCNT` register contains the inner loop count. This value selects the number of `DMA_CFG.MSIZE` size data transfers that make up the length of a row. For 1D DMA, the `DMA_XCNT` register specifies the number of `DMA_CFG.MSIZE` size data transfers for the entire work unit. The `DMA_XCNT` register is read/write prior to enabling the channel, but is read-only after enabling channel. Note that the DMA generates a configuration error if this register is 0x0 when a work unit begins.

Current Count (1D) or Intra-row XCNT (2D) Register

For 1D DMA, the DMA loads the DMA_XCNT_CUR register from the DMA_XCNT register at the beginning of each work unit. For 2D DMA, the DMA loads the DMA_XCNT_CUR register from the DMA_XCNT register after the end of each row. The DMA decrements the value in DMA_XCNT_CUR register each time a DMA_CFG.MSIZE size data transfer occurs. When the count in DMA_XCNT_CUR register expires, the work unit is complete. In 2D DMA, the DMA_XCNT_CUR value is 0 only when the entire transfer is complete.

31:0 (R/NW)	VALUE	Work Unit Outer Loop Counter Start Value. For 1D DMA, the DMA_XCNT_CUR.VALUE bit field holds the DMA_XCNT value at the beginning of each work unit. For 2D DMA, the DMA_XCNT_CUR.VALUE bit field holds the DMA_XCNT value after the end of each row.

Inner Loop Address Increment Register

The `DMA_XMOD` register contains a signed, two's-complement byte address increment. In 1D DMA, this increment is the stride that is applied after each `DMA_CFG.MSIZE` size data transfer. The `DMA_XMOD` register is read/write prior to enabling the channel, but is read-only after enabling the channel.

The `DMA_XMOD` register value is specified in bytes, regardless of the work unit size. In 2D DMA, this increment is applied after each `DMA_CFG.MSIZE` size data transfer in the inner loop, up to but not including the last `DMA_CFG.MSIZE` size data transfer in each inner loop. After the last `DMA_CFG.MSIZE` size data transfer in each inner loop, the `DMA_YMOD` register is applied instead, including the last `DMA_CFG.MSIZE` size data transfer of a work unit.

The `DMA_XMOD` field can be set to 0. In this case, DMA is performed repeatedly to or from the same address. This approach can be useful for transferring data between a data register and an external memory-mapped peripheral.

Outer Loop Count Start Value (2D only) Register

For 2D DMA, the `DMA_YCNT` register contains the outer loop count. This register is not used in 1D DMA mode. The `DMA_YCNT` register specifies the number of rows in the outer loop of a 2D DMA sequence. The `DMA_YCNT` register is read/write prior to enabling the channel, but is read-only after enabling channel. Note that the DMA generates a configuration error if this register is 0x0 when a work unit begins.

Current Row Count (2D only) Register

For 2D DMA, the DMA loads the `DMA_YCNT_CUR` register from the `DMA_YCNT` register at the beginning of each 2D DMA session. The `DMA_YCNT_CUR` register is not used for 1D DMA. The DMA decrements the `DMA_YCNT_CUR` register each time the `DMA_XCNT_CUR` register expires during 2D DMA operation, signifying the completion of an entire row transfer.

Outer Loop Address Increment (2D only) Register

The DMA_YMOD register contains a signed, two's-complement value. This byte address increment is applied after each decrement of the DMA_YCNT_CUR register. The value is the offset between the last word of one row and the first word of the next row. Note that DMA_YMOD is specified in bytes, regardless of the work unit size. The DMA_YMOD register is read/write prior to enabling the channel, but is read-only after enabling the channel.

39 Extended Memory DMA (EMDMA)

The Extended Memory DMA engine can be used in applications that copy data in a non-sequential manner. This includes delay lines, scatter and gather, and circular access types.

NOTE: Unlike previous SHARC processors which contained external port DMA, the current EMDMA module can access all memory locations (L1/L2/L3) for source and destination DMA operations.

EMDMA Features

EMDMA frees the processor core, allowing it to perform other operations while the data transfers between memories occurs as a background task.

EMDMA has the following features and capabilities.

- Standard mode DMA Transfer
- Chained mode with direction on-the-fly
- Tap list mode (scatter/gather)
- Delay line mode (write to read)
- All the DMA modes can operate in circular fashion
- In circular operation, some modes allow a write back of the index pointer for correct addressing of the next Transfer Control Block (TCB)

EMDMA Functional Description

The following sections provide information on the functional operations and operating modes of EMDMA.

Internal-to-internal DMA

This is accomplished by indexing all external parameter registers with internal addresses.

DMA bursting

DMA supports burst transfers only when the modifier is 1, for any other modifier values, single accesses are performed. The burst size is not user configurable and is chosen by the processor for optimal performance. The maximum burst size is 8 and the minimum is 1.

Transfer control blocks

The structure of a TCB is conceptually the same as that of a traditional linked-list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB may point to itself to continuously re-run the same DMA.

Chain pointer DMA

In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete.

ADSP-SC58x EMDMA Register List

The EMDMA controllers support a variety of direct memory access operations which can access any system memory and transfer the entire block of data. A set of registers govern EMDMA operations. For more information on EMDMA functionality, see the EMDMA register descriptions.

Table 39-1: ADSP-SC58x EMDMA Register List

Name	Description
`EMDMA_BASE`	External Base Address Register
`EMDMA_BUFLEN`	Circular Buffer Length Register
`EMDMA_CHNPTR`	Chain Pointer Register
`EMDMA_CNT0`	Internal Count Register
`EMDMA_CNT1`	External Count Register
`EMDMA_CTL`	External Memory DMA Control Register
`EMDMA_INDX0`	Internal Index Register
`EMDMA_INDX1`	External Index Register
`EMDMA_MOD0`	Internal Modifier Register
`EMDMA_MOD1`	External Modifier Register
`EMDMA_TCNT`	Delay Line Tap Count Register
`EMDMA_TPTR`	Tap List Pointer Register

Table 39-4: ADSP-SC58x EMDMA Trigger List Slaves

Trigger ID	Name	Description	Sensitivity
None			

DMA Addressing

Besides the traditional internal-to-external addressing type, the DMA module also supports internal-to-internal transfers. This is accomplished by indexing all external parameter registers with internal addresses. The DMA controller recognizes the transfer by addresses and not by an additional control bit setting.

All the DMA addresses given by EMDMA are word-aligned byte addresses. The programming for the index registers is provided in the *Register Descriptions* section.

NOTE: Similar to EPDMA on the previous generation of SHARC processors, EMDMA on the ADSP-SC58x processors also has both internal and external sets of DMA parameter registers. The register sets on the new ADSP-SC58x processors can point to either internal or external memory and are referred to as channel 0 and channel 1 in this manual. These channels should not be considered as two EPDMA channels (which is equivalent to two EMDMA module instances) of the previous SHARC processors.

DMA Burst Transfers

DMA supports burst transfers only when the modifier is 1. For any other modifier values, single accesses are performed.

The burst size is not user-configurable and is chosen by the processor for optimal performance. The maximum burst size is 8 and the minimum is 1.

The EMDMA uses appropriate burst transfer sizes for optimal throughput. For example, if the word count is 15, then 5 bursts are performed with burst sizes of 8+4+1+1+1 transfers.

Transfer Control Block (TCB) Memory Storage

The location of the DMA parameters for the next sequence comes from the chain pointer register that points to the next set of DMA parameters stored in the processor's internal memory. In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Assignment

The structure of a TCB is conceptually the same as that of a traditional linked-list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB may point to itself to continuously rerun the same DMA. The EMDMA reads each word of the TCB and loads it into the corresponding register. The end of the chain (no further TCBs are loaded) is indicated by a TCB with a chain pointer register value of zero.

The address field of the chain pointer registers is only 30 bits wide. If a program writes a symbolic address to bit 30 of the chain pointer there may be a conflict with the `EMDMA_CHNPTR.PCI` bit. Programs should clear the upper bits of the address then AND the `EMDMA_CHNPTR.PCI` bit separately, if needed.

Starting Chain Loading

A DMA sequence is defined as the sum of the DMA transfer from when the parameter registers initialize to when the count register decrements to zero. The EMDMA module has a chaining enable bit (`EMDMA_CTL.CHEN`).

To start the chain, write the internal (channel 0) index address of the first TCB to the chain pointer register (`EMDMA_CHNPTR`). When chaining is enabled, DMA transfers are initiated by writing a memory address to the chain pointer register. This is also an easy way to start a single DMA sequence, with no subsequent chained DMAs.

During TCB chain loading, the EMDMA loads the DMA channel parameter registers with values retrieved from system memory.

The address in the chain pointer register points to the highest address of the TCB. This contains the internal (channel 0) index parameter. This means that if a program declares an array to hold the TCB, the chain pointer register should point to the last location of the array and not to the first TCB location.

Buffered Chain Loading Register

The chain pointer register (`EMDMA_CHNPTR`) is buffered. Before the chain loading starts, the buffer is copied into the chain pointer register and is decremented after each register is loaded.

The chain pointer register can be loaded with a new address at any time during the DMA sequence (`EMDMA_CTL.CHEN` =1). This allows a DMA channel to have chaining status deactivated (chain pointer register = 0x0) until some event occurs that loads the chain pointer register with a non-zero value. Writing all zeros to the address field of the chain pointer register also deactivates chaining for the next TCB.

TCB Storage

The EMDMA supports many different types of DMA, resulting in different lengths of TCBs. The TCB size varies from six locations (chained DMA) to 13 locations (delay line DMA). The ***EMDMA TCBs*** table shows the required TCBs for chained DMA.

In the following tables, TCB refers to the start address of the TCB array.

Table 39-5: EMDMA TCBs

Address	Register
TCB	`EMDMA_CHNPTR`
TCB + 0x1	`EMDMA_MOD1`
TCB + 0x2	`EMDMA_INDX1`
TCB + 0x3	`EMDMA_CNT0`
TCB + 0x4	`EMDMA_MOD0`
TCB + 0x5	`EMDMA_INDX0`

The order the descriptors are fetched with circular buffering enabled is shown in the ***EMDMA TCBs for Circular DMA*** table.

Table 39-6: EMDMA TCBs for Circular DMA

Address	Register
TCB	`EMDMA_CHNPTR`
TCB + 0x1	`EMDMA_BUFLEN`
TCB + 0x2	`EMDMA_BASE`
TCB + 0x3	`EMDMA_MOD1`
TCB + 0x4	`EMDMA_INDX1`
TCB + 0x5	`EMDMA_CNT0`
TCB + 0x6	`EMDMA_MOD0`
TCB + 0x7	`EMDMA_INDX0`

For delay line DMA, TCB loading is split into two sequences to improve overall priority. The first TCB loads the write parameters (`EMDMA_INDX0` – `EMDMA_BUFLEN`) and the second loads the read parameters (`EMDMA_INDX0` – `EMDMA_CHNPTR`). This two stage loading is transparent to the application. The order the descriptors are fetched with circular buffering enabled is shown in the ***EMDMA TCBs for Scatter/Gather DMA*** table.

Table 39-10: EMDMA_CTL Register Bit to Operating Modes (Continued)

Bit (Name)	Standard	Chained	Scatter/Gather	Delay Line
17–16 (DFS)	Valid			
19–18	N/A			
20 (DMAS0)	Valid			
21 (CHS)	N/A	Valid	N/A	Valid
22 (TLS)	N/A		Valid	N/A
23 (WBS)	N/A			Valid
24 (DMAS1)	Valid			
25 (DIRS)	Valid			
31–26	N/A			

NOTE: Reading additional bit-field information from N/A (Not applicable) bits does not generate a meaningful result.

A program sets up a DMA channel by writing the transfer's parameters to the DMA parameter registers.

NOTE: The `EMDMA_CNT1` parameter register (read only) is a copy of the `EMDMA_CNT0` register. If `EMDMA_CNT0` is written, the `EMDMA_CNT1` register is updated automatically.

Standard DMA

A standard DMA (once it is configured) transfers data from location A to location B. An interrupt can be used to indicate the end of the transfer. To start a new DMA sequence after the current one is finished, a program must first clear the DMA enable bit (`EMDMA_CTL.EN`), write new parameters to the index, modify, and count registers (parameter registers), then set the DMA enable bit to re-enable DMA.

This DMA type resembles the traditional DMA type to initialize the different internal and external parameters (channel0 and channel1) (index, modify and count) registers and configuration of the DMA control registers.

Circular Buffered DMA

Circular buffered DMA resembles the traditional core DAG circular buffered mode by using registers for circular buffering. In this mode, the DMA needs two additional registers (base and length) to support reads and writes to a circular buffer. The *Circular Buffering Write DMA* and *Circular Buffering Read DMA* figures illustrate circular buffered DMA, in contrast with the *Standard Write DMA* figure.

Figure 39-3: Standard Write DMA

NOTE: Circular buffering is available for all operating modes (standard, chained, tap list and delay line DMA).

Chained DMA Mode

Chained DMA sequences are a set of multiple DMA operations, each auto-initializing the next in line. It is used to support automated access by a linked list (repetitive reads and writes to a defined location defined by the individual TCBs). To start a new DMA sequence after the current one is finished, the EMDMA automatically loads new index, modify, and count values pointed to by that channel's `EMDMA_CHNPTR` register. Using chaining, programs can set up consecutive DMA operations and each operation can have different attributes.

DMA data transfers can be set up as continuous or periodic. With chained DMA, the attributes of a specific DMA are stored in internal memory and are referred to as a Transfer Control Block or TCB. Extended Memory DMA loads these attributes in chains for execution. This allows for multiple chains that are finite or infinite.

NOTE: When chaining is enabled, polling should not be used to determine DMA status only because the DMA appears inactive if it is sampled while the next TCB is loading. In such cases where chaining is enabled, along with the polling of DMA status bit, polling of the chaining status bit should also occur to so that the correct status of the DMA is known. For example, the `EMDMA_CTL.CHS` bit should be polled as well as the `EMDMA_CTL.DMAS0` and `EMDMA_CTL.DMAS1` bits when EMDMA is configured in DMA chaining mode.

Data Direction On-the-Fly

A change of external memory data direction for each individual TCB in a chain sequence is allowed.

The `EMDMA_CHNPTR.CPDR` bit changes the data flow direction. If the `EMDMA_CHNPTR.CPDR` =0, writes through channel 0 are performed; if `EMDMA_CHNPTR.CPDR` =1, channel 0 reads are performed. This works similarly to the `EMDMA_CHNPTR.PCI` bit. The `EMDMA_CTL.OFCEN` and `EMDMA_CTL.CHEN` bits must be set (=1) to enable this functionality.

NOTE: If chaining is enabled with the `EMDMA_CTL.OFCEN` =1, then the `EMDMA_CTL.TRAN` bit has no effect, and the data direction is determined by the `EMDMA_CHNPTR.CPDR` bit.

Write Back Circular Index Pointer

Operating the DMA in circular mode requires some special considerations. The index pointer of start address within the buffer may wrap around for the case when IC × IM > EL or it does not finish if IC × IM < EL where:

IC is the value of the `EMDMA_INDX0` register

IM is the value of the `EMDMA_MOD0` register

EL is the value of the `EMDMA_BUFLEN` register

In both cases, the TCB start address is no longer valid.

Setting the `EMDMA_CTL.WRBEN` bit writes (at the end of current TCB block) the current index address + 1 into the TCB memory which is the start address for the next TCB. This bit is only selectable for chained DMA mode. For tap list and delay line modes, this bit is hardwired to 0 or 1.

Scatter/Gather DMA

The purpose of scatter/gather DMA is the transfer of data from/to non-contiguous memory blocks.

The scatter/gather DMA type is a fixed block size scatter/gather DMA that relies on tap list entries in system memory to calculate the (Channel 1 DMA Address) to scatter/gather the DMA. If the DMA direction is Channel 1 write (`EMDMA_CTL.TRAN` =1) then it is a scatter DMA. If `EMDMA_CTL.TRAN` =0 then it is a gather DMA. This mode also supports chained and circular buffer chained DMAs.

See the ***Scatter DMA (Writes)***, ***Gather DMA (Reads)***, ***Circular Buffering Scatter DMA (Writes)***, and ***Circular Gather DMA (Reads)*** figures.

EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × N		

Pre Modified Read/Write Index

For scatter/gather DMA, the tap list modifiers are employed and the number of taps is determined by the tap list count register (EMDMA_TCNT). The number of sequential reads (block size) from every tap is determined by the internal count register (`EMDMA_CNT0`), and is the same for every tap. The read/write pointer in external index register (`EMDMA_INDX1`) serves as the index address for these read/writes.

`TL[N]` is the first tap list entry in the memory as pointed to by the tap list pointer register (`EMDMA_TPTR`). The tap list entries are 27-bit signed integers. For each read/write block, the DMA state machine fetches the offset from the tap list. The offset is added to the `EMDMA_INDX1` register value to get the start address of the next block. The Channel 1 addresses are circular buffered if circular buffering is enabled (see the ***Circular Buffering Scatter DMA (Writes)*** and ***Circular Buffering Gather DMA (Reads)*** figures in Scatter/Gather DMA).

Once the `EMDMA_CNT0` register for the final tap decrements to zero (both `EMDMA_TCNT` and `EMDMA_CNT0` are zero), then the tap list DMA access is complete and the DMA completion interrupt is generated (if chaining is enabled the interrupt depends on the `EMDMA_CHNPTR.PCI` bit setting).

The write back mode (`EMDMA_CTL.WRBEN` bit) is hardwired to zero for tap list based DMA (as the addressing is pre-modify, and therefore the `EMDMA_INDX1` value coincides with the TCB value even at the end of the DMA).

Delay Line DMA

Delay line DMA is used to support reads and writes to delay line buffers with limited core interaction. In this sense, delay line DMA is a quantity of integrated writes followed by reads from channel 1 (a delay line DMA access). Delay line DMA is described in the following sections.

NOTE: Delay line DMA can only operate by using chained DMA mode (`EMDMA_CTL.CHEN` bit set). In order to use delay line DMA for a single DMA sequence, initialize the `EMDMA_CHNPTR` register to zero in the TCB.

NOTE: Delay line DMA can be used in any system memory.

The delay line DMA operation follows these steps:

1. Load the first half of TCB for writing (seven parameters).
2. DMA writes to the delay line buffer until IC = 0.
3. Update the EI index pointer if circular mode is enabled.
4. Load the second half of TCB for reading (six parameters).
5. DMA tap based reads from the delay line buffer until RC = 0.

   Jump to step 1.

Writes to delay line. The number of writes is determined by the `EMDMA_CNT0` register. The data is fetched from the `EMDMA_INDX0` register and the `EMDMA_MOD0` register is used as the internal modifier. The `EMDMA_INDX1` register serves as the external index and is incremented by the `EMDMA_MOD1` register after each write. These writes are circular buffered if circular buffering is enabled. See the ***Write to Delay Line Buffer*** figure.

BUFFER LENGTH (EMDMA_BUFLEN)

Figure 39-8: Write to Delay Line Buffer

When the writes are complete, (`EMDMA_CNT0` =0) the `EMDMA_INDX1` register, which serves as the write pointer of the delay line, is written back (`EMDMA_CTL.WRBEN` is hardwired to 1) to the TCB location from where it was fetched.

Reads from the delay line. For reads, the tap list (TL) modifiers are used and the number of reads is determined by the `EMDMA_CNT0` register. The write pointer in the `EMDMA_INDX0` register serves as the index address for these reads (reads start from where writes end). The `EMDMA_INDX0` register, along with tap list modifiers, are used in a pre-modify addressing mode to create the external address for the reads. Therefore, for each read, the DMA controller fetches the external modifier (`EMDMA_TCNT` register) from the tap list and the reads are circular buffered (if enabled). See the ***Read From Delay Line Buffer*** figure.

Figure 39-9: Read From Delay Line Buffer

Pre-Modified Read Index

Note that TL[N] is the first tap list entry in memory pointed to by the tap list pointer register (`EMDMA_TPTR`). Tap list entries are 27-bit signed integers. Therefore, for each read-block, the DMA state machine fetches the offset external modifier from the tap list. The reads are circular buffered if circular buffering is enabled.

NOTE: The channel 1 DMA address generation follows pre-modify addressing for reads in delay line DMA and therefore the `EMDMA_INDX1` register values are not updated. Also the `EMDMA_MOD1` register does not have any effect during these delay line reads. Once the read count completes, the EMDMA_CNT0 register decrements to zero (both EMDMA_CNT0 and EMDMA_TCNT are zero) for the final tap. Finally, the delay line DMA access completes and the DMA completion interrupt is generated. If chaining is enabled, the interrupt is dependent on the EMDMA_CHNPTR.PCI bit setting. The delay line DMA can only be initialized using the TCB. In order to use the delay line DMA for a single DMA sequence, initialize the EMDMA_CHNPTR register to zero in the TCB.

For each 32-bit tap read, the channel 1 read index is shown in the ***Read/Write Index Pre-Modify (Scatter/Gather DMA)*** table. Note that one tap list entry starts multiple reads.

Table 39-12: Read/Write Index Pre-Modify (Scatter/Gather DMA)

ADSP-SC58x EMDMA Register Descriptions

Extended Memory DMA (EMDMA) contains the following registers.

Table 39-13: ADSP-SC58x EMDMA Register List

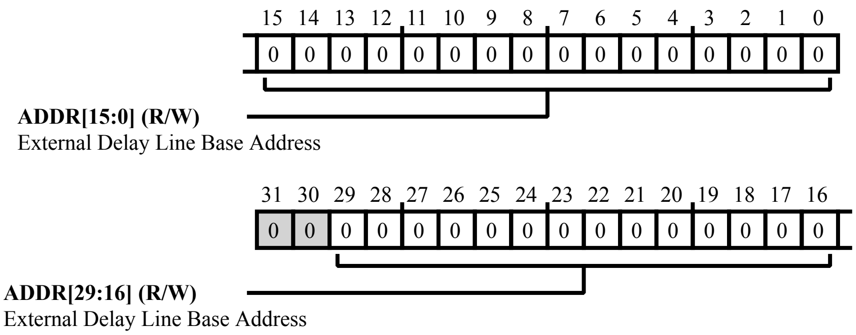
Name	Description
EMDMA_BASE	External Base Address Register
EMDMA_BUFLEN	Circular Buffer Length Register
EMDMA_CHNPTR	Chain Pointer Register
EMDMA_CNT0	Internal Count Register
EMDMA_CNT1	External Count Register

Table 39-13: ADSP-SC58x EMDMA Register List (Continued)

Name	Description
EMDMA_CTL	External Memory DMA Control Register
EMDMA_INDX0	Internal Index Register
EMDMA_INDX1	External Index Register
EMDMA_MOD0	Internal Modifier Register
EMDMA_MOD1	External Modifier Register
EMDMA_TCNT	Delay Line Tap Count Register
EMDMA_TPTR	Tap List Pointer Register

External Base Address Register

The `EMDMA_BASE` register contains the external base address of the Delay Line buffer. This is used for maintaining circular buffered read/writes to the delay line.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 39-15: EMDMA_BUFLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:0 (R/W)	CLEN	Delay Line Circular Buffer Length. The `EMDMA_BUFLEN.CLEN` bit field holds the circular buffer length for the Delay-line DMA.

Chain Pointer Register

The `EMDMA_CHNPTR` register contains the address of the next descriptor in memory when the `EMDMA_CTL.CHEN` bit =1. This register also has bits to change DMA directions for each descriptor and the PCI bit. Note that the lower 30-bits of this register are to be written with 30 MSB's of the Word Aligned Byte addresses of the corresponding next descriptor address.

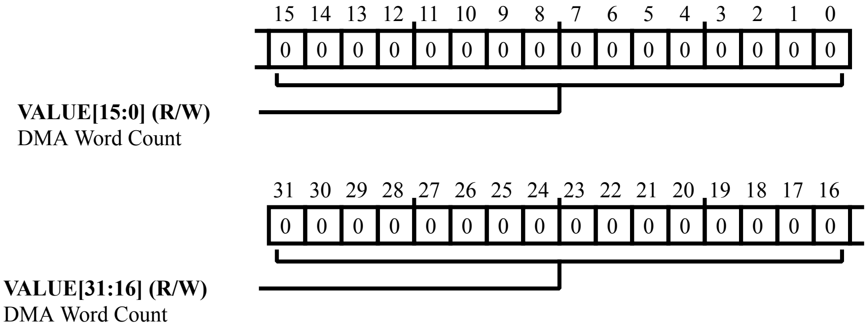
Table 39-16: EMDMA_CHNPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CPDR	CPDR DMA Direction for the next TCB. The `EMDMA_CHNPTR.CPDR` bit configures whether the DMA is a write to internal memory or a read from internal memory. Note that this setting is applicable only if `EMDMA_CTL.OFCEN` =1 and is not applicable for Delay Line DMA.	
		0	Write to Channel 0 (Channel 1 reads)
		1	Read from Channel 0 (Channel 1 Writes)
30 (R/W)	PCI	Program Controlled Interrupt. The `EMDMA_CHNPTR.PCI` bit PCI sets whether an interrupt is generated after the current TCB or if no interrupt is generated. (Only affects DMA if chaining is enabled)	
		0	Enable DMA Channel interrupt to occur at the completion of the entire DMA chained transfer
		1	Enable DMA Channel interrupt to occur at the completion of current DMA sequence
29:0 (R/W)	ADDR	Next Descriptor (Chain) Pointer Address. The `EMDMA_CHNPTR.ADDR` bit field provides the address of the next descriptor in memory.	

Internal Count Register

The `EMDMA_CNT0` register contains the number of words to be transferred for channel 0 DMA. Note: If Delay Line DMA is enabled then the `EMDMA_CNT0` register serves as the count register for the Delay Line writes.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 39-15: EMDMA_CTL Register Diagram

Table 39-19: EMDMA_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/NW)	DIRS	DMA Transfer Direction Status. The `EMDMA_CTL.DIRS` bit provides the DMA transfer status direction. This is useful for delay line DMA where the transfer direction changes with the state of the DMA state machine. For standard DMA, the `EMDMA_CTL.DIRS` bit reflects the state of the `EMDMA_CTL.TRAN` bit.	
		0	DMA direction is Channel 1 Reads
		1	DMA direction is Channel 1 Writes

Table 39-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	DMAS1	DMA External Interface Status. The `EMDMA_CTL.DMAS1` bit provides the DMA channel 1 transfer status.	
		0	Channel 1 DMA does not have any access pending
		1	Channel 1 DMA access are pending
23 (R/NW)	WBS	Write Back Status. The `EMDMA_CTL.WBS` bit provides the delay line write pointer write back status.	
		0	Write pointer write back is not active
		1	Write pointer write back is active
22 (R/NW)	TLS	TAP List Loading Status. The `EMDMA_CTL.TLS` bit provides the DMA tap list loading status.	
		0	TAP list loading is not active
		1	TAP list loading is active
21 (R/NW)	CHS	DMA Chaining Status. The `EMDMA_CTL.CHS` bit provides the DMA chaining status.	
		0	DMA chain loading is not active
		1	DMA chain loading is active
20 (R/NW)	DMAS0	DMA Transfer Status. The `EMDMA_CTL.DMAS0` bit provides the DMA channel 0 transfer status.	
		0	DMA idle
		1	DMA in progress
17:16 (R/NW)	DFS	DMA FIFO Status. The `EMDMA_CTL.DFS` bit field provides the DMA FIFO status.	
		0	FIFO EMPTY
		1	FIFO Partially Full
		2	Reserved
		3	FIFO Full

Table 39-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	INTDONE0	Internal DMA Completion Interrupt (Control). The `EMDMA_CTL.INTDONE0` bit configures when the DMA complete interrupt is generated. The `EMDMA_CTL.INTDONE0` =1 setting is provided for backward compatibility with older SHARC processors.	
		0	Interrupt on access completion (Channel 0 or Channel 1 DMA completion)
		1	Interrupt on Channel 0 DMA completion.
9 (R/W)	TLEN	Tap List DMA Enable. The `EMDMA_CTL.TLEN` bit enables scatter/gather tap list DMA.	
		0	Disables the tap list based scatter/gather DMA
		1	Enables the tap list based scatter/gather DMA
8 (R/W)	OFCEN	On the Fly Control Loading Enable. The control bits in `EMDMA_CHNPTR` register are used to describe the next TCB behavior if the `EMDMA_CTL.OFCEN` bit is set and therefore the DMA controls can be changed from TCB to TCB. 0 = disables the control bits in the `EMDMA_CHNPTR` register 1 = Enables the control bits in the `EMDMA_CHNPTR` register. If chaining is enabled with `EMDMA_CTL.OFCEN` bit set then the `EMDMA_CTL.TRAN` bit has no effect, and direction is determined by `EMDMA_CHNPTR.CPDR` bit.	
7 (R/W)	WRBEN	Write Back Enable. The `EMDMA_CTL.WRBEN` bit enables write back of the EIEP register after reads and or writes.Write back is automatically enabled for delay line DMA. WRBEN is applicable only if chaining is enabled (`EMDMA_CTL.CHEN` =1).	
5 (R/W)	DFLSH	Flush DMA FIFO. The `EMDMA_CTL.DFLSH` bit flushes the DMA FIFO. The buffer is only flushed if this bit is set. It can be set with the enable bit. Setting this bit also clears the `EMDMA_CTL.DFS` bit.	
4 (R/W)	CBEN	Circular Buffering Enable. The `EMDMA_CTL.CBEN` bit enables circular buffering. Circular buffering can be used with normal DMA as well, if circular buffering is enabled with chaining for normal DMA then ELEP and EBEP should be part of the TCB.	
		0	Disables circular buffering with delay line DMA
		1	Enables circular buffering with delay line DMA

Table 39-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DLEN	Enable Delay Line DMA. The `EMDMA_CTL.DLEN` bit enables delay line DMA. This bit is applicable only if the `EMDMA_CTL.CHEN` bit =1.	
		0	Delay-line DMA disabled
		1	Delay-line DMA enabled
2 (R/W)	CHEN	Enable Chaining. The `EMDMA_CTL.CHEN` bit enables DMA chaining.	
		0	Chaining disabled
		1	Chaining enabled
1 (R/W)	TRAN	DMA Direction. The `EMDMA_CTL.TRAN` bit determines the DMA data direction. Note: If delay line DMA is enabled then this bit does not have any effect. For delay line DMA, transfer direction depends on the state of delay line transfers. For Internal-Internal or External-External DMA this bit has to be set.	
		0	Write through Channel 0 (Channel 1 reads)
		1	Read from Channel 0(Channel 1 writes)
0 (R/W)	EN	DMA Enable. The `EMDMA_CTL.EN` bit enables DMA.	
		0	Disable DMA
		1	Enable DMA

Internal Index Register

The `EMDMA_INDX0` register contains the start address of the buffer for Channel 0 DMA. Note: For delay line DMA the `EMDMA_INDX0` register serves as the delay line write index which is the start address of the channel 0 DMA buffer for the channel 1 write data.

Delay Line Tap Count Register

The `EMDMA_TCNT` register is the tap count register for Delay Line DMA. This register holds the length of the tap list (the number of taps). The total number of words read from the delay line is equal to the `EMDMA_TCNT` (tap count) multiplied by the `EMDMA_CNT1` (read block size).

Tap List Pointer Register

The `EMDMA_TPTR` register holds the address of an array in memory which holds offsets to be used when accessing a Delay-line in system memory. The offset represents the first address of each read block. Note that the lower 30-bits of this register are to be written with 30 MSBs of the Word Aligned Byte address of the Array.

40 Cyclic Redundancy Check (CRC)

The CRC peripheral performs the cyclic redundancy check (CRC) of the block of data that is presented to the peripheral. The peripheral provides a means to verify periodically the integrity of the system memory, the contents of memory-mapped registers (MMRs), or communication message objects. It is based on a CRC32 engine that computes the signature of 32-bit data presented to the peripheral.

The dedicated hardware compares the calculated signature of the operation to a pre-loaded expected signature. If the two signatures fail to match, the peripheral generates an error.

The source channel of the memory-to-memory DMA channels can provide data. The CRC optionally forwards data to memory through the destination DMA channel. Alternatively, the peripheral supports data presented by any qualified master of the CRC peripheral bus.

The CRC peripheral implements a reduced table-look-up algorithm to compute the signature of the data. The CRC uses a programmable 32-bit CRC polynomial to generate the look-up table (LUT) contents automatically.

More CRC peripheral modes allow for initializing large memory sections with a constant value, or for verifying that sections of memory are equal to a constant value.

NOTE: CRC is supported by standard bandwidth MDMA only.

CRC Features

The CRC peripheral supports a number of key features.

- Memory scan modes for memory verification
- Memory transfer modes for on-the-fly CRC calculations while transferring data from one memory to another
- A programmable 32-bit CRC polynomial with automatic LUT generation
- Data mirroring options

The CRC module also includes the following features.

- CRC checksum computation and comparison modes
- 32-bit programmable CRC polynomial with bit reverse option
- Automatic look-up table (LUT) generation

- Data mirroring options for endian and reflected polynomial cases
- Automatic clear and preset of results
- Fault and error interrupt reporting
- DMA and MMR based operation

Because the CRC module is closely tied to memory-to-memory DMA (MDMA) channel pairs, the use cases include the following features.

- Memory scan mode with CRC compute or compare
- Memory transfer mode with CRC compute or compare
- Memory fill operation with 32-bit data patterns
- Memory verify operation
- MMR write access to FIFO of destination DMA
- MMR read access to FIFO of source DMA
- Profiting from advanced DMA features, like descriptor mode and bandwidth control or monitor

CRC Functional Description

The CRC peripheral supports a number of modes of operation that allow for the initialization and verification of regions of memory. The peripheral supports efficient memory-fill and verification operations on regions of memory with or against a constant value. These modes of operation do not require the CRC engine to calculate a signature. Other modes of operation allow for the calculation of CRC signature and verification for a memory region. The modes allow for on-the-fly CRC calculation when performing memory-to-memory DMA transfers from one memory region to another.

To minimize the need for core accesses, the peripheral interfaces with one or more (depending on processor features) memory-to memory DMA (MDMA) channels. This connectivity permits flexible configuration, in which data can be written-to or read-from the peripheral using DMA transactions, core transactions, or a combination of both.

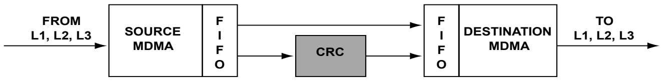

Figure 40-1: Memory Flow

ADSP-SC58x CRC Register List

The Cyclic Redundancy Check (CRC) unit includes the data comparison, polynomial operation, and look up table generation features needed for CRC operation. The CRC provides CRC protection as specified by many functional safety requirements. This unit facilitates the system software's ability to periodically check the correctness of the code/data available in memory. A set of registers govern CRC operations. For more information on CRC functionality, see the CRC register descriptions.

Table 40-1: ADSP-SC58x CRC Register List

Name	Description
`CRC_COMP`	Data Compare Register
`CRC_CTL`	Control Register
`CRC_DCNT`	Data Word Count Register
`CRC_DCNTCAP`	Data Count Capture Register
`CRC_DCNTRLD`	Data Word Count Reload Register
`CRC_DFIFO`	Data FIFO Register
`CRC_FILLVAL`	Fill Value Register
`CRC_INEN`	Interrupt Enable Register
`CRC_INEN_CLR`	Interrupt Enable Clear Register
`CRC_INEN_SET`	Interrupt Enable Set Register
`CRC_POLY`	Polynomial Register
`CRC_RESULT_CUR`	CRC Current Result Register
`CRC_RESULT_FIN`	CRC Final Result Register
`CRC_STAT`	Status Register

ADSP-SC58x CRC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
176	CRC0_DCNTEXP	CRC0 Datacount expiration	Level	
177	CRC1_DCNTEXP	CRC1 Datacount expiration	Level	
178	CRC0_ERR	CRC0 Error	Level	
179	CRC1_ERR	CRC1 Error	Level	

CRC Definitions

To make the best use of the CRC, it is useful to understand the following terms.

CRC

Acronym for Cyclic Redundancy Check. An error detection code that can detect changes within a block of data.

CRC Polynomial

The 32-bit polynomial used by the CRC engine to generate the look-up table required for the CRC implementation

LUT

Acronym for the Look-up Table. The look-up table is automatically generated from the supplied 32-bit CRC polynomial.

DMA

Acronym for Direct Memory Access. Used to describe a data transfer that takes place through a DMA channel allowing data distribution around a system without intervention from the core.

MDMA

Acronym for Memory-To-Memory DMA transfer that often requires the use of two DMA channels to transfer data from one memory region to another memory region. One DMA channel is configured as a source channel and the second as a destination channel.

CRC Block Diagram

Figure 40-2: CRC Block Diagram

Peripheral DMA Bus

The CRC peripheral provides both an incoming and outgoing datapath to the peripheral DMA bus. The MDMA source channel is interfaced to the incoming datapath providing data to the CRC peripheral. For memory transfer and data fill modes, the CRC uses the MDMA destination channel to either output the data from the CRC FIFO or use the data for the fill operation.

MMR Access Bus

The core uses the MMR access bus to access all the memory-mapped registers of the peripheral for configuration, status, and debug purposes. The core can also use the MMR access bus to feed data to the CRC peripheral or read data from the FIFO of the CRC peripheral. The CRC operation is an alternative to the DMA channel operation to read data from the FIFO.

Data received by MMR writes can transfer to destination DMA. Similarly, data received by source DMA can be output through the MMR interface. Optionally, intermediate results can be made available to the MMR interface.

Mirror Block

The mirror block individually controls bit-reversing of the polynomial, the computation results, and the expected result. Bit mirroring, byte mirroring, word swapping, and any combination of these operations can control endian and the reflection of processed data.

Data FIFO

The CRC data FIFO is a 32-bit-wide 4-entry FIFO. The FIFO is accessible to both the peripheral DMA bus and the MMR access bus. The FIFO status is accessible from the `CRC_STAT` register.

DMA Request Generator

The DMA request generator is responsible for granting incoming DMA requests from the source DMA channel and issuing outgoing DMA requests to the destination DMA channel.

CRC Engine

The CRC engine is a 32-bit CRC engine that implements the reduced table look-up scheme. The CRC engine provides support for a user-programmable 32-bit polynomial that the CRC uses to load the look-up table parameters required for the CRC calculation. The CRC engine is a two-cycle implementation operating on 16 bits of data per cycle.

Compare Logic

The compare logic takes the final CRC signature and compares it to the expected CRC signature, generating a CRC compare error when the signatures do not match. A compare error can cause an error interrupt request to the Cortex-M4 system or to SEC1.

CRC Architectural Concepts

A 32-bit polynomial is required before calculation of the CRC signature can occur. The CRC uses the polynomial to generate the contents of an internal look-up table that the reduced table look-up implementation requires. The look-up table is automatically generated when the polynomial is written. It must be initialized prior to any operation that requires the use of the CRC engine.

The mirror block logic can manipulate the data presented to the CRC engine before the CRC uses the data in the calculation of the CRC signature. The data mirror operation is configurable to allow for bit reversing, byte reversing, and 16-bit word swapping operations on the incoming data. For memory transfer compute-and-compare operations, programs can configure the peripheral to output the data in the same form in which it was received. Or, the operation can output the mirrored data in the same manner that it is presented to the CRC engine.

While the CRC peripheral is in operation, the status of the FIFO is continually updated and reflected in the `CRC_STAT` register. The FIFO status is required for core-based accesses to the CRC peripheral. The status indicates when:

- The CRC peripheral can receive data
- Data is available for reading from the FIFO
- The result of the `CRC_RESULT_CUR` register has been updated

The status of the `CRC_RESULT_CUR` register indicates that the current CRC calculation has completed and the result is available.

Look-up Table

The look-up table consists of a set of sixteen 32-bit registers that hardware populates automatically when a write access takes place to the `CRC_POLY` register. 16 clock cycles are required to generate all 16 look-up table entries. The status of the process for generating the look-up table is reflected in `CRC_STAT.LUTDONE` allowing for software to poll on the completion of the event or for generation of an interrupt.

NOTE: Hardware must populate the look-up table before any operation using the CRC peripheral can take place, even if the operation does not use the CRC engine. The peripheral does not issue any data requests until the table generation process is complete. In addition, the `CRC_STAT.IBR` field, that indicates the input buffer status as required for core-based transfers, is only valid upon completion of the process for generating the look-up table.

Data Mirroring

The data mirror block can be configured to manipulate the incoming data before the data passes to the CRC engine and, optionally, to the FIFO. This configuration allows the peripheral to handle various forms of endianness and to function with reflected polynomials.

There are three configuration bits that control the data mirroring process: `CRC_CTL.BITMIRR`, `CRC_CTL.BYTMIRR`, and `CRC_CTL.W16SWP`. The ***Data Mirroring Options*** table details how these options affect the incoming data and the output generated by the mirror block.

Table 40-3: Data Mirroring Options

W16SWP	BYTMIRR	BITMIRR	Output Data
0	0	0	Dout[31:0] = Din[31:0]
0	0	1	Dout[31:0] = Din[24:31],Din[16:23],Din[8:15],Din[0:7]
0	1	0	Dout[31:0] = Din[7:0],Din[15:8],Din[23:16],Din[31:24]
0	1	1	Dout[31:0] = Din[0:7],Din[8:15],Din[16:23],Din[24:31]
1	0	0	Dout[31:0] = Din[15:0], D[31:16]
1	0	1	Dout[31:0] = Din[8:15],Din[0:7], Din[24:31],Din[16:23]
1	1	0	Dout[31:0] = Din[23:16],Din[31:24], Din[7:0],Din[15:8]
1	1	1	Dout[31:0] = Din[16:23],Din[24:31], Din[0:7],Din[8:15]

When the CRC is configured to operate in the memory transfer compute-and-compare mode, the bit-reversed output data can be written to the FIFO. This feature is controlled through the `CRC_CTL.FDSEL` field.

In addition to providing bit swapping and mirror options to the incoming data, the CRC peripheral also supports bit mirroring on the following registers.

- `CRC_RESULT_CUR` and `CRC_RESULT_FIN`, controlled through the `CRC_CTL.RSLTMIRR` field. When mirroring is enabled, the values to be written to these registers are fully bit-reversed before the write operation occurs.
- `CRC_POLY`, controlled through the `CRC_CTL.POLYMIRR` field. When mirroring is enabled, the 32-bit polynomial is fully bit-reversed before the write operation to the register occurs.
- `CRC_COMP`, controlled through the `CRC_CTL.CMPMIRR` field. When mirroring is enabled, the contents to be loaded to this register are fully bit-reversed before the write operation occurs.

FIFO Status and Data Requests

The CRC peripheral provides indication of the input and output buffer status through `CRC_STAT.IBR` and `CRC_STAT.OBR` respectively. For core-based operations, software must monitor these status fields prior to writing to or reading from the CRC FIFO. No write to the CRC FIFO can occur while `CRC_STAT.IBR` indicates that the buffer is not ready to accept data. Similarly, the CRC FIFO cannot be read until `CRC_STAT.OBR` indicates that data is available.

The memory scan modes of operation only require the monitoring of the input buffer status. The memory transfer, compute-and-compare mode uses both input and output buffer status. If the current result of the CRC computation is required, then software must verify that the current operation has completed and that the intermediate result is ready. The `CRC_STAT.IRR` indicates the status.

NOTE: The memory transfer fill mode of operation requires the use of a DMA channel. The CRC does not support core reads from the CRC FIFO for this mode of operation.

Memory transfer, compute-and-compare mode uses burst transactions to make the most efficient use of the available resources. In this mode, when the FIFO is initially empty and the peripheral is enabled, the `CRC_STAT.IBR` bit indicates that the CRC is ready to accept data. The peripheral generates data requests to the source DMA channel (if the CRC uses DMA). While the number of words remaining in the `CRC_DCNT` register is greater than the FIFO depth, the peripheral issues data requests or accepts incoming data in bursts. The peripheral continues until the CRC FIFO becomes full.

Once full, the `CRC_STAT.IBR` and `CRC_STAT.OBR` bits are updated, and then the CRC issues outgoing data requests. Only when the FIFO is empty can the peripheral accept further incoming data, and the `CRC_STAT.IBR` and `CRC_STAT.OBR` bits are updated once again.

Once `CRC_DCNT` is decremented such that the number of words waiting for processing is less than the number required to fill the FIFO, the burst mode of operation is disabled. Incoming data is accepted as long as the FIFO is not full. Outgoing data is available as long the FIFO is not empty. Therefore, there are no restrictions requiring the word count to be a multiple of the FIFO depth.

All other CRC modes of operation indicate that incoming data can be accepted as long as the FIFO is not full. Outgoing data is available as long as the FIFO is not empty.

The `CRC_CTL.OBRSTALL` and `CRC_CTL.IRRSTALL` bit configurations also influence how the CRC generates data requests and status bits. The following list describes the bits.

- The `CRC_CTL.OBRSTALL` bit can be configured such that the CRC peripheral stalls as soon as there is output data available in the FIFO. Use this mode of operation only in memory transfer, compute-and-compare mode. This mode results in the processing of one 32-bit word at a time. The peripheral does not request or accept incoming data until the current value being processed is read from the peripheral.
- The `CRC_CTL.IRRSTALL` bit can be configured so that the CRC peripheral stalls all further incoming data requests until the `CRC_RESULT_CUR` register is read after being updated. Use this mode of operation for CRC signature generation. It is not applicable to memory transfer data-fill mode or memory scan data-verify mode of operation.

CRC Operating Modes

The following sections describe the various operating modes of the CRC interface.

Data Transfer Modes

The CRC peripheral supports two main categories of operation involving data transfers:

- Memory scan mode
- Memory transfer mode

Memory scan modes are read-only operations that allow the contents of memory to be read into the peripheral and verified for correctness. There are two forms of memory scan mode:

- CRC compute-and-compare performs a CRC calculation on data presented to the peripheral and compares the CRC result with a pre-determined and pre-loaded result. An error is generated when the results differ.
- Data verify compares each 32-bit data word presented to the CRC peripheral to a pre-loaded 32-bit value and generates an error when the data differs.

Both of these modes of operation require, at the most, a single DMA channel to read the data from memory into the peripheral. No data is forwarded to the data output or destination DMA. The CRC can also use core-driven transfers for either of these modes of operation.

The memory transfer modes involve memory write or memory read-and-write operations allowing for memory to be initialized or transferred from one region of memory to another. There are two forms of memory transfer mode:

- CRC compute-and-compare performs a full data transfer from one memory region to another memory region. The CRC generates a signature on the data presented and compares it with a pre-determined and pre-loaded result. An error is generated when the results differ.
- Data fill initializes a region of memory with a pre-loaded 32-bit constant value.

The CRC compute-and-compare mode of operation requires both incoming and outgoing data channels. The operation occurs either using DMA channels, using core-driven write or read operations to and from the FIFO or using a combination of both. The data fill mode of operation requires only a memory write DMA destination channel—this mode does not support core driven operations.

Memory Scan Compute-and-Compare Mode

In this mode of operation, the CRC engine of the peripheral is enabled. The mode is configured through the `CRC_CTL.OPMODE` field and the CRC engine performs a 32-bit CRC operation on the incoming data stream.

The length of the data stream is configured through the `CRC_DCNT` register. The accumulated result of the CRC operation is contained in the `CRC_RESULT_CUR` register. As the CRC engine processes each 32-bit word, the `CRC_DCNT` register is decremented and `CRC_RESULT_CUR` is updated.

Once `CRC_DCNT` decrements to zero, the contents of the `CRC_RESULT_CUR` register are copied to `CRC_RESULT_FIN` and `CRC_STAT.DCNTEXP` is updated accordingly. The CRC uses the `CRC_COMP` register to store the expected result of the operation. After the CRC calculation, `CRC_COMP` is compared with `CRC_RESULT_FIN` and `CRC_STAT.CMPERR` is updated to reflect the status of the compare operation. `CRC_STAT.CMPERR` must be cleared before the next CRC operation is performed.

The CRC peripheral also contains the `CRC_DCNTRLD` register. The CRC uses this register to reload `CRC_DCNT` upon completion of the CRC operation in preparation for the next transfer.

The initial seed of the CRC computation can be configured through `CRC_CTL.AUTOCLRZ` and `CRC_CTL.AUTOCLRF`. This configuration provides a way to reset `CRC_RESULT_CUR` to 0x00000000, 0xFFFFFFFF or to leave the current register contents untouched for the next operation.

The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Scan Data Verify

In this mode of operation, the CRC engine of the peripheral is not required. The mode is enabled through the `CRC_CTL.OPMODE` field. Each 32-bit word of the data stream is compared with a constant value that is stored in the `CRC_COMP` register. The `CRC_DCNT` register contains the number of words for comparison. The `CRC_DCNT` register is decremented upon receiving a new 32-bit word from the data stream. If the compare operation fails, the `CRC_STAT.CMPERR` bit is updated and the contents of `CRC_DCNT` are captured in the `CRC_DCNTCAP` register. This information can be used to identify the location in the data stream where the error occurred. Clear the `CRC_STAT.CMPERR` field to reenable capturing of further errors.

Once `CRC_DCNT` decrements to zero, `CRC_STAT.DCNTEXP` is updated accordingly to signal the end of the operation. The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Transfer Compute-and-Compare Mode

In this mode of operation, the CRC engine of the peripheral is enabled. The mode is configured through the `CRC_CTL.OPMODE` field and the CRC engine performs a 32-bit CRC operation on the incoming data stream.

The length of the data stream is configured through the `CRC_DCNT` register. The accumulated result of the CRC operation is contained in the `CRC_RESULT_CUR` register. As the CRC engine processes each 32-bit word, the `CRC_DCNT` register is decremented and `CRC_RESULT_CUR` is updated.

Once `CRC_DCNT` decrements to zero, the contents of the `CRC_RESULT_CUR` register are copied to `CRC_RESULT_FIN` and `CRC_STAT.DCNTEXP` is updated accordingly. The CRC uses the `CRC_COMP` register to store the expected result of the operation. Upon completion of the CRC calculation, `CRC_COMP` is compared with `CRC_RESULT_FIN` and `CRC_STAT.CMPERR` is updated to reflect the status of the compare operation. Clear `CRC_STAT.CMPERR` before the next CRC operation is performed.

The CRC peripheral also contains `CRC_DCNTRLD` register. The CRC uses this register to reload `CRC_DCNT` upon completion of the CRC operation in preparation for the next transfer.

The initial seed of the CRC computation can be configured through `CRC_CTL.AUTOCLRZ` and `CRC_CTL.AUTOCLRF`. This configuration provides a means to reset `CRC_RESULT_CUR` to 0x00000000, 0xFFFFFFFF or to leave the current register contents untouched for the next operation.

The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Transfer Data Fill Mode

In this mode of operation, the CRC engine of the peripheral is not required. The mode is enabled through the `CRC_CTL.OPMODE` field. The `CRC_FILLVAL` register is written with a 32-bit value. The CRC uses this value to initialize a block memory through the memory-to-memory DMA destination channel. When the CRC peripheral and the DMA destination channel are enabled, the contents of the `CRC_FILLVAL` register is written to the DMA channel to initialize the memory region. The `CRC_DCNT` register contains the number of words for the write operation.

Once `CRC_DCNT` decrements to zero, `CRC_STAT.DCNTEXP` is updated accordingly to signal the end of the operation. The peripheral can be configured to allow for the data expiration event to generate an interrupt.

CRC Event Control

The CRC peripheral can enable certain CRC status operations to generate an interrupt event to the Cortex-M4 system event controller. There, a CRC error can be qualified as a system fault.

Interrupt Signals

The CRC peripheral can generate two interrupt requests that are optionally enabled as interrupts with the Cortex-M4 core NVIC, or as events to SEC1 for fault operations. One is a CRC status interrupt and the other is a CRC error interrupt.

The `CRC_STAT.CMPERR` status bit can be configured as an interrupt and is signaled through the CRC error interrupt signal. The `CRC_STAT.CMPERR` status field is set whenever the CRC peripheral performs a compare operation that fails. This status can be the result of a failed memory scan data-verify operation that compares the contents of a memory range with a constant 32-bit value. Or, it can be the result of a CRC signature calculated for a memory region that does not match the expected pre-programmed result for a memory-compare operation.

The `CRC_STAT.DCNTEXP` status bit is set when the `CRC_DCNT` register has decremented to zero. The status indicates that the CRC peripheral has now processed all the data requested for the current CRC operation. The CRC can also use this signal to generate an interrupt. The interrupt is signaled on the CRC status interrupt signal.

Both these status bits can be configured to generate and interrupt through the `CRC_INEN` register. The `CRC_INEN` register also has bit set, `CRC_INEN_SET`, and bit clear `CRC_INEN_CLR` equivalent registers that the CRC uses for the enabling and disabling of these interrupt sources.

The `CRC_STAT` register has two write one to clear (W1C) fields for clearing the two interrupt sources.

NOTE: Disabling the CRC peripheral through the `CRC_CTL.BLKEN` bit does not result in the clearing of interrupt sources. Clear the interrupt sources using a W1C operation to the `CRC_STAT` register.

CRC Programming Model

It is important to note the following restrictions when using the CRC peripheral with the DMA channels:

1. When enabling the CRC peripheral and the DMA channels, enable the CRC peripheral prior to enabling the DMA channels.
2. When disabling the CRC peripheral and the DMA channels, disable the DMA channels prior to disabling the CRC peripheral.

CRC Mode Configuration

Describes a number of tasks showing the various operation modes of the CRC peripheral.

- Look-up Table Generation
- Core Driven Memory Scan Compute-and-Compare Mode
- DMA Driven Memory Scan Compute-and-Compare Mode
- Core Driven Memory Scan Data Verify Mode
- DMA Driven Memory Scan Data Verify Mode
- Core Driven Memory Transfer Compute-and-Compare Mode
- DMA Driven Memory Transfer Compute-and-Compare Mode
- DMA Driven Memory Transfer Data Fill Mode

Look-up Table Generation

Describes the steps required to initialize the CRC peripheral LUT.

1. Write the 32-bit CRC polynomial of choice to the `CRC_POLY` register.

   ADDITIONAL INFORMATION: This operation results in the CRC peripheral starting the LUT initialization process. The `CRC_STAT.LUTDONE` bit is updated to reflect the operation is in progress.

2. Poll the `CRC_STAT.LUTDONE` bit until the status bit indicates that the operation is completed.

The CRC peripheral has completed initialization of all the LUT registers and is now ready for data operations. The `CRC_STAT.LUTDONE` bit remains in the current state until the `CRC_POLY` register is written again, or the peripheral or processor are reset.

Core Driven Memory Scan Compute-and-Compare Mode

Performs CRC signature calculation and verification for a region of memory using core transactions. The CRC peripheral is configured such that it operates in burst mode due to the stalling options configured through disabling the `CRC_CTL` register.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per `CRC_CTL.BLKEN`

1. Initialize the `CRC_DCNT` register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the `CRC_DCNTRLD` register.

ADDITIONAL INFORMATION: This value is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the `CRC_RESULT_CUR` register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the `CRC_COMP` register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the `CRC_INEN` register.

   ADDITIONAL INFORMATION: The CRC uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize `CRC_CTL` register with the `CRC_CTL.OPMODE` bit set to memory scan compute-and-compare mode and the `CRC_CTL.BLKEN` bit configured to enable the CRC peripheral.

   - Disable the `CRC_CTL.OBRSTALL` and `CRC_CTL.IRRSTALL` bit options for this task example.
   - Configure all mirroring and bit reversal options.
   - Configure CRC auto-clear options.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Write memory region data to the CRC peripheral.

   a. While `CRC_STAT.IBR` bit indicates that the input buffer is ready, write the `CRC_DFIFO` register with 32-bit data.

      ADDITIONAL INFORMATION: Repeat this step until all data has been written.

8. Poll the `CRC_STAT.DCNTEXP` bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures that all the data has been processed.

9. Poll the `CRC_STAT.CMPERR` bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write to the `CRC_STAT` register to clear both the `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR` bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear of these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The integrity check of the memory through the expected CRC signature has completed. The final result is indicated through the `CRC_STAT.CMPERR` bit and the corresponding interrupt when enabled.

Clear any W1C CRC status bits before performing more CRC operations.

DMA Driven Memory Scan Compute-and-Compare Mode

Performs CRC signature calculation and verification for a region of memory using DMA transactions. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured through disabling `CRC_CTL`.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the `CRC_CTL.BLKEN` bit.

1. Initialize the `CRC_DCNT` register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the `CRC_DCNTRLD` register.

   ADDITIONAL INFORMATION: This value is used to reload the `CRC_DCNT` register upon completion of current operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the `CRC_RESULT_CUR` register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the `CRC_COMP` register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final operation.

5. Initialize the `CRC_INEN` register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the `CRC_CTL` register with the `CRC_CTL.OPMODE` bit set to memory scan compute compare mode and the `CRC_CTL.BLKEN` bit configured to enable the CRC peripheral.

   - Disable the `CRC_CTL.OBRSTALL` and `CRC_CTL.IRRSTALL` bit options for this task example.
   - Configure all mirroring and bit reversal options.

- Configure all CRC auto clear options.

The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer from the memory region and writes the data to the CRC peripheral.

8. Poll the `CRC_STAT.DCNTEXP` bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if the counter expired interrupt is disabled. Polling ensures all the data has been processed.

9. Poll the `CRC_STAT.CMPERR` bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write the `CRC_STAT` register to clear both the `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR` bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The integrity check of the memory through the expected CRC signature has completed and the final result indicated is through `CRC_STAT.CMPERR` and the corresponding interrupt, when enabled.

Clear any W1C CRC status bits before performing a further CRC operation. Clear any W1C status bits of the memory-to-memory source DMA channel before the next CRC operation.

Core Driven Memory Scan Data Verify Mode

Reads a region of memory using core transactions and performs a compare operation on each 32-bit word against a single pre-loaded 32-bit constant. The compare error interrupt is enabled to capture and log the location of any compare errors.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per `CRC_CTL.BLKEN`

The interrupt service routine for the compare error interrupt reads and stores the contents of `CRC_DCNTCAP` register to a buffer before clearing the compare error interrupt.

1. Initialize the `CRC_DCNT` register.

ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the `CRC_DCNTRLD` register.

   ADDITIONAL INFORMATION: This value is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the `CRC_COMP` register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the memory region is expected to be filled with. Each 32 bit of data presented to the peripheral is compared with this value.

4. Initialize the `CRC_INEN` register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the `CRC_CTL` register with the `CRC_CTL.OPMODE` bit set to memory scan data verify mode and the `CRC_CTL.BLKEN` bit configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

6. Write memory region data to the CRC peripheral.

   a. Poll the `CRC_STAT.IBR` bit until input buffer is ready.

   b. Write the `CRC_DFIFO` register with 32-bit data.

      ADDITIONAL INFORMATION: Repeat these two steps until the entire memory region has been written to the CRC peripheral.

7. Poll the `CRC_INEN_SET.DCNTEXP` bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

8. Check if the buffer used to capture the `CRC_DCNTCAP` register upon a compare error has any new entries.

   ADDITIONAL INFORMATION: The values captures in the buffer provide a means to locate where in the memory region the failures occurred.

9. Write to the `CRC_STAT` to clear both the `CRC_INEN_SET.DCNTEXP` and `CRC_INEN.CMPERR` bits.

   ADDITIONAL INFORMATION: If interrupts were enabled, the clear these status bits within the interrupt handlers for the respective interrupts.

   The CRC memory scan-verify operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The result of the integrity check of the memory with the 32-bit constant is indicated through the `CRC_INEN.CMPERR` bit and the corresponding interrupt, when enabled. Each comparison error is traceable due to the logging of `CRC_DCNTCAP` from within the compare error interrupt handler.

Clear any W1C CRC status bits before performing a further CRC operation.

DMA Driven Memory Scan Data Verify Mode

The memory scan data verify mode reads a region of memory using DMA transactions and performs a compare operation on each 32-bit word against a single pre-loaded 32-bit constant. The compare error interrupt is enabled to capture and log the location of any compare errors.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the `CRC_CTL.BLKEN` bit

The interrupt service routine for the compare error interrupt reads and stores the contents of the `CRC_DCNTCAP` register to a buffer before clearing the compare error interrupt.

1. Initialize the `CRC_DCNT` register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the `CRC_DCNTRLD` register.

   ADDITIONAL INFORMATION: The CRC module uses this register to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the `CRC_COMP` register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the memory region is expected to be filled with. Each 32 bit of data presented to the peripheral is compared with this value.

4. Initialize the `CRC_INEN` register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the `CRC_CTL` register with the `CRC_CTL.OPMODE` bit set to memory scan data verify mode and `CRC_CTL.BLKEN` configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write the data.

6. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer from the memory region and writes the data to the CRC peripheral.

7. Poll the `CRC_STAT.DCNTEXP` bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

8. Check if the buffer used to capture the `CRC_DCNTCAP` register upon a compare error has any new entries.

   ADDITIONAL INFORMATION: The values captures in the buffer provide a means to locate where in the memory region the failures occurred.

9. Write the `CRC_STAT` register to clear both the `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR` bits.

   ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

   The CRC memory scan-verify operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The result of the integrity check of the memory with the 32-bit constant is indicated through the `CRC_STAT.CMPERR` bit and the corresponding interrupt when enabled. Each comparison error is traceable due to the logging of the `CRC_DCNTCAP` register from within the compare error interrupt handler.

Clear any W1C CRC status bits and DMA status bits before performing a further CRC operation.

Core Driven Memory Transfer Compute-and-Compare Mode

The memory transfer compute-and-compare mode performs CRC signature calculation and verification for a region of memory using core transactions while copying the contents to another memory region. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured through disabling the `CRC_CTL` register.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the `CRC_CTL.BLKEN` bit

1. Initialize the `CRC_DCNT` register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the `CRC_DCNTRLD` register.

ADDITIONAL INFORMATION: This value is used to reload the `CRC_DCNT` register upon completion of the current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the `CRC_RESULT_CUR` register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the `CRC_COMP` register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the `CRC_INEN` register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the `CRC_CTL` register with the `CRC_CTL.OPMODE` bit set to memory scan compute-and-compare mode and the `CRC_CTL.BLKEN` bit configured to enable the CRC peripheral.

   a. Disable the `CRC_CTL.OBRSTALL` bit and the `CRC_CTL.IRRSTALL` bit options for this task example.

   b. Configure all mirroring and bit reversal options.

   c. Configure CRC auto clear options

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Write memory region data to the CRC peripheral and read it back to the new destination.

   a. While the `CRC_STAT.IBR` bit indicates that the input buffer is ready, write the `CRC_DFIFO` register with 32-bit data.

   b. While the `CRC_STAT.OBR` bit indicates that the output buffer is ready, read the `CRC_DFIFO` register and store data to new destination.

      ADDITIONAL INFORMATION: Repeat these two steps until all required data has been processed through the CRC peripheral and copied to the new destination.

8. Poll the `CRC_STAT.DCNTEXP` bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if the counter expired interrupt is disabled. Polling ensures all the data has been processed.

9. Poll the `CRC_STAT.CMPERR` bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write the `CRC_STAT` register to clear both `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR` bits.

ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation. The memory region has also been copied to its new destination.

The memory region has been copied to a new location and an integrity check of the memory through the expected CRC signature has also completed. The final result is indicated through the `CRC_STAT.CMPERR` bit and the corresponding interrupt when enabled.

Clear any W1C CRC status bits before performing a further CRC operation.

DMA Driven Memory Transfer Compute-and-Compare Mode

The memory transfer compute-and-compare mode performs CRC signature calculation and verification for a region of memory using DMA transactions. The memory region is also copied to another memory region using memory-to-memory DMA transfers. The CRC peripheral is configured such that it operates in burst mode due to the stalling options configured through disabling `CRC_CTL`.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the `CRC_CTL.BLKEN` register.

1. Initialize the `CRC_DCNT` register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the `CRC_DCNTRLD` register.

   ADDITIONAL INFORMATION: This value is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the `CRC_RESULT_CUR` register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the `CRC_COMP` register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the `CRC_INEN` register.

ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the `CRC_CTL` register with the `CRC_CTL.OPMODE` bit set to memory scan compute compare mode and `CRC_CTL.BLKEN` configured to enable the CRC peripheral.
    a. Disable the `CRC_CTL.OBRSTALL` and the `CRC_CTL.IRRSTALL` bit options for this task example.
    b. Configure all mirroring and bit reversal options
    c. Configure CRC auto clear options

    The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode and destination DMA channel for memory write STOP mode.

    ADDITIONAL INFORMATION: This step starts the data transfer from one memory region to another through the memory-to-memory DMA channels and the CRC peripheral.

8. Poll the `CRC_STAT.DCNTEXP` bit if the interrupt was disabled.

    ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

9. Poll the `CRC_STAT.CMPERR` bit if the interrupt was disabled to check for a compare error.

    ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write the `CRC_STAT` register to clear both the `CRC_STAT.DCNTEXP` and the `CRC_STAT.CMPERR` bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation. The memory region has also been copied to its new destination.

The integrity check of the memory through the expected CRC signature has completed and the final result is indicated through the `CRC_STAT.CMPERR` bit and the corresponding interrupt when enabled. The memory region has also been copied to its final destination.

Clear any W1C CRC status bits before performing a further CRC operation. Also, clear any W1C status bits of the memory-to-memory source and destination DMA channels before the next CRC operation.

DMA Driven Memory Transfer Data Fill Mode

This mode initializes a region of memory to a constant 32-bit value using DMA transactions.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the `CRC_CTL.BLKEN` bit

1. Initialize the `CRC_DCNT` register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the `CRC_DCNTRLD` register.

   ADDITIONAL INFORMATION: This value is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the `CRC_FILLVAL` register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the CRC module uses to fill the memory region.

4. Initialize the `CRC_INEN` register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of block completion. Configure these interrupts as required. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the `CRC_CTL` register with the `CRC_CTL.OPMODE` bit set to memory transfer fill mode and the `CRC_CTL.BLKEN` bit configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and is ready for the DMA channel to write data.

6. Configure and enable the memory-to-memory destination DMA channel for memory write STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer taking the constant 32-bit value from the CRC peripheral and writing the data to the DMA channel.

7. Poll the `CRC_STAT.DCNTEXP` bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures that all the data has been processed.

8. Write the `CRC_STAT` register to clear the `CRC_STAT.DCNTEXP` bit.

   ADDITIONAL INFORMATION: If interrupts were enabled, then clear this status bit within the interrupt handlers for the respective interrupts.

   The CRC memory transfer fill operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation.

The memory region is now filled with the constant data and the CRC peripheral is ready to be configured for a new operation.

Clear any W1C CRC status bits and DMA status bits before performing a further CRC operation.

ADSP-SC58x CRC Register Descriptions

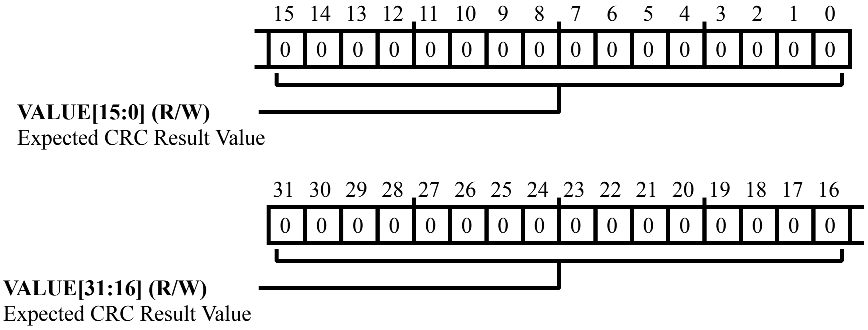
Cyclic Redundancy Check Unit (CRC) contains the following registers.

Table 40-4: ADSP-SC58x CRC Register List

Name	Description
`CRC_COMP`	Data Compare Register
`CRC_CTL`	Control Register
`CRC_DCNT`	Data Word Count Register
`CRC_DCNTCAP`	Data Count Capture Register
`CRC_DCNTRLD`	Data Word Count Reload Register
`CRC_DFIFO`	Data FIFO Register
`CRC_FILLVAL`	Fill Value Register
`CRC_INEN`	Interrupt Enable Register
`CRC_INEN_CLR`	Interrupt Enable Clear Register
`CRC_INEN_SET`	Interrupt Enable Set Register
`CRC_POLY`	Polynomial Register
`CRC_RESULT_CUR`	CRC Current Result Register
`CRC_RESULT_FIN`	CRC Final Result Register
`CRC_STAT`	Status Register

Data Compare Register

The `CRC_COMP` register contains the value corresponding to the expected CRC result or signature for the current data stream. At the end of the operation, the content of this register is used to compare against the result produced by the CRC operation. In data verify mode, each incoming data value is compared with the content of this register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Expected CRC Result Value

Figure 40-4: CRC_CTL Register Diagram

Table 40-6: CRC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	CMPMIRR	COMPARE Register Mirroring. The CRC_CTL.CMPMIRR bit enables data mirroring for the CRC_COMP compare register. When enabled, the 32-bit value in this register is fully bit mirrored (reversed). The bit-reversed value is used for comparison with the CRC_RESULT_FIN register.	
		0	Disable compare mirroring
		1	Enable compare mirroring
21 (R/W)	POLYMIRR	Polynomial Register Mirroring. The CRC_CTL.POLYMIRR bit enables data mirroring for the CRC_POLY polynomial register. When enabled, the 32-bit value in this register is fully bit mirrored (reversed). The bit-reversed value is used for CRC computations.	
		0	Disable polynomial mirroring
		1	Enable polynomial mirroring

Table 40-6: CRC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	RSLTMIRR	Result Register Mirroring. The `CRC_CTL.RSLTMIRR` bit enables data mirroring for the `CRC_RESULT_CUR` and `CRC_RESULT_FIN` result registers. When enabled, the 32-bit values in these registers are fully bit mirrored (reversed).	
		0	Disable result mirroring
		1	Enable result mirroring
19 (R/W)	FDSEL	FIFO Data Select. The `CRC_CTL.FDSEL` bit selects whether the CRC writes modified or unmodified data to the FIFO in memory transfer mode. If enabled, the data written is affected by the state of the data mirroring selections (`CRC_CTL.BITMIRR`, `CRC_CTL.BYTMIRR`, and `CRC_CTL.W16SWP`) before being written to the FIFO.	
		0	Write unmodified data to FIFO
		1	Write modified data to FIFO
18 (R/W)	W16SWP	Word16 Swapping. The `CRC_CTL.W16SWP` bit enables the CRC's data mirror block to swap the upper and lower 16-bit words within the 32-bit input data, before further processing.	
		0	Disable word16 swapping
		1	Enable word16 swapping
17 (R/W)	BYTMIRR	Byte Mirroring. The `CRC_CTL.BYTMIRR` bit enables the CRC's data mirror block to mirror the bytes within the 32-bit input data, before further processing.	
		0	Disable byte mirroring
		1	Enable byte mirroring
16 (R/W)	BITMIRR	Bit Mirroring. The `CRC_CTL.BITMIRR` bit enables the CRC's data mirror block to mirror the bits within each byte of the 32-bit input data, before further processing.	
		0	Disable bit mirroring
		1	Enable bit mirroring
13 (R/W)	IRRSTALL	Intermediate Result Ready Stall. The `CRC_CTL.IRRSTALL` bit enables stalling the state machine for input data when there is a valid intermediate result to be read in the `CRC_RESULT_CUR` register. This feature should be used only in CRC computation modes (for example, `CRC_CTL.OPMODE` =1 or =3).	
		0	Do not stall
		1	Stall on IRR

Table 40-6: CRC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	OBRSTALL	Output Buffer Ready Stall. The `CRC_CTL.OBRSTALL` bit enables stalling the state machine for input data when there is valid data in the output buffer. This feature should be used only in memory-to-memory transfer modes (for example, `CRC_CTL.OPMODE` =1).	
		0	Do not stall
		1	Stall on OBR
9 (R/W)	AUTOCLRF	Auto Clear to One. The `CRC_CTL.AUTOCLRF` bit enables auto clear to one when the CRC is in intermediate results ready stall mode (`CRC_CTL.IRRSTALL`=1) and the CRC data count expires (`CRC_DCNT`=0). Note that the `CRC_CTL.AUTOCLRZ` bit must be disabled, or the `CRC_CTL.AUTOCLRF` bit has no effect.	
		0	No auto clear
		1	Auto clear
8 (R/W)	AUTOCLRZ	Auto Clear to Zero. The `CRC_CTL.AUTOCLRZ` bit enables auto clear to zero when the CRC is in intermediate results ready stall mode (`CRC_CTL.IRRSTALL`=1) and the CRC data count expires (`CRC_DCNT`=0). Note that `CRC_CTL.AUTOCLRF` must be disabled, or the `CRC_CTL.AUTOCLRZ` has no effect.	
		0	No auto clear
		1	Auto clear
7:4 (R/W)	OPMODE	Operation Mode. The `CRC_CTL.OPMODE` bit field selects the memory transfer or scan mode.	
		0	Reserved
		1	CRC compute/compare memory transfer
		2	Data fill memory transfer
		3	CRC compute/compare memory scan
		4	Data verify memory scan
0 (R/W)	BLKEN	Block Enable. The `CRC_CTL.BLKEN` bit enables and disables the CRC operation.	
		0	Disable
		1	Enable

Data Word Count Register

The `CRC_DCNT` register holds the word count that is used for the CRC operation. On transfer of every 32-bit word, the CRC decrements by 1 the content of this register. When the count decrements to zero, this event triggers a CRC compare action, and the `CRC_DCNT` register is automatically loaded from the `CRC_DCNTRLD` register for the next CRC operation.

Note that the initial value programmed into the `CRC_DCNT` register may be different from what is programmed in the `CRC_DCNTRLD` register.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Data Word Count. The `CRC_DCNT.VALUE` bit field holds the word count that is used for the CRC operation.

Data Count Capture Register

The `CRC_DCNTCAP` register captures the `CRC_DCNT` value when a compare operation fails in data verify mode. This capture can be used to track the position of an error in the data stream. The capture operation is enabled only if the `CRC_STAT.CMPERR` bit indicates no compare error. After an error occurs and the data count is captured, no further errors are logged until the `CRC_STAT.CMPERR` bit is cleared. To obtain the position of an error in the data stream, subtract the `CRC_DCNTCAP` register value from the initial `CRC_DCNT`.

31:0 (R/W)	VALUE	Data Count Capture Value. The `CRC_DCNTCAP.VALUE` bit field contains the `CRC_DCNT` value when a compare operation fails in data verify mode.

Data Word Count Reload Register

The CRC_DCNTRLD register holds the value that the CRC automatically loads into CRC_DCNT when the CRC_DCNT decrements to 0. At startup, the value programmed in CRC_DCNT and the CRC_DCNTRLD register could be different. So, for the first iteration, the CRC operation happens for the count initially programmed in the CRC_DCNT register. While for subsequent CRC operations, the count is taken from the CRC_DCNTRLD register.

31:0 (R/W)	VALUE	Reload Value. The CRC_DCNTRLD.VALUE bit field holds the value that automatically loads into CRC_DCNT when the CRC_DCNT decrements to 0.

Data FIFO Register

In memory transfer mode (non-data fill mode), the data from the DMA or processor core buses is written into the `CRC_DFIFO` on each input data grant (DMA grant or core write). Data is read from this FIFO on each output data grant (DMA grant or core read). FIFO status information is available in the `CRC_STAT` register. Whenever, the FIFO has valid data, output data requests are generated.

Note that in non-memory transfer mode and in data fill mode, the input data does not get written into this FIFO. So, this register should not be read in these modes.

Interrupt Enable Register

The `CRC_INEN` register unmasks (enables) or masks (disables) interrupt requests generated in the CRC from going to the processor core.

Note that CRC interrupts are not disabled when the CRC is disabled (`CRC_CTL.BLKEN` =0).

		0	No effect
		1	Set bit

Polynomial Register

The `CRC_POLY` register holds a 32-bit polynomial for CRC operations. Bit 31 corresponds to the coefficient of x31 of the CRC polynomial, bit 30 corresponds to the coefficient of x30, and so on through bit 0. A coefficient of x32 is assumed to be "1" for any polynomial that is selected. Based on the polynomial in the `CRC_POLY` register, the CRC generates a look-up table (LUT), which is used to compute the CRC of the incoming data stream.

Table 40-15: CRC_POLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	CRC Polynomial Value. The `CRC_POLY.VALUE` bit field holds the 32-bit polynomial for CRC operations.

CRC Current Result Register

The `CRC_RESULT_CUR` register holds the current or intermediate CRC result. It is updated when new data is written into the CRC. Each time the `CRC_DCNT` expires, the CRC loads the value from this register into the `CRC_RESULT_FIN` register. The `CRC_RESULT_CUR` register may be set to auto clear to zero or auto clear to ones when `CRC_DCNT` expires by configuring the `CRC_CTL.AUTOCLRZ` and `CRC_CTL.AUTOCLRF` bits. Before starting a CRC operation, the `CRC_RESULT_CUR` register should be programmed to the desired value.

Note that this register can be read by the processor core at any time.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Intermediate CRC Result. The `CRC_RESULT_CUR.VALUE` bit field holds the current or intermediate CRC result.

CRC Final Result Register

The `CRC_RESULT_FIN` register holds the final CRC computed for a data stream. A data stream is a DMA of `CRC_DCNT` number of words into the CRC. When `CRC_DCNT` decrements to zero for each data stream, the CRC loads the `CRC_RESULT_FIN` register with the value from the `CRC_RESULT_CUR` register.

Figure 40-16: CRC_STAT Register Diagram

Table 40-18: CRC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22:20 (R/NW)	FSTAT	FIFO Status. The CRC_STAT.FSTAT indicates the current FIFO status. This field is read-only.	
		0	FIFO empty
		1	FIFO has 1 data
		2	FIFO has 2 data
		3	FIFO has 3 data
		4	FIFO has 4 data (full)
19 (R/NW)	LUTDONE	Look-Up Table Done. The CRC_STAT.LUTDONE bit indicates that the CRC has generated the look-up table for the current polynomial. This read-only bit is cleared at reset and cleared when the CRC_POLY is written.	
		0	No status
		1	LUT generation done

Table 40-18: CRC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/NW)	IRR	Intermediate Result Ready. The `CRC_STAT.IRR` bit indicates that the CRC has updated the `CRC_RESULT_CUR` register with intermediate CRC results for the new data written to the CRC. The processor core should read from the `CRC_RESULT_CUR` register only after detecting `CRC_STAT.IRR` =1. This read-only bit is cleared by CRC hardware and is valid when the `CRC_CTL.IRRSTALL` bit is enabled.	
		0	No status
		1	Intermediate results ready
17 (R/NW)	OBR	Output Buffer Ready. The `CRC_STAT.OBR` bit indicates that the CRC has data ready for the processor core to read. The processor core should read from the CRC only after detecting `CRC_STAT.OBR` =1. This read-only bit is cleared by CRC hardware.	
		0	No status
		1	Output buffer ready
16 (R/NW)	IBR	Input Buffer Ready. The `CRC_STAT.IBR` bit indicates that the CRC is ready to accept a processor core write. The processor core should write to the input register only after detecting that `CRC_STAT.IBR` =1. This read-only bit is cleared by CRC hardware.	
		0	No status
		1	Input buffer ready
4 (R/W1C)	DCNTEXP	Data Count Expired. The `CRC_STAT.DCNTEXP` bit indicates that the `CRC_DCNT` has expired. This W1C bit is not automatically cleared when the CRC is disabled (`CRC_CTL.BLKEN` =0). When the CRC sets this bit on `CRC_DCNT` expiry, the CRC generates the `CRC_INEN.DCNTEXP` interrupt.	
		0	No status
		1	Data counter expired
1 (R/W1C)	CMPERR	Compare Error. The `CRC_STAT.CMPERR` bit indicates that a CRC mismatch or data mismatch has been detected. This W1C bit is not automatically cleared when the CRC is disabled (`CRC_CTL.BLKEN` =0). When the CRC sets this bit on detecting a mismatch, the CRC generates the `CRC_INEN.CMPERR` interrupt. While this bit is set, the `CRC_DCNTCAP` register is disabled from capturing the data count values.	
		0	No status
		1	Compare error

41 Housekeeping ADC (HADC)

The Housekeeping ADC is a 12-bit (with 10-bit accuracy), successive approximation ADC. It operates from single supply and features throughput rates up to 1 MSPS. The HADC can be used for the collection of housekeeping parameters like voltages, temperatures in the system or for any general-purpose use as well.

HADC Features

The HADC supports following features:

- 12-bit ADC core with built-in sample and hold
- ENOB = 10 bit
- 8 input channels which can be extended to 15 channels by putting an external channel multiplexer
- Throughput rates up to 1MSPS
- Single ended operation
- External reference 2.5 V to 3.3 V
- Analog input 0 V to 3.3 V.
- Selectable ADC clock frequency through a pre-scaler
- Conversion type adaptable to each application: allows single or continuous conversion with option of auto-scan
- 16 data registers (individually addressable) to store conversion values
- Auto sequencing capability provides up to 15 *auto-conversions* in a single session. Each conversion can be programmed to select any of the available input channels.

HADC Functional Description

The HADC provides the analog to digital conversion capability for general-purpose housekeeping tasks, such as voltage and temperature monitoring. The core of HADC is a 12-bit SAR ADC, providing multiple analog input channels.

The HADC has the following functionality:

Fixed and continuous conversion modes

ADC converts the input channel sequence for a fixed number of times or continuously converts an input channel sequence.

Auto scanning

All the input channels can be sampled in a sequential manner.

Channel sequence programming

The sequence of a channel can be selected by programming the channel mask register. If the bit corresponding to the channel is programmed to zero, that channel is included in the auto-scan chain.

ADSP-SC58x HADC Register List

The Housekeeping ADC (HADC) provides a general purpose, multi-channel successive approximation A-to-D converter. A set of registers governs HADC operations. For more information on HADC functionality, see the HADC register descriptions.

Table 41-1: ADSP-SC58x HADC Register List

Name	Description
`HADC_CHAN_MSK`	Channel Mask Register
`HADC_CTL`	Control Register

None			

HADC Definitions

The following definitions are helpful when using the HADC module.

Auto-scan

Auto-scan is a feature which allows the multiple channels to be scanned and converted in sequence one after the other.

HADC Wakeup Time

It is the time required by the module after coming out of power down before it can start converting.

Signal-to-Noise and Distortion Ratio (SINAD)

The measured ratio of signal-to-noise and distortion at the output of the ADC. The signal is the rms amplitude of the fundamental. Noise is the sum of all non-fundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio depends on the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal-to-noise and distortion ratio for an ideal N-bit converter with a sine wave input is given by:

Signal-to-(Noise + Distortion) = (6.02 N + 1.76) dB

Total Harmonic Distortion (THD)

The ratio of the rms sum to the harmonics to the fundamental.

Peak Harmonic or Spurious Noise

The ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Typically, the value of this specification is determined by the largest harmonic in the spectrum, but for ADCs where the harmonics are buried in the noise floor, it is a noise peak.

Integral Nonlinearity

The maximum deviation from a straight line passing through the endpoints of the ADC transfer function. The endpoints are zero scale, a point 1 LSB below the first code transition, and full scale, a point 1 LSB above the last code transition.

Differential Nonlinearity

The difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Offset Error

The deviation of the first code transition (00...000) to (00...001) from the ideal—that is, GND1 + 1 LSB.

Offset Error Match

The difference in offset error between any two channels.

Gain Error

The deviation of the last code transition (111...110) to (111...111) from the ideal (that is, REFIN – 1 LSB) after the offset error has been adjusted out.

Gain Error Matching

The difference in gain error between any two channels.

Power Supply Rejection Ratio (PSRR)

PSRR is defined as the ratio of the power in the ADC output at full-scale frequency, f, to the power of a 100 mV p-p sine wave applied to the ADC VDD supply of frequency, f_S. The frequency of the input varies from 5 kHz to 25 MHz. PSRR (dB) = 10 log(Pf/Pf_S) where: Pf is the power at frequency, f, in the ADC output. Pf_S is the power at frequency, f_S, in the ADC output.

HADC Block Diagram

The ***HADC Block Diagram*** figure shows the functional blocks within the HADC and the interface to the processor core and the peripherals. The HADC has an internal 8 channel multiplexer that is controlled by a programmable sequencer which selects the desired channel or sequence of channels. The eight channels of the internal multiplexer can be expanded by providing an external multiplexer, increasing the total number of channels to 15.

HADC Architectural Concepts

The HADC is based on a 12-bit SAR ADC that provides a simple register-based access model to obtain the results of conversion. The digital front end of the HADC provides a set of registers to configure the mode of operation, sampling frequency, and input channel selection control. The ADC supports multiple input analog channels which can be individually selected or deselected for conversion. The results of each analog channel are stored in a register. The core can access the register to read the conversion results once the conversion is complete. The HADC also provides the interrupts on completion of each channel conversion to avoid polling by the core. The following sections provide more details about the architecture of the HADC.

Converter Operation

The housekeeping ADC is a 12-bit successive approximation ADC based around a capacitive DAC. The ***ADC Acquisition Phase*** figure and the ***ADC Conversion Phase*** figure show simplified schematics of the ADC. The ADC is comprised of control logic, SAR, and a capacitive DAC. The components are used to add and subtract fixed amounts of charge from the sampling capacitor to bring the comparator back into a balanced condition. The ***ADC Conversion Phase*** figure shows the ADC during its acquisition phase. SW2 is closed and SW1 is in Position A. The comparator is held in a balanced condition and the sampling capacitor acquires the signal on the selected V_{IN} channel.

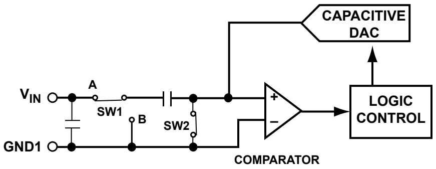

Figure 41-2: ADC Acquisition Phase

When the ADC starts a conversion (see the ***ADC Conversion Phase*** figure), SW2 opens and SW1 moves to Position B, causing the comparator to become unbalanced. The control logic and the capacitive DAC are used to add and subtract fixed amounts of charge to bring the comparator back into a balanced condition. When the comparator is rebalanced, the conversion is complete. The control logic generates the ADC output code.

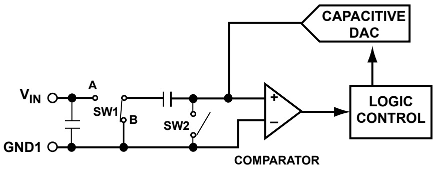

Figure 41-3: ADC Conversion Phase

Auto-Scan

The HADC features auto-scan mode where all the input channels can be sampled in a sequential manner. The number of channels enabled in auto-scan mode can be selected by programming the `HADC_CHAN_MSK` register. If the bit corresponding to the channel is set high, that particular channel is masked, and is not included in the auto-scan chain. In this way programs can sample all, none, or a selected set of channels by writing a high or a low for the individual channel. Auto sequencing allows the system to convert the same channel multiple times, allowing programs to perform oversampling algorithms.

For example, if the `HADC_CHAN_MSK` register bits [3:0] are set to 1101, then channel 0, channel 2 and channel 3 are not included in the auto-scan chain. Whether the conversion is a single or fixed number or continuous depends on the status of `HADC_CTL.CONT` bit. If this bit is low, the `HADC_CTL.FIXEDCNV` bits determine the number of sequence conversions.

The maximum number of fixed sequence conversions is 15. By default, the first eight channels of the HADC are enabled and extended channels are masked. An extended channel is the increased number of channels when a single channel of ADC is externally multiplexed, effectively increasing the total number of available channels. The total number of channels supported is 15. The program must configure the `HADC_CHAN_MSK` register to enable any desired channel.

Channel Sequence Programming

The sequence of a channel can be selected by programming the `HADC_CHAN_MSK` register. If the bit corresponding to the channel is programmed to zero, that channel is included in the auto-scan chain. If the program must get the conversion results from a particular channel, then the bit corresponding to that channel should be zero. Channels 8-15 are virtual channels, in that they can connect an external multiplexer and increase the effective number of channels. As the output of the external multiplexer is routed to channel 7, this channel is not available (or converted) separately when the virtual channels are not masked in the `HADC_CHAN_MSK` register. The auto-scan section has more details.

ADC Transfer Function

The output coding is straight binary for the analog input channel conversion. The designed code transitions occur at successive LSB values (that is, 1 LSB, 2 LSBs, and so forth). The LSB size is $V_{REF}/4096$ for the HADC. The *ADC Transfer Function* figure shows the ideal transfer characteristic for straight binary coding.

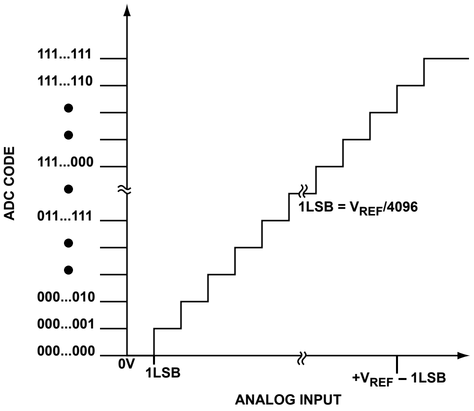

Figure 41-4: ADC Transfer Function

Results

The HADC takes 20 cycles of f_{SAMPLE} for one channel conversion. (The value of the `HADC_CTL.FDIV` bit field determines f_{SAMPLE}). The time taken to complete one sequence depends on the number of channels in the auto-scan chain. There is a latency of 1 cycle from the time the channel is selected internally to sample to the time the data is ready. After the end of each channel conversion, the data is written into the corresponding data register. An interrupt is generated (if the interrupt mask is not enabled) to signal that the data is ready for that particular channel.

HADC Operating Modes

The HADC has two modes of operation described in the following sections.

Fixed Conversion Mode

In this mode, the ADC converts the input channel sequence for a fixed number of times. The frequency is configured in the `HADC_CTL.FIXEDCNV` bit field. To use this mode, clear the `HADC_CTL.CONT` bit.

Continuous Conversion Mode

In this mode ADC continuously converts an input channel sequence, as long as `HADC_CTL.STARTCNV` bit is held high. To use this mode, set the `HADC_CTL.CONT` bit.

HADC Event Control

The HADC generates different events depending on the state of the ADC and the status of channel conversions. It can generate an event for each of the following conditions:

- When ADC is ready for conversion
- At the end of sequence conversion
- At the end of each individual channel conversion

Each of these events can generate an interrupt. To generate an interrupt on any desired event, clear the respective bit in the `HADC_IMSK` register.

HADC Programming Model

Following sections provide some guidelines for HADC programming.

Powering Up the HADC

To power-up the HADC, program the following bits in the `HADC_CTL` register.

- Deassert the `HADC_CTL.PD` bit (HADC power down)
- Set the `HADC_CTL.NRST` bit (Reset)
- Set the `HADC_CTL.ENLS` bit (Enable level shifters)

After deasserting `HADC_CTL.PD`, the HADC requires a finite wake-up time (t_{WAKEUP}) before it can start converting. The HADC requires only two f_{SAMPLE} clocks from the assertion of the `HADC_CTL.NRST` bit before the module is ready to convert. (`HADC_CTL.PD` is low). Poll the `HADC_STAT.RDY` bit. A 1 on this bit indicates that the HADC is ready to convert data.

Enabling the HADC

Setting the `HADC_CTL.STARTCNV` bit enables the HADC. When this bit is kept high, the HADC can work in either continuous or fixed conversion mode. After the `HADC_CTL.STARTCNV` bit is set =1, the `HADC_CHAN_MSK` can still be re-programmed, but the new sequence only comes into effect after the current sequence conversion is complete.

ADSP-SC58x HADC Register Descriptions

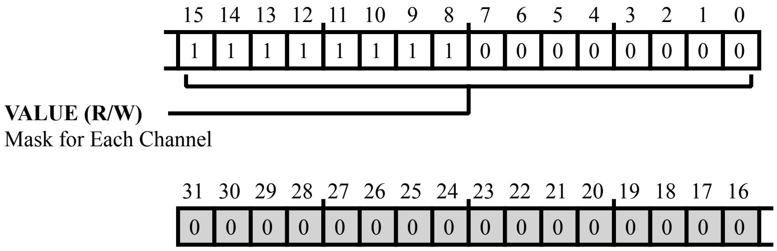
Housekeeping ADC (HADC) contains the following registers.

Table 41-6: ADSP-SC58x HADC Register List

Name	Description
`HADC_CHAN_MSK`	Channel Mask Register
`HADC_CTL`	Control Register
`HADC_DATA[nn]`	Channel Data Registers
`HADC_IMSK`	Interrupt Mask Register
`HADC_STAT`	Status Register

Channel Mask Register

The `HADC_CHAN_MSK` register provides bits that mask each channel. The first MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the mask is set for a particular channel, that channel is not converted. By default, channels 0-7 are not masked and the extended channels 8-15 are masked.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

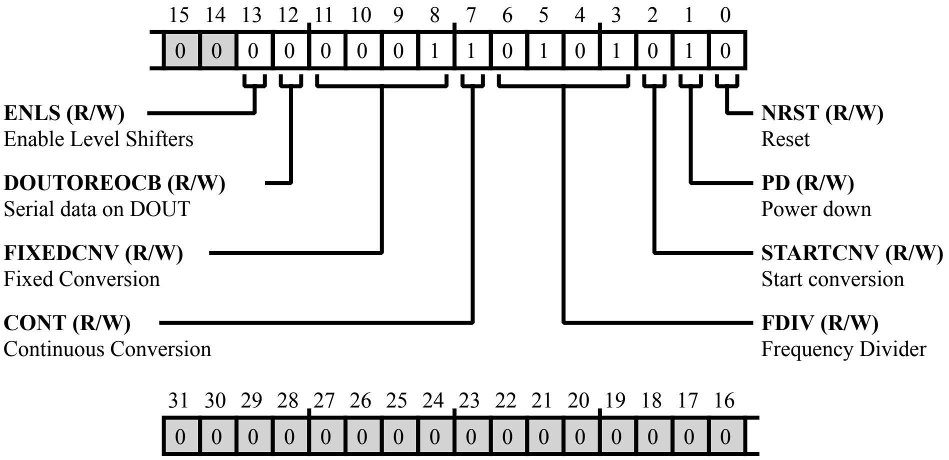
Table 41-7: HADC_CHAN_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Mask for Each Channel. The `HADC_CHAN_MSK.VALUE` bit field is the mask bit for each channel. The first MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the mask is set for a particular channel, that channel is not converted. By default, channels 0-7 are not masked and the extended channels 8-15 are masked.

Control Register

The HADC_CTL register contains control bits that configure various module settings start or reset the module.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 1 1 0 1 0 1 0 1 0

Continuous Conversion
NRST (R/W)
Reset
PD (R/W)
Power down
STARTCNV (R/W)
Start conversion
FDIV (R/W)
Frequency Divider
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 41-6: HADC_CTL Register Diagram

Table 41-8: HADC_CTL Register Fields

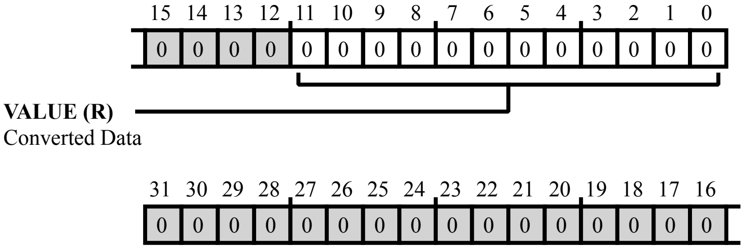
Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	ENLS	Enable Level Shifters. Setting the `HADC_CTL.ENLS` bit enables the level shifters, allowing the HADC analog side (which works in the VDD_EXT domain) to work with the digital core and interface is (in the VDD_INT domain).	
		0	Disable down level shifters
		1	Enable down level shifters
12 (R/W)	DOUTOREOCB	Serial data on DOUT. If the `HADC_CTL.DOUTOREOCB` bit =1, serial data arrives on the EOC_DOUT pin. If this bit =0 (default) it acts as an EOC only if the external multiplexer is connected.	
		0	Reserved
		1	Reserved
11:8 (R/W)	FIXEDCNV	Fixed Conversion. The `HADC_CTL.FIXEDCNV` bit configures the number of conversions = FIXEDCNV. This value determines how many times a sequence is converted when the HADC is in fixed conversion mode. This only applies when the `HADC_CTL.CONT` bit =0. Before changing the `HADC_CTL.FIXEDCNV` bit, clear the `HADC_CTL.NRST` bit (=0).	

Table 41-8: HADC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CONT	Continuous Conversion. When the `HADC_CTL.CONT` bit =0, the ADC converts a sequence for a fixed number of times. This number is configured using the `HADC_CTL.FIXEDCNV` bit field. When the `HADC_CTL.CONT` bit =1, the ADC continuously converts a given sequence, provided the `HADC_CTL.STARTCNV` is held high.	
		0	ADC converts sequence for fixed number of times
		1	ADC continuously converts given sequence
6:3 (R/W)	FDIV	Frequency Divider. The `HADC_CTL.FDIV` bit field configures f_{SAMPLE}=f_{CLK}=/(FDIV+1). Select f_{CLK} and `HADC_CTL.FDIV` values so that f_{SAMPLE} is in the range of 50 kHz to 22.5 MHz. The minimum value for `HADC_CTL.FDIV` is 1. Before changing the `HADC_CTL.FDIV` bits, clear the `HADC_CTL.NRST` bit.	
2 (R/W)	STARTCNV	Start conversion. The `HADC_CTL.STARTCNV` bit needs to be set for the ADC to start converting data. If the ADC is running in non continuous mode, it is reset by hardware after the desired number of conversions is completed.	
		0	No action
		1	Start converting
1 (R/W)	PD	Power down. The `HADC_CTL.PD` bit powers down the analog circuitry of the ADC. After this bit returns to 0 a finite power-up time is required before the ADC can start converting data.	
		0	No action
		1	Power down the analog circuitry of the ADC
0 (R/W)	NRST	Reset. The `HADC_CTL.NRST` bit resets the ADC.	
		0	Reset the ADC
		1	No action

Channel Data Registers

The `HADC_DATA[nn]` registers N ranges from 0-15. Each corresponding to an ADC channel. ADC_DATA_0 corresponds to channel 0, ADC_DATA_1 to channel 1 and so on.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R)
Converted Data
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

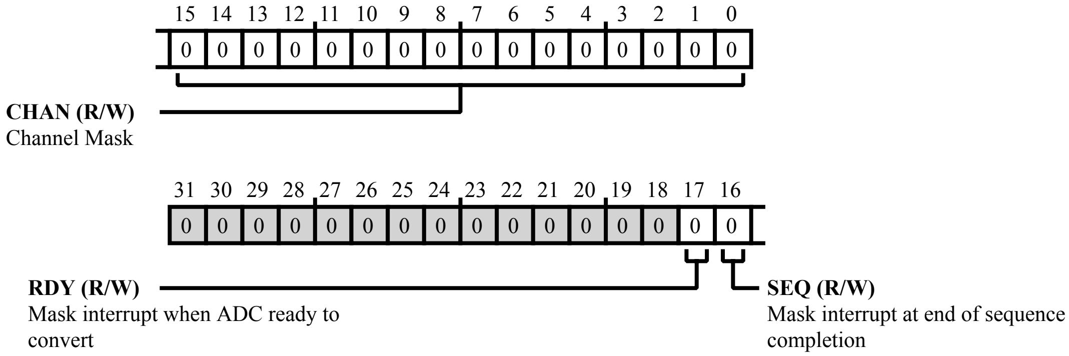
Figure 41-7: HADC_DATA[nn] Register Diagram

Table 41-9: HADC_DATA[nn] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/NW)	VALUE	Converted Data. The `HADC_DATA[nn].VALUE` bit field contains the digital code for the sampled analog value. Each channel has its own data register.

Interrupt Mask Register

The HADC_IMSK register masks (disables) or unmasks (enables) the interrupts as programmed. The reset value of the HADC_IMSK register is 0x08, masking these interrupts after reset.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CHAN (R/W)
Channel Mask
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RDY (R/W)
Mask interrupt when ADC ready to convert
SEQ (R/W)
Mask interrupt at end of sequence completion

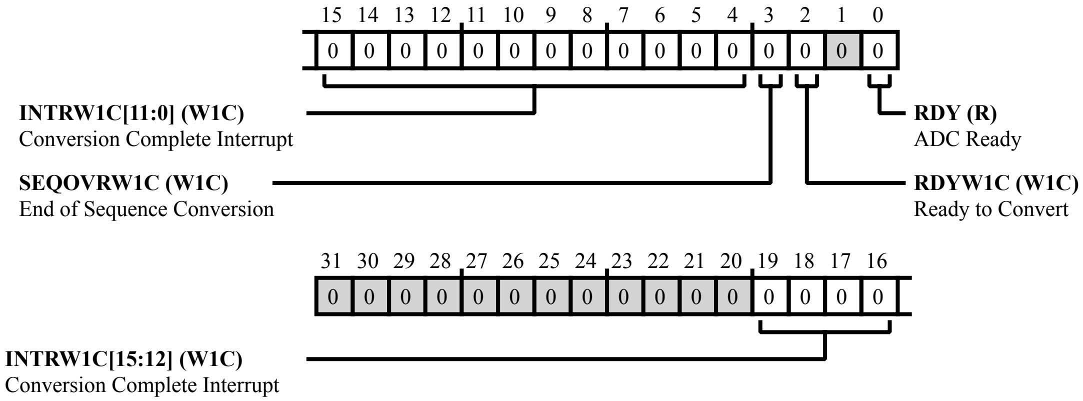
Figure 41-8: HADC_IMSK Register Diagram

Table 41-10: HADC_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RDY	Mask interrupt when ADC ready to convert. The HADC_IMSK.RDY bit masks the interrupt generated when ADC is ready to convert.	
16 (R/W)	SEQ	Mask interrupt at end of sequence completion. The HADC_IMSK.SEQ bit masks the interrupt which is generated at the end of sequence completion.	
		0	Interrupt is unmasked
		1	Interrupt is masked
15:0 (R/W)	CHAN	Channel Mask. The HADC_IMSK.CHAN bit field provides the interrupt mask bit for each channel. N ranges from 0-15. The MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the interrupt mask for a particular channel is high, no interrupt is generated when that channel finishes the end of data conversion.	

Status Register

The `HADC_STAT` register contains bits that provide status information on the HADC module.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
INTRW1C[11:0] (W1C)
Conversion Complete Interrupt
SEQOVRW1C (W1C)
End of Sequence Conversion
RDY (R)
ADC Ready
RDYW1C (W1C)
Ready to Convert
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
INTRW1C[15:12] (W1C)
Conversion Complete Interrupt

Figure 41-9: HADC_STAT Register Diagram

Table 41-11: HADC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:4 (RX/W1C)	INTRW1C	Conversion Complete Interrupt. The `HADC_STAT.INTRW1C` bit field indicates when the corresponding ADC channel completes conversion. N ranges from 0-15 and the MSB corresponds to channel 15, the second MSB to channel 14 and so on. These bits are sticky and are W1C.
3 (RX/W1C)	SEQOVRW1C	End of Sequence Conversion. The `HADC_STAT.SEQOVRW1C` bit indicates the end of a sequence conversion and is a sticky status bit which is W1C.
2 (RX/W1C)	RDYW1C	Ready to Convert. The `HADC_STAT.RDYW1C` bit is the stick version of the `HADC_STAT.RDY` bit.
0 (R/NW)	RDY	ADC Ready. The `HADC_STAT.RDY` bit is set (=1) when the ADC is ready to convert data.

42 System Security

The requirement to protect content, keys, IP and other sensitive information have become increasingly prevalent. The processor contains several modules and system elements that contribute to creating a secure operating environment for trusted code to execute. The modules and system elements that can be used are:

- Boot Kernel
- Secure Core
- System Protection Unit (SPU)
- System Memory Protection Unit (SMPU)
- DEBUG through the Test Access Port Controller (TAPC)
- One-Time Programmable (OTP) memory
- Cryptographic Accelerators (optionally)

NOTE: This product includes security features that can be used to protect embedded non-volatile memory contents and prevent execution of non-authorized code. When security is enabled on this device (either by the ordering party or the subsequent receiving parties), Analog Devices' ability to conduct Failure Analysis on returned devices will be limited. Please contact Analog Devices, Inc. for details on the Failure Analysis limitations for this device.

Security Features

The security infrastructure items in the system provide the following features:

- Secure operating environment for secure code execution
- Protect sensitive IP from theft by malicious users or competitors
- Protect sensitive data (for example cipher keys)
- Allow debugging while still maintaining security

Security Functional Description

In order to provide secure operating environment in a system, it requires the involvement of multiple elements.

Boot Kernel

The Boot Kernel is the root of trust for a secure system. Since the boot kernel is developed by Analog Devices, Inc and is stored in ROM and can't be changed, it can be trusted. The boot kernel validates the authenticity of the application binary image that needs to be booted in. It also handles decrypting the binary image if it's encrypted.

Verifying the authenticity of the application binary asserts that

1. The image hasn't been tampered with or altered
2. The image came from a trusted developer

If the image is encrypted, it ensures confidentiality since the boot image is stored on an external storage device and can be more easily read or stolen than in the part.

Once the boot kernel can verify and optionally decrypt the boot image, it can be loaded into the processor for execution. At this point, the *chain of trust* is continued with the verified application.

Secure Booting

Secure booting is when the boot kernel uses cryptographic algorithms to perform checks on the application binary and to decrypt it. Secure booting is done when security is enabled. If security is not enabled the boot kernel does not verify any signatures nor does it perform any decryption on the application binary. See Security Mode Configuration.

Secure Core

In a system with multiple master and slave resources, not everything is considered secure. There are secure and non-secure peripherals and secure and non-secure segments of memory.

For a system to be considerd secure, a secure core that can access and execute instructions (verified application) from secure memory must be configured. Typically, in a single core processor, either the core is hardwired to be secure or the core can switch between secure and non-secure modes.

System Protection Unit (SPU)

The SPU in the system serves two functions. First, it acts as a gatekeeper, guarding against non-secure accesses to secure resources (peripherals). Second, it is used to define which resources in the system are secure or non-secure masters and which resources in the system are secure or non-secure slaves.

NOTE: Even thought the SPU can be configured by secure or non-secure master, the first steps that the verified secure application should perform are:

1. Configure the SPU as a secure slave itself so only other secure masters can configure it

2. Define and configure the secure masters and slaves using the SPU

This way, once the SPU is secure and other secure masters and slaves are configured, non-secure masters cannot tamper with the security privileges of secure masters and slaves nor can non-secure resources be changed to a secure resource.

System Memory Protection Unit (SMPU)

Similar to the SPU protecting the MMR address range for peripherals, the SMPU can guard memory ranges or pages. Memory pages can be configured as secure or non-secure. Again, like in the case of the SPU, the SMPU can guard against non-secure transaction attempts to secure memory.

NOTE: A verified application should reside in memory configured as secure. By default the SMPU has all memory configured as secure. If the program needs to update the memory protections via the SMPU, the application and it's data should remain in secure memory.

Debug

The typical way of accessing a system is through the debug port via a JTAG or serial wire interface. If these access points are not secure sensitive IP such as cipher keys can be exposed and code can be changed to disable other security settings. To guard against this type of attack or security hole and still provide debugging capabilities for a developer, a debug unit with security features is used.

When the developer first receives the part, they can define a JTAG/DEBUG key that is programmed into OTP memory. Once security is enabled, the debug unit compares the key sent from the host debugger with the key inside the system. If a match occurs, debug access to secure resources are allowed.

One-Time-Programmable (OTP) Memory

Customer programmable OTP memory is used to safely and securely store sensitive information such as cipher keys.

In a public key algorithm (for example ECDSA which is used in secure boot), the public key is used to verify the digital signature that accompanies the application binary. The private key is used by the developer on the host development machine to create the digital signature. The public and private key pair is unique and the public key needs to be stored in non-volatile, one-time-programmable memory. If the public key is allowed to be changed than users can generate their own public/private key pairs and successfully boot in malicious code. This can either re-purpose the part or change security configurations to allow easier access to sensitive information stored elsewhere in OTP memory.

When security is not enabled, OTP can be accessed freely. When a user decides to set the LOCK bit in OTP memory to enable security, portions of the OTP, specifically the first 6K bits and another 1K bits for the customer boot information are will also be locked. From then on, only secure masters will be allowed to access those memory regions.

Cryptographic Accelerators

Cryptographic algorithms are mathematical tools to help provide security. Hardware engines provide some advantages but are not necessarily required. For computationally expensive operations like those used in Elliptic Curve Cryptography, like ECDSA used in secure boot, the operations can be accelerated while the core performs other tasks. Also, it's less likely that the hardware engine can be hacked to change the results.

Security Mode Configuration

Because the processor is unsecure by default, if security is not required then no steps need to be done.

To enable security features, use the following procedure.

- Generate the public/private key pair on the host development machine.[1]
- Program OTP memory with the public key.[2]
- Program OTP memory with the decryption key if the application binary needs to be encrypted.[2]
- Program OTP memory with the debug/JTAG key.[2]
- Develop the application and sign it, creating the digital signature with the private key.[1]
- If confidentiality is required, encrypt the application binary before signing it.
- Set the LOCK bit in OTP memory to enable security. After this, subsequent boots are secure boots.[2, 3]

[1] Software tools are provided with developments tools to generate keys, sign boot streams and also perform encryption. Refer to the development tools manuals for information on usage.

[2] Refer to the OTP Chapter for programming the OTP and other related information.

[3] Refer to the Booting Chapter for more information on Secure Booting and other related information.

Status and Error Signals

In a fully functional secure system, non-secure resources should not even attempt to access a secure resource. If this does occur, then either the code has been altered or replaced with malicious code or the system contains a bug.

Errors or error events are dependant on the configuration of the SPU and SMPU, the protection units which guard against security violations. In the case of the SMPU, the error can simply be captured, captured and interrupt generated, or the access prevented without capturing any error. It is the developer's responsibility to:

1. Determine if there was an error due to a blocked access.
2. Determine how to handle a blocked access (for example fix the bug (offline), or try to use a different resource (run time)).

43 System Protection Unit (SPU)

In a system with multiple system MMR masters, configurations of peripherals can be changed unintentionally leading to bad data or even system malfunctions. The peripherals are shared resources in the system. The SPU restricts access to certain MMRs, similar to the functionality of a semaphore.

The SPU also protects peripherals based on security settings. It is part of the overall security infrastructure of the processor.

SPU Features

The SPU has the following features:

- Write-protect system MMR from certain system masters and core masters.
- Simultaneously lock multiple peripheral configuration registers through a global lock mechanism.
- Write-protect and block access to its own write-protection registers from other system masters.
- Defined security privileges to peripherals and system resources.
- Security protection to guard secure peripheral MMRs against non-secure accesses.

SPU Functional Description

The following sections provide information on the function of the SPU.

ADSP-SC58x SPU Register List

The System Protection Unit (SPU) provides a set of registers that can protect system resources from errant writes. The protection categories are global lock (protects configuration registers) and write protect register lock (protects the write protect register). For more information on SPU functionality, see the SPU register descriptions.

Table 43-1: ADSP-SC58x SPU Register List

Name	Description
SPU_CTL	Control Register
SPU_SECURECHK	Secure Check Register

Table 43-1: ADSP-SC58x SPU Register List (Continued)

Name	Description
`SPU_SECURECTL`	Secure Control Register
`SPU_SECUREC[n]`	Secure Core Registers
`SPU_SECUREP[n]`	Secure Peripheral Register
`SPU_STAT`	Status Register
`SPU_WP[n]`	Write Protect Register n

ADSP-SC58x SPU Interrupt List

Table 43-2: ADSP-SC58x SPU Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
241	SPU0_INT	SPU0 Interrupt	Level	

Peripheral Register Write Protection

The SPU has a write-protection register (`SPU_WP[n]`) associated with each peripheral. Each of these write-protection registers has the exact same bits that correspond to a particular SMMR master (Core 0, Core 1, MDMA, for example). When the bits are set, the SPU locks the corresponding SMMR masters from accessing the register address space of the associated peripheral. The bits in the register can be cleared to allow access to the registers of the peripheral again. When the SPU intiates the write-protection register, any writes that are in-progress complete before the SPU blocks subsequent writes.

In the ***SPU Write Protect Registers*** figure, each write-protect register in the SPU is associated with a particular peripheral.

Figure 43-1: SPU Write Protect Registers

In the figure, a write-protect register in the SPU module blocks write-attempts to the MMR space of the associated peripheral. The bits in the write-protect register specify from which masters to block write-access.

NOTE: A SPU write protection register (`SPU_WP[n]`) exists for the SPU alone. If all defined bits are set in this register for the SPU, any configurations in the SPU are locked and cannot be changed. Only a system reset can restore access to the SPU.

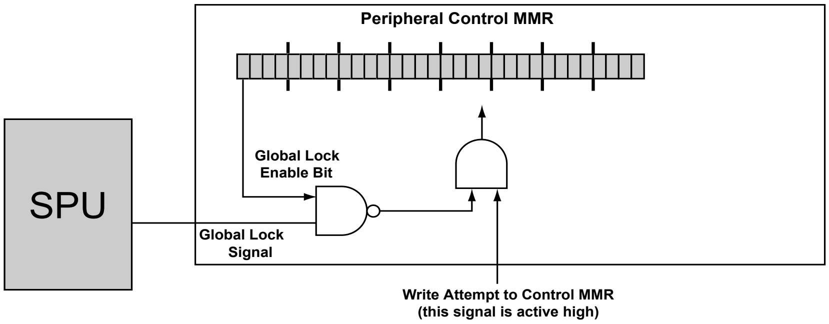
Global Locking

The SPU also has global locking capability. When enabled by setting `SPU_CTL.GLCK` bit field to a value other than 0xAD, a system-wide global lock signal is active. Some peripherals have a lock enable bit in their control register. When this bit is set, the peripheral recognizes the global lock signal and blocks further write-accesses to its own control register. Access to the configuration register of the peripheral is enabled when the global lock is turned off in the SPU.

The ***Global Locking*** figure is a conceptual diagram. The diagram shows how the SPU module (or any peripheral) blocks any write attempts to its control register when:

- The global lock signal from the SPU is active, and
- The global lock enable bit is set in the control register of the peripheral



Peripheral Control MMR
SPU
Global Lock Enable Bit
Global Lock Signal
Write Attempt to Control MMR (this signal is active high)

Figure 43-3: Global Locking

The SPU can write-protect its own registers. When the `SPU_CTL.WPLCK` bit is set and global locking is enabled, the SPU blocks accesses to the SPU write-protection registers. To enable write access to the write-protection registers in the SPU, disable the global locking.

SPU Block Diagram

The *SPU System-Level Block Diagram* shows a system-level block diagram of where the SPU is located in the system. It resides between the SMMR interface and the system crossbar. Depending on the configuration of the SPU write-protect registers, it can block access to some peripherals from certain SMMR masters.

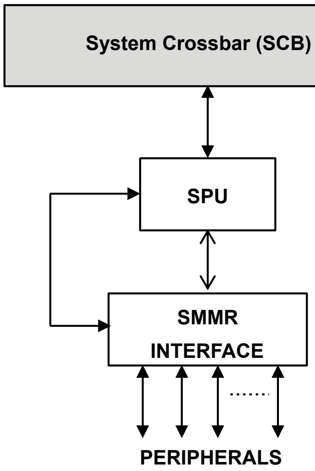


Figure 43-4: SPU System-Level Block Diagram

SPU Architectural Concepts

As shown in the block diagram, the SPU sits between the system crossbar (SCB) and the SMMR interface to the peripherals. The SPU gates any MMR access to any peripheral from any master that comes through the SCB. Depending on the configuration of the write-protection registers in the SPU, the SPU does or does not allow the MMR write to go through.

The SPU also checks whether the transaction is a secure or non-secure transaction and blocks it according to the configured security setting for the target destination. A secure master can generate secure read or secure write transactions which can access secure or non-secure slaves. A non-secure master can generate non-secure read or non-secure write transactions and can only access non-secure slaves.

SPU Event Control

The system protection unit provides write-protection against MMRs peripherals and its own write-protect registers. If a write attempt is made to any locked MMR peripheral the SPU has write-protected, it blocks the write. The SPU generates a bus error to the master that attempted the write. That master does or does not generate an event, based on the returned error.

The SPU can be configured to generate an interrupt for the write-protection violation by setting the `SPU_CTL.PINTEN` bit. The SPU can also be configured to generate an interrupt for a security violation by setting the `SPU_SECURECTL.SINTEN` bit. If either one or both bits is triggered, the `SPU_STAT.VIRQ` bit is set.

The SPU can also lock its own registers from write attempts. If a write-attempt is made to a locked register in the SPU, the SPU blocks it and records it as an error in the `SPU_STAT.LWERR` bit. Again, the SPU generates a bus error to the master that attempted the write.

The master does or does not generate an event, based on the returned error.

The SPU does not generate an event for a blocked write access to an SPU register. If the `SPU_CTL.PINTEN` bit is set, the SPU triggers an interrupt for this blocked access attempt.

The global lock is enabled by setting the `SPU_CTL.GLCK` bit to something other than 0xAD. If the lock bit is set in that same configuration register, a peripheral can block write access to its configuration register. When the SPU blocks a write attempt, the peripheral logs and reports the failed attempt. The SPU is unaware and therefore does not provide any indication of a failed write attempt to the configuration register of the peripheral.

SPU Programming Model

The system protection unit (SPU) consists of write-protect registers. Each one corresponds to a different peripheral instance. Bits in the write-protect registers correspond to system masters that can modify the MMR contents of the peripherals. By writing to these write-protect registers, the corresponding memory-mapped registers of the peripheral are write-protected against masters whose bits in the write-protect register are set.

The SPU globally locks the control register of the peripheral. Peripherals that support this feature have a lock enable bit in their control register. The peripheral blocks any additional write attempts to its control register from any master when:

- The global lock signal is active from the SPU, and
- The lock enable bit of the peripheral is set

If the lock enable bit of a peripheral is not set and the global lock signal is active, access to that control register of the peripheral is still allowed. To grant access again, disable the global lock signal from the SPU by writing the value 0xAD into the `SPU_CTL.GLCK` bit field.

Another protection mechanism that the SPU offers is write-protection against the write-protection registers. If the write protect register lock bit (`SPU_CTL.WPLCK`) is set and the global lock signal is active, writes to the write-protect registers of the SPU are blocked. To reenable access to the write-protect registers in the SPU, deactivate the global lock signal by writing 0xAD into the `SPU_CTL.GLCK` bit field.

For security, the SPU provides a set of `SPU_SECUREC[n]` registers (one for each processor core from Analog Devices) to configure their security settings. The SPU also provides a set of `SPU_SECUREP[n]` registers (one for each peripheral instance) to configure their security settings.

Enabling and Disabling the SPU

The SPU is always operating. There are no bits to enable or disable the SPU. The SPU configuration can be updated at any time. Any ongoing transactions finish before a new configuration is in effect. By default, the SPU does not write-protect any of the MMRs.

Write-Protecting the SPU

The SPU is treated like any other peripheral in the system. As such, the SPU also has an associated write-protection register. If this write-protection register is configured to block all writes from all masters, any SPU configuration remains the same until the next system reset.

Checking the Security State

In some cases while running a peripheral, an application system master does not know whether they are a secure master generating secure transactions or not. The SPU provides a means for checking the security state of the master through the `SPU_SECURECHK` register. When read by a secure master, the register reads 0xFFFFFFFF and when read by a non-secure master, the value is 0x00000000.

SPU Mode Configuration

The SPU can provide address range-wide protection by write-protecting the peripherals MMR address range from system MMR masters. It can also provide register wide protection using global locking. Peripherals that support this feature can enable it in their respective configuration register. When the SPU enables the global lock signal, all subsequent writes to the configuration register of the peripheral are blocked until the global lock signal is deasserted. Similarly, the write-protection registers of the SPU can be write-protected using the global lock signal as well. The SPU uses all these modes of operation together.

Locking Write-Protect Registers

Use the following steps to lock (write-protect) a register.

1. Set the `SPU_CTL.WPLCK` bit and configure the `SPU_CTL.GLCK` field to something other than 0xAD.

The SPU write-protect registers are blocked from further write accesses.

Protecting a Peripheral

Use the following procedure to protect a peripheral.

1. Determine which peripheral needs protection and locate the corresponding write-protect register (`SPU_WP[n]`) in the SPU. See the "Write-Protect and Secure Peripheral Registers" section.
2. Determine the SMMR masters from which the peripheral needs protection. Then, set the corresponding bit or bits in the write-protect register (`SPU_WP[n]`) for the peripheral. See the "Write-Protect and Secure Peripheral Registers" section.

After setting the write-protect register for the particular peripheral, the identified SMMR masters are blocked from writing to any MMR in the address space of the peripheral. This block remains in place until the bits in the write-protect register are cleared.

Configuring Security Privileges of a Peripheral

Use the following procedure to configure the security privileges of a peripheral.

1. Determine the peripheral and its corresponding secure peripheral register (`SPU_SECUREP[n]`) in the SPU. See the "Write-Protect and Secure Peripheral Registers" section.
2. If the peripheral is to be a secure slave only accepting secure transactions, set bit 0 (`SPU_SECUREP[n].SSEC`).
3. If the peripheral is to be a secure master that generates secure transactions (keeping in mind not all peripherals can be masters), set bit 1 (`SPU_SECUREP[n].MSEC`).

This procedure sets the security privileges of a peripheral.

> **NOTE:** Only a secure master can set security privileges, keeping the chain of trust intact. If a non-secure master configures the security privileges, it can undermine security protection.

ADSP-SC58x SPU Register Descriptions

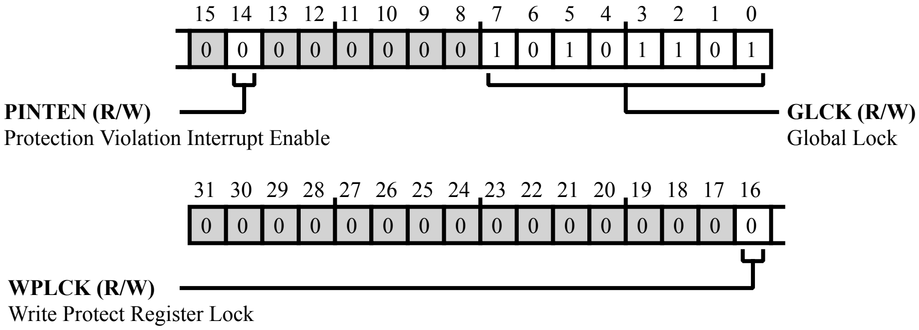
System Protection Unit (SPU) contains the following registers.

Table 43-3: ADSP-SC58x SPU Register List

Name	Description
`SPU_CTL`	Control Register
`SPU_SECURECHK`	Secure Check Register
`SPU_SECURECTL`	Secure Control Register
`SPU_SECUREC[n]`	Secure Core Registers
`SPU_SECUREP[n]`	Secure Peripheral Register
`SPU_STAT`	Status Register
`SPU_WP[n]`	Write Protect Register n

Control Register

The SPU control register (SPU_CTL) provides a global lock for configuration registers as well as control for locking the write protect (SPU_WP[n]) registers. It also controls the generation of an interrupt to report blocked accesses.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Secure Control Register

The SPU Secure Control Register (`SPU_SECURECTL`) allows the user to lock write access to all the `SPU_SECUREC[n]` and `SPU_SECUREP[n]` registers as well as configure the interrupt generation in an event of a security error. It also allows bulk clear of the SSEC bits and/or MSEC bits in the `SPU_SECUREP[n]` registers.

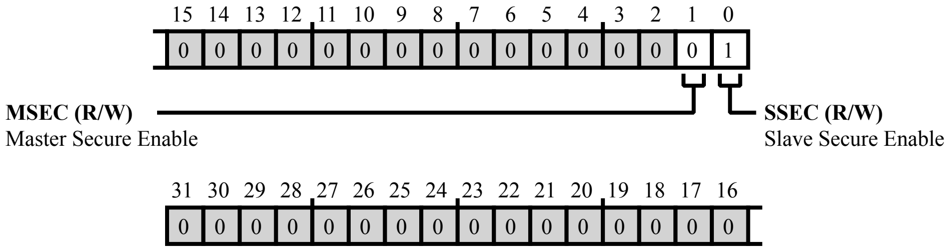
Table 43-7: SPU_SECUREC[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	CSEC[n]	Core Secure. The `SPU_SECUREC[n].CSEC[n]` bit controls whether non-secure accesses are allowed to L1 memory of the processor core. When =1, the core (as a slave) is set as secure meaning only secure transactions are allowed to L1.	
		0	Disable
		1	Enable

Secure Peripheral Register

In the system, each SPU_SECUREP[n] register is assigned to a specific MMR address range associated with one peripheral. Each SPU_SECUREP[n] has a Slave Secure (SSEC) bit and a Master Secure (MSEC) bit. When the Slave Secure (SSEC) bit is set, the SPU will only allow Secure Masters generating secure transactions to access the peripheral's MMR address space. When the Master Secure (MSEC) bit is set, the associated peripheral will be secure and will generate secure transactions.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 43-9: SPU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Lock Write Error. The `SPU_STAT.LWERR` indicates whether there has been an attempted write to a register in the SPU with its lock bit (`SPU_CTL.WPLCK` or SCRLCK) set while `SPU_CTL.GLCK` was asserted. This bit is W1C.	
		0	Inactive
		1	Active
30 (R/W1C)	ADDRERR	Address Error. The `SPU_STAT.ADDRERR` indicates whether there has been an attempted write to a read-only register or an access an invalid address in the SPU MMR address range. This bit is W1C.	
		0	Inactive
		1	Active
12 (R/W1C)	VIRQ	Violation Interrupt Request. The `SPU_STAT.VIRQ` bit indicates that a security and/or protection violation has been detected and interrupt asserted. This is a W1C bit.	
		0	Inactive
		1	Active
0 (R/NW)	GLCK	Global Lock Status. The `SPU_STAT.GLCK` indicates whether the global lock is enabled or disabled.	
		0	Disabled (global_lock=0)
		1	Enabled (global_lock=1)

Write Protect Register n

In the system, each `SPU_WP[n]` register is assigned to a specific MMR address range associated with one peripheral. When the appropriate bits are set, writes to the peripheral from a specific master are blocked and an error is returned to the master. For more information, see the processor specific additional information for the `SPU_WP[n]` register.

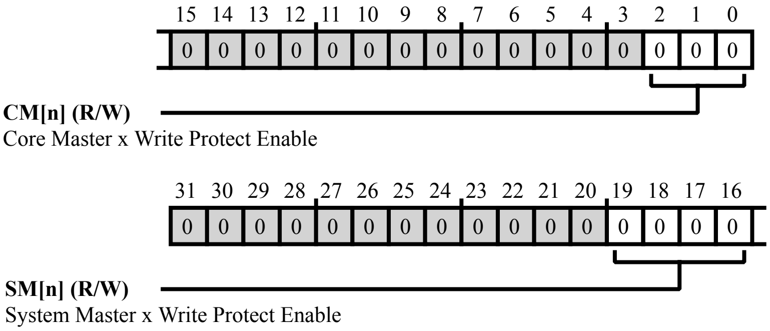

Figure 43-11: SPU_WP[n] Register Diagram

Table 43-10: SPU_WP[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	SM[n]	System Master x Write Protect Enable. The `SPU_WP[n].SM[n]` bits correspond to different system masters in the system. When a particular bit is set in this field, the corresponding system master cannot write to the corresponding peripheral's MMR address space. The write attempt is blocked by the SPU.
2:0 (R/W)	CM[n]	Core Master x Write Protect Enable. The `SPU_WP[n].CM[n]` bits correspond to different cores in the system. When a particular bit is set in this field, the corresponding core cannot write to the corresponding peripheral's MMR address space. The write attempt is blocked by the SPU. Core ID 0 = M0 Supervisor and Core ID 1 = M4 Controller.

ADSP-SC5xx Write-Protect, Secure Peripheral and Secure Core Registers

The SPU consists of a collection of write-protect registers each of which are associated with a specific peripheral or slave. The SPU also has a collection of secure peripheral registers which are also associated with specific peripherals. The table gives the write-protect register and secure peripheral number for each of the peripherals that are provided with write protection and security through the SPU. The SPU for ADSP-SC5xx is configured with 188 write-protect registers and also 188 secure peripheral registers. The number corresponding to a peripheral correlates to both the Write-Protect register and the Secure Peripheral register.

For each processor, there are different numbers of masters that are able to access the SMMR space. The ***SPU_WPn.CMn and SPU_WPn.SMn Bits*** table shows which bits enable the protection against which master.

Table 43-11: SPU_WPn.CMn and SPU_WPn.SMn Bits

Bit Number	Bit Name	Description
0	CM_WP[0]	ARM Core 0
1	CM_WP[1]	SHARC Core 1
2	CM_WP[2]	SHARC Core 2
15	SM_WP[0]	PCIe
16	SM_WP[1]	DBG
17	SM_WP[2]	Embeded Trace Router (ETR)
18	SM_WP[3]	Enhanced Bandwidth MDMA

For each peripheral, there is a corresponding write-protect register, `SPU_WP[n]`, and secure peripheral register, `SPU_SECUREP[n]`. The table shows the write-protect register and secure peripheral number for each peripheral.

ADSP-SC5xx Specific Information

The information in this section applies specifically to the ADSP-SC5xx processor models

Global Locking

The global lock signal from the SPU along with the peripheral lock bit can be used to provide lock functionality for the control MMR of the peripheral. The Global Lock (`SPU_CTL.GLCK`) field determines whether global lock is enabled or not. Global Lock is disabled if the `SPU_CTL.GLCK` field is 0xAD (default value), otherwise it is enabled. The following is a list of peripherals that have the global lock bit in their control MMR.

- General-Purpose IO (GPIO)
- System Event Controller (SEC0)
- Trigger Routing Unit (TRU0
- Clock Generation Unit (CGU0)
- Clock Generation Unit1 (CGU1)
- Clock Distribution Unit (CDU0)
- Dynamic Power Management (DPM)
- Reset Control Unit (RCU0)

- System Protection Unit (SPU0)
- L2 Memory Controller (L2CTL0)
- L2 Memory Controller (L2CTL1)
- L2 Memory Controller (L2CTL2)

44 Security Packet Engine (PKTE)

The PKTE is a security packet engine designed to off-load the host processor to improve the speed of applications requiring cryptographic processing. The packet engine contains a set of modules for encryption and decryption, hashing, and pseudo-random number generation.

PKTE Features

The PKTE has the following features.

- Hardware assisted processing for the cryptographic ciphers, hashes, and pseudo-random number generation
- Header and trailer processing for Internet security protocols
- DMA capability to move data in and out of the engine efficiently and to allow the engine to run autonomously while moving data
- Interrupt controller to signal module status and errors
- Clock manager for enabling or disabling different features to save power

NOTE: Not all algorithms, decrypt, and hash functions and extra features are available on all product models. For complete information on included features, see the product-specific data sheet.

NOTE: This packet engine provides support for various network security protocols by processing headers and trailers as well as accelerating cryptographic functions. Not all processors have direct support for Ethernet. As such, the packet engine can still be used if Ethernet is indirectly used.

PKTE Functional Description

The packet engine contains a set of modules for encryption and decryption, hashing, and pseudo-random number generation. The following sections describe these functional blocks.

ADSP-SC58x PKTE Register List

The Security Packet Engine (PKTE) provides security-related features. A set of registers governs PKTE operations. For more information on PKTE functionality, see the PKTE register descriptions.

Table 44-1: ADSP-SC58x PKTE Register List

Name	Description
PKTE_ARC4STATE_ADDR	Packet Engine ARC4 State Record Address
PKTE_ARC4STATE_BUF	Starting Entry of 256-byte ARC4 State Buffer
PKTE_BUF_PTR	Packet Engine Buffer Pointer Register
PKTE_BUF_THRESH	Packet Engine Buffer Threshold Register
PKTE_CDRBASE_ADDR	Packet Engine Command Descriptor Ring Base Address
PKTE_CDSC_CNT	Packet Engine Command Descriptor Count Register
PKTE_CDSC_INCR	Packet Engine Command Descriptor Count Increment Register
PKTE_CFG	Packet Engine Configuration Register
PKTE_CLK_CTL	PE Clock Control Register
PKTE_CONT	PKTE Continue Register
PKTE_CTL_STAT	Packet Engine Control Register
PKTE_DATAIO_BUF	Starting Entry of 256-byte Data Input/Output Buffer
PKTE_DEST_ADDR	Packet Engine Destination Address
PKTE_DMA_CFG	Packet Engine DMA Configuration Register
PKTE_ENDIAN_CFG	Packet Engine Endian Configuration Register
PKTE_HLT_CTL	Packet Engine Halt Control Register
PKTE_HLT_STAT	Packet Engine Halt Status Register
PKTE_IMSK_DIS	Interrupt Mask Disable Register
PKTE_IMSK_EN	Interrupt Mask Enable Register
PKTE_IMSK_STAT	Interrupt Masked Status Register
PKTE_INBUF_CNT	Packet Engine Input Buffer Count Register
PKTE_INBUF_INCR	Packet Engine Input Buffer Count Increment Register
PKTE_INT_CFG	Interrupt Configuration Register
PKTE_INT_CLR	Interrupt Clear Register
PKTE_INT_EN	Interrupt Enable Register
PKTE_IUMSK_STAT	Interrupt Unmasked Status Register
PKTE_LEN	Packet Engine Length Register
PKTE_OUTBUF_CNT	Packet Engine Output Buffer Count Register
PKTE_OUTBUF_DECR	Packet Engine Output Buffer Count Decrement Register
PKTE_RDRBASE_ADDR	Packet Engine Result Descriptor Ring Base Address
PKTE_RDSC_CNT	Packet Engine Result Descriptor Count Registers

Table 44-1: ADSP-SC58x PKTE Register List (Continued)

Name	Description
PKTE_RDSC_DECR	Packet Engine Result Descriptor Count Decrement Registers
PKTE_RING_CFG	Packet Engine Ring Configuration
PKTE_RING_PTR	Packet Engine Ring Pointer Status
PKTE_RING_STAT	Packet Engine Ring Status
PKTE_RING_THRESH	Packet Engine Ring Threshold Registers
PKTE_SA_ADDR	Packet Engine SA Address
PKTE_SA_ARC4IJPTR	ARC4 i and j Pointer Register
PKTE_SA_CMD0	SA Command 0
PKTE_SA_CMD1	SA Command 1
PKTE_SA_IDIGEST[n]	SA Inner Hash Digest Registers
PKTE_SA_KEY[n]	SA Key Registers
PKTE_SA_NONCE	SA Initialization Vector Register
PKTE_SA_ODIGEST[n]	SA Outer Hash Digest Registers
PKTE_SA_RDY	SA Ready Indicator
PKTE_SA_SEQNUM[n]	SA Sequence Number Register
PKTE_SA_SEQNUM_MSK[n]	SA Sequence Number Mask Registers
PKTE_SA_SPI	SA SPI Register
PKTE_SRC_ADDR	Packet Engine Source Address
PKTE_STAT	Packet Engine Status Register
PKTE_STATE_ADDR	Packet Engine State Record Address
PKTE_STATE_BYTE_CNT[n]	State Hash Byte Count Registers
PKTE_STATE_IDIGEST[n]	State Inner Digest Registers
PKTE_STATE_IV[n]	State Initialization Vector Registers
PKTE_USERID	Packet Engine User ID

ADSP-SC58x PKTE Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
130	PKTE0_IRQ	PKTE0 Interrupt	Level	

PKTE Definitions

Command Descriptor

An 8-word structure that is either written directly into the packet command MMR set or is placed in a Command Descriptor Ring (CDR) in the processor memory. The packet engine sequentially processes the structure. The command descriptor contains the information that varies for every packet. This information includes pointers to the SA record, the state information, the source packet, and the destination packet.

Command Descriptor Ring (CDR)

A circular contiguous portion of memory which is used to manage one or more command descriptions for the packet engine.

Result Descriptor

When the packet engine completes the processing of a packet, it writes a result descriptor with the state information. The result descriptor can be read directly from the result register set or from the Result Descriptor Ring (RDR) in the processor memory.

Result Descriptor Ring (RDR)

A circular contiguous portion of memory which holds the mirror or copy of the CDR but contains the result descriptors. The RDR and CDR can be overlaid on top of each other.

Security Association (SA) Record

A structure that contains the remainder of the information the packet engine requires to process a packet. Most of the information fields in the SA record such as the key and encryption mode are static for the lifetime of the association. The fields do not require frequent manipulation by the processor core. The SA record non-static fields are the sequence number and sequence number mask. The SA record can have a corresponding state record for saving results from the current operations that are useful for future operations. The state record can hold the IV, the hash byte count, and the intermediate hash digest.

Cipher

A method or algorithm to encrypt or decrypt information

Hash

A cryptographic hash is a function that takes an arbitrary block of data and returns a fixed-size bit string. Four main properties define the function:

- It is easy to compute a hash value for any given input

- It is infeasible to generate the original input from a given hash
- It is infeasible to modify the input without changing the resulting hash
- It is infeasible to find two different inputs that result in the same hash

Autonomous Ring Mode (ARM)

Mode of operation in which most of the parameters as well as the data are set up in memory and moved to the engine for configuration and processing through DMA.

Target Command Mode (TCM)

Mode of operation where some parameters are set up in memory and moved into the packet engine through DMA while the other parameters are directly written to the registers. DMA moves the input and output data in and out of the engine.

Direct Host Mode (DHM)

Mode of operation that does not use DMA. All parameters are directly written to and read from the MMRs. The input and output are written to and read from the FIFO buffers.

Cipher Module

The cipher module does the symmetric encrypt or decrypt operations for:

- Data Encryption Standard (DES)
- Triple-DES
- ARC4
- Advanced Encryption Standard (AES) algorithms

The cipher module supports standard modes for DES and AES that include Electronic Code Book (ECB) and Cipher Block Chaining (CBC). The key size for DES is 56 bits, for Triple-DES is 168 bits. The AES module also provides support for AES counter-modes for IPsec and SRTP. All AES modes can use key sizes of 128 bits and 192/256 bits. Key scheduling is automatic and done in parallel with the encrypt or decrypt operation.

Hash Module

The hash module is tightly coupled with the encrypt or decrypt module and provides hardware accelerated one-way hash functions. Operations that combine both hash and encrypt or decrypt functions are provided to reduce processing time for data that needs both applied. For hash-then-decrypt operations, the packet engine performs parallel execution of both functions from the input buffer. For encrypt-then-hash operations, the processing is pipelined from the input buffer to provide minimum latency. An offset can be specified between the start of hashing and the start of encryption to support protocols such as IPsec or SRTP. The HMAC keyed hashing mechanism is supported for MD5, SHA-1, SHA-2-224 and SHA-2-256. The SSL-MAC is supported for MD5 and SHA-1. A second AES-CBC module for the hash function enables parallel processing for AES-CCM, a combined hash and encrypt algorithm.

Pseudo-Random Number Generator

Cipher algorithms that operate in CBC mode or counter-mode, require an IV. This IV must not be secret; however the IV must be unpredictable and unique for each execution of the encryption process. Pseudo-random number generators are deterministic algorithms that output statistically independent and unbiased numbers. True random number generators are non-deterministic and use the randomness that occurs in a physical process. The packet engine incorporates an ANSI X9.31 compliant Pseudo Random Number Generator (PRNG) that it can use to generate unique IVs using strong encryption. The ANSI X9.31 PRNG is defined as part of the ANSI X9 standards that are used to secure financial transactions. The function can also be used for pseudo-random number generation as part of an implementation of the digital signature standard described in NIST FIPS PUB 186-2.

The PRNG function, as defined by ANSI X9.31, is based on the AES cipher. This section describes the function to promote understanding of the different inputs and outputs of the PRNG function itself.

NOTE: The PRNG in the packet engine is only based on the AES cipher with 128-bit keys. Other ciphers and key lengths are not supported for the PRNG based on ANSI X9.31.

Let $e \times K(Y)$ represent the AES encryption of Y under the key K.

The PRNG function uses three inputs:

- K, a 128-bit key
- V, a 128-bit seed value
- DT, a 128-bit date/ time vector which is updated on each iteration

The intermediate value I is the result of an AES encryption of the data and time vector under key K.

$I = e \times K(DT)$

That value I is then XOR-ed with the seed V and AES encrypted under key K. The result R is the output of the PRNG function.

$R = e \times K(I \text{ XOR } V)$

A new seed value V is generated from the AES encryption of the result R XOR'ed with the intermediate value I under the key K.

$V = e \times K(R \text{ XOR } I)$

The PRNG function is deeply integrated inside the datapath of the packet engine. The function is controlled indirectly through the PRNG mode bits in the `PKTE_CTL_STAT.PRNGMD` bit field of the command descriptor and the IV source selection bits in the `PKTE_SA_CMD0.IVSRC` bit field of the SA record.

The PKTE module supports four different modes.

1. Load IV from PRNG for the current operation: `PKTE_CTL_STAT.PRNGMD` = 0b00 and `PKTE_SA_CMD0.IVSRC` = 0b11.
2. PRNG init mode initializes the PRNG with a key, seed, and date/time value: `PKTE_CTL_STAT.PRNGMD` = 0b01.

   Before the PRNG function can be used, it must be initialized with a key, seed, and date/time value. At initialization, the key, seed, and date/time values are programmed. Other PRNG operations do not change the key, however the seed, and date/time values are updated (not re-programmed). The date/time is updated every 128 system clock cycles.

   The date/time is a 128-bit value with randomly distributed number of ones and zeros. It must not be all zeros.

   The ***SA Record for PRNG Init Operation*** table shows how the key, seed and date/time values are loaded into the PKTE registers for initialization.

   Table 44-3: SA Record for PRNG Init Operation

Parameter	SA Field	Description
K	SA_KEY0	PRNG key [127:96]
	SA_KEY1	PRNG key [95:64]
	SA_KEY2	PRNG key [63:32]
	SA_KEY3	PRNG key [31:0]
V	SA_IDIGEST0	PRNG seed [127:96]
	SA_IDIGEST1	PRNG seed [95:64]
	SA_IDIGEST2	PRNG seed [63:32]
	SA_IDIGEST3	PRNG seed [31:0]
DT	SA_ODIGEST0	PRNG date/time [127:96]
	SA_ODIGEST1	PRNG date/time [95:64]
	SA_ODIGEST2	PRNG date/time [63:32]
	SA_ODIGEST3	PRNG date/time [31:0]

3. PRNG generate mode generates pseudo-random data on initialized key, seed, and date/time value: `PKTE_CTL_STAT.PRNGMD` = 0b10.

   The PRNG function can be used to generated pseudo-random data for other purposes than IVs. For this mode, the PRNG must have been initialized once with the PRNG init mode.

   The PRNG generate mode uses the initialized key and unique changing date/time value as inputs. The pseudo-random data is output to the output buffer of the packet engine.

   The `LEN` field in the command descriptor indicates the amount of pseudo random data that is generated in multiples of 16 bytes. The maximum is 255 × 16 = 4080 bytes.

In autonomous ring mode, the output data is copied to the host memory at the destination address in the command descriptor. In direct host mode, the host must read the data directly from the output buffer. No SA record is used for this function.

Directly after the PRNG generate mode, a new pseudo-random number is generated and available for the next operation that uses the option `PKTE_SA_CMD0.IVSRC = PRNG`.

4. PRNG test mode generates pseudo-random data on initialized key, seed, and input (test) data: `PKTE_CTL_STAT.PRNGMD` = 0b11.

   The PRNG test mode can be used to test the correctness of the PRNG function. This mode is similar to the PRNG generate mode, except that the data is read from the input buffer of the packet engine, instead of the date/time value.

   For this mode, the PRNG must have been initialized once with the PRNG Init mode.

   The `LEN` field in the command descriptor indicates the amount of pseudo-random data to be generated in multiples of 16 bytes. The maximum is limited to the `LEN` field in bytes.

   In autonomous ring mode, the output data is copied to the host memory at the destination address in the command descriptor. In the direct host mode, the host must read the data directly from the output buffer. No SA record is used for this function.

   Directly after the PRNG test mode, a new pseudo-random number is generated and available for the next operation that uses the option `PKTE_SA_CMD0.IVSRC = PRNG`.

Packet Engine Processing Details

This section describes data processing through the packet engine. It describes padding and supported algorithms for each protocol.

A valid Security Association (SA) must be created before packet processing can start. A formatted SA record must reside in memory and be accessible to the packet engine. The host processor application is responsible for these tasks.

Crypto Padding

Padding is the process of adding data to fill-out a fixed-size plain text data structure. Three factors determine when to use a pad field:

1. If a block cipher encryption algorithm is used, a pad field is used to expand the plain text to a multiple of the block size.
2. Padding can be used to ensure that the cipher text terminates on an n-byte boundary.
3. Padding can conceal the actual length of the payload.

To facilitate peak encrypt or decrypt performance, the packet engine supports the following most commonly used padding functions in hardware:

1. Pad generation and insertion of pad bytes to the end of plain text prior to encryption, for outbound operations.

2. Pad verification to check for correct padding after decrypting a packet for inbound operations.
3. Pad consumption to strip the pad bytes from the plain text data after decrypting a packet, for inbound operations.

Pad Generation and Insertion

The pad type and quantity of bytes the packet engine inserts depends on the plain text length and the value of the following fields:

- `PKTE_SA_CMD0.PADTYPE` and `PKTE_SA_CMD0.EXTPAD` defines the type of padding
- `PKTE_CTL_STAT.PADVAL` defines a value that is inserted in the pad
- `PKTE_SA_CMD0.CIPHER` enforces a certain pad alignment
- `PKTE_SA_CMD1.CIPHERMD` enforces a certain pad alignment
- `PKTE_SA_CMD0.SCPAD` allows stream ciphers to be padded
- `PKTE_CTL_STAT.PADCTLSTAT` controls the pad alignment

The `PKTE_CTL_STAT.PADCTLSTAT` bit field of the result descriptor returns the total number of inserted pad bytes.

Pad Types

The pad type bit field (`PKTE_SA_CMD0.PADTYPE`) and the extended pad bit (`PKTE_SA_CMD0.EXTPAD`) select the pad type for the extended protocol group. The packet engine can generate different pad types in hardware as described in the ***Pad Examples*** table.

The `PKTE_CTL_STAT.PADVAL` bit field, together with the number of pad bytes, defines the value that is inserted in the pad. The format of the pad and the use of this field is best explained in an example (see the ***Pad Examples*** table).

For the IPsec pad type, this field holds the value that is inserted into the next header field (in the ESP trailer) of the innermost operation's header. For the Constant pad type or the Constant SSL pad type, this field holds the inserted fixed constant pad value. For all other pad types, this field is not used and must be zero.

Table 44-4: Pad Types

Pad Type	Value	Description
IPSec	0b000	Append 0 to 255 pad bytes, followed by a pad length byte and a next header byte. The first pad byte appended to the plain text is numbered 1, with subsequent pad bytes making up a monotonically increasing sequence: 1, 2, 3 and up. Append the pad length field that indicates the number of pad bytes (0–255), where a value of zero indicates no pad bytes present. Append the next header byte as specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor. A minimum of 2 bytes are appended; zero pad bytes plus the pad length byte plus the next header byte, in which case the `PKTE_CTL_STAT.PADCTLSTAT` field in the result descriptor returns 0x02. A maximum of 257 bytes can be appended, in which case the `PKTE_CTL_STAT.PADCTLSTAT` field in the descriptor returns 0x01.
PKCS#7	0b001	Appends 1–128 pad bytes with a pad byte value equal to the pad length (1–128).
Constant	0b010	Appends 0–255 pad bytes of a user-specified character to the plain text data. This character is specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor.
Zero	0b011	Appends 0–255 pad bytes of 0x00 to the plain text data.
Constant SSL	0b110	Appends 0–255 pad bytes of a user-specified character to the plain text data, followed by a ‘pad length’ byte (0–255). This character is specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor. A total of 256 bytes can be appended, in which case the pad field returns 0x00.

For example, the ***Pad Examples*** table shows the appended pad for any of the pad types for an outbound (encrypt) operation. The table shows a plain text input of 2 bytes using the 8-byte block cipher crypto-algorithm DES-ECB and a `PKTE_CTL_STAT.PADVAL` field value of 0xAA.

Table 44-5: Pad Examples

Pad Type	Pad field (extended to Plain Text)	`PKTE_CTL_STAT`
IPSec	0x01, 0x02, 0x03, 0x04, 0x04, 0xAA	0x06
PKCS#7	0x06, 0x06, 0x06, 0x06, 0x06, 0x06	0x06
Constant	0xAA, 0xAA, 0xAA, 0xAA, 0xAA, 0xAA	0x06
Zero	0x00, 0x00, 0x00, 0x00, 0x00, 0x00	0x06
Constant SSL	0xAA, 0xAA, 0xAA, 0xAA, 0xAA, 0x05	0x06

Pad Length

The ***Pad Alignment*** table lists the alignment (boundaries) to which the packet engine will pad, based on:

- The selected crypto-algorithm
- Crypto mode
- The value of the pad stream cipher bit
- The value of pad control

The minimum number of inserted pad bytes depends on the cipher algorithm, selected using the `PKTE_SA_CMD0.CIPHER` bit field, and the cipher mode, selected using the `PKTE_SA_CMD1.CIPHERMD` bit field.

For block ciphers, the plain text data is always (as a minimum) padded to the next block boundary. More pad bytes beyond the algorithm or protocol alignment requirements can be inserted using the pad control (`PKTE_CTL_STAT.PADCTLSTAT`) in the command descriptor. This feature can be used for *traffic flow security* to conceal the number of plain text bytes in an encrypted packet.

Encrypt operations that use block ciphers have minimum pad requirements based on their block size. The packet engine enforces a minimum pad alignment for block ciphers according to the ***Pad Alignment*** table. For ESP outbound operations, the minimum pad alignment is forced to 4 bytes.

For stream ciphers and null crypto the data is never padded when the stream cipher pad bit (`PKTE_SA_CMD0.SCPAD`) =0. When `PKTE_SA_CMD0.SCPAD` =1 the plain text data is padded to the length as defined by the `PKTE_CTL_STAT.PADCTLSTAT` bits in the command descriptor.

NOTE: The SSL protocol does not allow padding to exceed the ciphers block length. This length is 8 bytes for DES/Triple-DES and 16 bytes for AES. For SSL, the packet engine does not enforce this pad alignment value. The host processor must ensure that the `PKTE_CTL_STAT.PADCTLSTAT` bit field is configured correctly.

Table 44-6: Pad Alignment

Pad Control PADCTLSTAT = PKTE_CTL_STAT[31:24]			0x00	0x01[*1]	0x02	0x04	0x08	0x10	0x20	0x40	0x80[*2]
Crypto Algorithm	**Crypto Mode**	**Pad Stream Ciphers**	**%8**	**%1**	**%4**	**%8**	**%16**	**%32**	**%64**	**%128**	**%256**
DES	ECB, CBC	N/A	8	8	8	8	16	32	64	128	256
AES	ECB, CBC	N/A	16	16	16	16	16	32	64	128	256
	CTR, ICM with ESP	N/A	8	4	4	8	16	32	64	128	256
	CTR, ICM no ESP	no	0	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256
NULL	with ESP	N/A	8	4	4	8	16	32	64	128	256
	no ESP	no	8	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256
ARC4	with ESP	N/A	8	4	4	8	16	32	64	128	256
	no ESP	no	0	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256

*1 If `PKTE_CTL_STAT.PADCTLSTAT` is configured for no padding (0x01), it does not mean that no padding bytes are inserted. When PKCS#7 padding is selected, a pad length field with a value =1 is inserted. When SSL or TLS padding is selected, a pad length field with a value =0 is inserted. When IPsec padding is selected, a pad length field is forced to (`PKTE_CTL_STAT.PADCTLSTAT`=0x20). When zero pad and constant pad are selected, no pad bytes are inserted.

*2 Pad type PKCS#7 supports a maximum length of 128 pad bytes, so the packet engine overrules a 256-byte alignment (`PKTE_CTL_STAT.PADCTLSTAT`=0x80) to a 128-byte boundary (`PKTE_CTL_STAT.PADCTLSTAT`=0x40).

The packet engine does not constrain the pad type that is used for an operation; any pad type can be used for each operation. The user must be aware that some protocol specifications only allow specific pad types. The SRTP specification does not have padding defined as padding performed by RTP. The host must pad the RTP packet.

The host software can implement padding that is not supported in hardware. In this case, the host must select the *zero pad* type and set the `PKTE_CTL_STAT.PADCTLSTAT` bit field in the packet descriptor to zero (no padding). The hardware padding engine does not add any bytes. When using a block cipher, the host must insert pad bytes. Then, the data to be encrypted (plain text and pad bytes) are a multiple of the block ciphers boundary. For stream ciphers, any number of pad bytes can be added.

Pad Verification and Consumption

The packet engine can validate a pad type against the expected values. The value of the following bits controls the pad verify function:

- `PKTE_SA_CMD0.PADTYPE` and `PKTE_SA_CMD0.EXTPAD` define the type of padding
- `PKTE_SA_CMD0.CIPHER` enforces a certain pad alignment
- `PKTE_SA_CMD1.CIPHERMD` enforces a certain pad alignment
- `PKTE_SA_CMD0.SCPAD` allows stream ciphers to be padded

When packet processing is complete, the status byte in the first word of the result descriptor reports the pad verification status. Refer to the Table 44-28 Extended Error Codes - Status Encoding table.

The `PKTE_CTL_STAT.PADCTLSTAT` bits in the first word of the result descriptor return the total number of detected pad bytes and returns zero for a pad verify error.

When the IPsec pad type is selected, the `PKTE_CTL_STAT.PADVAL` bit field of the result descriptor returns the next header field. For IPsec ESP outbound operations, this field returns the decimal value 50. For IPsec inbound operations and basic inbound operations that use the IPsec pad mode, the packet engine returns the next header field it detects on the header of the innermost operation. This value is typical for the payload protocol, such as TCP or UDP. However, in bundling scenarios or in IPv6 with destination option headers, another header value could be seen. For all other inbound operations, the returned pad value is zero.

Pad verification is performed for inbound (decrypt) operations that use IPsec, TLS/DTLS or PKCS#7 pad type:

- In combination with a block cipher algorithm: DES-ECB, DES-CBC, AES-ECB, AES-CBC,
- In combination with a stream cipher and stream cipher padding `PKTE_SA_CMD0.SCPAD` enabled: AES-CTR, AES-ICM and ARC4
- In combination with null-crypto (no encryption).

Pad Types

The `PKTE_SA_CMD0.PADTYPE` bit field and the extended pad `PKTE_SA_CMD0.EXTPAD` bit selects the pad type for the extended protocol group pad type. The packet engine can verify the different pad types in hardware as described in the ***Pad Types*** table.

The constant and zero pad types are not verified since they do not include a pad length field. The SSL pad type is not verified since it does not have a defined pattern.

Table 44-7: Pad Types

Pad Type	SA_CMD0[18, 7:6]	Description
IPSec	0b000	Verify that the pad field includes 0–255 pad bytes, followed by a correct pad length and a next header byte. Verify that pad bytes appended to the plain text are an incremental count, starting at one. Verify that the pad length field is the number of pad bytes (0–255), where a value of zero indicates no pad bytes present. Verify that a next header byte is present as the last byte of the packet, the value is not verified. This is after removal of the ICV. The total number of detected pad bytes is returned in the `PKTE_CTL_STAT.PADCTLSTAT` field in the result descriptor. **NOTE:** A minimum of 2 bytes must be present, zero pad bytes plus the pad length byte plus the next header byte. In this case the `PKTE_CTL_STAT.PADCTLSTAT` field in the descriptor returns 0x02. A maximum of 257 bytes can be present, in which case the `PKTE_CTL_STAT.PADCTLSTAT` field in the result descriptor returns 0x01. The value of the next header byte is returned in the `PKTE_CTL_STAT.PADVAL` field in the result descriptor.
PKCS#7	0b001	Verify that the pad field includes 1–128 pad bytes, with a pad byte value equal to the pad length (1–128).

When a block cipher is used and the payload is not padded to the nearest block size boundary, as required by the protocol, a *block size error* is generated for all pad types.

Pad Consumption

The packet engine can optionally consume the decrypted pad bytes for an inbound operation that uses the IPsec, SSL, TLS/DTLS, or PKCS#7 pad types. The pad types constant and zero are not consumed since they do not include a pad length field.

Pad consumption (or stripping) is selected on a flow-by-flow basis in the SA-record with the `PKTE_SA_CMD1.CPYPAD` bit. When this bit is set, the length returned in the LEN field of the result descriptor is the total length of the plain text including the pad. When the `PKTE_SA_CMD1.CPYPAD` is disabled, the detected pad length, as returned in the `PKTE_CTL_STAT.PADCTLSTAT` bits, is subtracted from the total length and then returned in the LEN field of the result descriptor.

The pad is always written to the result packet buffer in memory. When the `PKTE_SA_CMD1.CPYPAD` bit is disabled, only the result length is corrected.

Crypto and Hash Algorithms

The packet engine supports a wide range of crypto and hash algorithms to accelerate basic operations and protocol operations. These algorithms are:

- Basic Encrypt and Basic Decrypt Operations
- Basic Hash Operations
- Basic Encrypt-Hash and Basic Hash-Decrypt Operations
- IPSec ESP Operations
- SRTP Operations

The following tables provide allowed algorithm combinations. Those algorithms not listed in the tables are invalid and can give unexpected results.

NOTE: Not all crypto and hash algorithms are available on all product models. For information on algorithm availability, see the product-specific data sheet.

IV Processing

An initialization vector (IV) is necessary to start a cipher stream or a block cipher in any of the streaming modes of operation. The IV must be unique for each packet. The IV ensures that all cipher texts are unique even if produced by the same encryption key. This functionality prevents every packet from needing a unique encryption key.

Depending on the packet engine operation, the IV can be loaded from different sources. The IV format depends on the algorithm and the source of the IV. The ***Format of the IV*** table provides an overview of all IV formats.

Table 44-15: Format of the IV

Algorithm	IV Source (**`PKTE_SA_CMD0.IVSRC`**)	Format	IV Offset (**`PKTE_SA_CMD1.HSHCOFFST`**)
DES/Triple-DES (CBC)	Previous Result of IV	Internal IV register [63:0]	0x00
	Input Buffer	Input buffer [63:0]	0x02
	Saved IV	State Record Saved IV [63:0]	0x00
	Automatic	PRNG output [63:0]	0x00
AES (CBC)	Previous Result of IV	Internal IV register [127:0]	0x00
	Input Buffer	Input Buffer [127:0]	0x04
	Saved IV	State Record Saved IV [127:0]	0x00
	Automatic	PRNG output [127:0]	0x00
AES (ICM) for Basic and SRTP	Input Buffer	Input Buffer [127:0]	0x04
	Saved IV	State Record Saved IV [127:0]	0x00
AES (CTR) for Basic and IPsec	Input Buffer	SA_NONCE || Input Buffer[63:0] || 0x00000001	0x02
	Saved IV	State Record Saved IV [127:0]	0x00
	Automatic	SA_NONCE || PRNG output [95:32] || 0x00000001	0x00

Notes:

1. The `PKTE_SA_CMD1.HSHCOFFST` bit field provides the IV offset. The offset is only applicable for basic hash or encrypt operations. For protocol operations, the offset is automatically enforced.

2. AES-CTR: The Nonce value as described in RFC 3686, is mapped to the `PKTE_SA_NONCE` register. This Nonce value remains constant for the lifetime of the security association.
3. The host processor controls the IV update using the save-IV bit (`PKTE_SA_CMD0.SVIV`). When part of a packet is processed using a stream cipher and the encrypt or decrypt data is not an integer multiple of the block size, the saved IV is invalid. It must not be used to resume processing the packet.
4. The packet engine supports automatic IV generation for outbound operations. A new IV is generated for every packet with the internal PRNG. This automatic IV generation can be used for all DES, Triple-DES, and AES modes that use an IV, except for AES-ICM mode.
5. For outbound operations, automatic IV generation is the most efficient. No additional I/O is required, and the host processor does not need to provide the IV. When the saved IV option supplies the IV, the IV must be changed for each packet sent. This activity happens when the packet engine writes back the IV to the state record after processing.
6. Outbound IPsec operations put the IV explicitly at the front of the packet. For an inbound IPsec operation, loading from the input buffer is most efficient and always used.
7. CBC processing must not use a predictable IV. Do not use the saved IV and previous result IV options for CBC processing. Refer to RFC 3602 for more details.

ARC4 Processing

The ARC4 algorithm supports two modes of operation: stateless and stateful. For SSL, TLS and DTLS operations that use the ARC4 algorithm, the mode must be set to stateful.

Stateless Mode. Each packet is processed with a newly initialized ARC4 key taken from the key field of the SA record. In this mode, the state information from the SA is never to be read.

CAUTION: If an ARC4 operation in stateless mode is interrupted by an *Interface Error* and the ARC4 state building process is aborted, the next packet fails. The ARC4 is not reset between two packets. For the next packet the ARC4 proceeds from the internal state that it was aborted. Even a soft-reset does not reset the ARC4 internal state, a hardware reset is required.

Stateful Mode. When the `PKTE_CTL_STAT.INITARC4` bit =1, the ARC4 algorithm initializes using the key specified in the SA record. When the `PKTE_CTL_STAT.INITARC4` bit =0, the ARC4 context is read from the ARC4 state field of the SA record and the*i* and *j* pointer field of the SA record. The encrypt and decrypt processing continues from this algorithm state.

The packet engine supports ARC4 key sizes of 40 bits to 128 bits. Longer keys can be used, but they cannot be made inside the packet engine.

The host processor applies ARC4 key scheduling function to the s-box and puts the 256-byte result into the ARC4 state record. It writes the *i* and *j* pointers in the SA (initial $i = 1, j = 0$). The host programs the packet engine and specifies stateful operation to continue the ARC4 algorithm.

Hash State Loading

The hash state can be loaded from various sources, depending on the selected protocol and hash algorithm. The ***Different Sources for Loading the Hash State*** table provides a list of all the options.

Table 44-16: Different Sources for Loading the Hash State

Hash Algorithm `PKTE_SA_CMD0.HASHSRC` =	From SA 0b00	RESERVED 0b01	From State 0b10	No Load 0b11
SHA-1	yes	-	yes	Yes
SHA-224	Yes	-	Yes	Yes
SHA-256	Yes	-	Yes	Yes
Null hash	x	x	x	x

Sequence Number Processing

The packet engine supports sequence number generation and verification for IPsec and extended SSL, TLS, and DTLS protocol operations.

A Sequence Number (SN) is an unsigned number that a sender must implement and a receiver can use to support anti-replay service (replay attacks) for a specific SA. This processing includes detection of the same packet that arrives more than once and detection of packets that arrive in an incorrect sequence and is outside an accepted level of order relative to the last received packet.

The packet engine supports the following options.

- SSL v3.0 with 64-bit SN generation and overflow protection (see The SSL Protocol Version 3.0).
- DTLS v1.0 with 48-bit SN generation, verification, and overflow protection (see RFC 4347).
- DTLS full anti-replay support using 64-bit Sequence Number mask.
- IPsec full anti-replay support using 64-bit Sequence Number mask.
- Sequence number loaded from SA for outbound operations and is retrieved from the input packet for inbound operations.

The sequence number and sequence number mask fields are part of the SA record.

Sequence Number Processing in Extended SSL/TLS

SSL and TLS use an implicit sequence number of 64 bits that is not send in the packet but part of the hash.

For inbound operations, no sequence number verification is performed; instead an incorrect sequence number results in an authentication error (`PKTE_CTL_STAT.AUTHERR`).

For outbound operations, with `PKTE_SA_CMD0.HDRPROC` enabled and `PKTE_SA_CMD1.ENSQNCHK` enabled, the packet engine generates a sequence number error when the 64-bit sequence number counter overflows (counter is 2^{64}-1 and increments to 0). The host processor must not send the packet.

For both outbound and inbound operations, with `PKTE_SA_CMD0.HDRPROC` enabled and `PKTE_SA_CMD1.ENSQNCHK` enabled, the packet engine reads the sequence number from the `PKTE_SA_SEQNUM[n]` registers in the SA. When the operation is finished, the packet engine stores the incremented sequence number in the same SA fields. The sequence number mask `PKTE_SA_SEQNUM_MSK[n]` registers in the SA are not used.

For both outbound and inbound operations, with `PKTE_SA_CMD0.HDRPROC` disabled, the packet engine does not increment the sequence number. It expects the host to provide the sequence number through the input buffer as part of the header.

Sequence Number Processing in DTLS

DTLS uses an explicit sequence number of 64 bits that is sent in the packet. The DTLS sequence number is composed of the epoch (16 bits) and packet sequence number (48 bits) that together form the 64-bit number, like the TLS sequence number. The epoch is incremented after each *Change Cipher Spec* message. The packet sequence number is incremented per packet starting from zero after each change cipher spec message.

For outbound operations, with `PKTE_SA_CMD0.HDRPROC` enabled, the packet engine reads the sequence number from the `PKTE_SA_SEQNUM[n]` fields in the SA, then inserts the sequence number in the packet. Then the packet engine stores the incremented sequence number in the `PKTE_SA_SEQNUM[n]` fields in the SA. The sequence number mask `PKTE_SA_SEQNUM_MSK[n]` fields in the SA are not used.

For outbound operations, with `PKTE_SA_CMD0.HDRPROC` enabled and `PKTE_SA_CMD1.ENSQNCHK` enabled, the packet engine generates a sequence number error when the 48-bit sequence number counter overflows (counter is $2^{48} - 1$ and increments to 0). The host must not send the packet.

For outbound operations, with `PKTE_SA_CMD0.HDRPROC` disabled or `PKTE_SA_CMD1.ENSQNCHK` disabled, the packet engine does not increment and verify a sequence number counter overflow, and therefore never generates a sequence number error. With `PKTE_SA_CMD0.HDRPROC` disabled the Packet Engine does not update the sequence number and sequence number mask fields in the SA and expects the host to provide the sequence number through the input buffer as part of the header.

For inbound operations, with `PKTE_SA_CMD0.HDRPROC` enabled and `PKTE_SA_CMD1.ENSQNCHK` enabled, the packet engine verifies the `PKTE_SA_SEQNUM[n]` fields against the sequence number in the packet using the `PKTE_SA_SEQNUM_MSK[n]` from the SA. Three situations can occur:

1. If the received sequence number falls outside and above the 64-bit sequence number mask, the mask is shifted. The packet engine updates the SA with the received sequence number and the shifted sequence number mask.
2. If the received sequence number falls inside the 64-bit sequence number mask and is not a duplicate sequence number (the same as received before), the corresponding bit in the mask is set. The packet engine updates the SA with the received sequence number and the updated sequence number mask.
3. If the received sequence number falls outside the 64-bit sequence number mask or matches and earlier received number a sequence number error is generated. The packet engine does not update the sequence number and sequence number mask fields in the SA. The host must discard the packet.

For inbound operations, with `PKTE_SA_CMD0.HDRPROC` disabled or `PKTE_SA_CMD1.ENSQNCHK` disabled, the packet engine does not verify the sequence number against the sequence number in the packet and therefore never generates a sequence number error.

With `PKTE_SA_CMD0.HDRPROC` disabled the packet engine does not update the sequence number and sequence number mask fields in the SA and expects the host to provide the sequence number through the input buffer as part of the header.

The following tables provide details of sequence number processing.

Table 44-17: Sequence Number Generation and Verification Control (Outbound)

Header Processing SA_CMD0[19]	Anti-Replay Service SA_CMD1[29]	Description
Outbound		
1	1	Sequence number generation (increment)
1	1	Sequence number overflow check (2^{32}–1) to zero for IPsec, (2^{48}–1) to zero for DTLS and (2^{64}–1) to zero for Extended SSL/TLS.
1	0/1	Sequence number update in SA
0/1	0/1	Extended sequence number update in SA

Table 44-18: Sequence Number Generation and Verification Control (Inbound)

Header Processing SA_CMD0[19]	Anti-Replay Service SA_CMD1[29]	Description
Inbound		
1	1	Sequence number verification (check against sequence number and sequence number mask in SA). Applicable only for IPsec and DTLS.
1	0/1	Sequence number update in SA, except on authentication error
1	1	Sequence number mask update in SA. Applicable only for IPsec and DTLS.
0/1	0/1	Extended sequence number update in SA

Table 44-19: Header Processing Enabled, Anti-replay Service Enabled

	IPsec ESP	Ext. SSL	Ext. TLS	DTLS
Header processing enabled, anti-replay service enabled

PKTE Architectural Concepts

The following descriptions provide details on the functional blocks within the security packet engine.

Packet Engine

The packet engine contains symmetric cipher and hash engines. It is optimized to off-load intensive cryptographic operations from the host processor. It can perform parallel and pipelined encryption and hashing operations, reducing the latency, and processing time for packets that need both operations applied. The processor core provides the command information and packet data for the packet engine. The packet engine can run autonomously, using its local DMA controller to perform DMA transfers across the main bus to access the memory of the processor core. The DMA process incorporates flow-control to guarantee proper data flow. Two elements provide the command information that defines the processing for each packet:

- Command descriptor
- SA record

When the packet engine finishes the operation, it updates the SA record, when needed, and provides a result descriptor.

The packet engine has four different modes of operation. The modes give the processor core various levels of control over the command information and packet data transfers to and from the packet engine.

- Autonomous Ring Mode (ARM)
- Target Command Mode (with and without result descriptor ring) (TCM)
- Direct Host Mode (DHM)

Input/Output FIFO Buffers

The data for the packet engine is buffered at both input and output. These buffers decouple the DMA I/O process from the cipher and hash modules inside the packet engine. This functionality enables large DMA burst sizes and allows the crypto-engines to process data during I/O latency periods. Data moves automatically from the input buffer through the encryption and hash engines to the output buffer. If the output buffer is full, the process stops until the data is read and space is available in the output buffer. Each buffer is a 256-byte dual-port RAM.

Parallel Operations

The hash functionality and encrypt or decrypt functionality are tightly coupled. Operations that combine both hash and encrypt or decrypt functions are available to reduce processing time for data that must apply both. For hash-then-decrypt operations, the packet engine performs parallel execution of both functions from the input buffer. For encrypt-then-hash operations, the processing is pipelined from the input buffer to provide minimum latency. An offset can be specified between the start of the hashing and the start of the encryption to support protocols such as IPSec and SRTP.

DMA Controller

The packet engine uses a high-performance DMA controller for autonomous data transfers for:

- Command descriptor reads
- SA record and state record reads
- Packet data read
- Result packet writes
- SA record and state record writes
- Result descriptor writes

Interrupt Controller

The packet engine includes an interrupt controller that, under programmable configuration control, can generate an interrupt on completion of certain operations. Individual interrupts can be masked and cleared. The interrupt registers show both the raw and masked interrupt status of the internal interrupts. The processor core can use interrupts, together with their associated threshold settings, to optimize the overall packet processing in the system. One interrupt can inform the processor core that the input side of the packet engine is almost empty to avoid a stall-on-empty condition. One interrupt can inform the host that the output side is almost full to avoid a stall-on-full condition. The controller uses several interrupts to inform the processor core about errors inside the packet engine. All available interrupts are combined into a single output port as either a level- or edge-active programmable interrupt output.

Clock Controller

The packet engine includes a clock controller that generates clock enable signals. A clock manager external to the packet engine uses the clock enable signals to switch the clocks to modules in the packet engine, reducing power consumption. The power saving can be significant, depending on the crypto-operation and the idle time of the packet engine. The clock controller generates the clock enable signals dynamically depending on the current crypto-operation. A clock control register provides the processor core the possibility to override this dynamic process.

PKTE Operating Modes

The packet engine can be configured in one of three command modes. For all modes the packet engine can generate an interrupt at completion of packet processing:

- Autonomous Ring Mode (ARM). The core prepares descriptors in the CDR and then initiates a descriptor fetch by triggering the packet engine. When a packet operation is complete, the packet engine writes the result descriptor out into a ring in host memory using the system master bus interface.
- Target Command Mode (TCM). The core directly writes the command descriptors to the packet command register set to initiate a packet operation. This process eliminates an extra DMA transfer to fetch a descriptor, but requires the core to synchronously initiate packet processing. This mode can be configured both without RDR or with RDR. In the latter case, the packet engine writes the result descriptor out into the RDR in host memory using the system master bus interface.
- Direct Host Mode (DHM). The core has full control over the packet engine and uses the system slave bus interface. The core provides all the command descriptors, SA record and state record, and packet input data. When the packet engine completes processing, the core must read the packet output data, the SA record, the state record, and the result descriptors.

Autonomous Ring Mode (ARM)

The *Autonomous Ring Mode* allows the packet engine and the host processor to operate asynchronously. A queue of multiple packets in the host processor memory can be processed continuously to provide the highest possible throughput. The packet engine autonomously fetches the command descriptor, the SA record, and optionally the state record and the input data from host processor memory. After the packet engine finishes processing, it autonomously writes the output data, updates the SA record and state record and writes the result descriptor in the host processor memory. It accesses the host processor memory through DMA read transfers across the system bus master.

This mode uses both command descriptor ring (CDR) and result descriptor ring (RDR).

Physically the CDR, RDR, SA record, source packet, and result packet can all be in different memories depending on the system memory architecture. The host processor writes command descriptors to the CDR in host processor memory. Then, it writes to the `PKTE_CDSC_INCR` register with the number of command descriptors that it prepared in the CDR. This write to the `PKTE_CDSC_INCR` register is the trigger for the packet engine to fetch the command descriptors sequentially from the CDR. When a command descriptor is fetched and written to the internal packet command register set, the descriptor is validated. If the ownership bits are set for the packet engine and the command is valid, processing starts. If not, that command is discarded and a result descriptor is written to the RDR with the error code *invalid command descriptor*. In this mode, the host processor can set a threshold on the CDR and enable an associated interrupt. The packet engine generates an interrupt when the number of command descriptors in the CDR is equal or below the threshold value.

The SA record and state record that contains the crypto context information are stored in a memory area. The packet engine autonomously accesses the memory area through DMA transfers across the system bus master. Also, the source packet and result packet are stored in a memory area that the packet engine autonomously accesses through the same bus master interface.

After decoding the command descriptor, the packet engine fetches the SA record and then, optionally, the state record.

Then, the source packet is fetched and stored in the input buffer. Packets less than the size of the input buffers are fetched entirely at once. Larger packets are fetched in parts that completely fill the input buffer. The packet engine initiates a new fetch each time the number of empty spaces in the input buffer reaches its threshold value. When the first packet data is available in the input buffer, the crypto engines start processing the data. After processing, the crypto engines write the result packet to the output buffer.

The packet engine writes the result packet from the output buffer to host processor memory when the number of bytes in the output buffer reaches its threshold value. Packets less than the threshold value are written entirely at once. Larger packets are written in parts that completely empty the output buffer

The source packet data fetching, data processing, and result packet data writing are parallel processes that continue until the last result packet is written to host processor memory. Then, the packet engine optionally writes the SA record and the state record to update the crypto context information. As a final step, the packet engine writes the result descriptor to the RDR. The host processor must either poll the RDR or wait for an interrupt from the packet engine to determine when packet processing is complete.

Target Command Mode (TCM)

This mode provides a synchronous interface between the processor core and the packet engine. The Command Descriptor Ring (CDR) is disabled and the processor core initiates packet processing by writing the command descriptor directly to the internal command descriptor MMRs of the packet engine. The Result Descriptor Ring (RDR) is optional.

- For `PKTE_CFG.MODE` =01, the RDR is disabled and the processor core reads the result descriptor directly from the internal result descriptor register set for the packet engine.
- For `PKTE_CFG.MODE` =10, the RDR is enabled and stored in a memory area that the packet engine can access through its master bus interface as in autonomous ring mode.

In target command mode, the packet engine autonomously fetches the SA record, state record, source packet data as in autonomous ring mode. Also, as in ARM, after processing, the packet engine updates state fields of the SA record and state record in the host processor memory.

Direct Host Mode (DHM)

This mode provides a synchronous interface between the processor core and the packet engine. The packet engine is under full control of the processor core. The host processor writes the command descriptors, SA record, and state record directly to the packet engine registers. Then, the processor core writes the source packet data into the input buffer. When processing is complete, the processor core reads back the result packet data from the output buffer.

Finally, it reads the result descriptor, the updated SA record, and state record directly from the packet engine registers.

PKTE Event Control

The following section provides information about interrupts in the PKTE module.

PKTE Interrupt Signals

The Packet Engine has an internal Interrupt Controller with 9 interrupt sources. There are 7 registers associated with the interrupt controller:

1. Interrupt Unmasked Status - `PKTE_IUMSK_STAT`
2. Interrupt Mask Status - `PKTE_IMSK_STAT`
3. Interrupt Clear Register - `PKTE_INT_CLR`
4. Interrupt Enable Register - `PKTE_INT_EN`
5. Interrupt Mask Disable - `PKTE_IMSK_DIS`
6. Interrupt Mask Enable - `PKTE_IMSK_EN`
7. Interrupt Configuration - `PKTE_INT_CFG`

The ***Packet Engine Interrupt Controller Block Diagram*** shows the blocks of the interrupt controller.

PKTE_IMSK_STAT
MASK LOGIC
PKTE_IMSK_STAT
OR LOGIC
OUT_IRQ REGISTER
OUT_IRQ

Figure 44-2: Packet Engine Interrupt Controller Block Diagram

All of the interrupt sources are pulse or level events in their native form.

These interrupts are captured and stored at their unmasked and masked status in their respective `PKTE_IUMSK_STAT` and `PKTE_IMSK_STAT` registers. This allows the host processor to read the status of any interrupt source either before or after the mask is applied.

The `PKTE_INT_EN` register provides a mask to select what interrupt source are enabled to the output interrupt request. Writing a one to the `PKTE_INT_CLR` register resets both the masked and unmasked interrupt.

The `PKTE_IMSK_EN` and `PKTE_IMSK_DIS` registers can be set to enable and disable individual interrupts respectively in the `PKTE_INT_EN` register. This avoids the need for read-modify-write operations from the host processor.

Ring Interrupts

Two interrupts are provided for efficient ring management: The CDR threshold interrupt (*cdrthrs*h) and the RDR threshold interrupt (*rdrthrsh*).

Command Descriptor Ring

The CDR threshold interrupt (cdrthrsh) is a level-based interrupt and connects to the threshold value in the `PKTE_RING_THRESH.CDRTHRSH` bit field. It enables the host processor to efficiently fill the CDR. The host processor writes command descriptors to the CDR with this interrupt masked until the CDR is full. Then the host processor enables the CDR threshold interrupt. When the interrupt is activated, the host processor clears the interrupt and it is guaranteed that it can put CDR threshold number of descriptors in the CDR.

Example Configuration:

```
PKTE_RING_CFG.RINGSZ=256,
PKTE_RING_THRESH.CDRTHRSH=224,
PKTE_INT_EN.CDRTHRSH=0 /*(IRQ disabled)*/
```

1. The host writes 8 Command Descriptors at once, then writes the `PKTE_CDSC_INCR` register to 8.
2. This is repeated until there are less than 8 empty entries in the CDR.
3. The fill level is now equal to he threshold (224)
4. The host enables the CDR threshold IRQ (`PKTE_INT_EN.CDRTHRSH=1`)
5. The packet engine processes packets and the fill level (`PKTE_CDSC_CNT` register) decreases.
6. Then the CDR threshold IRQ is activated as the fill level equals 224.
7. The host handles the interrupt, clears it and continues with step 1.

Result Descriptor Ring

The RDR threshold interrupt (rdrthrsh) is a level-based interrupt and connects to the threshold value in the `PKTE_RING_THRESH.RDRTHRSH` bit field and the timeout value in the RD timeout (`PKTE_RING_THRESH.RDTO`) bit field. It enables the host processor to efficiently empty the RDR. The timeout reminds the host processor that when the threshold kicks in result descriptors stay long in the RDR and must be processed to reduce latency. The timeout counts when the ring is not empty, regardless of the fill level and restarts when the host processor writes the `PKTE_RDSC_CNT` register. Initially the host processor enables the RDR threshold interrupt. When the interrupt is activated the host processor reads result descriptors until the RDR is empty or contains less than the `PKTE_RING_THRESH.RDRTHRSH` number of descriptors.

Example Configuration:

```
PKTE_RING_CFG.RINGSZ=256,
PKTE_RING_THRESH.RDRTHRSH=32, timeout=1ms
PKTE_INT_EN.RDRTHRSH=1     /*(IRQ enabled)*/
```

1. The Packet Engine writes the Result Descriptor, timeout counter starts.
2. The Packet Engine writes 32 more Result Descriptors, fill level (`PKTE_RDSC_CNT` register) increases to 33.
3. The fill level exceeds threshold within 1ms, the RDR threshold IRQ is activated.
4. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the `PKTE_RDSC_DECR` register with 8. The write to the `PKTE_RDSC_DECR` register restarts the timeout counter. The fill level is now under the threshold but there are still 25 descriptors left.
5. The Packet Engine writes 8 more Result Descriptors, fill level increases to 33.
6. The fill level exceeds threshold within 1 ms, the RDR threshold IRQ is activated.
7. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the `PKTE_RDSC_DECR` register with 8. The write to the `PKTE_RDSC_DECR` register restarts the timeout counter. The fill level is now under the threshold but there are still 25 descriptors left.
8. After 1 ms, the timeout counter interrupt is activated.
9. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the `PKTE_RDSC_DECR` register with 8. This is repeated until there are less than 8 full entries in the RDR. The fill level is now under the threshold and the RDR threshold IRQ interrupt is inactive. Each write to the `PKTE_RDSC_DECR` register restarts the timeout counter.

PKTE Programming Model

The host processor must always follow a pre-defined sequence of five phases required by the packet engine on a per packet basis when using direct host mode. The following sections describe the five phases.

Phase 1. Write the Command Descriptor

1. Write the first command descriptor word with status and control information to the `PKTE_CTL_STAT` register.
2. Optionally, write the user ID to the `PKTE_USERID` register.
3. Write the last descriptor word to the `PKTE_LEN` register.
4. Write the value 0x1 to the `PKTE_CDSC_CNT` register. This opertion triggers the packet engine to validate the command descriptor. If the command descriptor is invalid, an error is generated. (See the `PKTE_CTL_STAT` section in the Register Descriptions). If the command descriptor is valid, the packet engine waits for an `PKTE_SA_RDY` register write.

Phase 2. Write the State Registers, (ARC4 Buffer) and SA Registers

All required fields of the SA record and state record must be written. The fields required depend on the operation. The last field to be written is the `PKTE_SA_RDY` register. This register triggers the packet engine to start processing.

1. Write the required state record fields.
    - ARC4 state
    - IV
    - Digest count
    - State digest
2. Write the required SA record data.
3. To complete the SA record and state record, write the `PKTE_SA_RDY` register.

Phase 3. Write the Source Packet Data and Read Result Packet Data

The packet engine has input and output buffers. If a source packet is smaller than the size of the input buffer, then the packet can be written in one part. Otherwise, it must be written in multiple parts. The same applies to the output data. If the result packet size is smaller than the size of the output buffer, then the packet can be read in one part. Otherwise, it must be read in multiple parts.

> **NOTE:** An outbound packet that is smaller than the size of the input buffer can increase in size due to padding and does not always fit in the output buffer. Conversely, an inbound packet that is larger than the size of the input buffer can decrease in size, and due to de-padding, can fit in the output buffer. If the input buffer becomes empty or the output buffer becomes full, the engine stalls.

Two following steps describe different situations:

- Source packet smaller than the size of the input buffer, start at step 1.
- Source packet larger than the size of the input buffer, start at step 3.

The host processor must follow these steps:

1. Write the source packet data. Write the full source packet to the input buffer. Go to step 4.
2. Write the input buffer count register (`PKTE_INBUF_CNT`) with the number of valid bytes that are written to the input buffer. This value must correspond to the value in the`PKTE_LEN.TOTLEN` field of the command descriptor rounded up to the next multiple of 4 bytes. Go to step 5 to check the packet engine status.
3. Write part of the source packet data. The `PKTE_STAT.IBUFEMPTYCNT` field indicates the amount of free space in the input buffer. Programs write the number of bytes determined by the setting in the `PKTE_BUF_THRESH` register. Write the (partial) source packet to the input buffer. The host processor must resume where it ended the previous write operation. Do not write more than the buffer size at once. Go to step 4.

4. Write the PKTE_INBUF_CNT register with the number of valid bytes written to the input buffer. Go to step 5 to check the packet engine status.
5. Check packet engine status. Wait for an interrupt or poll the PKTE_STAT register for any of the following conditions:
   - Condition 1 - An error interrupt or any of the bits [7:5] in the PKTE_STAT register becomes active to indicate a packet processing error. Depending on the type of error, the host processor must take appropriate action. Usually, the result packet is not valid after a processing error has occurred. Go to phase 5 to read the result descriptor.
   - Condition 2 - An operation done interrupt or the PKTE_STAT.OPDN bit becomes active (the packet engine completed processing). Go to step 8 to read the remaining output data.
   - Condition 3 - An output buffer threshold interrupt or the PKTE_STAT.OBUFREQ bit becomes active. Go to step 6 to read a block of output data.
   - Condition 4 - An input buffer threshold interrupt or the PKTE_STAT.IBUFREQ bit becomes active. Go to step 3 to write a block of input data.
6. Read part of the output data. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of bytes in the output buffer. This value is rounded up to full words. Programs read the number of bytes indicated in the PKTE_BUF_THRESH register. Read the (partial) output packet from the output buffer. The host processor must resume where it ended the previous read operation. Do not read more than the input buffer size at once. Go to step 7.
7. Write the PKTE_OUTBUF_CNT register with the number of valid bytes read from the output buffer. Go to step 5 to check the packet engine status.
8. Read the remaining output data. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of bytes in the output buffer. This value is rounded up to words. Read the (partial) packet output data from the output buffer. The host processor must resume where it ended the previous read operation. Go to step 9.
9. Write the PKTE_OUTBUF_CNT register with the number of valid bytes read from the output buffer. Go to phase 4.

Phase 4. Read the Result Descriptor

1. Read the first result descriptor word from the PKTE_CTL_STAT.
2. Optionally read the user ID from the PKTE_USERID register.
3. Read the last result descriptor word from the PKTE_LEN register.
4. Write the value 0x1 to the PKTE_RDSC_DECR register. This operation allows the packet engine to accept new command descriptors. Go to phase 5.

Phase 5. Read the SA Record and State Record

Depending on the operation, the SA record or state record is updated. Check the bit fields [23:16] in the `PKTE_CTL_STAT` register for the following conditions:

- Condition 1 - At least one error bit in the bit fields [23:16] of the `PKTE_CTL_STAT` register is set. Do not update the local host processor maintained version of the SA record and state record but take any required action.
- Condition 2 - None of the error bits in the bit fields [23:16] of the `PKTE_CTL_STAT` register is set, the packet is processed normally (without errors). Update the host processor maintained version of the SA record and state record with the result read from the packet engine registers:
  - ARC4 state
  - Sequence number
  - Sequence number mask
  - Result IV
  - Result digest count
  - Result digest

PKTE Mode Configuration

Before using the packet engine, it must be configured. The mode of the packet engine must be defined and the PRNG (if used) must be initialized.

Configure the packet engine in one of three command modes:

- Autonomous Ring Mode: `PKTE_CFG.MODE` =b'11
- Target Command Mode: `PKTE_CFG.MODE` =b'10
- Direct Host Mode: `PKTE_CFG.MODE` =b'00

PKTE Programming Concepts

The following sections provide conceptual information for programming the PKTE.

Packet Engine Descriptor

IMPORTANT: Depending on the mode, ARM, TCM, or DHM, the descriptor is either:

- in the memory of the host processor in the command descriptor ring, or
- written directly to the descriptor registers in the packet engine

References to descriptor registers are for either the register that is mirrored in the descriptor structure in memory or for the actual register itself.

Command descriptors are host-supplied commands that control the real-time operation of the packet engine. The packet engine returns result descriptors at the end of an operation that provide the status information to the host. The ***Command Descriptor Structure*** and the ***Result Descriptor Structure*** tables show these descriptors.

When the packet engine is configured for autonomous ring mode, command descriptors and result descriptors reside in a ring in host memory. Command descriptors are automatically fetched from the Command Descriptor Ring (CDR) through DMA into the command descriptor registers. When an operation is complete, the result descriptors are automatically read from the packet engine and through DMA to the Result Descriptor Ring (RDR).

When the packet engine is configured for direct host mode, the host processor manually writes the command descriptor directly to the internal command descriptor MMR set. When an operation is complete, the host processor manually reads the result descriptor directly from the result descriptor MMR set.

The target command mode is a combination of the direct host mode and the autonomous ring mode. The host processor writes the command descriptor directly to the internal command descriptor register set. When an operation is complete there are two options.

1. The host processor can read the result descriptor directly from the result descriptor registers.
2. The result descriptors reside in a ring in host memory and the result descriptors are automatically DMA'd from the packet engine to the RDR.

When the host processor writes a command descriptor to the command descriptor registers, the packet engine is triggered when the host processor updates the `PKTE_CDSC_CNT` register. This functionality guarantees that all fields in the command descriptor are valid before the command is executed.

Descriptor Processing

This section describes the functional steps of the packet engine while processing the command descriptors.

Descriptor Ring Configuration

At initialization, the host processor specifies the size of the Command Descriptor Ring (CDR). The Result Descriptor Ring (RDR) has the same size.

NOTE: In some configurations, these two rings overlay each other with the results written on top of the command descriptors. This configuration is called overlaid ring mode.

When the packet engine is configured and enabled, it fetches the descriptors from the CDR using system bus master reads.

Descriptor Ring Processing

To validate the descriptor exchange between the host processor and the packet engine, the ownership bits `PKTE_CTL_STAT.PERDY` and `PKTE_CTL_STAT.HOSTRDY` are used. One pair of ownership bits is in the first word of the descriptor (`PKTE_CTL_STAT`), and one pair is in the last word (`PKTE_LEN`). The ‘consumer’ of a descriptor must verify that both ownership pairs match to ensure that a race condition did not occur between one party writing and the other party reading the descriptor. A race condition can occur when a memory locking scheme is not used.

Each pair [`PKTE_CTL_STAT.PERDY`, `PKTE_CTL_STAT.HOSTRDY`] of ownership bits provide 3 states:

- b'00 = idle or null descriptor
- b'01 = host processor has written a descriptor in the CDR and passed ownership to the packet engine
- b'10 = packet engine processing complete: packet engine has written the descriptor in the RDR and passed ownership back to the host.
- b'11 = Reserved

At initialization, the host sets the entire CDR memory area to zero, when the CDR is used.

1. The host processor writes one or more command descriptors to the CDR. The host processor must set the `PKTE_CTL_STAT.HOSTRDY` bit to 1 and the `PKTE_CTL_STAT.PERDY` bit to 0 to indicate that ownership has passed to the packet engine. These bits are mirrored in the `PKTE_LEN` descriptor word.
2. The host processor must write the `PKTE_CDSC_INCR` register with the number of new valid command descriptors in the CDR.
3. The packet engine reads and validates one command descriptor.
4. The packet engine reads the SA record and state record, processes the packet and updates the SA record and state record.
5. If the rings are not overlaid and the `PKTE_CFG.ENCDRUPDT` bit is 1, the packet engine writes the result descriptor to the CDR with the `PKTE_CTL_STAT.HOSTRDY` bit set to 0 and `PKTE_CTL_STAT.PERDY` bit set to 1. These bits are mirrored in the `PKTE_LEN` descriptor word.
6. The packet engine writes the result descriptor to the RDR. The packet engine sets the `PKTE_CTL_STAT.PERDY` bit to 1 and the `PKTE_CTL_STAT.HOSTRDY` bit to 0 to indicate that the ownership has passed to the host. These bits are mirrored in the `PKTE_LEN` descriptor word.
7. The packet engine decrements the value in the `PKTE_CDSC_CNT` register. If the value is not zero, the packet engine reads with the next command descriptor (step 3).
8. The packet engine increments the value in the `PKTE_RDSC_CNT` register.
9. The host processor reads one or more result descriptors from the RDR and processes the results.
10. The host processor must write the `PKTE_RDSC_DECR` register with the number of processed result descriptors in the RDR.

Ownership of the Descriptor

The ownership of the command descriptor and result descriptor is set by ownership bits in the first and last word of the respective descriptor, in the `PKTE_CTL_STAT` register and the `PKTE_LEN` register. For the command descriptor, it is the processor core that sets the ownership to the packet engine. For the result descriptor, it is the packet engine that sets the ownership to the host processor.

The packet engine reads the ownership bits before processing, irrespective of the mode of the packet engine. The ownership bits are used to validate and identify the descriptor. When two separate rings are used, the packet engine can be programmed to clear the ownership bits of the command descriptors in the CDR so the host processor knows which descriptors are processed.

NOTE: This update of the ownership bits can be disabled in the `PKTE_CFG` register when the host processor actively counts the number of descriptors in the CDR to prevent ring wrapping.

Figure 44-3: Descriptor Rings in Autonomous Ring Mode

Description and Use of the SA Record and State Record Structure

The SA record is a packed structure that contains the remainder of the information needed by the packet engine to process a packet. Most of the information fields in the SA record, such as the key and encryption mode, are static for the lifetime of the association. The fields do not require frequent manipulation by the host processor. The SA record non-static fields are the sequence number and sequence number mask.

The SA record can have a corresponding state record that is used to save results from the current operations that can be used for future operations. The state record can hold the IV, the hash byte count, and the intermediate hash digest.

If an SA record is used for operations that use ARC4 processing in stateful mode, it has a corresponding ARC4 state record that holds the ARC4 State.

In this manual, the state record and the ARC4 state record are referred to as state record.

There is no practical limit to how many SA records and corresponding state records the packet engine can support.

In the autonomous ring mode and target command mode, once the packet engine has validated a command descriptor, it automatically fetches the SA record and optional state record. After processing, the packet engine updates the stateful fields in the SA record and state record in the host processor memory.

In direct host mode, after the descriptor is validated, the host must write the SA record directly into the internal registers of the packet engine. After processing, the host reads the stateful fields from the SA registers of the packet engine and saves them back to the SA record in the host processor memory.

SA Record Structure

The *SA Record Structure* table shows the structure for an SA Record. When using direct host mode, the corresponding elements are accessed directly with the registers. When using autonomous ring mode or target command mode, the SA Record is defined, configured and accessed in host memory.

Table 44-22: SA Record Structure

Word Offset	Description (name)	Use
0	PKTE_SA_CMD0[31:0]	SA Control word 0 (all operations)
1	PKTE_SA_CMD1[31:0]	SA Control word 1 (all operations)
2	PKTE_SA_KEY0[31:0]	Key word (DES, Triple-DES, AES-128/192/256, ARC4,)
3	PKTE_SA_KEY1[63:32]	Key word (DES, Triple-DES, AES-128/192/256, ARC4,)
4	PKTE_SA_KEY2[95:64]	Key word (Triple-DES, AES-128/192/256, ARC4,)
5	PKTE_SA_KEY3[127:96]	Key word (Triple-DES, AES-128/192/256, ARC4,)
6	PKTE_SA_KEY4[159:128]	Key word (Triple-DES, AES-192/256)
7	PKTE_SA_KEY5[191:160]	Key word (Triple-DES, AES-192/256)
8	PKTE_SA_KEY6[223:192]	Key word (AES-256)
9	PKTE_SA_KEY7[255:224]	Key word (AES-256)
10	PKTE_SA_IDIGEST0[31:0]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
11	PKTE_SA_IDIGEST1[63:32]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
12	PKTE_SA_IDIGEST2[95:64]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
13	PKTE_SA_IDIGEST3[127:96]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
14	PKTE_SA_IDIGEST4[159:128]	Inner Hash digest (Basic Hash and HMAC with SHA-1, SHA-224, SHA-256)
15	PKTE_SA_IDIGEST5[191:160]	Inner Hash digest (Basic Hash and HMAC with SHA-224, SHA-256)
16	PKTE_SA_IDIGEST6[223:192]	Inner Hash digest (Basic Hash and HMAC with SHA-224, SHA-256)
17	PKTE_SA_IDIGEST7[255:224]	Inner Hash digest (Basic Hash and HMAC with SHA-256)
18	PKTE_SA_ODIGEST0[31:0]	Outer Hash digest (HMAC with MD5,, SHA-1, SHA-224, SHA-256)
19	PKTE_SA_ODIGEST1[63:32]	Outer Hash digest (HMAC with MD5,, SHA-1, SHA-224, SHA-256)
20	PKTE_SA_ODIGEST2[95:64]	Outer Hash digest (HMAC with MD5,, SHA-1, SHA-224, SHA-256)

Table 44-22: SA Record Structure (Continued)

Word Offset	Description (name)	Use
21	PKTE_SA_ODIGEST3[127:96]	Outer Hash digest (HMAC with MD5,, SHA-1, SHA-224, SHA-256)
22	PKTE_SA_ODIGEST4[159:128]	Outer Hash digest (HMAC with SHA-1, SHA-224, SHA-256)
23	PKTE_SA_ODIGEST5[191:160]	Outer Hash digest (HMAC with SHA-224, SHA-256)
24	PKTE_SA_ODIGEST6[223:192]	Outer Hash digest (HMAC with SHA-224, SHA-256)
25	PKTE_SA_ODIGEST7[255:224]	Outer Hash digest (HMAC with SHA-256)
26	PKTE_SA_SPI[31:0]	SPI (IPsec), Type[23:16] / Version [15:0] (SSL, TLS, DTLS)
27	PKTE_SA_SEQNUM0[31:0]	Sequence Number (IPsec, SSL, TLS, DTLS with Header Processing)
28	PKTE_SA_SEQNUM1[63:32]	
29	PKTE_SA_SEQNUM_MSK0[31:0]	Sequence Number Mask (IPsec, DTLS inbound with Header Processing)
30	PKTE_SA_SEQNUM_MSK1[63:32]	
31	PKTE_SA_NONCE[31:0] / PKTE_SA_READY	Nonce value (AES-CTR, AES-ICM)/ARC4, i & j pointers (ARC4,)/SA ready indicator (Direct Host Mode)

Some of these fields may be updated by the packet engine. These include:

- PKTE_SA_SEQNUM0
- PKTE_SA_SEQNUM1
- PKTE_SA_SEQNUM_MSK0
- PKTE_SA_SEQNUM_MSK1

All the other fields remain unchanged.

SA State Structure

The security association state structure contains information that may be updated after each packet, such as the IV and the intermediate hash result. The ***SA State Structure*** table shows the SA state structure and usage. In direct host mode, the elements are accessed directly using the PKTE registers. In target command mode and autonomous ring mode, this structure is defined and updated in host memory.

Table 44-23: SA State Structure

Word Offset	Description (name)	Use
0	PKTE_STATE_IV0[31:0]	Initialization Vector (DES, Triple DES, AES)

Table 44-23: SA State Structure (Continued)

Word Offset	Description (name)	Use
1	PKTE_STATE_IV1[63:32]	Initialization Vector (DES, Triple DES, AES)
2	PKTE_STATE_IV2[95:64]	Initialization Vector (AES)
3	PKTE_STATE_IV3[127:96]	Initialization Vector (AES)
4	PKTE_STATE_BYTE_CNT0[31:0]	Current hash byte count (MD5, SHA-1, SHA-224, SHA-256)
5	PKTE_STATE_BYTE_CNT1[63:32]	Current hash byte count (MD5, SHA-1, SHA-224, SHA-256)
6	PKTE_STATE_IDIGEST0[31:0]	Inner Hash digest (mirror of PKTE_SA_IDIGEST0)
7	PKTE_STATE_IDIGEST1[63:32]	Inner Hash digest (mirror of PKTE_SA_IDIGEST1)
8	PKTE_STATE_IDIGEST2[95:64]	Inner Hash digest (mirror of PKTE_SA_IDIGEST2)
9	PKTE_STATE_IDIGEST3[127:96]	Inner Hash digest (mirror of PKTE_SA_IDIGEST3)
10	PKTE_STATE_IDIGEST4[159:128]	Inner Hash digest (mirror of PKTE_SA_IDIGEST4)
11	PKTE_STATE_IDIGEST5[191:160]	Inner Hash digest (mirror of PKTE_SA_IDIGEST5)
12	PKTE_STATE_IDIGEST6[223:192]	Inner Hash digest (mirror of PKTE_SA_IDIGEST6)
13	PKTE_STATE_IDIGEST7[255:224]	Inner Hash digest (mirror of PKTE_SA_IDIGEST7)

ARC4 State Structure

The ***ARC4 State Structure*** table describes the state structure used with ARC4. When using the PKTE in direct host mode, these fields are accessed with the registers, starting at the value in the `PKTE_ARC4STATE_BUF` register. When using the PKTE in autonomous ring mode or target command mode, these fields are defined and accessed in a structure in host memory.

Table 44-24: ARC4 State Structure

Word Offset	Description (name)*1	Use
0	PKTE_ARC4_STATE0[3:0]*2	ARC4 (Basic, SSL and TLS)
1	PKTE_ARC4_STATE1[7:4]	
...	...	
62	PKTE_ARC4_STATE2[251:248]	
63	PKTE_ARC4_STATE3[255:252]	

*1 The indices in these fields indicate bytes.

*2 There are no corresponding named registers for these fields. PKTE_ARC4_STATE0 corresponds to `PKTE_ARC4STATE_BUF` and PKTE_ARC4_STATE1 corresponds to the 32-bit register following `PKTE_ARC4STATE_BUF` and so on.

Configuring Operations in the PKTE

The operation (cipher, hash function, and others) that the PKTE performs is configured primarily in the `PKTE_SA_CMD0` register. The following sections include a series of tables to help configure the least significant 16 bits of the `PKTE_SA_CMD0` register. These fields include:

- The operation code field (`PKTE_SA_CMD0.OPCD`)
- The direction field (`PKTE_SA_CMD0.DIR`)
- The operation group field (`PKTE_SA_CMD0.OPGRP`)
- The padding type (`PKTE_SA_CMD0.PADTYPE`)
- The cipher selection (`PKTE_SA_CMD0.CIPHER`)
- The hash selection (`PKTE_SA_CMD0.HASH`)

Basic Operations and Decoding

Table 44-25: Basic Operation Decoding

Error Code Description

The `PKTE_CTL_STAT` register is used to configure the packet engine for processing in Direct Host Mode (DHM) or Target Command Mode (TCM). The `PKTE_CTL_STAT` structure element in memory is used when the packet engine is configured for Autonomous Ring Mode (ARM). In both cases, when an operation is started, errors are reported in the status field (bits [23:16]) of this register or structure element. The ***Extended Error Codes - Status Encoding*** table provides a guide on how to decipher the meaning of the bits that are set when an error occurs.

Extended Error Codes

The following table provides information about the extended errors associated with the PKTE module.

Table 44-28: Extended Error Codes - Status Encoding

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b0000_0000	0x00	NA	Successful completion. No errors occurred during processing of the packet.	Packet fully processed
0b----_---1	0x-1	NA	Authentication Error. For an inbound IPsec ESP operation, the Integrity Check Value (ICV) does not match the computed value. For an inbound SRTP operation, the authentication tag does not match the computed value. For a basic SSL/TLS, Extended SSL/TLS or DTLS operation the Message Authentication Code (MAC) does not match the computed value.	Packet fully processed
0b----_--1-	0x-2	NA	Pad Verify Error. For inbound operations that use pad type Constant TLS, IPsec or PKCS#7, the decrypted pad does not match the expected values for the selected pad type.	Packet fully processed
0b----_-1--	0x-4	NA	Sequence Number Error. For an inbound IPsec or DTLS operation, there was a fault in the Anti-Replay Sequence Number. For an outbound IPsec packet, the sequence number overflows; count is 2^{32}– 1 and increments to 0. For an outbound DTLS operation, the sequence number overflows; count is 2^{48}– 1 and increments to 0. For an outbound SSL or TLS operation, the sequence number overflows; count is 2^{64}– 1 and increments to 0.	Packet fully processed
0b0000_1---	0x08	1	System Bus error. The master bus interface generates an error due to ERROR response from system slave. The slave bus interface generates an error due to request for non-word (32-bit) access.	Packet is aborted. The host must reject the packet and apply a hardware reset to the system.
0b0001_1---	0x18	2	Invalid Command Descriptor Error. The ownership bits in the command descriptor are not set to the packet engine, after the `PKTE_CDSC_CNT` register is incremented.	Command descriptor is ignored, no packet is processed. The packet must be re-queued or discarded.
0b0010_1---	0x28	3	Invalid Crypto Operation Error. A reserved operation is selected.	The SA record is ignored, no packet is processed. The packet must be re-queued or discarded.

Table 44-28: Extended Error Codes - Status Encoding (Continued)

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b0011_1---	0x38	4	Invalid Crypto Algorithm Error. A reserved cipher is selected, refer to `PKTE_SA_CMD0.CIPHER`. A reserved hash is selected, refer to `PKTE_SA_CMD0.HASH`.	The SA record is ignored, no packet is processed. The packet must be re-queued or discarded.
0b0100_1---	0x48	5	SPI Error. On an inbound packet, the 32-bit SPI value in the packet does not match the value in the SA while header processing is enabled. Note: A failure caused by an SPI mismatch, in general should not occur because the host checks the SPI and does not send an incorrect SPI to the packet engine.	Packet is fully processed. The host must reject the packet.
0b0101_1---	0x58	3	Zero Length Error. The packet length defined in the command descriptor `PKTE_LEN.TOTLEN` is zero, which is illegal.	Packet command is ignored, no packet processed. The host must reject the packet.
0b0110_1xxx	0x68	6	Invalid Packet Length Error. For Basic Encrypt-Hash and Hash-Decrypt operations: `PKTE_LEN.TOTLEN` < Hash/Encrypt Offset For IPsec ESP inbound operations: `PKTE_LEN.TOTLEN` < ICV length or `PKTE_LEN.TOTLEN` is non-4 byte aligned For SRTP inbound operations: `PKTE_LEN.TOTLEN` ≤ IV (opt.) + Bypass Offset + ROC For SSL inbound operations: `PKTE_LEN.TOTLEN` ≤ 1 or packet length > 65535 bytes (SSL packet-bypass length) For TLS and DTLS inbound operations: `PKTE_LEN.TOTLEN` ≤ 13 or payload length > 65535 bytes (data to be hashed) Note: For IPsec ESP the ICV is stripped before the length is checked.	Packet processing is aborted. Result packet length is zero. The host must reject the packet and apply a software reset of the packet engine.

Table 44-28: Extended Error Codes - Status Encoding (Continued)

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b0111_1xxx	0x78	7	Block Size Error. The length of the inbound packet defined in the Command Descriptor `PKTE_LEN.TOTLEN` is not a multiple of the DES or AES block cipher length. For outbound packets the size is always automatically aligned (padded) to the correct block size. The hashed packet length is not a multiple of the hash block size for intermediate hash operation. For a final hash operation no error is generated. Note: For IPsec ESP operations the ICV is stripped before the block size is checked.	Packet is fully processed. The host must reject the packet.
0b1000_1xxx	0x88	8	Processing Error. The number of bytes in the input buffer is more than defined in the `PKTE_LEN.TOTLEN` field. The number of bytes written to the output buffer is less than processed in the datapath.	Packet processing aborted. Result packet length is zero. The host must reject the packet and apply a software reset.
0b1010_1xxx 0b1111_1xxx	Reserved			

Number Format

When dealing with cryptographic functions, data and keys are large vectors. For instance, AES supports keys of sizes 128, 192, and 256 bits. When a key needs to be loaded or read, multiple 32-bit key registers are used, namely `PKTE_SA_KEY[n]` registers. The first key register `PKTE_SA_KEY[n]`0 holds bits 31:0, and `PKTE_SA_KEY[n]`1 holds the next thirty two bits 63:32, and so on.

Generally, for large vectors defined as Byte0, Byte1, Byte2, Byte3 and so on, the values are stored in the PKTE registers as PKTE_REG0 = Byte3Byte2Byte1Byte0, followed by PKTE_REG1 = Byte7Byte6Byte5Byte4 and so on.

PKTE Programming Examples

Use these examples to extend your understanding of PKTE features, operating modes, event control, and programming modes.

Calculating SHA in Direct Host Mode

This section describes how to configure the packet engine to calculate a hash digest using one of supported SHA algorithms in direct host mode. This configuration follows the procedure outlined in the *PKTE Programming Model* section.

1. Configure the packet engine for direct host mode by setting the `PKTE_CFG.MODE` bit =0

2. Set the ownership back to the packet engine to process a command descriptor by setting the `PKTE_CTL_STAT.PERDY` bit =0 and the `PKTE_CTL_STAT.HOSTRDY` bit =1.
3. Set the `PKTE_CTL_STAT.HASHFINAL` bit to indicate this command descriptor handles all the input data for the hash calculation. This configuration is needed for the packet engine because the last block requires special handling (see FIPS 180-4 for details).
4. Set size of the input data in bytes in the `PKTE_LEN.TOTLEN` bit field.
5. Also set the `PKTE_LEN.PEDONE` bit =0 and the `PKTE_LEN.HSTRDY` bit =1. These bits must be the same as the `PKTE_CTL_STAT.PERDY` and `PKTE_CTL_STAT.HOSTRDY` bits to guarantee ownership.
6. Set the `PKTE_CDSC_CNT` register =1 to trigger the packet engine to start validating the command descriptor. In this case, the `PKTE_CTL_STAT`, `PKTE_LEN` and `PKTE_CDSC_CNT` registers are the only command descriptor registers modified.
7. Configure the `PKTE_SA_CMD0` and `PKTE_SA_CMD1` registers to define the operation. For an SHA, set the `PKTE_SA_CMD0.OPCD` bit field =0b011 for hash operation and the `PKTE_SA_CMD0.OPGRP` bit field =0b00 for basic operation.
8. Select the specific SHA function using the `PKTE_SA_CMD0.HASH` bit field as follows.
   - For SHA-1, `PKTE_SA_CMD0.HASH` =0b0001
   - SHA-224, `PKTE_SA_CMD0.HASH` =0b0010
   - for SHA-256, `PKTE_SA_CMD0.HASH` =0b0011
9. Depending on the SHA selected, the appropriate digest length must be chosen for the `PKTE_SA_CMD0.DIGESTLEN` bit field as follows.
   - For SHA-1, `PKTE_SA_CMD0.DIGESTLEN` =0b0101 (5 words)
   - For SHA-224, `PKTE_SA_CMD0.DIGESTLEN` =0b0111 (7 words)
   - For SHA-256, `PKTE_SA_CMD0.DIGESTLEN` =0b1000 (8 words)
10. The SHA specifies initial constants. These constants can be pre-loaded or read from memory. In this example, by setting the `PKTE_SA_CMD0.HASHSRC` bit field =0b11, the packet engine provides the correct initial constants depending on the SHA chosen.
11. Next, set the `PKTE_SA_CMD1.CPYDGST` bit =1 and `PKTE_SA_CMD1.CPYPAD` bit =1 to move the result to the output buffer of the packet engine at the `PKTE_DATAIO_BUF` location.
12. At this point, write to the `PKTE_SA_RDY` register with any value to trigger the operation.
13. Start writing the input to the data buffer of the packet engine starting at the `PKTE_DATAIO_BUF` location.
14. Write the `PKTE_INBUF_CNT` register with the length of the input rounded up to the next multiple of 4. For example, if the input length is 30 bytes, set this register to 32.
15. Poll the `PKTE_STAT` register to see if any errors occurred or if the operation completed without errors.

Once the operation is done, the digest is available in the packet engine data I/O buffer.

NOTE: The input data or message is input into the packet engine data buffer in big endian format while the result or digest is little endian format.

Performing AES Decryption in Direct Host Mode

This section describes how to configure the packet engine to decrypt using AES-128 in direct host mode. This configuration follows the procedure outlined in the *PKTE Programming Model* section.

1. Configure the packet engine for direct host mode by setting the `PKTE_CFG.MODE` bit =0
2. Start configuring the command descriptor registers. Set the ownership back to the packet engine to process a command descriptor by setting the `PKTE_CTL_STAT.PERDY` bit =0 and the `PKTE_CTL_STAT.HOSTRDY` bit =1.
3. Next, configure the `PKTE_LEN.TOTLEN` bit field with the size of the packet or message to decrypt. If the entire input message (cipher text) fits into the 256-byte data I/O buffer of the packet engine, the process can be done in one shot.
4. Set the `PKTE_LEN.PEDONE` bit =0 and the `PKTE_LEN.HSTRDY` bit =1. These bits must have the same setting as the `PKTE_CTL_STAT.PERDY` and `PKTE_CTL_STAT.HOSTRDY` bits to guarantee ownership.
5. Set the `PKTE_CDSC_CNT` register =1 to trigger the packet engine to start validating the command descriptor. In this case, the `PKTE_CTL_STAT`, `PKTE_LEN`, and `PKTE_CDSC_CNT` registers are the only command descriptor registers modified.
6. Next, configure the `PKTE_SA_CMD0` and `PKTE_SA_CMD1` registers to define the operation.
   - For a AES decrypt inbound cipher operation, set the `PKTE_SA_CMD0.OPCD` bit field =0b000 and the `PKTE_SA_CMD0.DIR` bit field =0b1.
   - Set the`PKTE_SA_CMD0.OPGRP` bit field =0b00 for basic operation.
   - To choose the AES cipher, set the `PKTE_SA_CMD0.CIPHER` bit field =0b0011. Set the `PKTE_SA_CMD0.HASH` bit field to 0b1111 to choose the NULL function.
7. Next, set the `PKTE_SA_CMD1.AESKEYLEN` bit field to select the appropriate key length. In this case, setting it to 0b10 select 128 bits. Also, set `PKTE_SA_CMD1.CIPHERMD` bit field to select the mode. In this case, setting it to 0b01 select CBC mode.
8. Continue configuring the Security Association (SA) record by loading the key in the `PKTE_SA_KEY[n]` registers.
9. Next load the initialization vector in the SA state registers (`PKTE_STATE_IV[n]`).
10. Finally, write anything in to the `PKTE_SA_RDY` register to trigger the operation.
11. The input data can now be written into the data I/O buffer starting at `PKTE_DATAIO_BUF`.

12. After the data is written, write the length (or next multiple of 4) into `PKTE_INBUF_CNT` register.
13. Poll `PKTE_STAT` to see if any errors occurred or if the operation completed without errors.

Once the operation is done, the result can be found in the same data I/O buffer.

ADSP-SC58x PKTE Register Descriptions

Security Packet Engine (PKTE) contains the following registers.

Table 44-29: ADSP-SC58x PKTE Register List

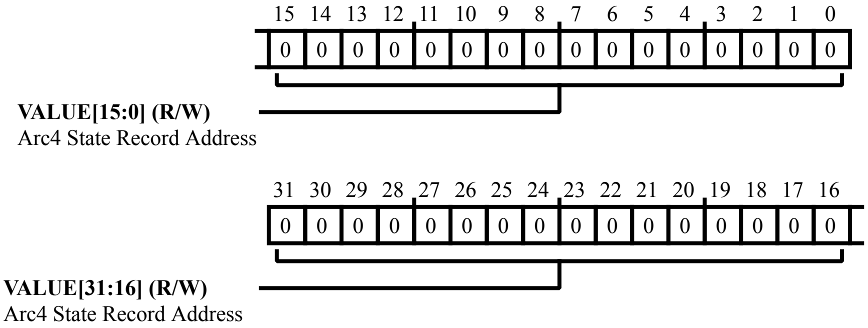
Name	Description
PKTE_ARC4STATE_ADDR	Packet Engine ARC4 State Record Address
PKTE_ARC4STATE_BUF	Starting Entry of 256-byte ARC4 State Buffer
PKTE_BUF_PTR	Packet Engine Buffer Pointer Register
PKTE_BUF_THRESH	Packet Engine Buffer Threshold Register
PKTE_CDRBASE_ADDR	Packet Engine Command Descriptor Ring Base Address
PKTE_CDSC_CNT	Packet Engine Command Descriptor Count Register
PKTE_CDSC_INCR	Packet Engine Command Descriptor Count Increment Register
PKTE_CFG	Packet Engine Configuration Register
PKTE_CLK_CTL	PE Clock Control Register
PKTE_CONT	PKTE Continue Register
PKTE_CTL_STAT	Packet Engine Control Register
PKTE_DATAIO_BUF	Starting Entry of 256-byte Data Input/Output Buffer
PKTE_DEST_ADDR	Packet Engine Destination Address
PKTE_DMA_CFG	Packet Engine DMA Configuration Register
PKTE_ENDIAN_CFG	Packet Engine Endian Configuration Register
PKTE_HLT_CTL	Packet Engine Halt Control Register
PKTE_HLT_STAT	Packet Engine Halt Status Register
PKTE_IMSK_DIS	Interrupt Mask Disable Register
PKTE_IMSK_EN	Interrupt Mask Enable Register
PKTE_IMSK_STAT	Interrupt Masked Status Register
PKTE_INBUF_CNT	Packet Engine Input Buffer Count Register
PKTE_INBUF_INCR	Packet Engine Input Buffer Count Increment Register
PKTE_INT_CFG	Interrupt Configuration Register
PKTE_INT_CLR	Interrupt Clear Register

Table 44-29: ADSP-SC58x PKTE Register List (Continued)

Name	Description
PKTE_INT_EN	Interrupt Enable Register
PKTE_IUMSK_STAT	Interrupt Unmasked Status Register
PKTE_LEN	Packet Engine Length Register
PKTE_OUTBUF_CNT	Packet Engine Output Buffer Count Register
PKTE_OUTBUF_DECR	Packet Engine Output Buffer Count Decrement Register
PKTE_RDRBASE_ADDR	Packet Engine Result Descriptor Ring Base Address
PKTE_RDSC_CNT	Packet Engine Result Descriptor Count Registers
PKTE_RDSC_DECR	Packet Engine Result Descriptor Count Decrement Registers
PKTE_RING_CFG	Packet Engine Ring Configuration
PKTE_RING_PTR	Packet Engine Ring Pointer Status
PKTE_RING_STAT	Packet Engine Ring Status
PKTE_RING_THRESH	Packet Engine Ring Threshold Registers
PKTE_SA_ADDR	Packet Engine SA Address
PKTE_SA_ARC4IJPTR	ARC4 i and j Pointer Register
PKTE_SA_CMD0	SA Command 0
PKTE_SA_CMD1	SA Command 1
PKTE_SA_IDIGEST[n]	SA Inner Hash Digest Registers
PKTE_SA_KEY[n]	SA Key Registers
PKTE_SA_NONCE	SA Initialization Vector Register
PKTE_SA_ODIGEST[n]	SA Outer Hash Digest Registers
PKTE_SA_RDY	SA Ready Indicator
PKTE_SA_SEQNUM[n]	SA Sequence Number Register
PKTE_SA_SEQNUM_MSK[n]	SA Sequence Number Mask Registers
PKTE_SA_SPI	SA SPI Register
PKTE_SRC_ADDR	Packet Engine Source Address
PKTE_STAT	Packet Engine Status Register
PKTE_STATE_ADDR	Packet Engine State Record Address
PKTE_STATE_BYTE_CNT[n]	State Hash Byte Count Registers
PKTE_STATE_IDIGEST[n]	State Inner Digest Registers
PKTE_STATE_IV[n]	State Initialization Vector Registers
PKTE_USERID	Packet Engine User ID

Packet Engine ARC4 State Record Address

The `PKTE_ARC4STATE_ADDR` register holds the start address of the SA ARC4 state record.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

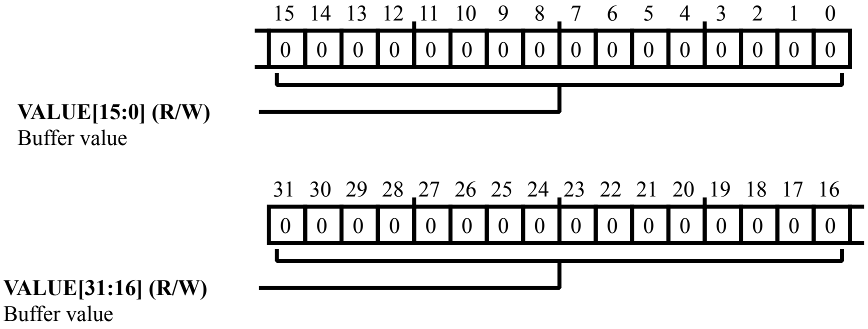
Table 44-30: PKTE_ARC4STATE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Arc4 State Record Address.

Starting Entry of 256-byte ARC4 State Buffer

The `PKTE_ARC4STATE_BUF` register is used to store the pre-processed key that initializes the ARC4 module. In direct host mode, before processing starts, the Host must write the ARC4 state, starting from the base address and increment the address pointer for each write. When processing completes the Host must read the ARC4 state and copy it to the local Host maintained state record. After a reset, a read from any address in the address range of the ARC4 buffer returns an undefined value.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

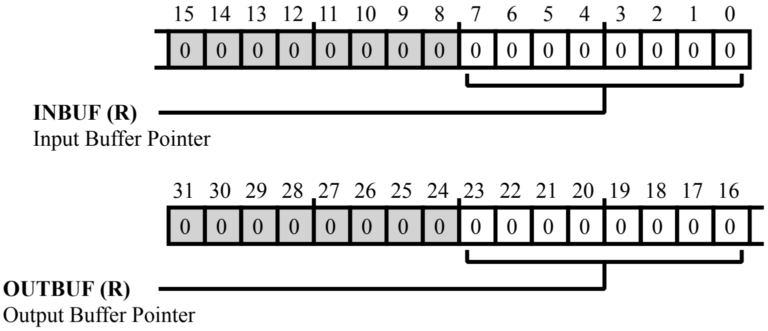
Table 44-31: PKTE_ARC4STATE_BUF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Buffer value. The `PKTE_ARC4STATE_BUF.VALUE` bit field stores the pre-processed key that initializes the ARC4 module.

Packet Engine Buffer Pointer Register

The PKTE_BUF_PTR register contains the offset of the next buffer address (entry) to be read or written by the packet engine. This register is used in direct host mode only.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
OUTBUF (R)
Output Buffer Pointer

Figure 44-6: PKTE_BUF_PTR Register Diagram

Table 44-32: PKTE_BUF_PTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/NW)	OUTBUF	Output Buffer Pointer. The PKTE_BUF_PTR.OUTBUF bit field indicates the offset of the next address (entry) in the output buffer that will be written next by the packet engine. This bit field is reset to zero after starting up and decremented by 4 at every output buffer write operation. Pointers wrap around; the maximum value this field can have equals the output buffer size minus 4.
7:0 (R/NW)	INBUF	Input Buffer Pointer. The PKTE_BUF_PTR.INBUF bit field indicates the offset of the next address (entry) in the input buffer that will be read next by the packet engine. The bit field is reset to zero after starting up and incremented by 4 at every input buffer read operation. Pointers wrap around; the maximum value this field can have equals the input buffer size minus 4.

Packet Engine Buffer Threshold Register

When in autonomous ring mode or target command mode, the `PKTE_BUF_THRESH` register defines the high- and low-level value at which the packet engine starts to transfer packet data in or out of the internal packet buffers. These parameters can be used to control the DMA burst size for packet data input and output from the packet engine. In direct host mode, this register contains both threshold values to reduce the amount of packet engine interrupts.

The input buffer threshold (ibufthrsh) interrupt indicates that the input buffer counter is less than or equal to the input buffer threshold value set in this register - this interrupt can be used to wake up a process that stalled on a full input buffer.

The output buffer threshold (obufthrsh) interrupt indicates that the output buffer counter exceeds the output buffer threshold setting. The output buffer interrupt remains active until the output buffer counter is decremented to zero again.

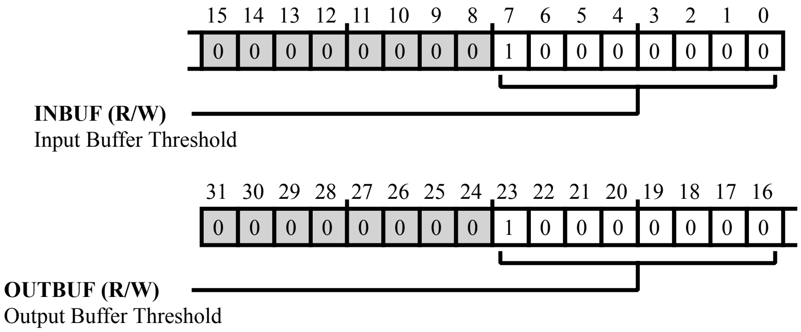

Figure 44-7: PKTE_BUF_THRESH Register Diagram

Table 44-33: PKTE_BUF_THRESH Register Fields

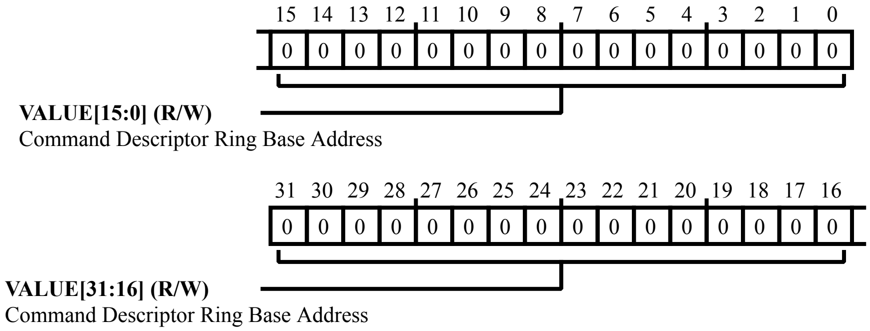
Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	OUTBUF	Output Buffer Threshold. The `PKTE_BUF_THRESH.OUTBUF` bit field specifies how many bytes must be available in the packet engine output buffer before an output transfer starts. Valid values range from 0 to 252, in multiples of 4. In autonomous ring mode, a value of 128 generally gives a good performance, but the optimal value depends on the system and application. In direct host mode, the output buffer threshold (obufthrsh) interrupt activates when the output buffer counter for the output buffer exceeds the value set in this field. A value of 128 generally gives a good performance, but the optimal value depends on the system and application.

Table 44-33: PKTE_BUF_THRESH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	INBUF	Input Buffer Threshold. The `PKTE_BUF_THRESH.INBUF` bit field specifies how many bytes must be free in the packet engine input buffer before an input transfer starts. Valid values range from 0 to 252, in multiples of 4. In autonomous ring mode, a value of 128 generally gives a good performance, but the optimal value depends on the system and application. In direct host mode, the input buffer threshold (ibufthrsh) interrupt activates when the input buffer counter for the input buffer is below or equal the value set in this field. A value of 128 generally gives a good performance, but the optimal value depends on the system and application.

Packet Engine Command Descriptor Ring Base Address

The `PKTE_CDRBASE_ADDR` register holds the command descriptor ring base address in host memory. It is only applicable in autonomous ring mode. The `PKTE_CDRBASE_ADDR` register is ignored for all other modes when command descriptors are directly written into the descriptor registers.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Command Descriptor Ring Base Address

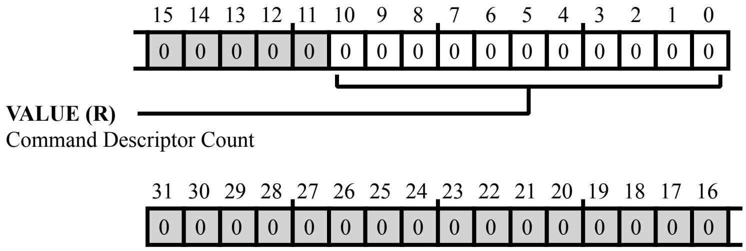
Figure 44-8: PKTE_CDRBASE_ADDR Register Diagram

Table 44-34: PKTE_CDRBASE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Descriptor Ring Base Address. The `PKTE_CDRBASE_ADDR.VALUE` bit field specifies the base location of the command descriptor ring in the host memory space.

Packet Engine Command Descriptor Count Register

The `PKTE_CDSC_CNT` register holds the counter for the number of descriptors in the Command Descriptor Ring (CDR). It is decremented by the packet engine each time a valid descriptor is read from the CDR and processed.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R)
Command Descriptor Count
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 44-9: PKTE_CDSC_CNT Register Diagram

Table 44-35: PKTE_CDSC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Command Descriptor Count. The `PKTE_CDSC_CNT.VALUE` bit field provides the number of command descriptors in the command descriptor ring. The packet engine decrements the counter when a valid command descriptor is read from the CDR and processed.

Packet Engine Command Descriptor Count Increment Register

The `PKTE_CDSC_INCR` register is accessible by the host connected through the system slave bus. The host can increment the command descriptor counter by writing a value between 1 and 255 to the lowest byte of this register.

In autonomous ring mode, the host must prepare 1 to 255 valid command descriptors in the CDR and then write this register with a value between 1 and 255. The write triggers the packet engine to fetch the command descriptors from the CDR. In direct host mode or target command mode, the host must write one valid command descriptor to the internal descriptor registers and then write this register with the value 1, to indicate that one valid descriptor is available.

A CDR threshold interrupt is activated when the command descriptor counter is less than or equal to the threshold value set in the `PKTE_RING_THRESH` register. This interrupt can be used to wake up a process that stalled on a full CDR.

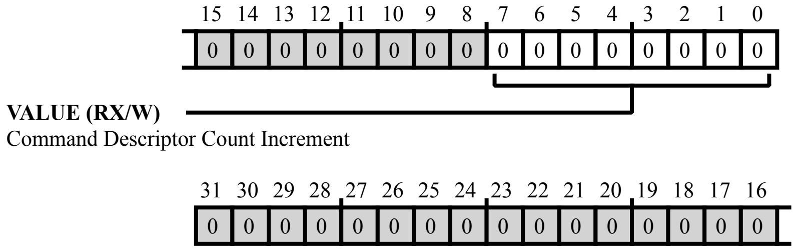


Figure 44-10: PKTE_CDSC_INCR Register Diagram

Table 44-36: PKTE_CDSC_INCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (RX/W)	VALUE	Command Descriptor Count Increment. The value written to the `PKTE_CDSC_INCR.VALUE` bit field is added to the command descriptor counter. The counter is protected against overflow (see the `PKTE_RING_STAT` register description). Note that bits[10:8] should be written with zeros.

Packet Engine Configuration Register

The `PKTE_CFG` register is used to select static settings that control the packet-processing path. This register is typically the last one to be written during the initialization sequence. These settings are typically set at initialization and not changed again.

SWPCDRD (R/W)
Swap CD RD

Figure 44-11: PKTE_CFG Register Diagram

Table 44-37: PKTE_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	SWPDAT	Swap Data. The `PKTE_CFG.SWPDAT` bit enables endian swap for packet data as configured in the `PKTE_ENDIAN_CFG.MSTRBSWP` bits for the packet data DMA read and write.	
		0	No Endian Swap
		1	Apply Endian Swap
17 (R/W)	SWPSA	Swap SA. The `PKTE_CFG.SWPSA` bit enables endian swap for a SA record as configured in the `PKTE_ENDIAN_CFG.MSTRBSWP` bits for the SA record and state record DMA read and write. If the `PKTE_ENDIAN_CFG.MSTRBSWP` bits specify no endian swap, this bit is ignored.	
		0	No Endian Swap
		1	Apply Endian Swap

Table 44-37: PKTE_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	SWPCDRD	Swap CD RD. The `PKTE_CFG.SWPCDRD` bit enables endian swap for descriptors as configured in the `PKTE_ENDIAN_CFG.MSTRBSWP` bits for the command descriptor DMA read and result descriptor DMA write. If the `PKTE_ENDIAN_CFG.MSTRBSWP` bits specify no endian swap, this bit is ignored.	
		0	No Endian Swap
		1	Apply Endian Swap
10 (R/W)	ENCDRUPDT	Enable CDR Update. The `PKTE_CFG.ENCDRUPDT` bit enables the packet engine to update, (clear the ownership bits) in the command descriptor in the CDR.	
		0	Do Not Clear Ownership Bits. The packet engine does not clear the ownership bits in the command descriptor when it completes an operation. The host application must clear the ownership bits in "old descriptors" before the packet engine is allowed to wrap around the CDR to re-encounter these "old descriptors". This setting has the advantage of eliminating a separate DMA write to the CDR.
		1	Clear Ownership Bits. The packet engine clears (set to zero) the ownership bits in the current command descriptor in the CDR. This prevents the packet engine from re-processing an "old descriptor" when it wraps around the CDR.
9:8 (R/W)	MODE	Packet Engine Mode. The `PKTE_CFG.MODE` bit field selects how the packet engine receives commands.	
		0	Direct Host Mode.
		1	Target Command Mode with Result Descriptor Ring Disabled.
		2	Target Command Mode with Result Descriptor Ring Enabled.
		3	Autonomous Ring Mode

PE Clock Control Register

The PKTE_CLK_CTL register controls the clock enable signals. This register can be used to enable the clock for read and write access to SA registers or to enable the required clock signals for certain crypto functions. The setting of this register overrides the packet engine dynamic clock enable.

In autonomous ring mode and target command modes, this register can be all zeros; the packet engine dynamically requests the external clock manager to activate the module clocks. This register can be used in combination with the debugging interface for internal register access.

In direct host mode, the clock enable bits for the packet engine (`PKTE_CLK_CTL.ENPECLK`) and for ARC4 (`PKTE_CLK_CTL.ENARC4CLK`) must be enabled to write and read the SA record and state record registers. All module clocks that are required for the current operation must be enabled during processing.

Note that all the clocks are enabled by default to reset all the registers within the packet engine. After a system reset the host can program this register to disable clocks for power reduction.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Continue Operating. The `PKTE_CONT.VALUE` bit field releases the packet engine from a halt state when written with any value in halt mode.

Packet Engine Control Register

The PKTE_CTL_STAT register has a dual function. Together with the data in the SA, this register provides the basic command information for the packet engine to process a packet. When the packet engine successfully or unsuccessfully completes an operation, the packet engine control/status register provides the result status for the host.

Table 44-40: PKTE_CTL_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	PADCTLSTAT	Pad Control/Pad Status. The PKTE_CTL_STAT.PADCTLSTAT bit field is used to control the pad boundary for pad insertion (outbound) and after processing returns the number of inserted (outbound) or detected (inbound) pad bytes. For the command descriptor, the enumerations below provide the codes for the pad boundary for the outbound operations. This can be used for traffic flow security to conceal the number of payload bytes in an encrypted packet. For the result descriptor inbound operations that use pad types SSL, TLS, IPsec or PKCS#7, it returns the number of detected pad bytes. For all other inbound operations, it returns zero since the other pad modes do not allow implicit determination of pad count. If a pad verify failure occurs, it returns zero. For an outbound operation, it returns the number of inserted pad bytes for all pad types. The pad value includes added bytes such as the pad length and the next header field in an IPsec ESP pad type.	
		0	Align packet end to modulo 8-byte boundary
		1	Align packet end to modulo 1-byte boundary

Table 44-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	Align packet end to modulo 4-byte boundary
		4	Align packet end to modulo 8-byte boundary
		8	Align packet end to modulo 16-byte boundary
		16	Align packet end to modulo 32-byte boundary
		32	Align packet end to modulo 64-byte boundary
		64	Align packet end to modulo 128-byte boundary
		128	Align packet end to modulo 256-byte boundary
23:20 (R/NW)	EXTERRCD	Extended Error Code. The `PKTE_CTL_STAT.EXTERRCD` bit field represents an encoded error condition.	
19 (R/NW)	EXTERR	Extended Error. The `PKTE_CTL_STAT.EXTERR` bit field provides an extended error code.	
		0	No Extended Error
		1	Extended Error
18 (R/NW)	SQNMERR	Sequence Number Error. The `PKTE_CTL_STAT.SQNMERR` bit indicates that for an inbound operation, there was a fault in the anti-replay sequence number. For an outbound operation, there was a sequence number overflow condition.	
		0	No Sequence Number Error
		1	Sequence Number Error
17 (R/NW)	PADERR	Pad Error. The `PKTE_CTL_STAT.PADERR` bit indicates that for an inbound operation the decrypted pad does not match the expected values.	
		0	No Pad Error
		1	Pad Error
16 (R/NW)	AUTHERR	Authentication Error. The `PKTE_CTL_STAT.AUTHERR` bit indicates that for an inbound operation the authentication value in the packet does not match the computed value.	
		0	No Authentication Error
		1	Authentication Error

Table 44-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:8 (R/W)	PADVAL	Pad Value. The `PKTE_CTL_STAT.PADVAL` bit field is used to pass the pad value between the host and the packet engine. Command Descriptor: (write-only) For outbound operations that use pad type IPsec, the host must populate this field with the value that is to be inserted into the next header field. For the IPsec ESP operation, this next header is part of the ESP trailer of the innermost operation's header and the value must be 50 decimal. For outbound encrypt operations that use the pad type constant or constant SSL, the host must specify the fixed constant value in this field. For all other outbound and inbound operations, this field is not used. Result Descriptor: (read only) For inbound operations that use pad type IPsec, the packet engine returns the next header field that it detects. For IPsec ESP inbound operations, this is the next header field in the innermost operation's header, which will typically be the value for the payload protocol, such as TCP or UDP. However, in bundling scenarios or in IPv6 with destination option headers, another header value could be seen. For all other outbound operations, the packet engine will not update this field. For all other inbound operations, the returned pad value is zero.	
7:6 (R/W)	PRNGMD	PRNG Mode. The `PKTE_CTL_STAT.PRNGMD` bits select the pseudo-random number generator mode.	
		0	Operation does not use the PRNG function.
		1	PRNG Init. PRNG is initialized with a SEED, KEY and an LFSR value as defined in the SA.
		2	PRNG Generate. Pseudo-random data is generated with the LFSR as input value. Before this mode can be used, the PRNG must be initialized with a valid SEED, KEY and LFSR using PRNG Init (`PKTE_CTL_STAT.PRNGMD`=b'01).
		3	PRNG Test. It can be used to test the PRNG function with custom input data. Before this mode can be used, the PRNG must be initialized once with a valid SEED using PRNG Init (`PKTE_CTL_STAT.PRNGMD`=b'01).

Table 44-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	HASHFINAL	Hash Final. When the `PKTE_CTL_STAT.HASHFINAL` bit is zero, the data to be hashed must be a multiple of the hash block size, 64 bytes for SHA-1, MD5, SHA-224, SHA-256. This bit is only applicable for Basic Hash, Basic Encrypt-Hash and Basic Hash-Decrypt operations that use the SHA-1, MD5, SHA-224, SHA-256 hash algorithm. The `PKTE_CTL_STAT.HASHFINAL` bit is overruled for HMAC operations that always completes the hash and always returns the last written value on a read by the host.	
		0	Perform Intermediate Hash Operation. The packet engine performs an intermediate hash operation by generating an intermediate hash digest on the data presented on the input. No hash pad is applied.
		1	Perform Final Hash Operation. The packet engine appends the required final hash pad and generates the final hash digest on the data presented on the input. This completes the hash operation.
3 (R/W)	INITARC4	Init ARC4. The `PKTE_CTL_STAT.INITARC4` bit initializes the ARC4 crypto algorithm with a new key. This bit always returns the last written value on a read by the Host. This bit is only applicable for operations that use the ARC4 algorithm and must be zero for all other operations.	
		0	Load ARC4 State and ARC4 i/j pointer from the SA The ARC4 State and ARC4 i/j pointer are loaded from the SA to continue the encrypt/decrypt processing from the previous algorithm state.
		1	Read ARC4 key from the SA-record and initialize ARC4 S-boxes using this key The ARC4 key is read from the SA-record, the ARC4 S-boxes are initialized using this key, prior to the encryption/decryption of data. This bit overrules Stateful mode as defined in bits [9:8] of PKTE_SA_CMD1.
1 (R/W)	PERDY	Packet Engine Ready. The `PKTE_CTL_STAT.PERDY` bit indicates that the packet engine has completed processing the command descriptor and returns the result descriptor with ownership set to the host. This bit can be reset to 0 by the host and the packet engine, but only the packet engine can set this bit. When the packet engine is idle (not processing), this bit always returns '1' on a read by the host.	

Table 44-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	HOSTRDY	Host Ready. The `PKTE_CTL_STAT.HOSTRDY` bit indicates that the host has populated the command descriptor. This bit can be reset to 0 by the host and the packet engine, but only the host can set this bit. When the packet engine is idle (not processing), this bit always returns '0' on a read by the host.

Starting Entry of 256-byte Data Input/Output Buffer

When in direct host mode, the source packet data is written here to be transferred to the packet engine. The host can monitor the available space in the input buffer through the `PKTE_STAT` register. This is also the location in the packet engine from where output data is read when in direct host mode. The host can monitor the available bytes in the output buffer through the `PKTE_STAT` register.

The <code>PKTE_DMA_CFG.MXBRSTSZ</code> bit field configures the maximum size of an unspecified length burst (INC) at the bus in bytes. When there is less data available than the <code>PKTE_DMA_CFG.MXBRSTSZ</code> bit field setting or the 1kB boundary will be crossed using a burst operation, then the length of the burst can be less than <code>PKTE_DMA_CFG.MXBRSTSZ</code>. Any requested transfers larger than this size are broken up in to multiple burst transfers of this size or less.</td></tr>
</table>

Packet Engine Endian Configuration Register

The packet engine incorporates a powerful interface specific endian handler. This endian handler allows byte lane swapping in each direction for data passing through the host interface.

The `PKTE_ENDIAN_CFG` register configures the byte order function for the peripheral bus master and peripheral bus slave interface. The bits for the peripheral bus master are combined in four sets of two bits; each group configures a byte swap function for a particular DMA transfer. The same applies for the peripheral bus slave interface.

The `PKTE_ENDIAN_CFG` register also defines the endian swapping that occurs for host-initiated target transfers and for packet engine master DMA read and write transfers. Individual endian swap enable bits in the configuration (`PKTE_CFG`) register can enable the endian swap for various transaction types: command descriptors and result descriptors, SA records and state records, packet data.

In direct host mode, only target operations are supported. Only the target endian configuration of this register is applicable.

Note: This register is typically programmed once during the initialization phase, although software is allowed to dynamically change the setting in this register just before initiating a data transfer. The developer will have to analyze the benefit of the cycles needed to write the endian register dynamically versus handling endian swapping for some data structures in the host system (most modern processors support a byte swap in zero cycles). Certainly the endian swap should be set correctly for the packet data, since this represents the majority of the data transferred.

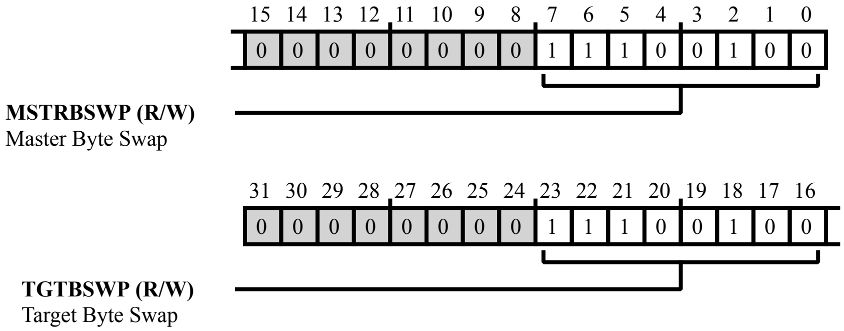

Figure 44-18: PKTE_ENDIAN_CFG Register Diagram

Table 44-44: PKTE_ENDIAN_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	TGTBSWP	Target Byte Swap. The `PKTE_ENDIAN_CFG.TGTBSWP` bit field configures the byte swap for peripheral bus target transfers. Note that only target word transfers are supported. Each double-bit field in this register specifies the source of the indicated byte lane. The field values are interpreted as follows: 00 = byte 0, 01 = byte 1, 10 = byte 2, 11 = byte 3. Note: Setting the value 0xE4 defines no swap (little endian) and setting value 0x1B defines a full byte swap within a 32-bit word (big endian).

Table 44-44: PKTE_ENDIAN_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	MSTRBSWP	Master Byte Swap. The `PKTE_ENDIAN_CFG.MSTRBSWP` bit field configures the byte swap for peripheral bus master multi-byte transfers, including command descriptors, result descriptors, SA records, state records and packet data. Separate controls in the `PKTE_CFG` register can enable this swap individually for each of the 4 types of data. Each double-bit field in this register specifies the source of the indicated peripheral bus byte lane. The field values are interpreted as follows: 00=byte 0, 01=byte 1, 10=byte 2, 11=byte 3. Note: Setting the value 0xE4 defines no swap (little endian) and setting value 0x1B defines a full byte swap within a 32-bit word (big endian).

Packet Engine Halt Control Register

Th `PKTE_HLT_CTL` register controls the packet engine halt mode. This register can be used for debugging purposes while processing in autonomous ring mode or target command mode. During the halt mode, the host can read all internal registers for examination without side-effects. When halted, the host should not write to any registers. To continue packet engine operation, the host must write to the `PKTE_CONT` (PKTE continue) register.

Table 44-45: PKTE_HLT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	WRRD	Halt On Write Result Descriptor. The `PKTE_HLT_CTL.WRRD` bit halts the packet engine in the HALT_WRITE_STATUS state after it completes a result descriptor write operation to the result descriptor ring. The host can use this bit to examine the result descriptor that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
4 (RX/W)	WRSA	Halt On Write SA. The `PKTE_HLT_CTL.WRSA` bit halts the packet engine in the HALT_WRITE_SA state after it completes an SA write operation to the host memory. The host can use this bit to examine the security context that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation

Table 44-45: PKTE_HLT_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (RX/W)	HWRDAT	Halt On Write Data. The `PKTE_HLT_CTL.HWRDAT` bit halts the packet engine in the HALT_DATA state after it completes writing the result packet data to the host memory. The host can use this bit to examine the result packet that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
2 (RX/W)	RDSA	Halt On Read SA. The `PKTE_HLT_CTL.RDSA` bit halts the packet engine in the HALT_READ_SA state after it completes an SA read operation from the host memory. The host can use this bit to examine the security context that is currently in the SA registers.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
1 (RX/W)	RDCD	Halt On Read Command Descriptor. The `PKTE_HLT_CTL.RDCD` bit halts the packet engine in the HALT_READ_DESCR state after it completes a command descriptor read operation from the command descriptor ring. It will halt whether the descriptor is valid or invalid. The host can use this bit to examine the command descriptor that is currently in the internal command descriptor registers.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
0 (RX/W)	EN	Enable Halt Mode. The `PKTE_HLT_CTL.EN` bit enables halt mode where the packet engine can halt processing at any processing state as indicated by bits [5:1]. When halted, the packet engine continues operation on a write to the `PKTE_CONT` register.	
		0	Do not enable halt mode
		1	Enable halt mode

Packet Engine Halt Status Register

The PKTE_HLT_STAT register reflects the status of the packet engine in halt mode. This register can be used for debugging purposes while processing in autonomous ring mode or target command mode. When the packet engine is halted, the host can read all internal registers for examination without side effects. The host should not write to any registers.

		1	Halt mode enabled

Interrupt Mask Disable Register

The host can use the PKTE_IMSK_DIS register to clear individual bits in the PKTE_INT_EN register for the host interrupt. This register is a bitmap for each of the possible interrupt sources: A 1 clears the interrupt enable bit, a 0 does not affect the interrupt enable bit in the PKTE_INT_EN register. Clearing the enable bits through this register avoids the time-consuming read-modify-write operation on the host.

10 (RX/W)	IBUFTHRSH	Input Buffer Threshold. Write the `PKTE_IMSK_DIS.IBUFTHRSH` bit to clear when the input buffer counter is less than or equal to the input buffer threshold value defined in `PKTE_BUF_THRESH.INBUF` bit.
9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. Write the `PKTE_IMSK_DIS.RDRTHRSH` bit to clear when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the `PKTE_RING_THRESH.RDRTHRSH` bit, or the RD counter for the RDR in the `PKTE_RDSC_CNT` register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. Write the `PKTE_IMSK_DIS.CDRTHRSH` bit to clear when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the `PKTE_RING_THRESH.CDRTHRSH` bit.

Interrupt Mask Enable Register

The host can use the PKTE_IMSK_EN register to set individual bits in the PKTE_INT_EN register for the host interrupt. This register is a bitmap for each of the possible interrupt sources: A 1 sets the interrupt enable bit, a 0 does not affect the interrupt enable bit in the PKTE_INT_EN register. Setting the enable bits through this register avoids the time-consuming read-modify-write operation on the host.

11 (RX/W)	OBUFTHRSH	Output Buffer Threshold. Set the `PKTE_IMSK_EN.OBUFTHRSH` bit to indicate that the output buffer counter exceeds the output buffer threshold value defined in the `PKTE_BUF_THRESH.OUTBUF` bit.
10 (RX/W)	IBUFTHRSH	Input Buffer Threshold. Set the `PKTE_IMSK_EN.IBUFTHRSH` bit to indicate the input buffer counter is less than or equal to the input buffer threshold value defined in `PKTE_BUF_THRESH.INBUF` bit.
9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. Set the `PKTE_IMSK_EN.RDRTHRSH` bit to indicate when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the `PKTE_RING_THRESH.RDRTHRSH` bit, or the RD counter for the RDR in `PKTE_RDSC_CNT` register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. Set the `PKTE_IMSK_EN.CDRTHRSH` bit to indicate when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the `PKTE_RING_THRESH.CDRTHRSH` bit.

Interrupt Masked Status Register

The PKTE_IMSK_STAT register provides interrupt status visibility to the host, after the interrupt mask is applied. This lets the host view the selected sources of interrupts that are directed to the interrupt output signal, that is connected to the system interrupt controller. As with the unmasked status register, all interrupt bits are latched and must be cleared using the PKTE_INT_CLR register in order to capture a subsequent event. A 1 indicates that the associated interrupt is present.

Table 44-51: PKTE_INBUF_INCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (RX/W)	VALUE	Input Buffer Increment. The value written is added to the input buffer counter. Valid values range from 4 to 256, in multiples of 4.

Interrupt Configuration Register

The PKTE_INT_CFG register configures the interrupt type that is sent to the interrupt line connected to the system interrupt controller. (Note that this only effects the final output of the interrupt subsystem).

Configuring the interrupt output type for pulse causes the interrupt signal to pulse low for two clock cycles when activated. When set for level, the interrupt signal is set low until cleared by the host (it follows the bit in the masked status register). For the host, this is typically set to level.

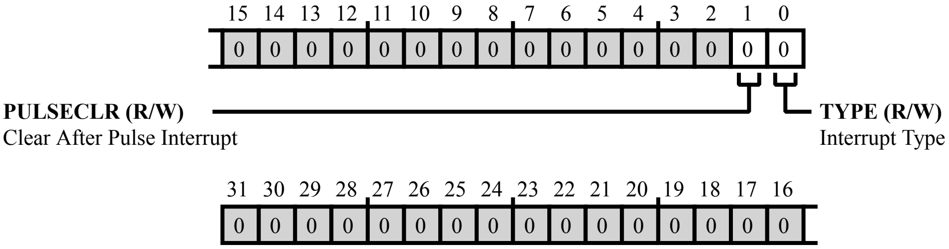

Figure 44-26: PKTE_INT_CFG Register Diagram

Table 44-52: PKTE_INT_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	PULSECLR	Clear After Pulse Interrupt. The PKTE_INT_CFG.PULSECLR bit clears the latched interrupt source after the pulse interrupt.	
		0	Manually clear pulse interrupt source. Do not automatically clear the interrupt sources after pulsing the interrupt output. Clear the source by writing to the PKTE_INT_CLR register.
		1	Automatically clear pulse interrupt source. After pulsing the interrupt output, automatically clear the sources.
0 (R/W)	TYPE	Interrupt Type. The PKTE_INT_CFG.TYPE bit selects the type, pulse or level, for the interrupt output to the system.	
		0	Level. The interrupt output is a level signal that is set low when an enabled interrupt is active until the interrupt is cleared.
		1	Pulse. The interrupt output is a two clock cycle low-active pulse, activated when an enabled interrupt is active.

Interrupt Clear Register

The `PKTE_INT_CLR` register allows the host processor to clear pending interrupts. A 1 written to a given bit in this register clears the corresponding interrupt. A 0 leaves the interrupt latch unchanged for that position.

9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. The `PKTE_INT_CLR.RDRTHRSH` bit is set when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the `PKTE_RING_THRESH.RDRTHRSH` bit, or the RD counter for the RDR in `PKTE_RDSC_CNT` register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. The `PKTE_INT_CLR.CDRTHRSH` bit is set when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the `PKTE_RING_THRESH.CDRTHRSH` bit.

Interrupt Enable Register

The `PKTE_INT_EN` register configures the interrupt mask for the host interrupt. This register is a bitmap for each of the possible interrupt sources. A 1 enables the interrupt source and a 0 disables the source. If an interrupt source is disabled, a cleared bit also clears the matching interrupt in the `PKTE_IMSK_STAT` register.

9 (R/W)	OPDN	Operation Done.
1 (R/W)	RDRTHRSH	RDR Threshold. Set the `PKTE_INT_EN.RDRTHRSH` bit for to trigger an interrupt when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the `PKTE_RING_THRESH.RDRTHRSH` bit, or the RD counter for the RDR in `PKTE_RDSC_CNT` register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (R/W)	CDRTHRSH	CDR Threshold. Set the `PKTE_INT_EN.CDRTHRSH` bit for to trigger an interrupt when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the `PKTE_RING_THRESH.CDRTHRSH` bit.

Interrupt Unmasked Status Register

The `PKTE_IUMSK_STAT` register provides interrupt status visibility to the host, prior to the interrupt mask being applied. Using this register, the host can view all potential sources of incoming interrupts. All of these sources, whether masked in or out, are latched in this register and must be cleared using the `PKTE_INT_CLR` register in order to capture a subsequent event. A 1 indicates that the associated interrupt is present.

Figure 44-30: PKTE_LEN Register Diagram

Table 44-56: PKTE_LEN Register Fields

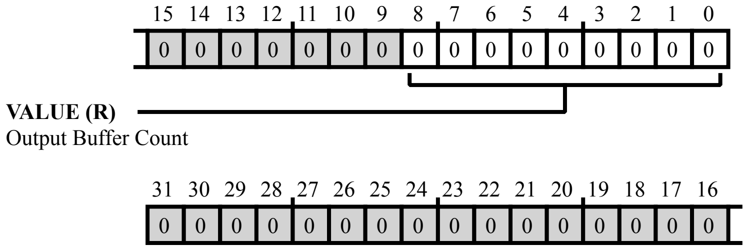
Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYPASS	Bypass. The PKTE_LEN.BYPASS bit field indicates the length of data in words that must bypass the packet engine and are directly copied from the source buffer to the destination buffer. The packet engine does not process this data. Valid bypass offsets range from 0 (0x00) to 255 (0xFF) words. For SRTP operations, this field specifies the offset in words between the hash and encrypt/decrypt data.
23 (R/W)	PEDONE	PE Done. The PKTE_LEN.PEDONE bit is a mirrored bit from the PKTE_CTL_STAT.PERDY bit. The bit is repeated here to guarantee ownership consistency between the first and last word. When the packet engine fetches a descriptor, these bits must match or the descriptor is discarded and fetched again.
22 (R/NW)	HSTRDY	Host Ready. The PKTE_LEN.HSTRDY bit is a mirrored bit of the PKTE_CTL_STAT.HOSTRDY bit. The bit is repeated here to guarantee ownership consistency between the first and last word. It should also be set along with the PKTE_CTL_STAT.HOSTRDY bit when the command descriptor is finished being populated. When the packet engine fetches a descriptor, these bits must match or the descriptor is discarded and fetched again.

Table 44-56: PKTE_LEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	TOTLEN	Total length. Command Descriptor: The `PKTE_LEN.TOTLEN` bit field indicates the total length (in bytes) of all data to be passed to the packet engines input buffer for an operation. Exceptions are the PRNG init and PRNG generate operations. The PRNG init operation does not require any input data; this field must be zero. For the PRNG generate operation, this field indicates the number of pseudo-random bytes to be generated. Valid lengths range from 16 (0x00010) to 255*16 = 4080 (0x00FF0) bytes in multiples of 16 bytes. Valid lengths for the basic operation range from 1 (0x00001) to 1,048,575 (0xFFFFF) bytes. This is the length of the data to be encrypted or hashed and includes the bypass data and padding bytes. Valid lengths for IPsec ESP range from 1 (0x00001) to 65535 (0x0FFFF) bytes. This is the length of the IP payload. Valid lengths for SSL v3.0, TLS v1.x and DTLS range from 1 (0x00001) to 16383 (0x03FFF). This is the length of the payload. Valid lengths for SRTP range from 1 (0x00001) to 65535 (0x0FFFF). This is the length of the payload. Note: A length of zero bytes is illegal and will result in an error status code in the result descriptor. Result Descriptor: Upon completion of an operation, the `PKTE_LEN.TOTLEN` field indicates the result length of the result packet. Valid lengths range from 1 (0x001) to 1,048,575 (0xFFFFF) bytes. This includes the bypass data and padding bytes. Note: When an extended error (`PKTE_CTL_STAT`[18]=1) is reported in the result descriptor and no packet data is processed, this field returns zero.

Packet Engine Output Buffer Count Register

The `PKTE_OUTBUF_CNT` register provides the number of data bytes there are in the output buffer. The `PKTE_OUTBUF_CNT` register is used in direct host mode only.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

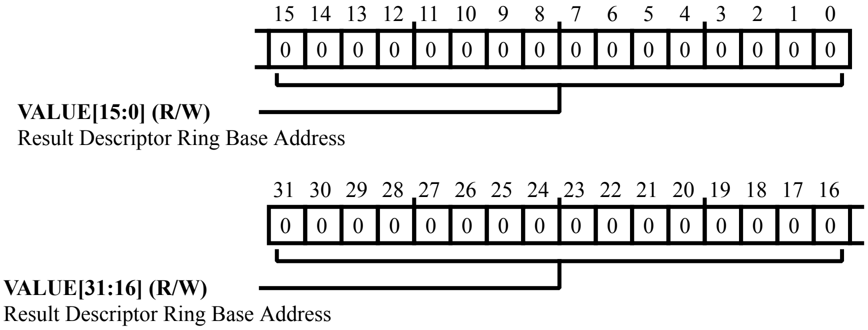
Table 44-58: PKTE_OUTBUF_DECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (RX/W)	VALUE	Output Buffer Count Decrement. The `PKTE_OUTBUF_DECR.VALUE` bit field is the value written is subtracted to the output buffer counter. Valid values range from 4 to 256, in multiples of 4.

Packet Engine Result Descriptor Ring Base Address

The PKTE_RDRBASE_ADDR register holds the result descriptor ring base address in host memory. It is only applicable in autonomous ring mode and target command mode with RDR enabled. Note that in target command mode, the CDR is not used, but the RDR must be configured when enabled so that the packet engine knows where to write the result descriptors.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

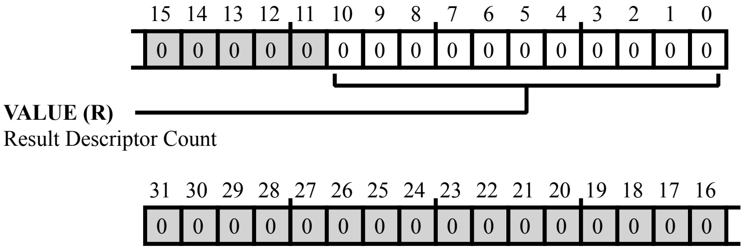
Table 44-59: PKTE_RDRBASE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Result Descriptor Ring Base Address. The `PKTE_RDRBASE_ADDR.VALUE` bit field specifies the base location of the result descriptor ring in the host memory space.

Packet Engine Result Descriptor Count Registers

The PKTE_RDSC_CNT register holds the counter for the number of descriptors in the Result Descriptor Ring (RDR). It is incremented by the packet engine each time a valid result descriptor is written to the RDR.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 44-34: PKTE_RDSC_CNT Register Diagram

Table 44-60: PKTE_RDSC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Result Descriptor Count. The PKTE_RDSC_CNT.VALUE bit field provides the number of result descriptors in the result descriptor ring. The packet engine increments the counter when a valid result descriptor is written to the RDR.

Packet Engine Result Descriptor Count Decrement Registers

The PKTE_RDSC_DECR register is accessible by the host connected through the system slave bus can decrement the result descriptor counter by writing a value between 1 and 255 to the lowest byte of this register.

With an RDR enabled, this is the number of result descriptors that have been read by the host. With an RDR disabled, this indicates that the host has read one valid result descriptor.

In autonomous ring mode or target command mode with the RDR enabled, the host must process 1 to 255 result descriptors from the RDR and then write this register with the number of result descriptors that have been processed by the host.

In direct host mode or target command mode with the RDR disabled, the host must read one result descriptor from the internal descriptor registers and then write this register with the value 1, to indicate that one valid descriptor is read. An RDR threshold interrupt is activated when the result descriptor counter exceeds the threshold value set in the PKTE_RING_THRESH register. This interrupt can be used to wake up a process that stalled on an empty RDR.

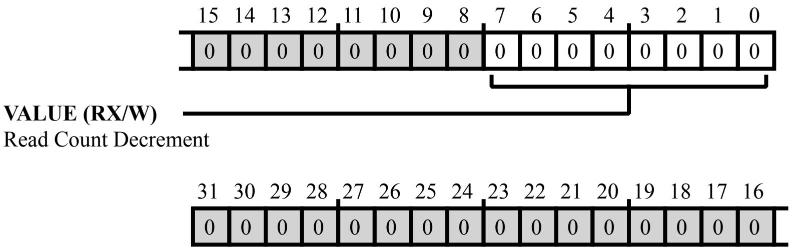

Figure 44-35: PKTE_RDSC_DECR Register Diagram

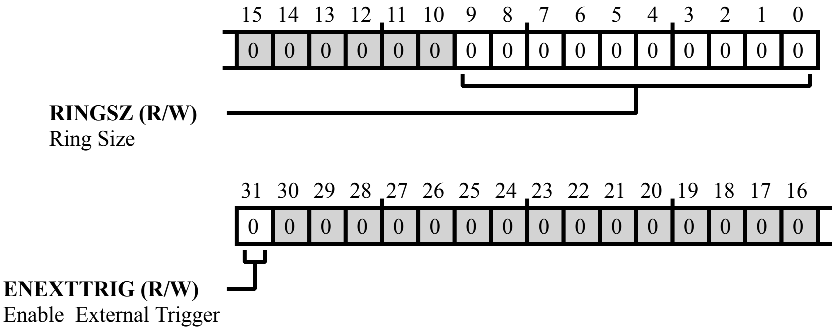
Table 44-61: PKTE_RDSC_DECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (RX/W)	VALUE	Read Count Decrement. The value written to the `PKTE_RDSC_DECR.VALUE` bit field is subtracted from the result descriptor counter. The counter is protected against underflow (See the PKTE_RING_STAT register). Note that bits [10:8] should be written with zeros.

Packet Engine Ring Configuration

The PKTE_RING_CFG register configures the size (in number of descriptor ring entries minus 1) for both the command descriptor ring and result descriptor ring in host memory. This register is only applicable for autonomous ring mode and target command mode with RDR enabled.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

ENEXTTRIG (R/W)
Enable External Trigger

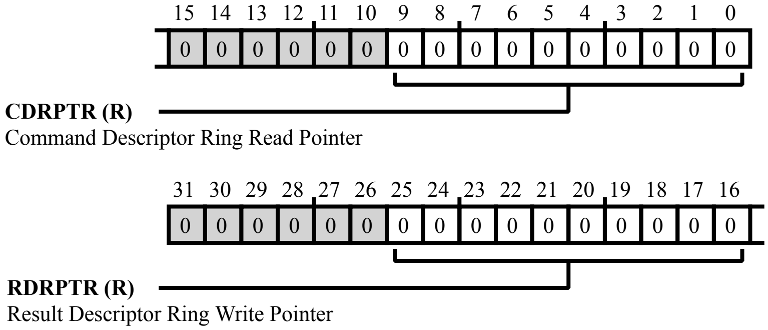
Figure 44-36: PKTE_RING_CFG Register Diagram

Table 44-62: PKTE_RING_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ENEXTTRIG	Enable External Trigger. The PKTE_RING_CFG.ENEXTTRIG signal enables the increment of the PKTE_CDSC_CNT register through the external input pin ext_cd_cnt_incr and enables the decrement of the PKTE_RDSC_CNT fields through the external input pin ext_rd_cnt_decr.
9:0 (R/W)	RINGSZ	Ring Size. The PKTE_RING_CFG.RINGSZ bit field specifies the size of the command ring in number of descriptors, minus 1. Valid sizes range from 1 (for 2 descriptors) to 1023 (for 1024 descriptors). The accompanying result ring will have the same size.

Packet Engine Ring Pointer Status

The PKTE_RING_PTR register holds the pointers to the current entry of the Command Descriptor Ring (CDR) and Result Descriptor Ring (RDR).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RDRPTR (R)
Result Descriptor Ring Write Pointer

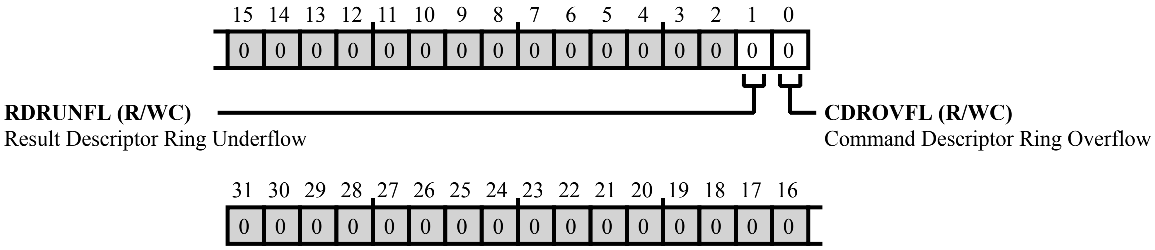
Figure 44-37: PKTE_RING_PTR Register Diagram

Table 44-63: PKTE_RING_PTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/NW)	RDRPTR	Result Descriptor Ring Write Pointer. The PKTE_RING_PTR.RDRPTR bit field indicates the entry number in the RDR that will be written next by the packet engine. The PKTE_RING_PTR.RDRPTR bit field is reset to zero after starting up and updated after every result descriptor write DMA operation. Pointers wrap around; the maximum value this field can have equals the contents of the ring size (PKTE_RING_CFG.RINGSZ) bit field.
9:0 (R/NW)	CDRPTR	Command Descriptor Ring Read Pointer. The PKTE_RING_PTR.CDRPTR bit field indicates the entry number in the CDR that will be read next by the packet engine. The PKTE_RING_PTR.CDRPTR bit field is reset to zero after starting up and updated after every command descriptor read DMA operation. Pointers wrap around; the maximum value this field can have equals the contents of the ring size (PKTE_RING_CFG.RINGSZ) field.

Packet Engine Ring Status

The `PKTE_RING_STAT` register gives indication of either a Command Descriptor Ring (CDR) overflow or a Result Descriptor Ring (RDR) underflow. A ring error (ringerr) interrupt in the interrupt controller is activated on a command descriptor ring overflow or a result descriptor ring underflow. This type of error can occur when the host and the packet engine get out-of-sync. The host can read this register to retrieve information on which ring is corrupted. The corrupted ring must be reset and reinitialized. See the `PKTE_CFG.RSTRING` bit.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 44-38: PKTE_RING_STAT Register Diagram

Table 44-64: PKTE_RING_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/WC)	RDRUNFL	Result Descriptor Ring Underflow. The `PKTE_RING_STAT.RDRUNFL` bit is set when the command descriptor count (`PKTE_RDSC_CNT`) register is decremented below zero. This bit is reset with a write of any value.
0 (R/WC)	CDROVFL	Command Descriptor Ring Overflow. The `PKTE_RING_STAT.CDROVFL` bit is set when the command descriptor count (`PKTE_CDSC_CNT`) register is incremented above the ring size (`PKTE_RING_CFG.RINGSZ`) bits. This bit is reset with a write of any value.

Packet Engine Ring Threshold Registers

To reduce the amount of packet engine result interrupts, the PKTE_RING_THRESH register contains threshold and time-out values.

The CDR threshold (cdrthrsh) interrupt indicates that the command descriptor counter is less than or equal to the CDR threshold (cdrthrsh) value set in this register. This interrupt can be used to wake up a process that stalled on a full CDR.

The RDR threshold (rdrthrsh) interrupt indicates that the result descriptor counter exceeds the result descriptor threshold set here, or that the result descriptor counter is non-zero for a time longer than the result descriptor time-out setting. The RDR result interrupt remains active until the result descriptor counter is decremented below the RDR threshold (rdrthrsh) value. In case the interrupt is the result of a time-out and the result descriptor counter is below the threshold value, the result descriptor counter must be decremented once before the interrupt can be cleared in the interrupt controller.

Figure 44-39: PKTE_RING_THRESH Register Diagram

Table 44-65: PKTE_RING_THRESH Register Fields

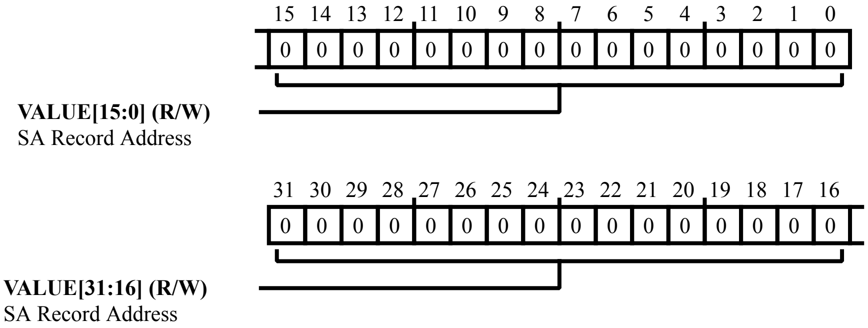
Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	TOEN	Timeout Enable. A 1 in the `PKTE_RING_THRESH.TOEN` bit indicates the result descriptor timeout counter is enabled. This bit can be used to de-activate the timeout counter to save power.

Table 44-65: PKTE_RING_THRESH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:26 (R/W)	RDTO	Read Descriptor Timeout. The timeout enable (`PKTE_RING_THRESH.TOEN`) bit in this register must be set to activate this `PKTE_RING_THRESH.RDTO` result descriptor timeout counter. The rdrthrsh interrupt activates when the RD counter for the RDR is non-zero for more than $2^{(N+10)}$ internal system clock cycles, where 'N' is the value set in this field. Valid settings range from 0 to 15. The minimum time-out value for N=0 is 1024 clock cycles and the maximum time-out value for N=15 is 33554432 clock cycles. At 100 MHz, this is 5.12 us for N=0 and ~335.55 ms for N=15. Note: The time-out delay may not be exact - expect a variation on the order of 1024 system clock cycles (just more than one microsecond at 100 MHz system clock frequency).
25:16 (R/W)	RDRTHRSH	Result Descriptor Ring Threshold. The rdrthrsh interrupt activates when the RD counter for the RDR exceeds the value set in the `PKTE_RING_THRESH.RDRTHRSH` field. Valid settings range from 0 to 1023.
9:0 (R/W)	CDRTHRSH	Command Descriptor Ring Threshold. The cdrthrsh interrupt activates when CD counter for the CDR is below or equal the value set in the `PKTE_RING_THRESH.CDRTHRSH` field. Valid settings range from 0 to 1023.

Packet Engine SA Address

The `PKTE_SA_ADDR` register holds the start address of the SA record.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

15:8 (R/W)	JPTR	J Pointer. The `PKTE_SA_ARC4IJPTR.JPTR` bit field contains the j pointer into s-box array for swapping bytes with i pointer.
7:0 (R/W)	IPTR	I Pointer. The `PKTE_SA_ARC4IJPTR.IPTR` bit field contains the i pointer into s-box array for swapping bytes with j pointer.

SA Command 0

The two SA command registers, `PKTE_SA_CMD0` and `PKTE_SA_CMD1`, are used to control the cryptographic operation of the packet engine. The `PKTE_SA_CMD0` register contains the major control bits to define an operation while the `PKTE_SA_CMD1` register contains the minor control bits. In direct host mode, this is a write-only register.

Table 44-68: PKTE_SA_CMD0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	SVHASH	Save Hash. The `PKTE_SA_CMD0.SVHASH` bit indicates that the Hash State is saved to the STATE_BYTE_CNT_X and STATE_IDIGEST_X fields in the SA record in memory after completion of a crypto operation.	
		0	Hash state is not saved
		1	Hash state is saved

Table 44-68: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	SVIV	Save IV. The `PKTE_SA_CMD0.SVIV` bit field indicates that for DES or the AES the Initialization Vector (IV) is saved to the STATE_IV_X fields in the state record , or the ARC4 state is saved to the ARC4 state record, after completion of the crypto operation.	
		0	ARC4 State is not saved.
		1	ARC4 State is not saved.
27:26 (R/W)	HASHSRC	Hash Source. The `PKTE_SA_CMD0.HASHSRC` bit field selects the source of the hash digest used by the algorithm.	
		0	From SA. Digest only hash byte count is forced to 0x40.
		1	Reserved
		2	From State. Read saved inner hash digest and saved hash byte count.
		3	No Load. Use the hash algorithm defined constants for the initial hash. Hash byte count is 0x00.
25:24 (R/W)	IVSRC	IV Source. The `PKTE_SA_CMD0.IVSRC` bit field selects the source of the initialization vector used by the crypto algorithm.	
		0	No load. Use previous result IV, not applicable for inbound data. This option should never be used for operations with DES-CBC or AES-CBC, (see RFC3602) or any AES counter modes
		1	From input buffer. The IV is provided as part of the input data stream.
		2	From State. Read STATE_IV_X, from the SA structure. Refer to inner hash digest register structure. Useful for resume operations.
		3	From internal PRNG. Not applicable for inbound operations.
23:20 (R/W)	DIGESTLEN	Digest Length. The `PKTE_SA_CMD0.DIGESTLEN` bit field defines the length of the hash digest in words as put in the output buffer.	
		0	3 Words (96-bit output)
		1	1 Word
		2	2 Words

Table 44-68: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	3 Words (IPsec)
		4	4 Words (MD5 and AES-based hash)
		5	5 Words (SHA-1)
		6	6 Words
		7	7 Words (SHA-224)
		8	8 Words (SHA-256)
		9	Reserved
		10	10 bytes (SRTP and TLS)
		11-15	Reserved
19 (R/W)	HDRPROC	Header Processing. The `PKTE_SA_CMD0.HDRPROC` bit enables header processing for protocol operations. There is no header-processing support for basic SSL, basic TLS and SRTP protocol operations as defined in the protocol group (see the Crypto and Hash Algorithms section). This bit must be zero for these operations; however, the protocol header must be supplied to the packet engine since it is part of the hash calculation. Refer to the protocol specifications for more information about header-processing support for a protocol.	
		0	No header processing
		1	Header processing; insert the protocol header for outbound operations, verify the protocol header for inbound operations.
18 (R/W)	EXTPAD	Extended Pad. The `PKTE_SA_CMD0.EXTPAD` bit extends the number of padding types. Used in combination with `PKTE_SA_CMD0.PADTYPE`.	
17 (R/W)	SCPAD	Stream Cipher Padding. The `PKTE_SA_CMD0.SCPAD` bit enables padding for stream ciphers algorithms.	
15:12 (R/W)	HASH	Hash Algorithm Select. The `PKTE_SA_CMD0.HASH` bit field selects the hash algorithm.	
		0	MD5
		1	SHA-1
		2	SHA-224
		3	SHA-256
		4-14	Reserved
		15	Null

Table 44-68: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8 (R/W)	CIPHER	Cipher Algorithm Select. The `PKTE_SA_CMD0.CIPHER` bit field selects the cipher algorithm to be used for encryption and decryption. Note: Each type of protocol operation supports different sets of crypto algorithms. Refer to the Crypto and Hash Algorithms general processing section for details of the supported algorithms.	
		0	DES
		1	Triple-DES
		2	ARC4
		3	AES
		4-14	Reserved
		15	Null
7:6 (R/W)	PADTYPE	Pad Type. The `PKTE_SA_CMD0.PADTYPE` bit field indicates the type of crypto that must be generated for outbound packets or checked for inbound packets.	
		0	Select IPSec operation (if Bit 18=0); Reserved (if Bit 18=1)
		1	PKCS#7 (if Bit 18=0); Select TLS/DTLS Pad, required for TLS/DTLS operation (if Bit 18=1)
		2	Constant pad (if Bit 18=0); Select Constant SSL Pad, required for SSL operation (if Bit 18=1)
		3	Zero pad (if Bit 18=0), Reserved (if Bit 18=1)
5:4 (R/W)	OPGRP	Operation Group. The `PKTE_SA_CMD0.OPGRP` bit field defines the operation groups. Refer to the Basic Operations and Decoding section for more information.	
		0	Basic operation group
		1	Protocol operation group
		2	Extended protocol operations group
		3	Reserved
3 (R/W)	DIR	Direction. The `PKTE_SA_CMD0.DIR` bit field selects the direction of operation.	
		0	Outbound operations
		1	Inbound operations

Table 44-68: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:0 (R/W)	OPCD	Operation Code. The `PKTE_SA_CMD0.OPCD` bit field selects the operation within the operation group.

SA Command 1

The PKTE_SA_CMD1 register contains the minor control bits that define an operation. In direct host mode, this is a write-only register.

ARC4KEYLEN (R/W)
ARC4 Key Length
HSHCOFFST (R/W)
Hash Crypt Offset
AESKEYLEN (R/W)
AES Key Length

Figure 44-43: PKTE_SA_CMD1 Register Diagram

Table 44-69: PKTE_SA_CMD1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	ENSQNCHK	Sequence Number Check Enable. The PKTE_SA_CMD1.ENSQNCHK bit defines that the key in the SA key field is an AES encrypt key or an AES decrypt key.	
		0	Disable sequence number check
		1	Enable sequence number check
28 (R/W)	AESDECKEY	AES Dec Key. If the PKTE_SA_CMD1.AESDECKEY bit is set, the key in loaded in the PKTE_SA_KEY[n] registers are expected to be the key from the last round from key expansion. If not set, the key loaded in the PKTE_SA_KEY[n] registers are expected to be the same key used during the encryption process.	
		0	AES key is an encrypt key.
		1	AES key is a decrypt key.

Table 44-69: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/W)	AESKEYLEN	AES Key Length. The `PKTE_SA_CMD1.AESKEYLEN` bit field select the size of the key used for the AES algorithm in increments of 64 bits.	
		0-1	Reserved
		2	128 Bits
		3	192 Bits
		4	256 Bits
		5-7	Reserved
28:24 (R/W)	ARC4KEYLEN	ARC4 Key Length.	
23:16 (R/W)	HSHCOFFST	Hash Crypt Offset. For Basic Encrypt-Hash and Basic Hash-Decrypt operations, the `PKTE_SA_CMD1.HSHCOFFST` bit field specifies the offset between the hash data and the encrypt/decrypt data. The data to be hashed is assumed to come first, with an offset to the beginning of encrypt/decrypt data. When `PKTE_SA_CMD1.BYTEOFFST`, bit 13, is zero, then the offset is defined in 32-bit words. When an initialization vector is loaded through the input buffer, valid values range from IV size to 255. In all other cases, valid values range from 0 to 255. When `PKTE_SA_CMD1.BYTEOFFST`, bit 13, is one, then the offset is defined in 8-bit bytes. When an initialization vector is loaded through the input buffer, valid values range from IV size to 255. In all other cases, valid values range from 4 to 255. (The IV size is two words for DES, Triple-DES and AES-CTR and four words for AES-CBC and AES-ICM operations). Other operations do not use these bits (a default value is applied by the packet engine).	
13 (R/W)	BYTEOFFST	Byte Offset. The `PKTE_SA_CMD1.BYTEOFFST` bit defines how the `PKTE_SA_CMD1.HSHCOFFST`, bits of this register are used.	
		0	HASH_CRYPT_OFFSET is defined in 32-bit words
		1	HASH_CRYPT_OFFSET is defined in 8-bit bytes
12 (R/W)	HMAC	Keyed-Hash SSL Message Authentication Code. For basic operations that include hashing, the `PKTE_SA_CMD1.HMAC` bit enables the HMAC processing, which calls for an extra outer hash operation.	
		0	Standard Hash
		1	HMAC Processing

Table 44-69: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	SSLMAC	Ssl Mac.	
		0	Standard Hash
		1	SSL-MAC processing
9:8 (R/W)	CIPHERMD	Cipher Mode. The `PKTE_SA_CMD1.CIPHERMD` bit field selects the crypto mode to be used for the cipher algorithm.	
		0	Electronic Code Book (ECB) used for DES and AES
		1	Cipher Block Chaining (CBC) used for DES and AES
		2	AES Counter Mode (CTR) for IPsec using a 32-bit counter
		3	AES Integer Counter Mode (ICM) for SRTP using a 16-bit counter. Note: This is implemented as a 32-bit counter, the Host must check for an overflow from the value 0xFF to zero and then refresh the IV.
3 (R/W)	CPYPAD	Copy Pad. The `PKTE_SA_CMD1.CPYPAD` bit indicates that the padding data for an inbound operation is copied to the output buffer and saved in memory.	
		0	Do not copy the padding to output
		1	Copy padding to output
2 (R/W)	CPYPAYLD	Copy Payload. The `PKTE_SA_CMD1.CPYPAYLD` bit indicates that the payload data is copied to the output buffer and saved in memory.	
		0	Do not copy the payload to output
		1	Copy payload to output
1 (R/W)	CPYHDR	Copy Header. The `PKTE_SA_CMD1.CPYHDR` bit indicates that the protocol header is copied to the output buffer and saved in memory. For Basic Encrypt-Hash and Basic Hash-Decrypt operations, the header is defined as the Hash/Crypt Offset data (authenticated only).	
		0	Do not copy the header to output
		1	Copy header to output

Table 44-69: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	CPYDGST	Copy Digest. The `PKTE_SA_CMD1.CPYDGST` bit copies the hash result is to the output buffer and saves in memory. The length of the hash result is defined by the `PKTE_SA_CMD0.DIGESTLEN` field.	
		0	Do not copy hash result to output
		1	Copy hash result to output, when the command descriptor `PKTE_CTL_STAT.HASHFINAL` bit is set.

SA Inner Hash Digest Registers

The `PKTE_SA_IDIGEST[n]` registers are a set of eight 32-bit read/write registers.

For MD5, SHA-1, SHA-224 and SHA-256, these read/write registers are used to enter a start hash state, and to read the interim or final hash digest.

For IPsec, TLS and DTLS operations that make use of MD5, SHA-1, SHA-224 or SHA-256 with basic hash or HMAC authentication with the `PKTE_SA_CMD0.HASHSRC` bits = 00 (from SA), these registers hold the pre-computed inner hash digest. This is the hash of the hash-key padded with 0x36 hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-MD5 with the `PKTE_SA_CMD0.HASHSRC` bits = 00 (from SA), these registers hold the inner hash pre-compute; this is the hash of the MAC_WRITE_SECRET padded with 0x36 hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-SHA-1 with the `PKTE_SA_CMD0.HASHSRC` bits = 00 (from SA), these registers hold the MAC_WRITE_SECRET. Note that it is not possible to calculate a hash pre-compute for SHA-1 in combination with SSL-MAC (specification flaw). The packet engine appends the hash-key pad (0x36 hex) and sets the starting hash byte count automatically to 60 decimal / 0x3C hex (to indicate that 60 bytes have already been prepared for the hash).

The reset value for these registers is zero.

SA Initialization Vector Register

The `PKTE_SA_NONCE` register is used for operations that make use of the IV value loaded from the SA record. This register is used both to enter a starting IV state, as well as for reading the interim or final IV. For IPsec outbound operations, it is recommended that the automatic IV insertion mode be used, this register is not needed. For IPsec inbound operations, the IV is extracted from the header of the packet.

SA Outer Hash Digest Registers

The `PKTE_SA_ODIGEST[n]` registers are a set of five eight 32-bit write-only registers.

For write operations, these registers contain the pre-computed outer hash digest for IPsec operations with basic HMAC operations with the `PKTE_SA_CMD0.HASHSRC` bits = 00 (from SA).

For MD5, SHA-1, SHA-224 and SHA-256, these read/write registers hold a start hash state, or the interim outer hash digest. They are only used for HMAC processing.

For IPsec, SSL, TLS, DTLS and SRTP operations that make use of MD5, SHA-1, SHA-224 or SHA-256 with HMAC authentication with the `PKTE_SA_CMD0.HASHSRC` bits = 00 (from SA), these registers hold the pre-computed outer hash digest. This is the hash of the hash-key padded with 0x5C hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-MD5 with the `PKTE_SA_CMD0.HASHSRC` bits = 00 (from SA), these registers hold the outer hash pre-compute; this is the hash of the MAC_WRITE_SECRET padded with 0x5C hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-SHA-1 with the `PKTE_SA_CMD0.HASHSRC` bits = 00 (from SA), these registers hold the MAC_WRITE_SECRET. Note that it is not possible to calculate a hash pre-compute for SHA-1 in combination with SSL-MAC (specification flaw). The packet engine appends the required hash-key pad (0x5C hex) and sets the starting hash byte count automatically to 60 decimal / 0x3C hex (to indicate that 60 bytes have already been prepared for the hash).

The reset value for these registers is zero.

SA Ready Indicator

In direct host mode, a write to the `PKTE_SA_RDY` register triggers the packet engine to start processing using the command descriptor, SA record and state record in the packet engine registers. This register MUST be written for all direct host mode packet operations. It is intended that this register is written in sequence; as the entire SA record is written.

SA Sequence Number Register

The `PKTE_SA_SEQNUM[n]` registers are a set of two read/write registers and are used for IPsec ESP, SSL, TLS, DTLS operations to specify the anti-replay sequence number value that is to be placed in the ESP header (outbound), or to be checked against for inbound packets. The packet engine manages this counter value for both inbound and outbound operations.

Outbound: The host writes the counter value stored in the SA record to this register to start an IPsec, SSL, TLS, DTLS operation. The packet engine automatically increments the count if header processing is selected. Upon successful completion, the host reads back this value and writes it to the SA record.

Inbound: The host writes the counter value stored in the SA record to this register to start an IPsec or DTLS operation. The packet engine automatically performs the specified inbound processing (per RFC 4303) as it processes the packet. As a result, the expected count value may or may not be updated during processing. Upon successful completion, the host should read back this value and write it to the SA record.

Note: The description is only for the direct host mode. The sequence number for autonomous ring mode and target command mode are updated by the packet engine.

The reset value of this register is zero.

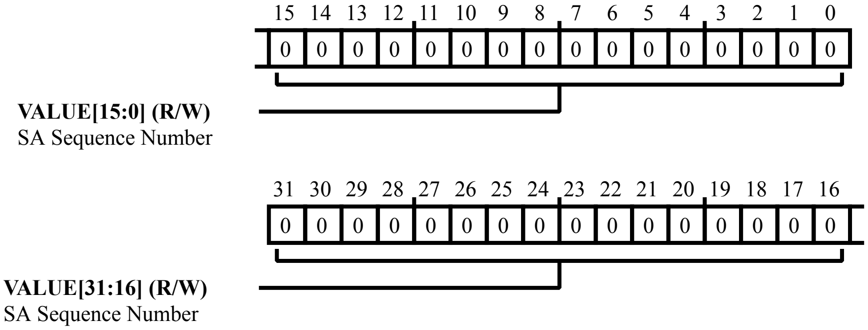

Figure 44-49: PKTE_SA_SEQNUM[n] Register Diagram

Table 44-75: PKTE_SA_SEQNUM[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Sequence Number.

SA Sequence Number Mask Registers

The `PKTE_SA_SEQNUM_MSK[n]` registers are a set of two read/write registers and are used for IPsec ESP and DTLS operations to specify the anti-replay sequence number mask value for inbound operations. The packet engine manages this counter value automatically.

Inbound: The host writes the counter value stored in the SA record into this register upon starting an IPsec, DTLS operation. The packet engine automatically performs the specified inbound processing (per RFC 4303) as it processes the packet. As a result, the new mask value may or may not be updated during processing. Upon successful completion, the host should read back this value and write it to the SA record.

Outbound: not used.

Note that the above description only applies to the direct host mode, for autonomous ring mode and target command mode the packet engine extracts the sequence number mask from the SA record.

Table 44-77: PKTE_SA_SPI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	SA SPI. The `PKTE_SA_SPI.VALUE` bit field is used for IPsec ESP operations to specify the Security. Parameters Index (SPI) value that is to be placed in the ESP header. There is no need to read back this value at the end of an operation, since the Packet Engine does not change it. For SSL, TLS and DTLS this register stores the 8-bit TYPE field in bits [23:16], and the 16-bit Version field in bits [15:0] that are part of the protocol header.

Packet Engine Source Address

The `PKTE_SRC_ADDR` register holds the starting (byte) address for the packet to be processed.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Packet Source Address. The `PKTE_SRC_ADDR.VALUE` bit field holds the starting (byte) address for the packet to be processed.

Packet Engine Status Register

The PKTE_STAT register is used to provide the status of the packet engine. This register is useful in the direct host mode to determine when data must be written to or read from the packet engine, or for debugging the software when errors occur. This register can be ignored in autonomous ring mode and target command mode where the DMA engine controls the packet data I/O. This is a read-only register. A write to any of the bits has no effect.

Figure 44-53: PKTE_STAT Register Diagram

Table 44-79: PKTE_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:22 (R/NW)	OBUFFULLCNT	Output Buffer Full Count. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of 32-bit words that are available in the packet engine output buffer. It works in conjunction with bit 11 from this register. When bit 11 is asserted, to indicate a request for output, the word count matches the specified output buffer threshold setting in the PKTE_BUF_THRESH register. For the last output for a given packet, any value from 1 dword to the full output buffer threshold can be seen. Transfers must be a multiple of full dwords. The application must read the PKTE_LEN field in the result descriptor to determine the exact byte-length of the result.

Table 44-79: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:12 (R/NW)	IBUFEMPTYCNT	Input Buffer Empty Count. The `PKTE_STAT.IBUFEMPTYCNT` bit field indicates the number of 32-bit empty spaces that are available in the packet engine input buffer. It works in conjunction with the `PKTE_STAT.IBUFREQ` bit (10) from this register. The value in the register is deducted from the specified packet length, so will never exceed the number of dwords that remain in the packet. For packets smaller than the buffer size, this register typically indicates that buffer space is available for the entire packet (rounded up to the nearest dword). For very large packets, these bits usually have a value around the maximum buffer size, indicating that the full input buffer is available.	
11 (R/NW)	OBUFREQ	Output Buffer Request Active. The `PKTE_STAT.OBUFREQ` bit indicates that the packet engine requests output data to be read from the output buffer.	
		0	No request for output data
		1	Request for output data
10 (R/NW)	IBUFREQ	Input Buffer Request Active. The `PKTE_STAT.IBUFREQ` bit indicates that the packet engine requests input data to be written to the input buffer.	
		0	No request for input data
		1	Request for input data
9 (R/NW)	OPDN	Operation Done. The `PKTE_STAT.OPDN` bit indicates that the packet engine has finished processing a packet when in direct host mode. This bit is zero in autonomous ring mode and target command mode.	
		0	Packet engine is idle
		1	Packet engine has finished processing a packet
8 (R/NW)	EXTERR	Extended Error. The `PKTE_STAT.EXTERR` bit indicates that an extended error occurred for this packet. For more information, refer to table Extended Error Codes - Status Encoding.	
		0	No extended error
		1	Extended error

Table 44-79: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	SNUMERR	Sequence Number Error. For an inbound operation, the `PKTE_STAT.SNUMERR` bit indicates that there was a fault in the anti-replay sequence number. For an outbound operation, there was a sequence number overflow condition. For more information, refer to table Extended Error Codes - Status Encoding.	
		0	No sequence number error
		1	Input done, all bytes written to input buffer
6 (R/NW)	PADERR	Pad Error. The `PKTE_STAT.PADERR` bit indicates that an inbound crypto pad fault is detected. For more information about pad verification, refer to the Pad Verification and Consumption section.	
		0	No pad error
		1	Pad error
5 (R/NW)	AUTHERR	Authentication Error. The `PKTE_STAT.AUTHERR` bit indicates that an inbound ICV (for IPsec) or TAG (for SRTP) or MAC (for SSL/TLS/DTLS) fault is detected; the value carried within the packet did not match the value just computed.	
		0	No authentication error
		1	Authentication error
4 (R/NW)	OUTHSHDN	Outer Hash Done. The `PKTE_STAT.OUTHSHDN` bit indicates that the outer hash processing for this packet is finished.	
		0	Outer hash busy
		1	Outer hash done
3 (R/NW)	INHSHDN	Inner Hash Done. The `PKTE_STAT.INHSHDN` bit indicates that the inner hash processing for this packet is finished.	
		0	Inner hash busy
		1	Inner hash done
2 (R/NW)	ENCRYPTDN	Encrypt Done. The `PKTE_STAT.ENCRYPTDN` bit indicates that the encryption or decryption for this packet is finished.	
		0	Encryption or decryption busy
		1	Encryption or decryption done

Table 44-79: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	OUTPTDN	PE Output Done. The `PKTE_STAT.OUTPTDN` bit indicates that the output data for the current packet is read from the packet engine output buffer.	
		0	Output not done, more output bytes available
		1	Output done, all bytes read from the output buffer
0 (R/NW)	INPTDN	Packet Engine Input Done. The `PKTE_STAT.INPTDN` bit indicates that the number of bytes specified in the command descriptor `PKTE_LEN` field is written into the packet engine input buffer.	
		0	Input not done, more input bytes expected
		1	Input done, all bytes written to input buffer

Packet Engine State Record Address

The `PKTE_STATE_ADDR` register holds the start address of the SA state record.

State Hash Byte Count Registers

The `PKTE_STATE_BYTE_CNT[n]` registers are used to enter a starting hash byte count, as well as to read the interim or final byte count.

For some hash operations, these registers are ignored and the byte count is internally set to 64 (0x40 hex) to indicate that the first 64 bytes (512 bits) hash block has been processed using a pre-computed hash state. These operations are:

All IPsec, SSL, TLS, DTLS and SRTP operations that use authentication; the "pre-computed" inner and outer hash digests are loaded from SA words 10 - 19.

Basic operations with `PKTE_SA_CMD0.HASHSRC` bits = 00 (from SA) specified. For Basic Hash with no HMAC, a pre-computed digest is loaded from SA words 10 - 14. For Basic Hash with HMAC, the inner and outer digests are loaded from SA words 10 - 19.

Note: Protocol operations can not be suspended in mid-packet and resumed later, therefore protocol operations do not use these registers.

State Inner Digest Registers

The `PKTE_STATE_IDIGEST[n]` registers consist of eight 32-bit registers. These read/write registers are used to read the interim or final hash digest. The `PKTE_STATE_IDIGEST[n]` registers are only used with basic operations involving basic hash, and are typically used for operations that must be suspended and resumed in the middle of a hash. The interim hash state can be read from these registers along with the hash byte-count from the previous register. Both can be restored when resuming the hash. The appropriate save hash state (`PKTE_SA_CMD0.SVHASH`=1) and load hash from state (`PKTE_SA_CMD0.HASHSRC`=0b10) settings must be used. These registers are a mirror of the SA record inner hash digest register.

31:0 (R/W)	VALUE	Saved Inner Hash Digest.

State Initialization Vector Registers

The `PKTE_STATE_IV[n]` consists of four 32-bit registers. These registers are used to enter a starting IV state and to read the interim or final IV. PKTE_STATE_IV0 and PKTE_STATE_IV1 are used with DES/3DES cipher while PKTE_STATE_IV0 to PKTE_STATE_IV3 are used with AES cipher. The reset value of these registers is zero.

Packet Engine User ID

The PKTE_USERID register is a read/write register that gives identification to a command descriptor and the resultant result descriptor. The host is free to use this field for its own purpose. The host can write a unique identifier to the register in direct host mode or includes it as part of the command descriptor in autonomous ring mode. The PKTE_USERID register value passes though the packet engine without alteration to the result descriptor to be read back by the host.

VALUE[31:16] (R/W)
Command Descriptor User ID

Figure 44-58: PKTE_USERID Register Diagram

Table 44-84: PKTE_USERID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Descriptor User ID. The PKTE_USERID.VALUE bit field gives identification to a command descriptor and the resultant result descriptor.

45 Public Key Accelerator (PKA)

The PKA helps offload computationally-intensive operations commonly found in public key cryptography algorithms.

PKA Features

The PKA engine provides the following basic operations:

- Large vector addition, subtraction, and combined addition/subtraction
- Large vector shift right or left
- Large vector multiplication, division (with and without quotient)
- Large vector compare and copy

The PKA engine provides the following complex operations:

- Large vector unsigned value modular exponentiation
- Large vector unsigned value modular exponentiation using the ‘Chinese Remainders Theorem’ (CRT) method with pre-calculated Q inverse vector
- Modular inversion: Given A and M, calculate B such that ((A × B) MOD M) = 1
- ECC point addition/doubling on elliptic curve $y^2 = x^3 + ax + b \pmod{p}$ with prime number *p* and input values *a* and *b* to the operation. Adding two identical points automatically performs point doubling.
- ECC point multiplication on elliptic curve $y^2 = x^3 + ax + b \pmod{p}$ with prime number *p* and input values *a* and *b* to the operation. A version of the ‘Montgomery ladder’ algorithm is used to provide side channel attack resistance.

The PKA also contains hardware logic to automatically zero out the PKA RAM buffer to clear out any information that is considered sensitive or secure.

PKA Functional Description

The following sections provide details on the function of the PKA module.

ADSP-SC58x PKA Register List

The Public Key Accelerator module (PKA) provides security-related features. A set of registers governs PKA operations. For more information on PKA functionality, see the PKA register descriptions.

Table 45-1: ADSP-SC58x PKA Register List

Name	Description
PKA_ALEN	PKA Vector_A Length
PKA_APTR	PKA Vector_A Address
PKA_BLEN	PKA Vector_B Length
PKA_BPTR	PKA Vector_B Address
PKA_COMPARE	PKA Compare Result
PKA_CPTR	PKA Vector_C Address
PKA_DIVMSW	PKA Most-Significant-Word of Divide Remainder
PKA_DPTR	PKA Vector_D Address
PKA_FUNC	PKA Function
PKA_RAM	Start of PKA RAM space
PKA_RESULTMSW	PKA Most-Significant-Word of Result Vector
PKA_SHIFT	PKA Bit Shift Value

PKA Definitions

The following definitions are helpful when using the PKA module.

Elliptic Curve Cryptography (ECC)

A form of public key cryptography based on elliptic curves over finite fields.

RSA

An acronym for Ron Rivest, Adi Shamir, and Leonard Adleman. It is another form of a public key cryptosystem.

Chinese Remainder Theorem (CRT)

A mathematical theorem used for simplifying time-consuming arithmetic used in public key algorithm computations.

Addition Chaining Table (ACT)

A method of speeding up exponentiation by repeatedly squaring the input and storing the result and reusing the result as input. ACT2 uses a table with 2 address bits (4 entries) and ACT4 uses a table with 4 address bits (16 entries).

PKA Architectural Concepts

The following sections describe the PKA architecture.

Public Key Co-Processor (PKCP)

The Public Key Co-Processor (PKCP) handles the basic large vector processing such as addition, subtraction, multiplication, etc.

Sequencer

The sequencer is small processor that is part of the PKA which handles the more complicated vector processing for public key algorithms. Algorithms include modular exponentiation and the ECC addition and ECC multiply used in Elliptic Curve Cipher algorithms. It executes instructions stored from an internal pre-programmed ROM that handles these operations.

RAM

Input and output vectors are stored in a 4 kB RAM buffer that is part of the MMR space. The address of PKA_RAM is the beginning of the RAM space. This memory is also used as a scratchpad or workspace for the sequencer and PKCP. Programs must place the vectors appropriately following the constraints described in the ***Functional Description*** section of this chapter.

PKA Block Diagram

The ***PKA Block Diagram*** shows the top-level block diagram of the PKA engine. The PKA engine is comprised of five parts:

1. Registers for input, output, status, and control
2. Public Key Co-processor (PKCP) module which performs the basic suite of big number (vector) operations typically found in public key cryptography applications
3. Sequencer which controls modular exponentiation, elliptic curve cryptography, and modular inversion operations.
4. Program ROM associated with the PKA engine exclusively for the sequencer
5. PKA RAM holds the large input and output values as well as the workspace/scratchpad required from the sequencer and PKCP for operations.

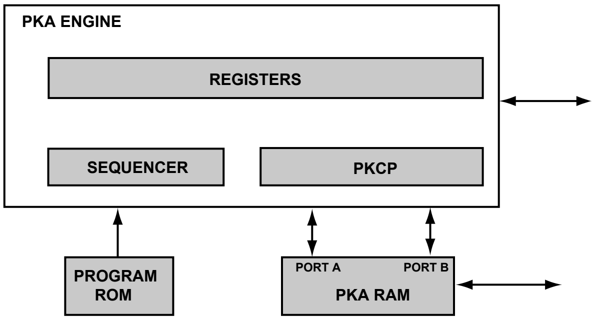

Figure 45-1: PKA Block Diagram

PKCP Vector Operations

The ***Summary of PKCP Vector Operations*** table lists the arguments and results for each PKCP vector operation.

Table 45-2: Summary of PKCP Vector Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
Multiply	A x B → C	Multiplicand	Multiplier	Product	N/A
Add	A + B → C	Addend	Addend	Sum	N/A
Subtract	A - B → C	Minuend	Subtracthend	Difference	N/A
AddSub	A + C - B → D	Addend	Subtracthend	Addend	Result
Right Shift	A >> Shift → C	Input	N/A	Result	N/A
Left Shift	A << Shift → C	Input	N/A	Result	N/A
Divide	A mod B → C, A div B → D	Dividend	Divisor	Remainder	Quotient
Modulo	A mod B → C	Dividend	Divisor	Remainder	N/A
Compare	A = B, A < B, A > B	Input 1	Input 2	N/A	N/A
Copy	A → C	Input	N/A	Result	N/A

To obtain correct result, the input vectors must meet the requirements presented in the ***Operational Restrictions on Input Vectors for PKCP Operations*** table.

Note the following:

- The PKCP does not check input restrictions
- A_Len and B_Len indicate the size of vectors A and B in (32-bit) words
- Max_Len equals 128 (32-bit) words, for example, the standard maximum vector size is 4096 bit

Table 45-3: Operational Restrictions on Input Vectors for PKCP Operations

Function	Requirement
Multiply	0 < A_Len, B_Len <= Max_Len
Add	0 < A_Len, B_Len <= Max_Len
Subtract	0 < A_Len, B_Len <= Max_Len Result must be positive (A>=B)
AddSub	0 < A_Len <= Max_Len (B and C operands have A_Len as length, B_Len ignored) Result must be positive ((A + C) >= B)
Right Shift	0 < A_Len <= Max_Len
Left Shift	0 < A_Len <= Max_Len
Divide, Modulo	1 < B_Len <= A_Len <= Max_Len Most significant 32-bit word of B operand cannot be zero
Compare	0 < A_Len <= Max_Len (B operand has A_Len as length, B_Len ignored)
Copy	0 < A_Len <= Max_Len

The host processor is responsible for allocating a block of contiguous memory in PKA RAM for the result vectors. The ***PKCP Result Vector Memory Allocation*** table indicates how much memory is allocated for the result vectors.

Table 45-4: PKCP Result Vector Memory Allocation

Function	Result Vector	Result Vector Length (in 32-bit words)
Multiply	C	A_Len + B_Len + 6 (the 6 ‘scratchpad’ words should be discarded)
Add	C	Max(A_Len, B_Len) + 1
Subtract	C	Max(A_Len, B_Len)
AddSub	D	A_Len + 1
Right Shift	C	A_Len
Left Shift	C	A_Len + 1 (when Shift Value is non-zero) A_Len (when Shift Value is zero)
Divide	C	Remainder → B_Len + 1 (one ‘scratchpad’ word should be discarded)
	D	Quotient → A_Len – B_Len + 1
Modulo	C	Remainder → B_Len + 1 (one ‘scratchpad’ word should be discarded)
Compare	None	Compare updates the PKA_COMPARE register
Copy	C	A_Len

Input vectors for an operation are always allowed to overlap in memory (partially or completely). The ***PKCP Result Vector/Input Overlap Restrictions*** table gives restrictions for the overlap of output and input vectors of the operations.

Table 45-5: PKCP Result Vector/Input Overlap Restrictions

Function	Result Vector	Restrictions
Multiply	C	No overlap with A or B vectors allowed
Add, Subtract	C	May overlap with A and/or B vector, provided the start address of the C vector does not lie above the start address of the vectors with which it overlaps
AddSub	D	May overlap with A, B and/or C vector, provided the start address of the D vector does not lie above the start address of the vectors with which it overlaps
Right Shift, Left Shift	C	May overlap with A vector, provided the start address of the C vector does not lie above the start address of the A vector
Divide	C	No overlap with A, B, or D vectors allowed
	D	No overlap with A, B, or C vectors allowed
Modulo	C	No overlap with A or B vectors allowed
Compare	None	Compare does not write a result vector
Copy	None	Same restrictions as for right or left shift, copy of a vector to a lower address is always allowed even if source and destination overlap†

†The copy operation can be used to fill memory by breaking the overlap restrictions, but it requires setting up TWO initial (32-bit) words. To zero a block of memory, set the A vector pointer to the block start, set the C vector pointer two words higher and the A vector length to the block length minus two (words). Fill the first two words of the block with constant zero and perform a PKCP copy operation to zero the remainder of the block.

Modular Exponentiation Operations

The ***Summary of ExpMod Operations*** table summarizes the modular exponentiation operations that the PKA supports.

Table 45-6: Summary of ExpMod Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	$C^A \bmod B \rightarrow D$	Exponent, length = A_Len	Modulus, length = B_Len	Base, length = B_Len	Result and Workspace
ExpMod-CRT	See below	Exp P followed by Exp Q at next higher even word address†, both A_Len long	Mod P + buffer word followed by Mod Q at next higher even word address‡, both B_Len long	Q inverse, length = B_Len	Input, Result (both 2xB-Len long) and Workspace

† If A_Len is even, Exp Q follows Exp P immediately – if A_Len is odd, there is one empty word between Exp Q and Exp P.

‡ If B_Len is even, there are two empty words between Mod P and Mod Q – if B_Len is odd, there is one empty (buffer) word between Mod Q and Mod P. Note that the engine may zero the words following Mod P and Mod Q.

The ExpMod-CRT operation performs the following computation steps. (These steps implement Garner's recombination algorithm after the basic exponentiations.)

- X <- (Input mod Mod P)Exp P mod Mod P
- Y <- (Input mod Mod Q)Exp Q mod Mod Q
- Z <- ((((X – Y) mod Mod P) · Q inverse) mod Mod P) · Mod Q
- Result <- Y + Z

The ExpMod-ACT2, -ACT4, and -variable functions implement the same mathematical operation but with a differently sized table with pre-calculated *odd powers*. The ExpMod-ACT2 function uses a table with two entries whereas ExpMod-ACT4 uses a table with eight entries. The ACT4 version gives better performance but needs more memory. ExpMod-variable and ExpMod-CRT operations allow the selection of a variable number (from 1 up to and including 16) of odd powers through the register normally used to specify the number of bits to shift for shift operations.

The exponentiation functions are extensions of the set of PKA functions. Input and result vectors are passed the same way as basic PKCP operations. The ***Restrictions on Input Vectors for ExpMod Operations*** table shows the restrictions on the input and result vectors for the exponentiation operations.

Table 45-7: Restrictions on Input Vectors for ExpMod Operations

Function	Requirements
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	0 < A_Len <= Max_Len 1 < B_Len <= Max_Len Modulus B must be odd (for example, the least significant bit must be ONE) Modulus B > 2^{32} Base C < Modulus B Vectors B and C must be followed by an empty 32-bit *buffer* word
ExpMod-CRT	0 < A_Len <= Max_Len 1 < B_Len <= Max_Len Mod P and Mod Q must be odd (for example, the least significant bits must be ONE) Mod P > Mod Q > 2^{32}(note that Mod P must be larger than Mod Q) Mod P and Mod Q must be co-prime (their GCD must be 1) 0 < Exp P < (Mod P – 1) 0 < Exp Q < (Mod Q – 1) (Q inverse · Mod Q) 1 (modulo Mod P) Input < (Mod P · Mod Q) Mod P and Mod Q must be followed by an empty 32-bit *buffer* word

The ***ExpMod Result Vector/Scratchpad Area Memory Allocation Starting at PKA_DPTR*** table shows the required scratchpad sizes for the exponentiation operations. These sizes depend on the PKA type. The 'M_Len' used in the table is the 'real' Modulus length in 32-bit words, for example, without trailing zero words at the end. (This description also applies to Mod P in an ExpMod-CRT operation and Modulus B in the other operations.) If the last word of the modulus vector as given is non-zero, 'M_Len' equals B_Len.

Table 45-8: ExpMod Result Vector/Scratchpad Area Memory Allocation Starting at PKA_DPTR

Function	Scratchpad Area Size (in 32-bit words), Result Vector is either M_Len or 2xM_Len 32-bit words long
ExpMod-ACT2	5 x (M_Len + 2)
ExpMod-ACT4	11 x (M_Len + 2)
ExpMod-variable	(# odd powers + 3) x (M_Len + 2)
ExpMod-CRT	(# odd powers + 3) x (M_Len + 2) + (M_Len + 2 – (M_Len MOD 2))

NOTE: During execution of an ExpMod-ACT2, -ACT4 or -variable operation, the last 34 bytes of the PKA RAM are used as the general scratchpad for the sequencer program execution. The ExpMod-CRT operation requires the last 72 bytes of the PKA RAM as the scratchpad. These (fixed location) areas may not overlap with any of the input vectors and/or the D vector scratchpad area. They can be used freely when executing basic PKCP operations.

Table 45-9: ExpMod Scratchpad Area / Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	D	Scratchpad area starting at D may not overlap with any of the other vectors, except that base C may be co-located with result vector D to save space (for example,`PKA_CPTR`= `PKA_DPTR` is allowed).
ExpMod-CRT	D	Scratchpad area starting at D may not overlap with any of the other vectors. This area is also the location of the main input vector (with length 2 x B_Len)

The ***Maximum Number of Odd Powers*** table indicates the maximum number of odd powers that can be used for different standard PKA RAM sizes and PKA types (non-CRT operations using `PKA_CPTR` = `PKA_DPTR`). As a rule of thumb, for optimal performance, use one odd power for *Verify* operations and 4 (or as many as the implemented PKA RAM size allows) for *Sign* operations. Note the following points about odd powers:

- Using more than eight odd powers is not advisable as the speed advantage for each extra odd power decreases rapidly (and can even become negative for short exponent vector lengths due to the extra pre-processing required).
- The maximum number of odd powers is 16 (limited by the firmware). All '16 odd powers' entries in the table above hit this limit – they are not limited by the PKA RAM size.

Table 45-10: Maximum Number of Odd Powers

Operation	Modulus and Exponent Sizes	Maximum Number of Odd Powers
Non-CRT	1024 bits	16
	2048 bits	10
	4096 bits	2
CRT	2 × 512 bits	16
	2 ×1024 bits	16
	2 × 2048 bits	6

The ***2K-bit Modular Exponentiation PKA RAM Allocation Examples*** table shows example PKA RAM vector allocations for modular exponentiation operations with and without using CRT. The *free space* start address is the first free byte following the vector workspace. The sequencer execution scratchpad of 34 bytes (non-CRT) or 72 bytes (using CRT) must fit between this address and the end of the PKA RAM. Note that the non-CRT operations use `PKA_CPTR` = `PKA_DPTR` to save space.

Table 45-11: 2K-bit Modular Exponentiation PKA RAM Allocation Examples

Operation	(sub-)vector	Start address (Byte Offset)	Size (words)	Buffer (words)
non-CRT (`PKA_ALEN` = 0x040, `PKA_BLEN` = 0x040, 4 odd-powers)	Exponent	0x000 (`PKA_APTR` = 0x000)	64	0
	Modulus	0x100 (`PKA_BPTR` = 0x040)	64	2
	Base	0x208 (`PKA_CPTR` = 0x082)	64	2
	Result	0x208 (`PKA_DPTR` = 0x082)	64	2
	Vector Workspace	0x208 (= Result)	7 × (64+2)=462	0
	Free space	0x940 (2368 bytes used)	-	-
using CRT (`PKA_ALEN` = 0x020, `PKA_BLEN` = 0x020, 4 odd-powers)	Exp P	0x000 (`PKA_APTR` = 0x000)	32	0
	Exp Q	0x080	32	0
	Mod P	0x100 (`PKA_BPTR` = 0x040)	32	2
	Mod Q	0x188	32	2
	Q inverse	0x210 (`PKA_CPTR` = 0x084)	32	0
	Input, Result	0x290 (`PKA_DPTR` = 0x0A4)	64	0
	Vector workspace	0x290 (= Result)	7 × (32+2)+32+2-0 = 272	0
	Free space	0x6D0 (1744 bytes used)	-	-

The following example in pseudo-code describes the execution of a non-CRT modular exponentiation operation using a 512 bits modulus and a 160 bits exponent, using actual test vectors:

```
// Perform a 512/160 bits
modular exponentiation without CRT (using 4 ‘odd-powers’)
// Exponent equals value 0x8FD84098_8A0930CC_9CDC1E8A_B246EB46_2D39F064
// write as vector A to PKA

Modular Inversion

Besides modular exponentiation, the sequencer also controls modular inversion operations.

Table 45-12: Summary of ModInv Operation

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ModInv	A^{-1} mod B → D	NumToInvert, length = A_Len	Modulus, length = B_Len	Not Used	Result and Workspace

The above function appears to be an extension of the set of basic PKCP functions with the following exceptions:

- Vector D not only addresses the result but also a workspace
- The `PKA_SHIFT` register field is used to return info on the operation's result.

Table 45-13: PKA_SHIFT Result Values for ModInv Operation

Function	PKA_SHIFT Register Field Value At Conclusion
ModInv	0 → success; VectorD holds result 7 → no inverse exists (GCD(A, B) != 1, for example, A and B have common factors); result undefined 31 → error, modulus even; result undefined other values are reserved

The following tables list the restrictions on the input and result vectors for the ModInv operation:

Table 45-14: Operational Restrictions on Input Vectors for the ModInv Operation

Function	Requirements
ModInv	0 < A_Len <= Max_Len 0 < B_Len <= Max_Len Modulus B must be odd (for example, the least significant bit must be ONE) Modulus B may not have value 1 (result is undefined, no error indicated) The highest word of the modulus vector, as indicated by B_Len, may not be zero.

Table 45-15: ModInv Scratchpad Area/Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ModInv	D	Scratchpad area starting at D may not overlap with any of the other vectors

The following table shows the required scratchpad sizes for the ModInv Operation:

Table 45-16: ModInv Result Vector/Scratchpad Area Memory Allocation (Both Starting at PKA_DPTR)

Function	Scratchpad area size (in 32-bit words), Result Vector is B_Length 32-bit words long
ModInv	5 x (M + ε(M)), with M = Max(A_Length, B_Length) ε(n) = 2 + (n MOD 2), for example, 2 (for n even) or 3 (for n odd)

NOTE: During execution of a ModInv operation, the last 34 bytes of the PKA RAM are used as general scratchpad for the sequencer program execution. This (fixed location) area may not overlap with any of the input vectors and/or the D vector scratchpad area during execution.

Modular Inversion with an Even Modulus

The ModInv operation requires the modulus to be odd. At first, this requirement appears to make the operation useless in the case of RSA key generation where the private key exponent *d* is derived from a chosen public exponent *e* as follows:

d = ModInv(e, φ); where φ = (p-1) × (q-1) and *p* and *q* both prime

Note that φ is even. However, since *e* must be odd (otherwise no inverse exists), *d* can be calculated as:

d = (1 + (φ × (e – ModInv(φ, e))) / e

With four more basic PKCP operations, ModInv can also be used to find inverse values in case the modulus is even.

Modular Inversion with a Prime Modulus

Modular inversion can be performed with a modular exponentiation using the modulus value minus two as exponent, provided that the modulus value is a prime. This is due to the following:

$(A^{M}) \bmod M = A \Rightarrow$

$(A^{M-1}) \bmod M = 1 \Rightarrow$

$(A^{M-2}) \bmod M = A{-}1 \pmod M$

Under the constraint that M is a prime value.

Especially with the large PKA engines containing an LNME, it is worthwhile to check whether this method is faster than using the ModInv operation directly. The modulus values for the ECC curves supported by this PKA engine must be prime, so this method can be used in ECDSA operations.

ECC Operations

Besides modular exponentiation and modular inversion, the sequencer also controls ECC operations.

Table 45-17: Summary of ECC Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ECC-ADD	Point addition/ doubling† on elliptic curve: $y^2 = x^3 + ax + b \pmod{p}$ pntA + pntC → pntD	pntA.x followed‡ by pntA.y both B_Len long (A_Len *not* used)	Curve parameter *p* followed‡ by *a* (*b* is not needed) all B_Len long	pntC.x followed by pntC.y both B_Len long	Result, for example, pntD.x followed‡ by pntD.y and workspace
ECC-MUL	Point multiplication on elliptic curve: $y^2 = x^3 + ax + b \pmod{p}$ *k* x pntC → pntD	Scalar *k* A_Len long	Curve parameter *p* followed‡ by *a*and *b* all B_Len long.	pntC.x followed‡ by pntC.y both B_Len long	Result, for example pntD.x followed‡ by pntD.y and workspace

† If pntA = pntC, a point doubling operation is performed automatically.

‡ All input components must be located on a 64-bit boundary and must have extra 'buffer' words (of 32 bits each) after their most significant word. ε must be 3 (B_Len odd) or 2 (B_Len even). Each result component (for example, pntD.x, pntD.y) is followed by ε buffer (zero) words.

The above functions appear to be extensions of the set of PKCP basic functions with the following exceptions:

- Input and result vectors can now be composite (for example, consist of two or three equal-sized subvectors)
- Vector D not only addresses the result but also a workspace
- The `PKA_SHIFT` register is used to return info on the result of the operation

Table 45-18: PKA_SHIFT Result Values for ECC Operations

Function	PKA_SHIFT Register Field Value at Conclusion
ECC-ADD ECC-MUL	0 → success; VectorD holds result point 7 → result is point-at-infinity; VectorD result point undefined 31 → error, (p not odd, p too short, etc); VectorD result point undefined Other values are reserved

The following tables below list the restrictions on the input and result vectors for the ECC operations.

Table 45-19: Operational Restrictions on Input Vectors for ECC Operations

Function	Requirements
ECC-ADD	1 < B_Len <= 24 (maximum vector length is 768 bits) Modulus p must be a prime > 2^{63} Effective modulus size (in bits) must be a multiple of 32† The highest word of the modulus vector, as indicated by B_Len, may not be zero. a< p and b< p pntA and pntC must be on the curve (this condition is not checked) Neither pntA nor pntC can be the point-at-infinity, although ECC-ADD can return this point as a result
ECC-MUL	0 < A_Len <= 24 (maximum vector length is 768 bits) 1 < B_Len <= 24 (maximum vector length is 768 bits) Modulus p must be a prime > 2^{63} Effective modulus size (in bits) must be a multiple of 32† The highest word of the modulus vector, as indicated by B_Len, may not be zero. a< p and b< p pntC must be on the curve (this condition is not checked) pntC cannot be the point-at-infinity, although ECC-MUL can return this point as a result

† Modulus lengths of 112 and 521 bits are exceptions to this rule.

Table 45-20: ECC Scratchpad Area/Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ECC-ADD ECC-MUL	D	Scratchpad area starting at D may not overlap with any of the other vectors

The >***ECC Result Vector/Scratchpad Area Memory Allocation*** table shows the required scratchpad sizes for the ECC operations:

Table 45-21: ECC Result Vector/Scratchpad Area Memory Allocation (Both Starting at PKA_DPTR)

Function	Scratchpad area size (in 32-bit words), Result Vector is 2x(B_Length+ ε †(B_Length)) 32-bit words long
ECC-ADD	2 × L + 5 x M, where L = B_Length + ε(B_Length) M = B_Length + 1 + ε(B_Length + 1)
ECC-MUL	18 x L + Max(8, L), where L = (B_Length + ε(B_Length))

† $\varepsilon(n) = 2 + (n \text{ MOD } 2)$, for example, 2 (for n even) or 3 (for n odd)

NOTE: During execution of an ECC-ADD or ECC-MUL operation, the last 72 bytes of the PKA RAM are used as a general scratchpad for the sequencer program execution. These (fixed location) areas must not overlap with any of the input vectors and the D vector scratchpad area during execution.

The ***ECC Point Multiplication PKA RAM Allocation Examples*** table shows example PKA RAM vector allocations for ECC point multiplication operations. The *free space* start address is the first free byte following the vector scratchpad. The sequencer execution scratchpad of 72 bytes must fit between this address and the end of the PKA RAM. Because of this requirement, a 521-bit ECC point multiplication cannot be performed with 2K byte PKA RAM.

Table 45-22: ECC Point Multiplication PKA RAM Allocation Examples

Modulus Length	(sub-)vector	Start Address (byte offset)	Size (words)	Buffer (words)
192 bits (=6 words, `PKA_ALEN`=0x006, `PKA_BLEN`=0x006)	Scalar *k*	0x000 (`PKA_APTR` = 0x000)	6	0

ADSP-SC58x PKA Register Descriptions

Public Key Accelerator (PKA) contains the following registers.

Table 45-23: ADSP-SC58x PKA Register List

Name	Description
PKA_ALEN	PKA Vector_A Length
PKA_APTR	PKA Vector_A Address
PKA_BLEN	PKA Vector_B Length
PKA_BPTR	PKA Vector_B Address
PKA_COMPARE	PKA Compare Result
PKA_CPTR	PKA Vector_C Address
PKA_DIVMSW	PKA Most-Significant-Word of Divide Remainder
PKA_DPTR	PKA Vector_D Address
PKA_FUNC	PKA Function
PKA_RAM	Start of PKA RAM space
PKA_RESULTMSW	PKA Most-Significant-Word of Result Vector
PKA_SHIFT	PKA Bit Shift Value

PKA Vector_A Length

During execution of basic PKCP operations, the PKA_ALEN register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_ALEN register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector A. The `PKA_APTR.VALUE` bit field is the location of Vector A within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Vector_B Length

During execution of basic PKCP operations, the `PKA_BLEN` register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the `PKA_BLEN` register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector B. The `PKA_BPTR.VALUE` bit field is the location of Vector B within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Compare Result

The `PKA_COMPARE` register provides the result of a basic PKCP Compare operation. It is updated when the `PKA_FUNC.RUN` bit is reset at the end of that operation. The status after a complex sequencer operation is unknown.

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/NW)	AGTB	Vector A is Greater Than Vector B. The `PKA_COMPARE.AGTB` bit shows the result of the basic compare operation is PKCP Vector_A is greater than Vector_B.
1 (R/NW)	ALTB	Vector A is Less Than Vector B. The `PKA_COMPARE.ALTB` bit shows the result of the basic compare operation is Vector_A is less than Vector_B.
0 (R/NW)	AEQB	Vector A is equal to Vector B. The `PKA_COMPARE.AEQB` bit shows the result of the basic compare operation is Vector_A is equal to Vector_B.

PKA Vector_C Address

During execution of basic PKCP operations, the PKA_CPTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_CPTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

Table 45-29: PKA_CPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	CPTR	Pointer to Vector C. The PKA_CPTR.CPTR bit field is the location of Vector C within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Most-Significant-Word of Divide Remainder

The `PKA_DIVMSW` register indicates the (32-bit word) address in the PKA RAM where the most significant non-zero 32-bit word of the Remainder result for the basic Divide and Modulo operations is stored. Bits [4:0] are loaded with the bit number of the most significant non-zero bit in the most significant non-zero word when MS one control bit is set. For Divide, Modulo and MS one reporting, this register is updated when the `PKA_FUNC.RUN` bit is reset at the end of the operation.

For the complex sequencer controlled operations, updating bits [4:0] of this register with the actual result's most significant bit location is done near the end of the operation. Note that the result is only meaningful if no errors were detected and that for ECC operations, the `PKA_DIVMSW` register provides information for the x-coordinate of the result point only.

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/NW)	ZERO	Remainder Result Vector is Zeros. The `PKA_DIVMSW.ZERO` bit shows the remainder result vector is all zeros, ignore the address returned in bits [10:0].
10:0 (R/NW)	ADDR	Address of Most-significant Nonzero Word. The `PKA_DIVMSW.ADDR` bit shows the address of the most significant non-zero 32-bit word of the remainder result vector in PKA RAM.

PKA Vector_D Address

During execution of basic PKCP operations, the PKA_DPTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_DPTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector D. The PKA_DPTR.VALUE bit field is the location of Vector D within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Function

The `PKA_FUNC` register contains the control bits to start basic PKCP as well as complex sequencer operations. The `PKA_FUNC.RUN` bit can be used to poll for the completion of the operation. Modifying bits [11:0] is made impossible during the execution of a basic PKCP operation.

During the execution of Sequencer controlled complex operations, this register is modified - the `PKA_FUNC.RUN` and `PKA_FUNC.STALLRSLT` bits are set to zero at the conclusion, but other bits are undefined.

Continuously reading this register to poll the `PKA_FUNC.RUN` bit is NOT allowed when executing complex sequencer operations (the sequencer cannot access the PKCP when this is done).

Leave at least one SCLK cycle between poll operations.

Stall Result

Figure 45-10: PKA_FUNC Register Diagram

Table 45-32: PKA_FUNC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/W)	STALLRSLT	Stall Result. When the `PKA_FUNC.STALLRSLT` bit is set, updating the `PKA_COMPARE`, `PKA_RESULTMSW` and `PKA_DIVMSW` registers, as well as resetting the Run bit, is stalled beyond the point that a running operation is actually finished. Use this to allow software enough time to read results from a previous operation when the newly started operation is known to take only a short amount of time. If a result is waiting, the result registers is updated and the Run bit is reset in the clock cycle following writing the Stall Result bit back to 0. The Stall result function may only be used for basic PKCP operations.
15 (R/W)	RUN	Run. Set the `PKA_FUNC.RUN` bit to instruct the PKA module to begin processing the basic PKCP or complex Sequencer operation. This bit is reset low automatically when the operation is complete. The complement of this bit is output as the pkaint1 interrupt. After a reset, the Run bit is always set to 1b but the first Sequencer firmware instruction sets this bit to 0 immediately after the hardware reset is released. A few clock cycles are needed before the first instruction is executed and the Run bit state has been propagated.
14:12 (R/W)	SEQOPS	Sequencer Operation Select. The `PKA_FUNC.SEQOPS` bit field select the complex Sequencer operation to perform. 0: None 1: ExpMod-CRT 2: ExpMod-ACT4 3: ECC-ADD 4: ExpMod-ACT2 5: ECC-MUL 6: ExpMod-variable 7: ModInv
11 (R/W)	CPY	Copy. Setting the `PKA_FUNC.CPY` bit performs the copy operation. For more information, see the "PKCP Vector Operations" section.
10 (R/W)	CMP	Perform Compare Operation. Setting the `PKA_FUNC.CMP` bit performs the compare operation. For more information, see the "PKCP Vector Operations" section.

Table 45-32: PKA_FUNC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	MODULO	Perform Modulo Operation. Setting the `PKA_FUNC.MODULO` bit performs the modulo operation. For more information, see the "PKCP Vector Operations" section.
8 (R/W)	DIV	Perform Divide Operation. Setting the `PKA_FUNC.DIV` bit performs the divide operation. For more information, see the "PKCP Vector Operations" section.
7 (R/W)	LSHFT	Perform Left Shift Operation. Setting the `PKA_FUNC.LSHFT` bit performs the Left shift operation. For more information, see the "PKCP Vector Operations" section.
6 (R/W)	RSHFT	Perform Right Shift Operation. Setting the `PKA_FUNC.RSHFT` bit performs the right shift operation. For more information, see the "PKCP Vector Operations" section.
5 (R/W)	SUB	Perform Subtract Operation. Setting the `PKA_FUNC.SUB` bit performs the subtract operation. For more information, see the "PKCP Vector Operations" section.
4 (R/W)	ADD	Perform Add Operation. Setting the `PKA_FUNC.ADD` bit performs the add operation. For more information, see the "PKCP Vector Operations" section.
3 (R/W)	MSONE	Most Significant One. Setting the `PKA_FUNC.MSONE` bit loads the location of the Most Significant one bit within the result word indicated in the `PKA_RESULTMSW` register into bits [4:0] of the `PKA_DIVMSW` register can only be used with basic PKCP operations, except for Divide, Modulo and Compare.
1 (R/W)	ADDSUB	Perform Combined Add/Subtract Operation. Setting the `PKA_FUNC.ADDSUB` bit performs the combined Add/Subtract operation. For more information, see the "PKCP Vector Operations" section.
0 (R/W)	MULT	Perform Multiply Operation. Setting the `PKA_FUNC.MULT` bit performs the multiply operation. For more information, see the "PKCP Vector Operations" section.

Start of PKA RAM space

The `PKA_RAM` register provides the the starting location of the RAM space to hold the input, output and other vectors.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	First Location in PKA RAM. The `PKA_RAM.VALUE` bit field provides the the starting location of the RAM space to hold the input, output and other vectors.

PKA Most-Significant-Word of Result Vector

The PKA_RESULTMSW register indicates the (word) address in the PKA RAM where the most significant non-zero 32-bit word of the result is stored and should be ignored for modulo operations. For basic PKCP operations, the PKA_RESULTMSW register is updated when the `PKA_FUNC.RUN` bit is reset at the end of the operation.

For the complex sequencer controlled operations, updating the final value matching the actual result is done near the end of the operation. Note that the result is only meaningful if no errors are detected and that for ECC operations, the PKA_DIVMSW register provides information for the x-coordinate of the result point only.

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/NW)	ZERO	Result Is Zero. The `PKA_RESULTMSW.ZERO` bit indicates the result vector is all zeros, ignore the address returned in bits [10:0].
10:0 (R/NW)	ADDR	Address of Most-significant Nonzero Word. The `PKA_RESULTMSW.ADDR` bit is the address of the most significant non-zero 32-bit word of the result vector in PKA RAM.

PKA Bit Shift Value

For basic PKCP operations, modifying the contents of the PKA_SHIFT register is made impossible while the operation is being performed. For the ExpMod-variable and ExpMod-CRT operations, the PKA_SHIFT register is used to indicate the number of odd powers to use (directly as a value in the range 1-16). For the ModInv and ECC operations, this register is used to hold a completion code.

4:0 (R/W)	VALUE	Bits to Shift. The `PKA_SHIFT.VALUE` bit field is the number of bits to shift the input vector (in the range 0-31) during a Rshift or Lshift operation.

46 Public Key Interrupt Controller (PKIC)

The Public Key Accelerator (PKA) and the True Random Number Generator (TRNG) share a common interrupt controller, the Public Key Interrupt Controller (PKIC). The host processor configures the PKIC to generate interrupts when certain operations are complete or interrupts are caused by errors.

PKIC Functional Description

The main purpose and function of the PKIC is to capture the interrupts from different sources, either from the PKA or the TRNG and combine them to one interrupt output. The interrupt controller is managed using the following register groups:

- Control for polarity, edge, and level detection and enabling of individual interrupts
- Acknowledgment (to clear edge detected interrupts)
- Status:
  - A raw source status register after edge detection, if edge selected.
  - A status register after masking with the interrupt enable control bits.

ADSP-SC58x PKIC Register List

The Public Key Processor Interrupt Controller (PKIC) provides security-related features. A set of registers governs PKIC operations. For more information on PKIC functionality, see the PKIC register descriptions.

Table 46-1: ADSP-SC58x PKIC Register List

Name	Description
PKIC_ACK	Acknowledge Register

Table 46-2: ADSP-SC58x PKIC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
129	PKIC0_IRQ	PKIC0 Interrupt	Level	

PKIC Programming Model

The following sections provide information on how to program the PKIC.

Enabling/Disabling and Status

The PKIC_EN_STAT register provides the mask to which interrupt source is enabled. There are two status registers, PKIC_RAW_STAT and PKIC_EN_STAT. They allow the host processor to read the status of the interrupt source before and after the mask is applied.

Level or Edge

All of the interrupt sources are level or edge events. The PKIC_TYPE_CTL register configures each interrupt to either level or edge. The PKIC_POL_CTL register controls the polarity of the signal.

These interrupts are latched at both status registers in case edge detection is selected. The edge detectors are reset by clearing the interrupts using the PKIC_ACK registers.

PKIC Programming Concepts

The following concepts help with proper programming for the PKIC module.

Interrupt Handling

When an interrupt is triggered, the handler must first examine this module, the PKIC to determine what triggered the interrupt. By reading the PKIC_EN_STAT, the bits that are set are the pending interrupts of the ones that were not masked. After determining the source of the interrupt, the appropriate action must be taken to service the interrupt from the corresponding module, the PKA, or the TRNG. After handling the interrupt in a particular module, the corresponding interrupt must be acknowledged and cleared in the PKIC to allow further interrupts.

While handling an interrupt, any events that would cause another interrupt would happen without triggering another interrupt.

Overlapping Registers

There are two sets of overlapping registers in the PKIC. The `PKIC_EN_STAT` and `PKIC_ACK` registers share one address. If read, the register tells which enabled interrupts are pending. If written to (W1C), the interrupt is acknowledged and cleared. The `PKIC_RAW_STAT` and `PKIC_EN_SET` registers are another pair that share the address. When read, the register tells which interrupts are pending and if written to will enabled certain interrupts. This register cannot be used to disable any interrupts.

ADSP-SC58x PKIC Register Descriptions

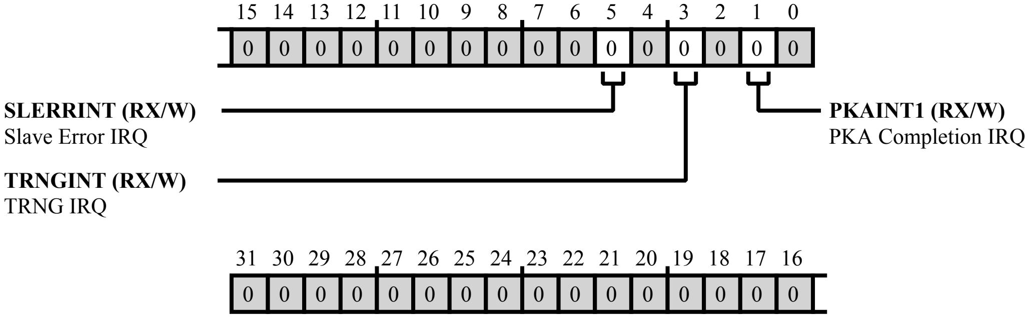
Public Key Processor Interrupt Controller (PKIC) contains the following registers.

Table 46-3: ADSP-SC58x PKIC Register List

Name	Description
`PKIC_ACK`	Acknowledge Register
`PKIC_EN_CLR`	Enable Clear Register
`PKIC_EN_CTL`	Enable Control Register
`PKIC_EN_SET`	Enable Set Register
`PKIC_EN_STAT`	Enabled Status Register
`PKIC_POL_CTL`	Polarity Control Register
`PKIC_RAW_STAT`	Raw Status Register
`PKIC_TYPE_CTL`	Type Control Register

Acknowledge Register

The `PKIC_ACK` register is used to acknowledge the interrupt and clear the corresponding interrupt bit in the status register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

47 True Random Number Generator (TRNG)

The TRNG engine provides a true, non-deterministic, noise source for generating keys, Initialization Vectors (IVs), and other random number requirements. Other non-cryptographic purposes include statistical sampling, retry timers for communications protocols and noise generation.

TRNG Features

The TRNG features include:

- Hardware-based non-deterministic random number generator
- ANSI X9.31 postprocessing (depending on processor)
- Redundant 'fail-safe' design with self-test circuits
- Reliable shot noise oscillator implementation with auto-tuning
- Debug output to allow monitoring of internal operation
- Alarm count overflow and auto-tuning error interrupts
- Buffer to allow generation of large blocks of random data in the background

TRNG Functional Description

The following sections provide details on the function of the TRNG module.

ADSP-SC58x TRNG Register List

The True Random Number Generator (TRNG) provides random number generation, intended mainly for security-related applications. A set of registers governs TRNG operations. For more information on TRNG functionality, see the TRNG register descriptions.

Table 47-1: ADSP-SC58x TRNG Register List

TRNG_RUNCNT	TRNG Run Count Registers
TRNG_RUN[n]	TRNG Run Test State and Result Registers
TRNG_STAT	TRNG Status Register
TRNG_TEST	TRNG Test Register

Random Number Generation

The random numbers that the TRNG generates are produced by sampling Free Running Oscillators (FRO). The (`TRNG_CTL.STARTUPCYC`) bit field along with `TRNG_CFG.MINREFCYC` (minimum refill cycles) and `TRNG_CFG.MAXREFCYC` (maximum refill cycles) bit fields determine the number of samples taken to generate the first random value and subsequent random values.

1. After enabling the TRNG (`TRNG_CTL.TRNGEN` bit =1), a number of FRO output samples defined by the `TRNG_CTL.STARTUPCYC` bit field are gathered in the main linear-feedback shift register (LFSR) before taking a snapshot of the LFSR and storing that snapshot in the random data buffer (after optional post-processing).
2. After taking a snapshot of the LFSR, a number of FRO output samples defined by the `TRNG_CFG.MINREFCYC` bit field, are gathered in the main LFSR. If the random data buffer is full, sample-taking continues until the number of samples (counting from the snapshot) matches the number of samples defined by the `TRNG_CFG.MAXREFCYC` bit field. At that point, the TRNG switches off the FROs and powers down.

3. If, after the `TRNG_CFG.MINREFCYC` sampling period, the random data buffer is not completely filled, a new snapshot of the LFSR is taken and stored in the random data buffer (after optional postprocessing). Control branches back to point step 2 above and a new `TRNG_CFG.MINREFCYC` sample period starts.

Locking Detection and Prevention

Lock detection in functional mode uses the sampled outputs of the individual FROs. A FRO alarm event is declared when a repeating pattern (of up to four sample lengths) is detected continuously for the number of samples defined in the alarm threshold `TRNG_ALMCNT.ALMTHRESH` bit field. The alarm event is logged by setting the bit that corresponds to the FRO that caused the alarm in the `TRNG_ALMMSK` register. If that bit was already set, the corresponding bit in the `TRNG_ALMSTP` register is set. The FRO is switched off to prevent further alarm events from that FRO. If the `TRNG_ALMMSK` register bit was not yet set, the FRO is restarted automatically in an attempt to break locking.

The shutdown count field in the alarm count `TRNG_ALMCNT.SHDNCNT` register monitors the number of FROs switched off. (It counts the number of 1 bits in the `TRNG_ALMSTP` register.) The shutdown threshold field (`TRNG_ALMCNT.SHDNTHRESH`) can be configured to generate the shutdown overflow interrupt (`TRNG_STAT.SHDNOVR`). When the shutdown count in the `TRNG_ALMCNT.SHDNCNT` bit field exceeds the shutdown threshold in the `TRNG_ALMCNT.SHDNTHRESH` bit field, the shutdown overflow bit (`TRNG_STAT.SHDNOVR`) is set to 1 (which can be used to generate an interrupt).

Software can use two strategies for the TRNG operation:

- *Monitored Operation*. Software checks the `TRNG_ALMMSK` register at regular intervals (on the order of seconds). If a bit is set in that register, then the program must also check the `TRNG_ALMSTP` register to determine if a FRO was shut down due to multiple alarm events. If no FROs are shut down, the program clears the `TRNG_ALMMSK` register to remove the incidental alarm events. If one or more FROs are shut down, the host processor can modify the delay selection of those FROs using the `TRNG_FRODETUNE` register to prevent further locking. For this type of operation, the shutdown threshold is normally set to a low value (two, for example). The shutdown overflow interrupt can then be used to signal abnormal operation conditions or the breakdown of FROs.
- *Unmonitored Operation.* Software sets the shutdown threshold to the acceptable number of FROs to be shut down before taking corrective actions. It then uses the shutdown overflow interrupt to initiate corrective actions (clearing the `TRNG_ALMMSK` and `TRNG_ALMSTP` registers, toggling bits in the `TRNG_FRODETUNE` register). The software must monitor the time interval between these interrupts. If they occur too often (for example, within a minute after each other), this frequency indicates abnormal operating conditions or the breakdown of FROs.

Run Testing

Run Test

The TRNG block counts the number of consecutive zeros and ones (runs) in the data stream shifted into the main LFSR. The run length and bit value is then used to increment a specific bucket counter for these values. After

20,000 bits, the bucket counters must be within specified limits for this test to pass. If not, a run fail interrupt (RUNFAIL) is generated.

Table 47-2: Allowable Limits on Runs of 0's and 1's

Run Count	Bit Value	Min (inclusive)	Max (inclusive)
1	0	2267	2733
	1	2267	2733
2	0	1079	1421
	1	1079	1421
3	0	502	748
	1	502	748
4	0	233	402
	1	233	402
5	0	90	223
	1	90	223
6 and up	0	90	233
	1	90	233

Long Run Test

The long run test fails immediately when a run longer than 33 bits is found and a long run fail (`TRNG_STAT.LRUNFAIL`) interrupt is generated.

Noise Source Test

A noise source failure is declared when a run of 48 or more identical bits is found and a noise fail interrupt (`TRNG_STAT.NOISEFAIL`) is generated.

The status and counts are stored in the `TRNG_RUNCNT` and `TRNG_RUN[n]` registers. Unless otherwise indicated, all counters and state bits in these registers are reset when writing a 1 to either the monobit fail acknowledge (`TRNG_INTACK.MBITFAIL`), the run fail acknowledge (`TRNG_INTACK.RUNFAIL`), or the poker fail acknowledge (`TRNG_INTACK.PKRFAIL`) bits.

Monobit Testing

The TRNG block performs the monobit test on blocks of 20,000 bits (in parallel with the run test and poker test). It monitors the number of zeros and ones in the data stream shifted into the main LFSR. At the start of the block, the counter is initialized to 10,000. Each 1 value increments the counter, each 0 value decrements the counter. After 20,000 bits, the counter value must be within 9310–10690 (inclusive) for this test to pass. If not, a monobit fail interrupt (`TRNG_STAT.MBITFAIL`) is generated. The AIS-31 standard (test T1, ref 0) specifies this run time testing of the TRNG and the parameters.

NOTE: The actual limits stated here are different than the limits stated in the AIS-31 standard due to the implementation. The circuitry in the TRNG uses an up-down counter while the standard just evaluates the sum of the 20,000 bits.

When the continue poker (`TRNG_TEST.CONTPKR`) bit is set to 1, the test is not stopped after 20,000 bits. The counter keeps incrementing and decrementing (protected against overflow and underflow). But, no actual limit checking happens. The offset from starting value 10,000 indicates the balance of 0 and 1 bits that were checked since the start of the continuous test. The offset is twice the number of missing or extra 1 bits. (An extra 1 bit adds an increment operation and removes one decrement operation. So, having 10,001 1 bits in the block gives a counter value of 10,002.)

Poker Testing

The poker test is run in parallel with the monobit test and run test. Counters in the `TRNG_POKER[n]` registers are used to count the occurrences of one specific 4-bit value in the data stream fed into the main LFSR. All of the counters are decremented by one every 64 data bits and reset to their start value every 20,000 bits. All counters start at a value of –1 and are decremented 312 times during the 20,000-bit test run.

Each 8-bit counter holds a two's complement value and does not overflow past the range of –128 to +127. At the end of the 20,000-bits block, the values of the counters that contain a single 1 bit appended at the least significant bit side are individually squared and then added. The poker test fails with a poker fail (PKRFAIL) interrupt when:

- the resulting sum (accumulated in the `TRNG_MONOBITCNT` register) is outside the range 1288 – 71750 (inclusive), or
- one of the counters tries to increment or decrement outside its limit range

NOTE: The poker test fails when the 4-bit values of the data stream are distributed too evenly (with eight counters having incremented 312 times and the others incremented 313 times). This failure is intentional. The minimum mean deviation from the expected value of 312.5 is 4.5. Failure at counter overflow is not an official part of the poker test as specified in the AIS-31 standard (ref 0). It can be shown that the maximum deviation for one counter's value from the mean value of 312.5 (without the poker test failing) is 129.5. Since this deviation is more than 40% of the mean value, it indicates that something is wrong. Here, the counter overflow failure is combined with the official poker test failure.

When the continue poker (`TRNG_TEST.CONTPKR`) bit is set to 1, the test does not stop after 20,000 bits. The counters keep incrementing and decrementing (the latter every 64 bits). A PKRFAIL interrupt is generated when one of the counters tries to increment or decrement outside its limit range.

Data for Tests

For the monobit test, run test and poker test circuits self-test, the test data written to the `TRNG_INPUT[n]`0 register is used for the monobit test and run test bit-by-bit. It executes from bit 31 down to bit 0. For the poker test, the written test data is used in eight blocks of 4 bits, starting from bits 31:28 down to bits 3:0.

When the `TRNG_TEST.CONTPKR` bit =0 during run test and poker test circuits self-tests, the state of the poker and runs test status registers is frozen after all calculations are made and after inputting 20,000 test bits. This state allows time to read the test results. These calculations take around 20 clock cycles to complete. The status registers are reset to their starting states when the first word for the next test block of test bits is written to the `TRNG_INPUT[n]`0 register. Then, the contents of this word are processed.

TRNG Block Diagram

The *System Block Diagram of the TRNG* diagram shows the system block for the TRNG. The system includes:

- Free Running Oscillators (FROs) that are the source of sampled bits
- A post-processing unit (processor dependent) for standards compliance
- Test circuitry to detect non-randomness due to failures in the system

TRNG Architectural Concepts

The random numbers are accessible to the host processor in four 32-bit registers allowing a single burst read of a 128-bit random number. Acknowledging the data ready (interrupt) state causes the TRNG to move a new value (when available in the data buffer) to the TRNG output register. The TRNG always tries to keep the data buffer completely full. Pulling out data starts the regeneration of a new number by:

- Enabling the FROs
- Capturing their outputs in the LFSR, and
- Cryptographically postprocessing the values from the LFSR

The process produces new random values to replenish the buffer.

The major functional blocks of the TRNG module are:

- The actual TRNG core with control and test circuits, optional post-processor, and optional data buffer control logic

- Free Running Oscillators (FROs) instantiated outside the TRNG core
- A 128-byte buffer RAM instantiated outside the TRNG core

In the TRNG core, the true entropy source uses FROs as the basic building block. The accumulation of timing jitter, caused (for the largest part) by shot noise, creates uncertainty intervals for the output transitions of each FRO. Sampling within an uncertainty interval generates a single bit of entropy, which is 'accumulated' in a LFSR. As the uncertainty interval is very narrow compared to the cycle time of a FRO, the mean amount of entropy generated per sample is small (less than 1/100 bit per sample). To increase the entropy generation rate, multiple FROs are used in parallel.

The FROs are asynchronous to one another and asynchronous to the sampling clock to make their behavior truly non-deterministic.

The output signals of the FROs are sampled at regular intervals (in general, at the TRNG core module clock frequency). The samples feed into an error detection circuit that checks for repeating patterns coming out of a FRO. If a repeating pattern persists for a configurable number of samples, the FRO is suspect of having synchronized to (a harmonic of) the sampling interval. This activity drastically reduces the amount of entropy generated by that FRO. The error detection circuit signals this activity as a FRO error event.

Error events can occur during normal operation. The FRO control circuit attempts to restart a FRO that on a first error event. A second error event causes an automatic shutdown of the FRO. Because there are multiple FROs, shutting down a FRO reduces the amount of entropy generated, but it does not immediately jeopardize the TRNG operation. A limit can be configured below which the number of operational FROs does not drop. If this limit is crossed, an interrupt can be generated on the host processor. Software on the host processor can then attempt to prevent frequent locking of a FRO by *de-tuning* it to a slightly different frequency.

An XOR tree combines the sampled outputs and feeds them into an 81-bit LFSR to accumulate entropy and whiten the random bits stream.

NOTE: Here, *whitening* means balancing the number of one and zero bits in the stream.

TRNG Operating Modes

The TRNG has the following operating modes.

Normal Reading Mode

In normal reading mode, random data can only be read out of the output registers of the TRNG module when the ready bit (`TRNG_STAT.RDY`) =1. Acknowledging the data by writing a 1 to the ready acknowledge bit in the `TRNG_INTACK.RDY` register clears the ready bit from the status register and clears the output registers. The registers remain at zero until the next 128-bit data block is available.

Secure Reading Mode

An attacker can try to read the output registers (without acknowledging the data) to obtain a copy of data to be read later by an application. To block this attack, secure reading mode is used. In this mode, enable reading from the output registers (by writing 0x00 to the open read gate bits (`TRNG_INTACK.OPENRDGATE`) before it is possible to access the output registers. Enabling the reading starts a timeout (controlled by the `TRNG_CFG.RDTIMEOUT` bit field). When this timeout expires, reading is disabled and the offered data is acknowledged so that it is not offered again. The host processor must set this timeout such that there is enough time to read the output registers and perform a normal data acknowledge (which aborts the timeout).

Test Mode

In addition to the test circuitry that operates during normal operation, the TRNG has a test mode that allows further diagnosis when errors occur. In test mode, programs have access to the main LFSR through the `TRNG_LFSR_L`, `TRNG_LFSR_M`, and `TRNG_LFSR_H` registers. Programs can also control the finite state machine sample counter using the `TRNG_CNT` register.

In test mode, the TRNG can be configured to test individual or a chosen set of FROs. It can also be configured to feed test patterns to the delay chain.

TRNG Data Transfer Modes

The host processor reads four 32-bit registers to access the random numbers. Once the registers are read and the data ready interrupt has been acknowledged, the TRNG moves more data from the internal buffer to the output registers (`TRNG_OUTPUT[n]`).

TRNG Event Control

There are eight events that the TRNG generates. The events are common error events from the run-time testing of the TRNG. While the TRNG is operating and generating random bits, test circuitry is also running statistical tests. The tests determine if the sources of the random bits have started to fail and are not truly producing random bits. There is also a single event to signal when data is ready in the output registers.

These events are captured in the `TRNG_STAT` register and can generate a single interrupt in the Public Key Interrupt Controller (PKIC). The individual events can be masked so the interrupt is not triggered. This configuration uses the `TRNG_CTL` register. The event and associated interrupt can be acknowledged in the `TRNG_INTACK` register.

The ***TRNG Interrupt Signals*** table lists all events or interrupts that the TRNG can generate.

TRNG Interrupt Signals

The TRNG provides a total of eight interrupts multiplexed into one output.

Table 47-3: TRNG Interrupt Signals

Interrupt	Name	Description
0	RDY	Ready. Random number is ready to be read from registers

Table 47-3: TRNG Interrupt Signals (Continued)

Interrupt	Name	Description
1	SHDNOVR	Shutdown Overflow. The number of FRO's automatically shut down due to failures or errors have gone above the threshold specified in `TRNG_ALMCNT.SHDNTHRESH`.
2	STUCKOUT	Stuck Out. Logic circuitry around the output registers has detected the same output has been provided twice.
3	NOISEFAIL	Noise Fail. Logic circuitry monitoring the data shifted into the main LFSR detected 48 identical bits, which is considered a noise source failure.
4	RUNFAIL	Run Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds value for at least one of the `TRNG_RUN[n]` counters after checking 20,000 bits.
5	LRUNFAIL	Long Run Fail. Logic circuitry monitoring the data shifted into the main LFSR detected 34 identical bits.
6	PKRFAIL	Poker Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds value in at least one of the 16 `TRNG_POKER[n]` counters or an out-of-bounds sum of squares values after checking 20,000 bits.
7	MBITFAIL	Monobit Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds number of 1's after checking 20,000 bits.

ADSP-SC58x TRNG Register Descriptions

True Random Number Generator (TRNG) contains the following registers.

Table 47-4: ADSP-SC58x TRNG Register List

Name	Description
`TRNG_ALMCNT`	TRNG Alarm Counter Register
`TRNG_ALMMSK`	TRNG Alarm Mask Register
`TRNG_ALMSTP`	TRNG Alarm Stop Register
`TRNG_CFG`	TRNG Configuration Register
`TRNG_CNT`	Counter Register
`TRNG_CTL`	TRNG Control Register
`TRNG_FRODETUNE`	TRNG FRO De-tune Register
`TRNG_FROEN`	TRNG FRO Enable Register
`TRNG_INPUT[n]`	TRNG Input Registers
`TRNG_INTACK`	TRNG Interrupt Acknowledge Register
`TRNG_LFSR_H`	TRNG LFSR Access Register
`TRNG_LFSR_L`	TRNG LFSR Access Register

Table 47-4: ADSP-SC58x TRNG Register List (Continued)

Name	Description
TRNG_LFSR_M	TRNG LFSR Access Register
TRNG_MONOBITCNT	TRNG Monobit Test Result Register
TRNG_OUTPUT[n]	TRNG Output Registers
TRNG_POKER[n]	TRNG Poker Test Result Registers
TRNG_RUNCNT	TRNG Run Count Registers
TRNG_RUN[n]	TRNG Run Test State and Result Registers
TRNG_STAT	TRNG Status Register
TRNG_TEST	TRNG Test Register

TRNG Alarm Counter Register

The TRNG_ALMCNT register, together with the TRNG_ALMMSK and TRNG_ALMSTP registers, can be used by the host processor to determine if the FRO/sample cycle locking is a problem. Note that incidental alarm events are expected to occur during normal operation. This register also controls the way the monobit test and poker test circuits operate (using the standard 20,000 bit blocks or running continuously).

SHDNCNT (R)
Shutdown Count
SHDNTHRESH (R/W)
Shutdown Threshold
SHDNFATAL (R/W)
Shutdown Fatal

Figure 47-2: TRNG_ALMCNT Register Diagram

Table 47-5: TRNG_ALMCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/NW)	SHDNCNT	Shutdown Count. This read-only field indicates the number of 1 bits in the TRNG_ALMSTP register, the number of FRO's that's been turned off.
23 (R/W)	SHDNFATAL	Shutdown Fatal. When the `TRNG_ALMCNT.SHDNFATAL` bit field is set, the shutdown overflow (SHDNOVR) interrupt is considered a fatal error requiring taking the complete TRNG engine off-line.
20:16 (R/W)	SHDNTHRESH	Shutdown Threshold. The `TRNG_ALMCNT.SHDNTHRESH` bit field provides the threshold setting for generating the shutdown overflow (SHDNOVR) interrupt, which is activated when the shutdown count (`TRNG_ALMCNT.SHDNCNT`) value in this register exceeds the threshold value set here.
15 (R/W)	STALLRUNPKR	Stall Run Poker. When the `TRNG_ALMCNT.STALLRUNPKR` bit is set, stalls the Monobit Test, Run Test and Poker Test circuits when either the `TRNG_STAT.MBITFAIL`, `TRNG_STAT.RUNFAIL` or `TRNG_STAT.PKRFAIL` bits =1. This allows inspection of the state of the result counters (which would otherwise be reset immediately for the next 20,000 bits block to test).

Table 47-5: TRNG_ALMCNT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	ALMTHRESH	Alarm Threshold. The `TRNG_ALMCNT.ALMTHRESH` bit field sets the alarm detection threshold for the repeating pattern detectors on each FRO. A FRO alarm event is declared when a repeating pattern (of up to four samples length) is detected continuously for the number of samples defined by this fields value. Reset value 255 (decimal) should keep the number of alarm events to a manageable level.

TRNG Alarm Mask Register

A set bit (=1) in the `TRNG_ALMMSK` register signifies an alarm event and is used by the host processor to determine which of the individual FROs generated the alarm. If a bit in this register is set, the corresponding bit in the `TRNG_ALMSTP` register is set and the FRO is turned off by clearing the corresponding bit in the `TRNG_FROEN` register. If a bit is not set, the FRO restarts automatically to try to break sample cycle locking that could have caused the alarm event.

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
FROS (R/W)
FRO Alarm Mask
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 47-3: TRNG_ALMMSK Register Diagram

Table 47-6: TRNG_ALMMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO Alarm Mask. The `TRNG_ALMMSK.FROS` bit field provides logging for the alarm events of individual FROs. A 1 in bit [n] indicates FRO n experienced an alarm event.

TRNG Alarm Stop Register

The `TRNG_ALMSTP` register is used by the host processor to determine which of the individual FROs generated more than one alarm event in quick succession. If a FRO generates an alarm event while a previous event is still logged in the `TRNG_ALMMSK` register, the corresponding bit in this register is set (=1) and the FRO is turned off by clearing (=0) the corresponding bit in the `TRNG_FROEN` register. The `TRNG_ALMCNT.SHDNCNT` bit field keeps track of the number of bits that are set in this register.

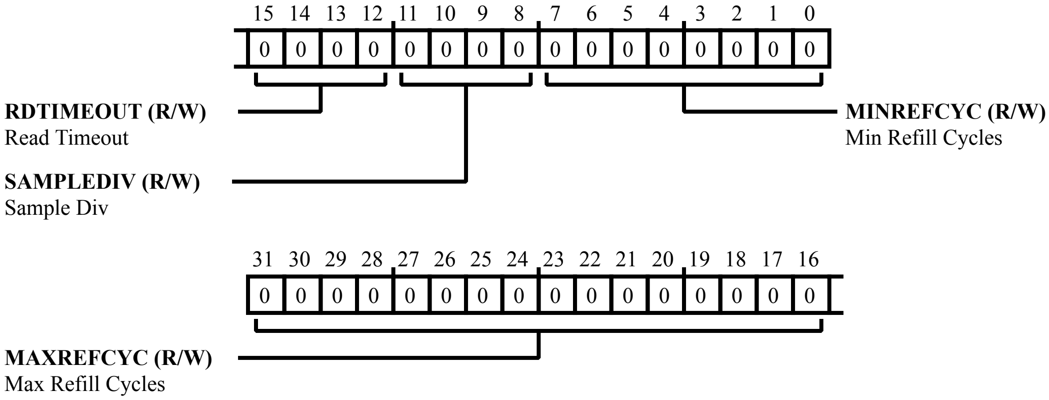
Figure 47-4: TRNG_ALMSTP Register Diagram

Table 47-7: TRNG_ALMSTP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO Alarm Stop Bits. The `TRNG_ALMSTP.FROS` bit field provides logging for the alarm events of individual FROs. A 1 in bit [n] indicates FRO n experienced more than one alarm event in quick succession and has been turned off. A 1 in this field forces the corresponding bit in the `TRNG_FROEN` register to 0.

TRNG Configuration Register

The `TRNG_CFG` register holds the lower and upper limits of the samples taken from the FROs in order to refill the random data buffer. This register also holds the time out value used for secure reading mode.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

MAXREFCYC (R/W)
Max Refill Cycles

Figure 47-5: TRNG_CFG Register Diagram

Table 47-8: TRNG_CFG Register Fields

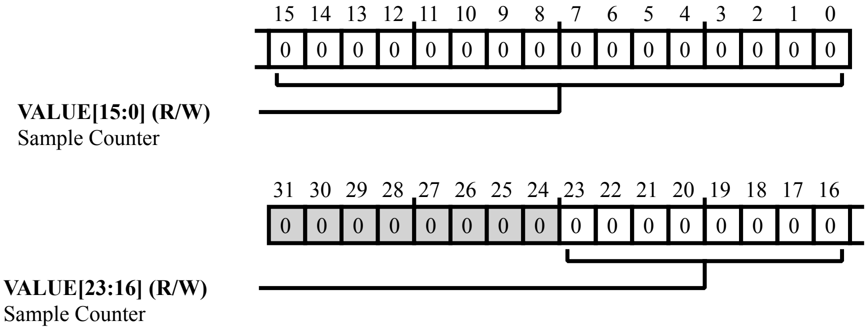
Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	MAXREFCYC	Max Refill Cycles. The `TRNG_CFG.MAXREFCYC` bit field determines the maximum number of samples (between 2^8 and 2^{24}) taken to re-generate entropy from the FROs after reading out a 64 bit random number. If the written value of this field is zero, the number of samples is 2^{24}, otherwise the number of samples equals the written value times 2^8. This field can only be modified while the `TRNG_CTL.TRNGEN` bit =0.
15:12 (R/W)	RDTIMEOUT	Read Timeout. The `TRNG_CFG.RDTIMEOUT` bit field controls the Secure Reading Mode. When this field is 0, Secure Reading Mode is disabled. Values in the range 115 enable Secure Reading and set a read gate closure timeout of approximately (read_timeout + 1) x 16 clock input cycles. This field can only be modified while the `TRNG_CTL.TRNGEN` bit =0.
11:8 (R/W)	SAMPLEDIV	Sample Div. The `TRNG_CFG.SAMPLEDIV` bit field directly controls the number of input cycles between samples taken from the FROs. The default value 0 indicates that samples are taken every cycle, maximum value 15 (decimal) takes one sample every 16 cycles. This field must be set to a value such that the slowest FRO (even under worst-case conditions) has a cycle time less than twice the sample period. The default configuration of the FROs allows this field to remain 0. This field can only be modified while `TRNG_CTL.TRNGEN`=0.

Table 47-8: TRNG_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	MINREFCYC	Min Refill Cycles. The `TRNG_CFG.MINREFCYC` bit field determines the minimum number of samples (between 2^6 and 2^{24}) taken to re-generate entropy from the FROs after reading out a 64 bit random number. If the value of this field is zero, the number of samples is fixed to the value determined by the maximum refill cycles (`TRNG_CFG.MAXREFCYC`) field, otherwise the minimum number of samples equals the written value times 64 (which can be up to 2^{14}). The number of samples defined here cannot be higher than the number defined by the `TRNG_CFG.MAXREFCYC` field (i.e. that field takes precedence). This field can only be modified while the `TRNG_CTL.TRNGEN` bit =0.

Counter Register

The `TRNG_CNT` register is used to access the main control Finite State Machine's (FSM) sample counter while the `TRNG_CTL.TSTMODE` bit =1.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 47-9: TRNG_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/W)	VALUE	Sample Counter. The `TRNG_CNT.VALUE` bit field is the sample counter used by control finite state machine. This counter can only be accessed when the `TRNG_CTL.TSTMODE` bit =1.

TRNG Control Register

The `TRNG_CTL` register must be written to start accumulating entropy before random numbers can be generated. In most cases, the `TRNG_CFG` register must also be written prior to writing the `TRNG_CTL` register. To enable the TRNG, set the `TRNG_CTL.TRNGEN` bit. This register also controls post-processing (if available). Note that when the `TRNG_CTL.TRNGEN` bit =1, the start up cycles field (`TRNG_CTL.STARTUPCYC`) and the post-processing enable bit (if available) are locked. Any writes to these fields are ignored.

STARTUPCYC (R/W)
Startup Cycles

Figure 47-7: TRNG_CTL Register Diagram

Table 47-10: TRNG_CTL Register Fields

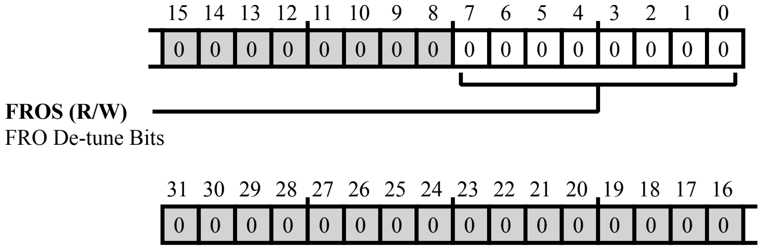
Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	STARTUPCYC	Startup Cycles. The `TRNG_CTL.STARTUPCYC` bit field determines the number of samples (between 2^8 and 2^{24}) taken to gather entropy from the FROs during startup. If the written value of this field is zero, the number of samples is 2^{24}, otherwise the number of samples equals the written value times 2^8 . This field can only be written when `TRNG_CTL.TRNGEN`=0 before the write.
10 (R/W)	TRNGEN	Enable TRNG. Setting the `TRNG_CTL.TRNGEN` bit to 1 starts the TRNG, gathering entropy from the FROs for the number of samples determined by the value in the `TRNG_CTL.STARTUPCYC` (Startup Cycles) field. Resetting this bit to 0 forces all TRNG logic back into the idle state immediately. Resetting this bit to 0 also performs the Un-instantiate operation, clearing all internal post-processor registers.

Table 47-10: TRNG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
8 (R/W)	TSTMODE	Test Mode. When the `TRNG_CTL.TSTMODE` bit is set, access is enabled to the `TRNG_CNT` and `TRNG_LFSR_L`, `TRNG_LFSR_M` and `TRNG_LFSR_H` registers (the latter are cleared before enabling access) and sets the `TRNG_STAT.NEEDCLK` bit for testing purposes. This bit must be set to 1 before various test modes in the `TRNG_TEST` register can be enabled.
7 (R/W)	MBITFAILMSK	Monobit Fail Mask. When the `TRNG_CTL.MBITFAILMSK` bit is set, this mask allows the `TRNG_STAT.MBITFAIL` bit to activate the (active HIGH) interrupt output.
6 (R/W)	PKRFAILMSK	Poker Fail Mask. When the `TRNG_CTL.PKRFAILMSK` bit is set, this mask allows the `TRNG_STAT.PKRFAIL` bit to activate the (active HIGH) interrupt output.
5 (R/W)	LRUNFAILMSK	Long Run Fail Mask. When the `TRNG_CTL.LRUNFAILMSK` bit is set, this mask allows the `TRNG_STAT.LRUNFAIL` bit to activate the (active HIGH) interrupt output.
4 (R/W)	RUNFAILMSK	Run Fail Mask. When the `TRNG_CTL.RUNFAILMSK` bit is set, this mask allows the `TRNG_STAT.RUNFAIL` bit to activate the (active HIGH) interrupt output.
3 (R/W)	NOISEFAILMSK	Noise Fail Mask. When the `TRNG_CTL.NOISEFAILMSK` bit is set, this mask allows the `TRNG_STAT.NOISEFAIL` bit to activate the (active HIGH) interrupt output.
2 (R/W)	STUCKOUTMSK	Stuck Out Mask. When the `TRNG_CTL.STUCKOUTMSK` bit is set, this mask allows the `TRNG_STAT.STUCKOUT` bit to activate the (active HIGH) interrupt output.
1 (R/W)	SHDNOVRMSK	Shutdown Overflow Mask. When the `TRNG_CTL.SHDNOVRMSK` bit is set, this mask allows the `TRNG_STAT.SHDNOVR` bit to activate the (active HIGH) interrupt output.
0 (R/W)	RDYMSK	Ready Mask. When the `TRNG_CTL.RDYMSK` bit is set, this mask allows the `TRNG_STAT.RDY` bit to activate the (active HIGH) interrupt output.

TRNG FRO De-tune Register

The TRNG_FRODETUNE register is used by the host processor to change the frequencies of individual FROs. This can reduce the number of alarm events generated by a specific FRO.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

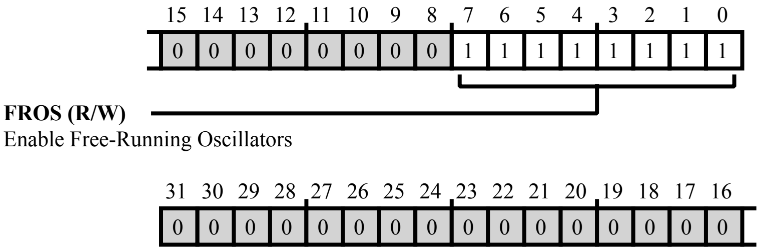
Figure 47-8: TRNG_FRODETUNE Register Diagram

Table 47-11: TRNG_FRODETUNE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO De-tune Bits. The TRNG_FRODETUNE.FROS bits De-tune the FROs. A 1 in bit [n] lets FRO n run approximately 5% faster. The value of one of these bits may only be changed while the corresponding FRO is turned off (by temporarily writing a 0 in the corresponding bit of the TRNG_FROEN register).

TRNG FRO Enable Register

The `TRNG_FROEN` register can be used by the host processor to enable and disable FROs individually. Only enabled FROs contribute to entropy generation, but require power to do so. Disabled FROs cannot generate alarm events.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 47-9: TRNG_FROEN Register Diagram

Table 47-12: TRNG_FROEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	Enable Free-Running Oscillators. The `TRNG_FROEN.FROS` bits are the enables for the individual FROs. A 1 in bit [n] enables FRO n. The default state is all ones to enable all FROs after power-up. Note that the FROs are not actually started up before the `TRNG_CTL.TRNGEN` bit is set to 1. These bits are automatically forced to 0 (and cannot be written to 1) when the corresponding bit in the `TRNG_ALMSTP` register has value 1.

TRNG Input Registers

The `TRNG_INPUT[n]` registers are used as input for post-processor testing (if post processing is available) and as input for Monobit Test, Run Test and Poker Test functionality tests (TRNG_INPUT0 only). They share their addresses with the corresponding `TRNG_OUTPUT[n]` registers. The least significant word is contained in the TRNG_INPUT0 register.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Input Bits for 32-bit Word n. The `TRNG_INPUT[n].VALUE` bit field is used to hold 32-bits of the 64-bit word of test data for 3-DES post-processor (if available). Or, the `TRNG_INPUT[n].VALUE` bit field is used to hold 32-bit data word for Run Test and Poker Test circuits self test. Can only be written to when the `TRNG_STAT.TSTRDY` bit =1.

TRNG Interrupt Acknowledge Register

The `TRNG_INTACK` register is written to acknowledge interrupts indicated in bits [7:0] of the `TRNG_STAT` register. Writing a 1 to any of the bits [7:2] has side effects in resetting various parts of the TRNG core logic which can also be used even if no interrupts are actually active.

When acknowledging the interrupts, these bits are write '1' to clear the associated bit in TRNG_STAT register. The bit in this register will also automatically be reset to zero.

When secure reading mode is enabled, write bits [7:0] of this register with zeros to enable TRNG data reads from the `TRNG_OUTPUT[n]` registers. Writing bits [7:0] also starts the (configurable) timeout counter that automatically acknowledges the TRNG data (and disables reads) if the `TRNG_INTACK.RDY` bit is not written with a 1 within that timeout period.

Figure 47-11: TRNG_INTACK Register Diagram

Table 47-14: TRNG_INTACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (RX/W1C)	MBITFAIL	Monobit Fail Acknowledge. Set the `TRNG_INTACK.MBITFAIL` bit to acknowledge the Monobit Fail Interrupt. This also resets all counter and state bits in the `TRNG_RUN[n]`, `TRNG_MONOBITCNT` and the `TRNG_POKER[n]` registers (except for the `TRNG_RUNCNT.LENMAX` field).
6 (RX/W1C)	PKRFAIL	Poker Fail Acknowledge. Set the `TRNG_INTACK.PKRFAIL` bit to acknowledge the Poker Fail Interrupt. This also resets all counter and state bits in the `TRNG_RUN[n]`, `TRNG_MONOBITCNT` and the `TRNG_POKER[n]` registers (except for the `TRNG_RUNCNT.LENMAX` field).

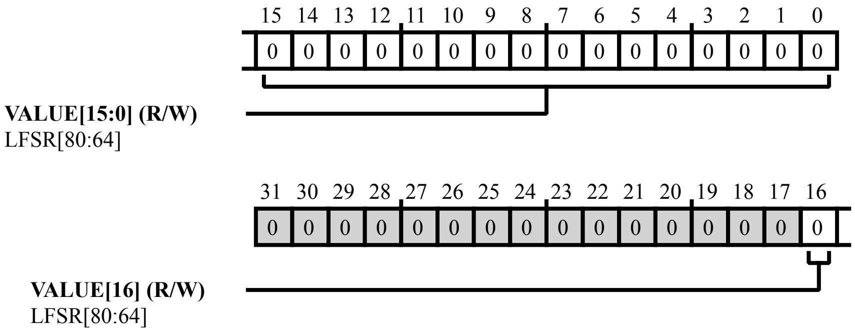
Table 47-14: TRNG_INTACK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (RX/W1C)	LRUNFAIL	Long Run Fail Acknowledge. Set the `TRNG_INTACK.LRUNFAIL` bit to acknowledge the Long Run Fail Interrupt. Also clears the `TRNG_RUNCNT.LENMAX` field.
4 (RX/W1C)	RUNFAIL	Run Fail Acknowledge. Set the `TRNG_INTACK.RUNFAIL` bit to acknowledge the Run Fail Interrupt. Also resets all counter and state bits in the `TRNG_RUN[n]`, `TRNG_MONOBITCNT` and the `TRNG_POKER[n]` registers (except for the `TRNG_RUNCNT.LENMAX` field).
3 (RX/W1C)	NOISEFAIL	Noise Fail Acknowledge. Set the `TRNG_INTACK.NOISEFAIL` bit to acknowledge the Noise Fail Interrupt. Setting this bit also clears the `TRNG_RUNCNT.LENMAX` (Run Length Max) field, the random data buffer, the `TRNG_OUTPUT[n]` registers and the `TRNG_STAT.RDY` bit.
2 (RX/W1C)	STUCKOUT	Stuck Out Acknowledge. Set the `TRNG_INTACK.STUCKOUT` bit to acknowledge the Stuck Out Interrupt. Setting this bit also clears the random data buffer, the `TRNG_OUTPUT[n]` registers and the `TRNG_STAT.RDY` bit.
1 (RX/W1C)	SHDNOVR	Shutdown Overflow Acknowledge. Set the `TRNG_INTACK.SHDNOVR` bit to acknowledge the Shutdown Overflow Interrupt.
0 (RX/W1C)	RDY	Ready Acknowledge. The `TRNG_INTACK.RDY` bit allows a new number (if it is ready in the random data buffer), to directly move into the result register. Once done, the `TRNG_STAT.RDY` bit is reset, after at most size clock cycles.
7:0 (RX/W)	OPENRDGATE	Open Read Gate. In Secure Reading Mode, the `TRNG_INTACK.OPENRDGATE` bit writes an all zeros value to bits [7:0] to enable reading of TRNG data from the `TRNG_OUTPUT[n]` registers. This starts the timeout counter that automatically acknowledges the TRNG data (and disables reading) if the `TRNG_INTACK.RDY` bit is not written with a 1 within that timeout period.

TRNG LFSR Access Register

The `TRNG_LFSR_H` register is used to access bits [80:64] of the main entropy accumulation LFSR while in test mode (`TRNG_CTL.TSTMODE` =1).

For security reasons, the LFSR contents are zeroed before enabling access.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 47-17: TRNG_LFSR_M Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	LFSR[63:32]. The `TRNG_LFSR_M.VALUE` bit field contains bits [63:32] of the main entropy accumulation LFSR. This field can only be accessed when the `TRNG_CTL.TSTMODE` bit =1. Contents are cleared (=0) before access is enabled.

TRNG Monobit Test Result Register

The `TRNG_MONOBITCNT` register accesses the counter used perform a Monobit Test as specified by the AIS-31 standard (test T1, ref 4). This test is performed on blocks of 20,000 bits (in parallel to the run test and Poker Test).

Note: Immediately after performing the actual Monobit Test at the end of the 20,000 bits block, the counter is used to accumulate the Poker Test results. As a result, the actual Monobit Test count result value can only be read in the `TRNG_MONOBITCNT` register if the test fails and the stall run Poker (`TRNG_ALMCNT.STALLRUNPKR`) bit =1.

The monobit test result register is read-only; writing it accesses the registers mapped at the same address. The counter in this register is reset when writing a 1 to either the monobit fail acknowledge (`TRNG_INTACK.MBITFAIL`), run fail acknowledge (`TRNG_INTACK.RUNFAIL`) or the poker fail acknowledge (`TRNG_INTACK.PKRFAIL`) bits.

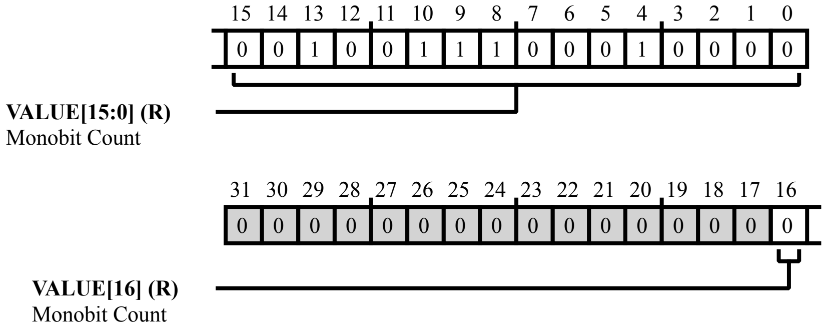

Figure 47-15: TRNG_MONOBITCNT Register Diagram

Table 47-18: TRNG_MONOBITCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16:0 (R/NW)	VALUE	Monobit Count. The `TRNG_MONOBITCNT.VALUE` bit field is the up/down counter which monitors 1 and 0 bits. After 20,000 bits, this counter should have a value in the range 9310 through 10690 (inclusive) to pass the Monobit Test. This counter is protected against overflow and underflow.

TRNG Output Registers

The `TRNG_OUTPUT[n]` registers provide read access to the 128-bit random number output. A subset of these registers are also used as output for post-processor testing (if available). They share their addresses with the TRNG_INPUT0 through TRNG_INPUT3 registers. The least significant word is contained in the TRNG_OUTPUT0 register.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Output Bits for 32-bit Word n. The `TRNG_OUTPUT[n].VALUE` bit field is used to holds 32 bits of the 128-bit word of random data. Only valid when the `TRNG_STAT.RDY` bit =1. Alternatively, this register holds the 32-bits of the 42-bit word of result data for 3-DES post-processing testing. Only valid when the `TRNG_STAT.TSTRDY` bit =1.

TRNG Poker Test Result Registers

The `TRNG_POKER[n]` registers are used to access the 16 counters used perform a poker test on blocks of 20,000 bits (in parallel to the monobit and run tests).

Poker test result registers are read-only; writing them accesses the registers mapped at these same addresses. All counters in these registers are reset when writing a 1 to either the monobit fail acknowledge (`TRNG_INTACK.MBITFAIL`), run fail acknowledge (`TRNG_INTACK.RUNFAIL`) or the poker fail acknowledge (`TRNG_INTACK.PKRFAIL`) bits.

Figure 47-17: TRNG_POKER[n] Register Diagram

Table 47-20: TRNG_POKER[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	CNT3	Poker Count n + 3. The `TRNG_POKER[n].CNT3` bit field provides the counter for 4-bit value 0x3, 0x7, 0xB, 0xF in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
23:16 (R/NW)	CNT2	Poker Count n + 2. The `TRNG_POKER[n].CNT2` bit field provides the counter for 4-bit value 0x2, 0x6, 0xA, 0xE in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
15:8 (R/NW)	CNT1	Poker Count n + 1. The `TRNG_POKER[n].CNT1` bit field provides the counter for 4-bit value 0x1, 0x5, 0x9, 0xD in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
7:0 (R/NW)	CNT0	Poker Count n. The `TRNG_POKER[n].CNT0` bit field provides the counter for 4-bit value 0x0, 0x4, 0x8, 0xC in the TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.

TRNG Run Count Registers

The TRNG_RUNCNT registers are used to access the 10 counters that perform a run test and long run test as specified by the AIS-31 standard (tests T3 and T4, ref 4). They are also used to perform the noise source failure test proposed in section E.5 of that same standard.

The TRNG_RUNCNT registers are read-only; writing them accesses the other registers which are mapped at the same addresses. Unless otherwise indicated, all counters and state bits in these registers are reset when writing a 1 to either the Monobit Fail acknowledge (`TRNG_INTACK.MBITFAIL`), Run Fail acknowledge (`TRNG_INTACK.RUNFAIL`) or the Poker Fail acknowledge (`TRNG_INTACK.PKRFAIL`) bits.

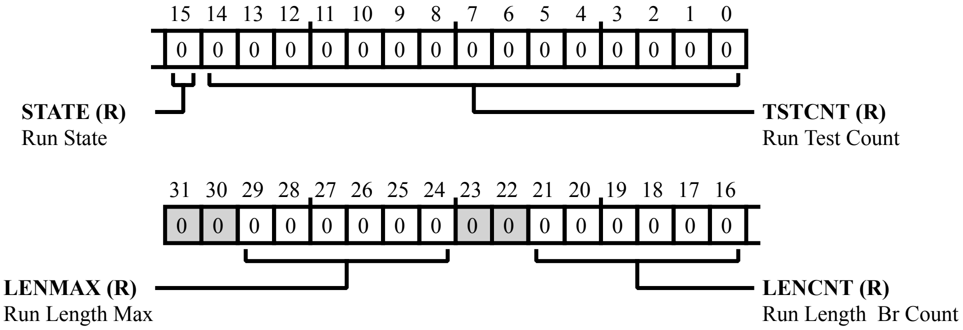

Figure 47-18: TRNG_RUNCNT Register Diagram

Table 47-21: TRNG_RUNCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/NW)	LENMAX	Run Length Max. The `TRNG_RUNCNT.LENMAX` bit field configures the maximum run length count value encountered since start of test. This value is reset back to zero when writing a 1 to either the Noise Fail acknowledge (`TRNG_INTACK.NOISEFAIL`) or the Long Run Fail acknowledge (`TRNG_INTACK.LRUNFAIL`) bits.
21:16 (R/NW)	LENCNT	Run Length Br Count. The `TRNG_RUNCNT.LENCNT` bit field configures the counter for the current run of consecutive 0/1 bits; cannot increment past its maximum value of 63.
15 (R/NW)	STATE	Run State. The `TRNG_RUNCNT.STATE` bit field provides th state of bits in the current run.
14:0 (R/NW)	TSTCNT	Run Test Count. The `TRNG_RUNCNT.TSTCNT` bit field configures the block length counter for the run and poker tests - counts up for 20,000 tested bits and then controls testing of the run_X_count_... and poker_count_X counters to contain expected values, after which they - and this counter - are reset for the next block.

TRNG Run Test State and Result Registers

The `TRNG_RUN[n]` registers holds the counts for the associated run bucket for 1's and 0's.

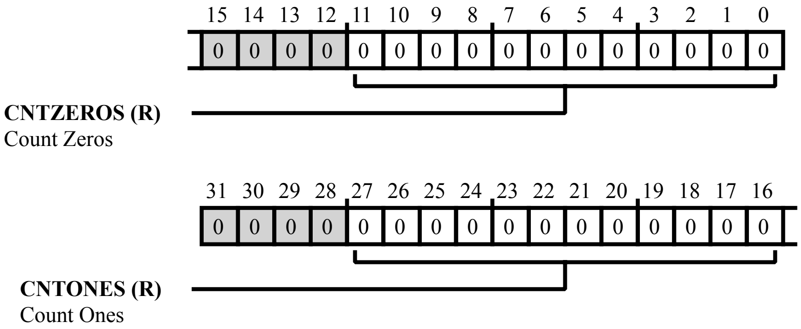

Figure 47-19: TRNG_RUN[n] Register Diagram

Table 47-22: TRNG_RUN[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/NW)	CNTONES	Count Ones. In TRNG_RUN1, this counter is for single bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 2267 to 2733 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 4095. In TRNG_RUN2, this counter is for two bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 1079 to 1421 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 2047. In TRNG_RUN3, this counter is for three bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 502 to 748 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 1023. In TRNG_RUN4, this counter for four bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 233 to 402 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 511. In TRNG_RUN5, this counter is for five bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 90 to 223 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255. In TRNG_RUN6, this counter for six and higher bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 90 to 233 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255.

Table 47-22: TRNG_RUN[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/NW)	CNTZEROS	Count Zeros. In TRNG_RUN1, this counter is for single bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 2267 to 2733 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 4095. In TRNG_RUN2, this counter is for two bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 1079 to 1421 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 2047. In TRNG_RUN3, this counter is for three bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 502 to 748 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 1023. In TRNG_RUN4, this counter is for four bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 233 to 402 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 511. In TRNG_RUN5, this counter is for five bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 90 to 223 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255. In TRNG_RUN6, this counter is for six and higher bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 90 to 233 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255.

TRNG Status Register

The TRNG_STAT register provides status results. This register shares the same address as the Interrupt Acknowledge (TRNG_INTACK) register.

Blocks Available

Figure 47-20: TRNG_STAT Register Diagram

Table 47-23: TRNG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/NW)	NEEDCLK	Need Clock. When the TRNG_STAT.NEEDCLK bit is set, it indicates that the TRNG is busy generating entropy or is in one of its test modes the module clock may not be turned off.
23:16 (R/NW)	BLKAVAIL	Blocks Available. This field indicates the number of 128 bits blocks of random data that are available in the random data buffer. If this value is non-zero, the output registers will be re-filled from the random data buffer immediately after acknowledging the TRNG_STAT.RDY by writing a '1' to TRNG_INTACK.RDY.
8 (R/NW)	TSTRDY	Test Ready. When the TRNG_STAT.TSTRDY bit is set, it indicates that data for known-answer tests on the Monobit Test, Run Test, Poker Test and post-processor functions can be written to the TRNG_INPUT[n] registers. When testing the post-processor, result data can be read from those same registers when this bit has become 1 again (after dropping to 0).

Table 47-23: TRNG_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	MBITFAIL	Monobit Fail. When the `TRNG_STAT.MBITFAIL` bit is set, the Monobit Test logic monitoring data, shifted into the main LFSR, detected an out-of-bounds number of 1s after checking 20,000 bits (test T1 as specified in the AIS-31 standard).
6 (R/NW)	PKRFAIL	Poker Fail. When the `TRNG_STAT.PKRFAIL` bit is set, the Poker Test logic monitoring data shifted into the main LFSR detected an out-of-bounds value in at least one of the 16 Poker Counters or an out of bounds sum of squares value after checking 20,000 bits (test T2 as specified in the AIS-31 standard).
5 (R/NW)	LRUNFAIL	Long Run Fail. When the `TRNG_STAT.LRUNFAIL` bit is set, the Run Test logic monitoring data shifted into the main LFSR detected a sequence of 34 identical bits (test T4 as specified in the AIS-31 standard).
4 (R/NW)	RUNFAIL	Run Fail. When the `TRNG_STAT.RUNFAIL` bit is set, the Run Test logic monitoring data shifted into the main LFSR detected an out-of-bounds value for at least one of the `TRNG_RUN[n].CNTZEROS` or `TRNG_RUN[n].CNTONES` counters after checking 20,000 bits (test T3 as specified in the AIS-31 standard).
3 (R/NW)	NOISEFAIL	Noise Fail. When the `TRNG_STAT.NOISEFAIL` bit is set, the Run Test logic monitoring data shifted into the main LFSR detected a sequence of 48 identical bits, which is considered a noise source failure as proposed in section E.5 of the AIS-31 standard.
2 (R/NW)	STUCKOUT	Stuck Out. When the `TRNG_STAT.STUCKOUT` bit is set, the logic around the output data registers detected that the TRNG generates the same value twice in a row.
1 (R/NW)	SHDNOVR	Shutdown Overflow. When the `TRNG_STAT.SHDNOVR` bit is set, the number of FROs shut down after a second error event (the number of 1 bits in the `TRNG_ALMSTP` register) has exceeded the threshold set by the `TRNG_ALMCNT.SHDNTHRESH` bit field.
0 (R/NW)	RDY	Ready. When the `TRNG_STAT.RDY` bit is set, data is available in the TRNG_OUTPUT0 to TRNG_OUTPUT3 registers. If a new number is already available in the random data buffer, that number is directly moved into the result register. In this case the ready status bit is asserted again, after at most six module clock cycles.

TRNG Test Register

The TRNG_TEST register can be used by the host processor to perform a number of tests on the TRNG logic including:

- Register controlled characterization by connecting the tst_fro_clk_out output to a selected FRO clock output
- FRO logic connectivity and error event detection checking by feeding known patterns through the FRO delay line and error event detection circuits
- Direct XOR-ed FRO outputs capture by disabling the main LFSR feedback logic
- Extend the Monobit Test and Poker Test by not resetting the Monobit count and Poker Test X counters after each 20,000 bits block
- Perform known answer tests on the Run Test, Poker Test and post-processor functions.

Figure 47-21: TRNG_TEST Register Diagram

Table 47-24: TRNG_TEST Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	IRQ	Test IRQ. When the TRNG_TEST.IRQ bit is set force irq output HIGH for interrupt signal connectivity testing.	
		0	Do not force IRQ high
		1	Force IRQ output high

Table 47-24: TRNG_TEST Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/W)	PATTERN	Test Pattern. The `TRNG_TEST.PATTERN` bit field sets up a repeating sequence of bits to be fed into the selected FRO delay chain `TRNG_TEST.PATTFRO` =1 and/or the selected FRO error detection circuit `TRNG_TEST.PATTDET` =1. This field is rotated right over one bit, once every sample period, when either of these control bits is 1. Therefore, bit [16] is the actual pattern bit fed into the test target.
12:8 (R/W)	SEL	Test Select. The `TRNG_TEST.SEL` bit field configures the number of the FRO to be tested, the value should be in the range of 0 to 7.
5 (R/W)	RUNPKR	Test Run Poker. When the `TRNG_TEST.RUNPKR` bit is set, it provides direct access to the inputs of the Monobit, Run and Poker Test circuits (writing input data in chunks of 32 bits to the TRNG_INPUT0 register). While this bit is 1, the TRNG is not allowed to generate entropy but any buffered random data is preserved, to be loaded into the output registers as soon as this bit is reset to 0 again. The `TRNG_STAT.NEEDCLK` bit is forced active while this bit is 1. The Monobit, Run and Poker Test circuits are reset to their initial states on any change of this bit.
4 (R/W)	CONTPKR	Continue Poker. When the `TRNG_TEST.CONTPKR` bit is set, Monobit Test and Poker Test keep running continuously by not resetting the Monobit count (`TRNG_MONOBITCNT`) and poker counters (`TRNG_POKER[n]` register) at the end of each 20,000 bits test block. This bit can only be set to 1 when `TRNG_CTL.TSTMODE` =1. 0 Do not continue poker test 1 Continue poker test
3 (R/W)	NOLFSRFB	No LFSR Feedback. When the `TRNG_TEST.NOLFSRFB` bit is set, it removes XNOR feedback from the main LFSR, converting it into a normal shift register for the XOR-ed outputs of the FROs (shifting data in on the LSB side). A 1 also forces the LFSR to sample continuously. This bit can only be set to 1 when `TRNG_CTL.TSTMODE` =1. 0 Keep XNOR feedback 1 Remove XNOR feedback

Table 47-24: TRNG_TEST Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	PATTDET	Test Pattern Detect. When the `TRNG_TEST.PATTDET` bit is set, it repeatedly feeds test pattern (PATTERN) into the error detection circuit of the FRO selected by the test select (`TRNG_TEST.SEL`) field. This bit can only be set to 1 when `TRNG_CTL.TSTMODE` =1.	
		0	Do not repeat feed test pattern
		1	Repeat feed test pattern
1 (R/W)	PATTFRO	Test Pattern FRO. When the `TRNG_TEST.PATTFRO` bit is set, it repeatedly feeds test pattern (PATTERN) into the delay chain of the FRO selected by the test select (`TRNG_TEST.SEL`) field by forcing the corresponding FRO enable (FROEN) output LOW. This bit can only be set to 1 when `TRNG_CTL.TSTMODE` =1.	
		0	Do not repeat feed test pattern
		1	Repeat feed test pattern
0 (R/W)	ENOUT	Test Enable Out. When the `TRNG_TEST.ENOUT` bit is set, it enables the tst_fro_clk_out output, connecting to the FRO selected by the test select (`TRNG_TEST.SEL`) field. This bit can only be set to 1 when `TRNG_CTL.TSTMODE` =1.	
		0	Disable tst_fro_clk_out
		1	Enable tst_fro_clk_out

48 Thermal Monitoring Unit (TMU)

The TMU provides on-chip temperature measurement which is important in applications that have substantial power consumption. The TMU is integrated into the processor die and digital infrastructure using an MMR-based system access to measure the die temperature variations in real-time.

TMU Features

The TMU supports the following features:

- On-chip temperature sensing
- Programmable over-temperature and under-temperature limits
- Programmable conversion rate
- Programmable clock source selection to run the sensor off an independent local clock
- Averaging feature available
- Temperature gain and offset correction options

TMU Functional Description

Following sections provide the functional description of TMU.

TMU Definitions

The following definitions are helpful when using the TMU module.

Thermal Diode

A special type of diode whose electrical properties change with the temperature in a defined way.

DTM

Dynamic thermal management is a set of techniques that adapt the run-time behavior of a processor to achieve the highest performance under thermal constraints.

TMU Architectural Concepts

The following sections provide information on the architecture and system integration of the TMU.

System Integration

Dynamic thermal management (DTM) techniques adapt the run-time behavior of a processor to achieve the highest performance under thermal constraints. One of the most important aspects of DTM is to capture the run-time variations in the temperature caused by power consumption variations due to workload changes.

The accuracy of thermal measurements directly affects the efficiency of thermal management as well as the performance of the processor. Temperature estimations lower or higher than the actual temperature may cause late or early activation of DTM techniques.

- Late activation of DTM can result in degraded reliability because the temperature may exceed the designated thresholds.
- Early activation of DTM can have significant impact on performance.

The TMU is an analog thermal sensor that consists of a temperature-sensing diode, a calibrated reference current source, and a current comparator. The sensor placement error is one of the most important sources of inaccuracy in values obtained from thermal sensors.

The TMU module provides the temperature monitoring capability to the chip and implements thermal management in the end system. It provides many features which ensure the minimum load on the software and also minimal or no external components for a flexible temperature monitoring system.

Digital Thermometer

The TMU functions as a digital thermometer with an MMR-based system access. The on-die temperature value is measured and digitized through an A/D converter. The temperature value is stored and updated periodically in an MMR register. The TMU can be configured to generate an interrupt as it crosses the upper temperature limit (`TMU_FLT_LIM_HI` register). A thermal event is also routed to the interrupt port of the sensor which is routed to the SEC, to ensure that core intervention is not required in the event of overheating.

Temperature Sensor Averaging

A temperature sensor averaging feature is to enhance the accuracy of the temperature measurements. To enable the temperature sensor averaging feature, the `TMU_AVG` bits must be enabled in the control register after power-up. In this mode, the averaging reduces the effect of noise on the temperature result. The temperature is measured each time a conversion is performed and a moving average method is used to determine the result in the temperature value register. The total time to measure a temperature channel is typically 1 ms.

TMU Event Control

The TMU generates different events depending on the state of the TMU temperature measurement and the different thresholds set in thresh hold registers. These events are reported in the `TMU_STAT` register as shown below. It can generate an event for each of following conditions.

- The fault high limit is configured in the `TMU_FLT_LIM_HI` register. The interrupt is generated when the temperature value is greater than or equal to this value.
- The alert high limit is configured in the `TMU_ALRT_LIM_HI` register. The `TMU_STAT.ALRTHI` status bit is set when the temperature value is greater than or equal to this value.
- The fault low limit is configured in the `TMU_FLT_LIM_LO` register. The `TMU_STAT.FLTLO` status bit is set when the temperature value is less than or equal to this value.
- The alert low limit is configured in the `TMU_ALRT_LIM_LO` register. The `TMU_STAT.FLTLO` status bit is set when the temperature value is less than or equal to this value.

Interrupts and status conditions can be masked (disabled) or unmasked (enabled) by setting and clearing bits in the `TMU_IMSK` register.

NOTE: Only `TMU_FLT_LIM_HI` generates an interrupt to core. Other events only result in status change in the `TMU_STAT` register.

Status and Error Signals

When the measured temperature value exceeds the high or low limits that are configured in the `TMU_FLT_LIM_HI`/`TMU_FLT_LIM_LO` and the `TMU_ALRT_LIM_HI`/`TMU_ALRT_LIM_LO` registers, corresponding thermal events are triggered.

The fault and alert events are sent to the core through the status register (`TMU_STAT`). Both the `TMU_STAT.FLTHI` and `TMU_STAT.ALRTHI` bits are sticky bits and are cleared by a W1C operation by the core.

The alert and fault registers can be programmed through the MMR bus interface as shown in the TMU block diagram. A write into the `TMU_FLT_LIM_HI`/`TMU_FLT_LIM_LO` and `TMU_ALRT_LIM_HI`/`TMU_ALRT_LIM_LO` registers or the `TMU_TEMP` register is not allowed when the events are being triggered.

TMU Programming Guidelines

The following section provides basic programming information for the TMU module.

To get the best performance and accuracy from the TMU, intialize the `TMU_GAIN`, `TMU_OFFSET` and `TMU_AVG` registers before enabling the module. Contact Analog Devices, Inc for the current best values to use.

After these registers are programmed, the rest of the TMU initialization can take place. This includes setting up the fault and alert limits and then enabling the TMU.

ADSP-SC58x TMU Register Descriptions

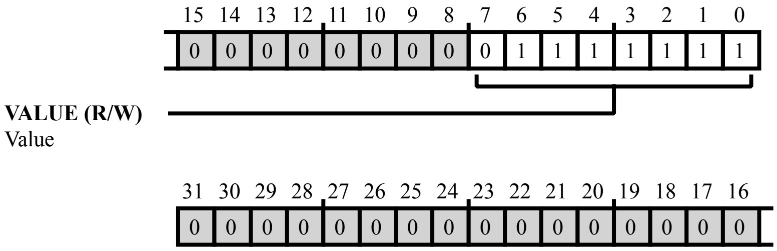
Thermal monitoring unit (TMU) contains the following registers.

Table 48-5: ADSP-SC58x TMU Register List

Name	Description
`TMU_ALRT_LIM_HI`	Alert High Limit Register
`TMU_ALRT_LIM_LO`	Alert Low Limit Register
`TMU_AVG`	Averaging Register
`TMU_CTL`	TMU Control Register
`TMU_FLT_LIM_HI`	Fault High Limit Register
`TMU_FLT_LIM_LO`	Fault Low Limit Register
`TMU_GAIN`	Gain Value Register
`TMU_IMSK`	Interrupt Mask Register
`TMU_OFFSET`	Offset Register
`TMU_STAT`	Status Register
`TMU_TEMP`	Temperature Value Register

Alert High Limit Register

The TMU_ALRT_LIM_HI register sets the temperature alert high limit as an integer value. The value is stored in two's complement format. Asserts TMU_STAT.ALRTHI if the TMU_TEMP value is greater than or equal to TMU_ALRT_LIM_HI. The TMU_ALRT_LIM_HI value should be programmed for value greater than 8'h3C (60 degC).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

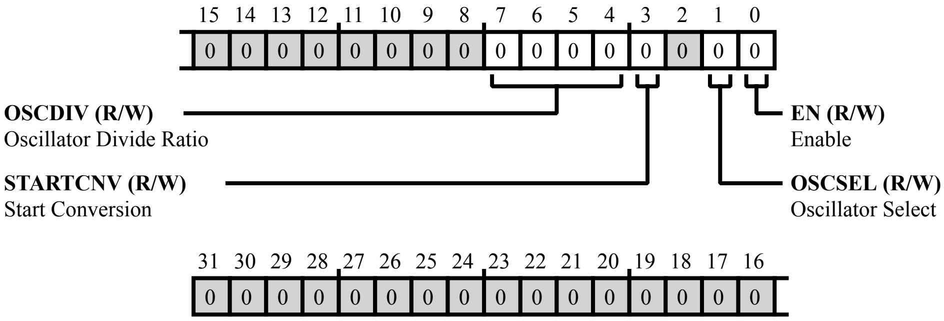
Table 48-8: TMU_AVG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	AVG_EN	Value. The `TMU_AVG.AVG_EN` bit enables averaging on the TMU. Averaging is done using the formula (7 x previous_avg_value + current_value)/8. Initially the current_value is taken as previous_avg_value.	
		0	No averaging
		1	Enable averaging

TMU Control Register

The TMU_CTL register contains bits that allow programs to configure and enable the TMU.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
OSCDIV (R/W)
Oscillator Divide Ratio
STARTCNV (R/W)
Start Conversion
EN (R/W)
Enable
OSCSEL (R/W)

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

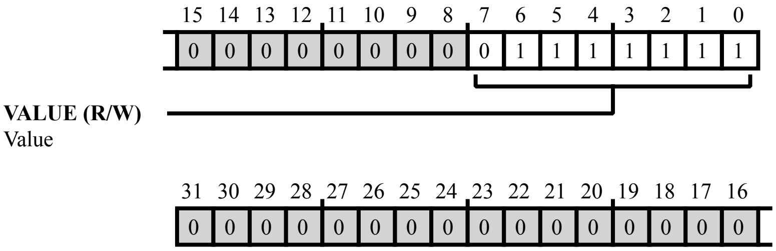
Figure 48-5: TMU_CTL Register Diagram

Table 48-9: TMU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/W)	OSCDIV	Oscillator Divide Ratio. The TMU_CTL.OSCDIV bit field configures the division ratio for the SCLK. SCLK is divided by (21 + 4 * TMU_CTL.OSCDIV). By default the SCLK is divided by 21.	
3 (R/W)	STARTCNV	Start Conversion. When the TMU_CTL.STARTCNV bit is set, ADC conversion starts.	
		0	ADC conversion not started
		1	Start ADC conversion
1 (R/W)	OSCSEL	Oscillator Select. The TMU_CTL.OSCSEL bit selects the local oscillator. By default the TMU works off the divided system clock (SCLK).	
		0	Select SCLK
		1	Select local oscillator
0 (R/W)	EN	Enable. The TMU_CTL.EN bit enables the TMU. By default the module is in power-down mode. The peripheral interface is active even in power-down mode (the TMU registers can be read/written).	
		0	Disable TMU
		1	Enable TMU

Fault High Limit Register

The `TMU_FLT_LIM_HI` register sets the temperature fault high limit as an integer value. The value is stored in two's complement format. Asserts `TMU_STAT.FLTHI` if the `TMU_TEMP` value is greater than or equal to `TMU_FLT_LIM_HI`. The `TMU_FLT_LIM_HI` value should be programmed for value greater than 8’h3C (60 degC).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 1 1 1 1 1 1 1

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 48-10: TMU_OFFSET Register Diagram

Table 48-14: TMU_OFFSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	VALUE	Value. The `TMU_OFFSET.VALUE` bit field provides the offset value which is used to correct the offset error in the `TMU_TEMP` register. This value is in a two's complement fixed point Q3.8 format where the 4 MSB's represent the integer part in two's complement format and the remaining 8 LSB's represent the decimal part. The offset value is applied after multiplying the gain.

Status Register

The TMU_STAT register bits indicate when an error or fault is detected.

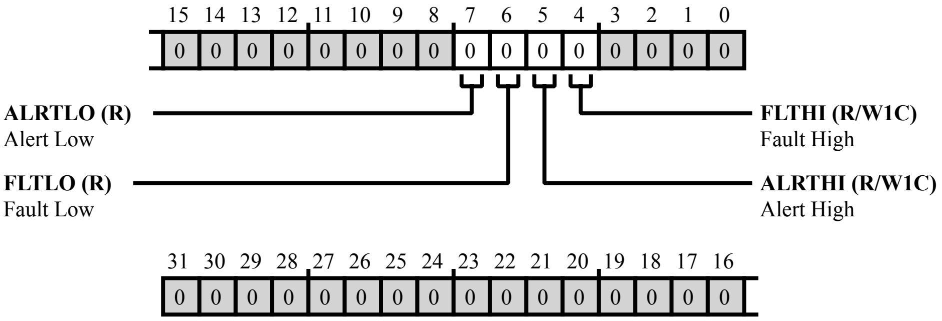

Figure 48-11: TMU_STAT Register Diagram

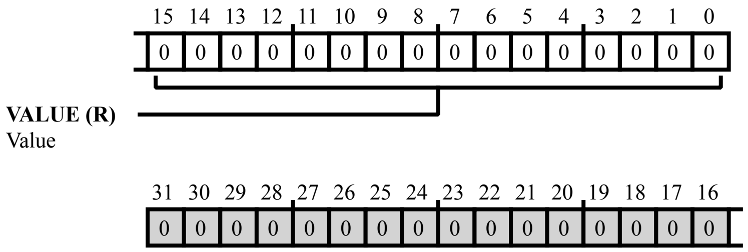
Table 48-15: TMU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	ALRTLO	Alert Low. The TMU_STAT.ALRTLO bit is set when the temperature value is less than or equal to the setting in the TMU_ALRT_LIM_LO register. The bit assertion is masked if TMU_IMSK.ALRTLO is HIGH.
6 (R/NW)	FLTLO	Fault Low. The TMU_STAT.FLTLO bit is set when the temperature value is less than or equal to the setting in the TMU_FLT_LIM_LO register. The bit assertion is masked if TMU_IMSK.FLTLO is HIGH.
5 (R/W1C)	ALRTHI	Alert High. The TMU_STAT.ALRTHI bit is set when the temperature value is greater than or equal to the setting in the TMU_ALRT_LIM_HI register. When Write1toClear is done on TMU_STAT.ALRTHI, it will be cleared only if the TMU_TEMP value is less than TMU_ALRT_LIM_HI value. If the bit is cleared by 'Write1toClear', The TMU_TEMP register is set to 16'h2C00 (effective temperature value of 44). The value 16'h2C00 will be changed according to gain, offset values from TMU_GAIN, TMU_OFFSET registers respectively.
4 (R/W1C)	FLTHI	Fault High. The TMU_STAT.FLTHI bit is set when the temperature value is greater than or equal to the setting in the TMU_FLT_LIM_HI register. When Write1toClear is done on TMU_STAT.FLTHI, it will be cleared only if the TMU_TEMP value is less than TMU_FLT_LIM_HI value. If the bit is cleared by 'Write1toClear', The TMU_TEMP register is set to 16'h2C00 (effective temperature value of 44). The value 16'h2C00 will be changed according to gain, offset values from TMU_GAIN, TMU_OFFSET registers respectively.

Temperature Value Register

The `TMU_TEMP` register provides the temperature value from the A/D converter and the status.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 48-12: TMU_TEMP Register Diagram

Table 48-16: TMU_TEMP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Value. The `TMU_TEMP.VALUE` bit field is the temperature value from A/D converter. This value is stored in two's complement fixed point Q7.8 format where the 8 MSB's represent the integer part in 2's complement, and the remaining 8 LSB's represent the decimal part.

49 Harmonic Analysis Engine (HAE)

The harmonic analysis engine (HAE) analyzes harmonic frequencies present on the voltage and current input samples. The HAE receives input samples from two source channels whose frequencies are 45–65 Hz. The HAE then processes the input samples and produces output results. The output results consist of power quality measurements of the fundamental and up to 12 more harmonics.

HAE Features

The HAE features include:

- Processing of two 24-bit signed input channels, consisting of one voltage and one current. The input full scale is limited to ~ +/-6,000,000
- Processing of fundamental frequencies between 45-65 Hz
- Processing of input samples at a nominal 8 kHz rate
- Processing of the fundamental plus 12 harmonic frequencies
- Active, reactive, apparent, I_{RMS}, V_{RMS}, and power factor on the fundamental frequency
- Active, reactive, apparent, I_{RMS}, V_{RMS}, power factor, I_{HD+n}, and V_{HD+n} on the 12 harmonic frequencies
- The accuracy of the measurements, relative to a full scale of +/-6,000,000:
    - Fundamental active or reactive powers 0.1% down to 1/1000 of full scale
    - Fundamental apparent power 0.2% down to 1/1000 of full scale
    - Fundamental I_{RMS}/V_{RMS} 0.1% down to 1/1000 of full scale
    - Fundamental power factor 0.3% based on active and apparent accuracy
    - Harmonic active or reactive powers 1% down to 1/1000 of full scale
    - Harmonic apparent power 2% down to 1/1000 of full scale
    - Harmonic I_{RMS}/V_{RMS} 1% down to 1/1000 of full scale
    - Harmonic power factor 3% based on active and apparent accuracy

  - Harmonic I_{HD+n} 2% down to 1/1000 FS based on the fundamental and harmonic I_{RMS}
  - Harmonic V_{HD+n} 2% down to 1/1000 FS based on the fundamental and harmonic V_{RMS}
- Twelve 6-bit fields for selecting harmonics to analyze, limited by bandwidth of the input signal. The fundamental component always is provided.

HAE Functional Description

The following sections provide a functional description of the HAE.

Harmonic engine

The hardware block of the harmonic engine works with other HAE blocks to co-process full and partial results

Harmonic Analyzer

The harmonic analyzer block works with the harmonic engine to co-process full and partial results.

Data Transfer Module

The data transfer module transfers three channels of data to and from the HAE module.

ADSP-SC58x HAE Register List

The Harmonic Analysis Engine (HAE) analyzes harmonics present on voltage and current input samples. The HAE receives input samples from two source channels, processes the samples, and produces output results. The output results consist of power quality measurements of the fundamental and up to twelve additional harmonic components. A set of registers governs HAE operations. For more information on HAE functionality, see the HAE register descriptions.

Figure 49-2: HAE Engine Block Diagram

The harmonic engine hardware block works with other HAE blocks to co-process full and partial results (see Harmonic Calculations). At the start of a new sampling period (described in Initialization), the harmonic engine cycles through predefined locations in data RAM, which contain the analyzer processing results. See Harmonic Analyzer for more information.

As the harmonic engine produces results in their final formats (described in HAE Result Ranges and Formats), the results are stored in the results memory (see Results Memory).

The HAE engine computes harmonic information for line frequencies 45–66 Hz. Neutral current can also be analyzed simultaneously with the sum of phase currents. See Theory of Operation for more information.

Harmonic Analyzer

The harmonic analyzer block works with the Harmonic Engine to co-process full and partial results.

To perform harmonic analysis, the HAE contains a pair of voltage and current inputs and a set of 12 indexes to indicate which harmonic components to extract. See Theory of Operation and Harmonic Calculations for more information.

High-Pass Filters (HPFs)

The voltage and current have the option of being high-pass filtered to remove DC offsets. The ***Frequency Response for High-Pass Filters*** figure shows the frequency response of the high-pass filters (the -3 dB point is around 1.1 Hz). The HPFs are enabled by default.

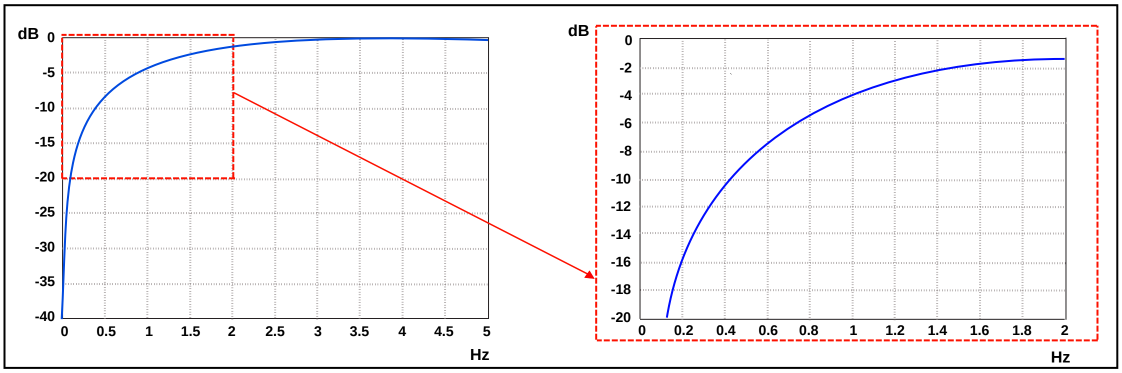

Figure 49-3: Frequency Response for High-Pass Filters

Digital Integrators

For cases when the current is sensed with a di/dt sensor, such as a Rogowski coil, the HAE offers an internal digital integrator for compensation. Ideally, it causes a perfect 90 degrees of phase shift at all the frequencies; at 50 Hz it is close to that value (see the ***Digital Integrator*** figure). The integrator is necessary to restore the signal to its original form before using the signal in HAE calculations. The digital integrator is disabled by default.

With digital integrator enabled for current channel, the amplitude of current will change with the frequency according to a slope of 20 dB per decade. For frequency of 50 Hz, the amplitude of current remains same after passing through the integrator. However, for other frequencies in the range 45-65 Hz, the amplitude of current changes with a slope of 20 dB per decade after passing through integrator.

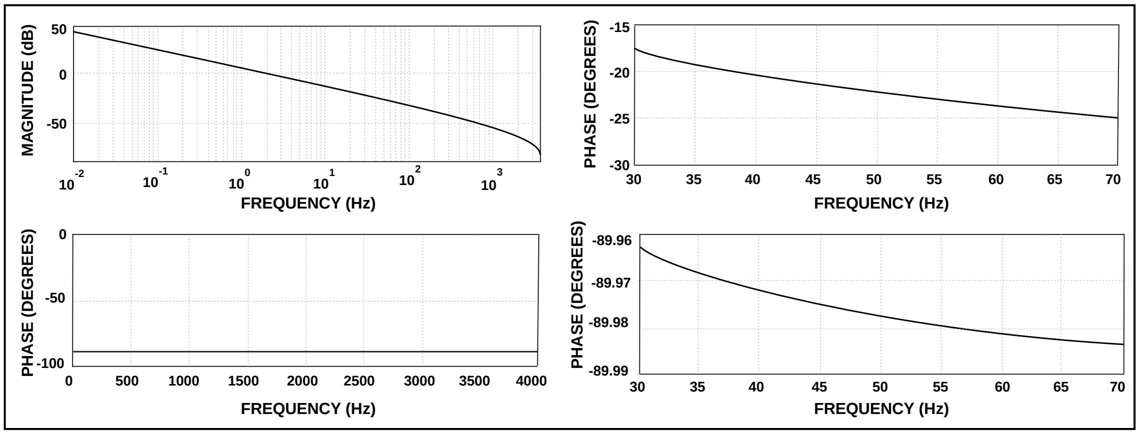

Figure 49-4: Digital Integrator

Phase-Locked Loop and Clock Control (PLL)

The fundamental frequency of the system is extracted from the voltage signal using the phase-locked loop and clock control (PLL) techniques. PLL techniques are optimized for signals with frequencies used in standard power grids around the world (50 Hz or 60 Hz). The techniques consider possible deviations of up to 5 Hz, so the final guaranteed operating range is from 45 Hz to 65 Hz.

The initial detection time of the frequency depends on its value and can take up to several seconds. This activity only happens at the start-up of the HAE block. Once the value of the fundamental frequency is detected, the PLL tracks it continuously.

Settling Times

The block that extracts all of the harmonic RMS and power values is replicated 12 times in parallel for all of the harmonic indexes plus once for the fundamental. Once an index for a particular harmonic changes, there is a settling time of about 700 mSec (~700 / 0.125 = 5600 8K samples). This settling time achieves less than 0.1% error needed for all the internal RMS and powers computations (see the ***Fundamental and Harmonic Values - Settling Times*** plots).

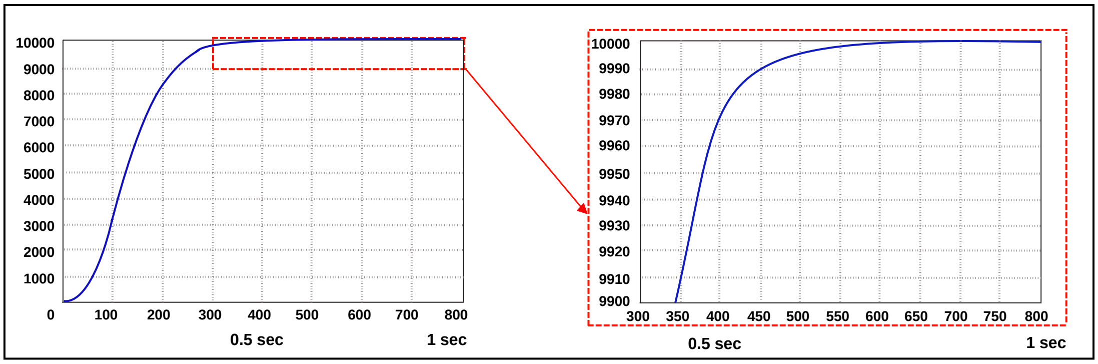

Figure 49-5: Fundamental and Harmonic Values - Settling Times

Data Transfer Module

The data transfer module transfers three channels of data to and from the HAE module.

RX I (Receive Current Sample) Channel

The RX I channel transfers HAE current (I) input samples from system memory through direct memory access (DMA). The RX I request occurs at a nominal 8 kHz rate, depending on the `HAE_CFG1.STARTDIV` bit field. The RX I samples typically come from a SINC filter through a memory buffer. For accurate harmonic results, derive the input samples at the same rate as the HAE sample loop. Therefore, program the SINC and HAE modules to be timing-matched. The SCLK0_0 / `HAE_CFG1.STARTDIV` determines the HAE sample loop, which must be programmed to be nominally 8 kHz in frequency. There is one `DWORD` transfer each HAE sample loop.

There is also an RX I memory-mapped location (`HAE_ISAMPLE` register) in peripheral space (MMR), which enables the MCU to provide the I channel samples, timed with the `HAE_STAT.RXIRQ` bit, if desired.

RX V (Receive Voltage Sample) Channel

The RX V channel transfers HAE voltage (V) input samples from system memory through DMA. The RX V request occurs at a nominal 8 kHz rate, depending on the `HAE_CFG1.STARTDIV` bit field. The RX V samples typically come from a SINC filter through a memory buffer. For accurate harmonic results, derive the input samples at the same rate as the HAE sample loop. Therefore, program the SINC and HAE modules to be timing-matched.

The SCLK0_0 / `HAE_CFG1.STARTDIV`, determines the HAE sample loop which must be programmed to be nominally 8 kHz in frequency. There is one `DWORD` transfer each HAE sample loop.

There is also an RX V memory-mapped location (`HAE_VSAMPLE` register) in peripheral space (MMR), which enables the MCU to provide the V channel samples, timed with the `HAE_STAT.RXIRQ` bit, if desired.

Example:

- The `HAE_STAT.RXIRQ` bit toggles prior to RX transfers:

  The RX interrupt is used internally in hardware to request I and V samples. The MCU can also use the interrupt when it supplies the input samples, rather than the DMA interface.

- RX transfers indicate that the RX channel is ready:

  The HAE RX channels request one RX sample at an 8 kHz rate, depending on the `HAE_CFG1.STARTDIV` bit field. The holding register stores the RX data, replacing the previous data. The holding register contents are moved up to an output register and driven to the Harmonic Analyzer module for processing. This operation amounts to a two-deep FIFO, allowing a full sample time of latency on the input sample arrival, nominally 125 uSec (8 kHz).

  If the MCU supplies the input samples, rather than the DMA RX interfaces, there are two memory-mapped locations (`HAE_ISAMPLE` and `HAE_VSAMPLE`), where the next samples are written. As previously mentioned, the HAE can use the `HAE_STAT.RXIRQ` bit to time the sample delivery.

TX (Transmit Results) Channel

The TX channel transfers HAE results from results memory to system memory through DMA. The results for the fundamental and 12 harmonics are stored in 13 8-location fields in the results memory. Therefore, the maximum number of `DWORD`s to transfer is 13 x 8 = 104. Use the `HAE_CFG3.CHANEN` bits to select the channels to transfer.

The HAE can request a transfer of results for each 8 kHz sample period, meaning that up to 104 `DWORDs` can be transferred each 125 uSec. Use the `HAE_CFG2.UPDATE` bit field to set the request rate to longer intervals. The results also are memory-mapped to peripheral address space, which enables the MCU to read the results, timed with the `HAE_STAT.TXIRQ` bit, if desired.

Example:

- The `HAE_CFG3.CHANEN` bit field is set to 0x009 to transfer the fundamental and harmonic contained in the `HAE_H3_INDX` register (programmed to 5th).

- The `HAE_STAT.TXIRQ` bit toggles prior to TX transfers:

  The HAE uses the TX interrupt internally in hardware to start the transfer. The MCU can also use the interrupt when the MCU reads the HAE results, rather than the DMA interface transferring it.

- TX transfers indicate that the HAE results data is ready:

  The HAE TX channel can transfer one `DWORD` every other clock. The internal hardware parses through the `HAE_CFG3.CHANEN` bit field, eventually traversing all 13 bits. If consecutive channels are enabled, two more

`IDLE` clocks are inserted between the adjacent channels for a total of three `IDLE` clocks. When channels are skipped, one more `IDLE` clock is inserted for each unselected channel. Therefore, there are 3 (inter-channel `IDLE`) + 2 (skipped channels) = 5 `IDLE` clocks between the fundamental and `HAE_H3_INDX` transfers.

Results Memory

The results memory is organized by the fundamental and 12 harmonic indexes. Each of the 13 potentially analyzed frequencies has eight locations dedicated to store various power quality measurements. Each frequency is offset from the next by eight locations.

The ***HAE Results Memory*** figure shows the results memory contents.

Figure 49-6: HAE Results Memory

RAM Parity Protection

HAE Results Upper Byte ID

The HAE results are stored in a 24-bit wide memory as shown in Results Memory.

When the system bus moves the results into memory, the HAE hardware appends a unique `CHANNEL:INDEX` identifier to the upper byte of each results location. The intent of the ID byte is to help in data parsing of HAE results.

The 32-bit appended result is as follows:

`CHANNEL[3:0]` ||	`INDEX[3:0]` ||	`RESULTS[23:0]`

The `CHANNEL` in the upper byte corresponds to `nn` in `Hnn_INDX` of that particular results location. The `INDX` in the upper byte corresponds to the `INDX` within the `Hnn_INDX` grouping.

For example, location `H7_PF` has `0x75` in the upper byte of the system bus transfer of that HAE results memory location.

HAE Result Ranges and Formats

The HAE results, stored in the results memory, have formats appropriate for the given measurement. Measurements accuracy is relative to the full scale value of the input samples, and the assumed full scale is +/~6,000,000. If the full scale is above this value, overflow can occur and the results are undefined. A lower full scale limits the dynamic range accuracy of the measurements. For example, a full scale, which is 50% lower than the assumed 6,000,000 full scale, has the dynamic range reduced by 50%. Potentially, this result can be better or worse, as determined by the ADC noise floor supplying the input samples.

The HAE results are as linear as the input samples, within the accuracy ranges specified earlier. The results assume a full-scale input sample of ~=/-6,000,000 and sufficiently low ADC noise floor. Evaluate the system using your specific ADC and full scale specifications to predict the HAE range of accuracy and expected results.

The RMS values of voltage and current calculated from HAE are exactly not same as the theoretical RMS values. The ratio between HAE calculated RMS value and the theoretical value is around 1.11. A gain factor should be added in the software so as to match the theoretical and HAE calculated RMS values. Calibration can be done by calculating the ratio between HAE calculated RMS value and the theoretical one for a particular amplitude of V and I signal and line frequency.

The following list gives the HAE result formats.

- I_{RMS} and V_{RMS}: both fundamental and harmonic I_{RMS} and V_{RMS} are unsigned magnitudes with full scale of ~4,200,000
- Active and reactive power: both active and reactive powers are signed numbers with full scale of ~+/-4,200,000
- Apparent power: apparent power is an unsigned magnitude with full scale of ~4,200,000
- Power factor: each LSB of the fundamental and harmonic power factors equates to a weight of 2^{-23}. Hence, the maximum register value of 0x7FFFFF equates to a power factor value of 1. The minimum register value of 0x800000 corresponds to a power factor of -1. If the power factor is outside of the -1 to +1 range because of offset and gain calibrations, the result is set at -1 or +1. The result depends on the sign of the fundamental reactive power.
- I_{HD+n}/V_{HD+n}: the harmonic distortion plus noise ratios are computed using the RMS of the fundamental and the RMS of the harmonic under analysis. In other words, the ratio only covers the particular harmonic under analysis versus the fundamental. The ratios are stored as 24-bit values in 3.21 signed format. The ratios are limited to +3.9999, and all greater results are clamped to it. The `HD+n` ratios cannot be negative.

HAE Operating Modes

The HAE uses the DMA interface to transfer data to and from system memory. The HAE configuration registers enable the module and calibrate its frequency (clock) divide and other parameters, as described in HAE Programming Model. The HAE triggers and status signals indicate system events and errors.

HAE Data Transfer Modes

The HAE uses the RX DMA interface to transfer data from system memory. Samples for the current (I) and voltage (V) channels of the AFE or SINC filter compose the data: two `WORDS` are transferred each 8 kHz sample period into the HAE (I and V).

The HAE uses the TX DMA interface to transfer data to system memory. The fundamental and selected harmonic results compose the data: up to 13 (fundamental + 12 harmonics) x 8 = 104 `DWORD`s are transferred each 8K sample period.

See Data Transfer Module for more information.

HAE Event Control

The HAE module uses DMA to transfer samples to and data from system memory. The HAE also can use TX and RX events to time the arrival of input samples and extract the results by the MCU:

- The MCU uses the RX event (`HAE_STAT.RXIRQ`) as an IRQ to time when to write the I and V samples into the HAE.
- The MCU uses the TX event (`HAE_STAT.TXIRQ`) as an IRQ to time when to read the HAE results.

HAE Interrupt Signals

The interrupt signals to the HAE module include:

- The RX interrupt to time the delivery of waveform samples as inputs to the HAE.
- The TX interrupt to time when the HAE results memory is ready with new values for the current sample.

The HAE generates the RX interrupts at a rate specified by the `HAE_CFG1.STARTDIV` bit field and the TX interrupts at a rate specified by the `HAE_CFG2.UPDATE` bit field. Refer to Data Transfer Module for more information.

HAE Status and Error Signals

The trigger and status signals to the HAE module include:

- `HAE_STAT.RDY` (HAE ready status). When the bit is set, the HAE is fully accessible.
- `HAE_STAT.RXIRQ` (RX IRQ status). The bit mirrors the RX interrupt.
- `HAE_STAT.TXIRQ` (TX IRQ status). The bit mirrors the TX interrupt.

The status bit requires a 1 to clear and reenable the corresponding interrupt for the next sample period. Refer to Data Transfer Module for more information.

HAE Programming Model

The following sections provide basic procedures for configuring various HAE operations.

Current and voltage data can be transferred from system memory to HAE. HAE results can be transferred to system memory using core and DMA accesses. DMA transfers can be set up to transfer a configurable number of I and V samples and HAE results between HAE and system memory automatically. Core-driven transfers use HAE interrupts to signal the processor core to provide I and V data to the sample registers and read the HAE results from the system memory.

The following sections provide recommended programming guidelines to be followed for core and DMA mode.

Configuring the HAE for DMA Transfers

- Enable HAE operations by configuring the `HAE_CFG2.EN` bit.
- Poll for HAE ready status from the `HAE_STAT.RDY` bit configuration.
- Initialize the HAE configuration registers to configure update and settle rates, HPF, integrator for di/dt sensor and line frequency.
- Choose the harmonic channels to be monitored by configuring the `HAE_H[nn]_INDX` registers and enable channels by configuring the `HAE_CFG3.CHANEN` bits.
- Configure the RX DMA channel 0 and the RX DMA channel 1 to receive I and V samples. Configure the TX DMA channel 0 to transmit harmonic calculation results.
- Set the HAE clock divider using the `HAE_CFG1.STARTDIV` field to 8 kHz.
- Set the `HAE_RUN` register.

Configuring the HAE for Core Transfers

- Enable HAE operations by configuring the `HAE_CFG2.EN` bit.
- Poll for HAE ready status using the `HAE_STAT.RDY` bit.
- Initialize the HAE configuration registers to configure update and settle rates, HPF, integrator for di/dt sensor and line frequency.
- Enable receive and transmit IRQ using the `HAE_CFG0` register.
- Configure the `HAE_VLEVEL` register depending on input voltage magnitude requirements.
- Configure the `HAE_H[nn]_INDX` registers to choose the harmonic channels to monitor. Enable the channels using the `HAE_CFG3.CHANEN` bits.
- Set the HAE clock divider using the `HAE_CFG1.STARTDIV` field to 8 kHz.

- Set the `HAE_RUN` register.
- At each receive IRQ (`HAE_STAT.RXIRQ` = 1), write I and V sample values to the `HAE_ISAMPLE` and the `HAE_VSAMPLE` registers respectively.
- At each transmit IRQ (`HAE_STAT.TXIRQ` = 1), read the HAE results from the HAE result RAM memory region based on the index.

HAE Programming Concepts

Using the HAE features to their greatest potential requires an understanding of some HAE-related concepts.

- Theory of Operation
- Initialization
- Harmonic Calculations
- Configuring Harmonic Calculations Update Rate

Theory of Operation

The HAE theory of operation can be described using the following scenario:

Consider a nonsinusoidal AC system supplied by a voltage, v(t), that consumes the current, i(t):

$$v(t) = \sum_{k=1}^{\infty} V_k \sqrt{2} \sin(k\omega t + \varphi_k)$$

$$i(t) = \sum_{k=1}^{\infty} I_k \sqrt{2} \sin(k\omega t + \gamma_k)$$

where:

- V_k, I_k are the RMS voltage and current, respectively, of each harmonic.
- Φ_k, γ_k are the phase delays of each harmonic.
- ω is the angular velocity at the fundamental (line) frequency f.

The HAE harmonic calculations are specified for line frequencies 45–65 Hz.

The maximum number of harmonics which the HAE can accept for a particular line frequency depends upon the bandwidth of the input waveforms supplied.

When the HAE analyzes I and V samples, the following metering quantities are computed:

- Fundamental current RMS: I_1
- Fundamental voltage RMS: V_1
- RMS of up to 12 harmonics of the current channel: I_n, n = 2, 3,…, 12
- RMS of up to 12 harmonics of the voltage channel: V_n, n = 2, 3,…, 12

- Fundamental active power: $P_1 = V_1 I_1 \cos(\varphi_1 - \gamma_1)$
- Fundamental reactive power: $Q_1 = V_1 I_1 \sin(\varphi_1 - \gamma_1)$
- Fundamental apparent power: $S_1 = V_1 I_1$
- Power factor of the fundamental:

  $$pf_1 = \operatorname{sgn}(Q_1)\cdot \frac{P_1}{S_1}$$

  Active power of up to 12 harmonics:

  $P_n = V_n I_n \cos(\varphi_n - \gamma_n)$, n = 2, 3,…, 12
- Reactive power of up to 12 harmonics:

  $Q_n = V_n I_n \sin(\varphi_n - \gamma_n)$, n = 2, 3,…, 12
- Apparent power of up to 12 harmonics:

  $S_n = V_n I_n$, n = 2, 3, …, 12
- Power factor of up to 12 harmonics:

  $$pf_n = \operatorname{sgn}(Q_n)\cdot \frac{P_n}{S_n}, \quad n = 2, 3, \ldots, 12$$
- Total harmonic distortion of the current channel:

  $$(THD)_I = \frac{\sqrt{I^2 - I_1^2}}{I_1}$$
- Total harmonic distortion of the voltage channel:

  $$(THD)_V = \frac{\sqrt{V^2 - V_1^2}}{V_1}$$
- Harmonic distortion of up to 12 harmonics on the current channel:

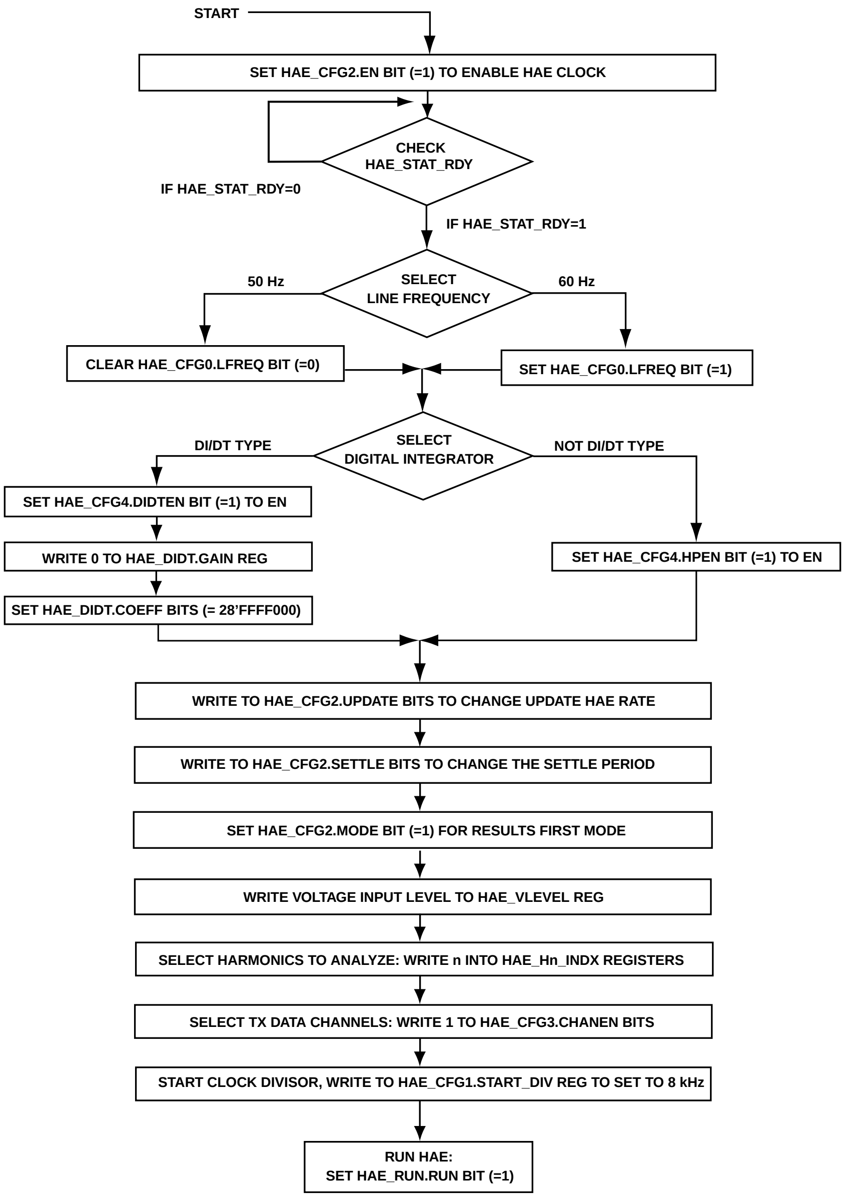
  $$HD_{I_n} = \frac{I_n}{I_1}, \quad n = 2, 3, \ldots, 12$$
- Harmonic distortion of up to 12 harmonics on the voltage channel:

  $$HD_{V_n} = \frac{V_n}{V_1}, \quad n = 2, 3, \ldots, 12$$

Initialization

The HAE typically is initialized with parameters and settings for a given usage scenario. It is interrupt-driven when new results are available.

The HAE programming depends on whether the line frequency is 50 Hz or 60 Hz. If the external sensor is a di/dt type, there are also some differences. The ***HAE Initialization*** flowchart shows the initialization sequence.



START
SET HAE_CFG2.EN BIT (=1) TO ENABLE HAE CLOCK
CHECK HAE_STAT_RDY
IF HAE_STAT_RDY=0
IF HAE_STAT_RDY=1
SELECT LINE FREQUENCY
50 Hz
60 Hz
CLEAR HAE_CFG0.LFREQ BIT (=0)
SET HAE_CFG0.LFREQ BIT (=1)
SELECT DIGITAL INTEGRATOR
DI/DT TYPE
NOT DI/DT TYPE
SET HAE_CFG4.DIDTEN BIT (=1) TO EN
WRITE 0 TO HAE_DIDT.GAIN REG
SET HAE_DIDT.COEFF BITS (= 28'FFFF000)
SET HAE_CFG4.HPEN BIT (=1) TO EN
WRITE TO HAE_CFG2.UPDATE BITS TO CHANGE UPDATE HAE RATE
WRITE TO HAE_CFG2.SETTLE BITS TO CHANGE THE SETTLE PERIOD
SET HAE_CFG2.MODE BIT (=1) FOR RESULTS FIRST MODE
WRITE VOLTAGE INPUT LEVEL TO HAE_VLEVEL REG
SELECT HARMONICS TO ANALYZE: WRITE n INTO HAE_Hn_INDX REGISTERS
SELECT TX DATA CHANNELS: WRITE 1 TO HAE_CFG3.CHANEN BITS
START CLOCK DIVISOR, WRITE TO HAE_CFG1.START_DIV REG TO SET TO 8 kHz
RUN HAE:
SET HAE_RUN.RUN BIT (=1)

Figure 49-7: HAE Initialization

Harmonic Calculations

When the harmonic engine runs, it computes information about the fundamental and up to 12 harmonics. The HAE simultaneously monitors the indexes of the additional 12 harmonics, provided by the 8-bit registers `HAE_H[nn]_INDX`. Write the index of the harmonic into the register for the harmonic to be monitored. If the second harmonic is monitored, write `2`. If harmonic 51 is desired, write `51`. The HAE always monitors the fundamental component, independent of the values written into `HAE_H[nn]_INDX`. Therefore, if one of these registers is equal to `1`, the HAE monitors the fundamental components multiple times. The maximum index allowed in the `HAE_H[nn]_INDX` registers is 63.

As a reference, the ***Harmonic Engine Outputs and Registers where Values are Stored*** table presents the harmonic engine outputs and registers that store the outputs.

Table 49-6: Harmonic Engine Outputs and Registers where Values are Stored

Quantity	Definition	HAE Registers
RMS of the Fundamental Component	V_1, I_1	`F_VRMS`, `F_IRMS`
RMS of a Harmonic Component	V_n, I_n, n = 2, 3,…, 12	`Hnn_VRMS`, `Hnn_XIRMS`
Active Power of the Fundamental Component	$P_1 = V_1 I_1 \cos(\varphi_1 - \gamma_1)$	`F_ACT`
Active Power of a Harmonic Component	$P_n = V_n I_n \cos(\varphi_n - \gamma_n)$, n = 2, 3,…, 12	`Fnn_ACT`
Reactive Power of the Fundamental Component	$Q_1 = V_1 I_1 \sin(\varphi_1 - \gamma_1)$	`F_REACT`
Reactive Power of a Harmonic Component	$Q_n = V_n I_n \sin(\varphi_1 - \gamma_1)$, n = 2, 3,…, 12	`Hnn_REACT`
Apparent Power of the Fundamental Component	$S_1 = V_1 I_1$	`F_APP`
Apparent Power of a Harmonic Component	$S_n = V_n I_n$, n = 2, 3, …, 12	`Hnn_APP`
Power Factor of the Fundamental Component	$pf_1 = \mathrm{sgn}(Q_1) \cdot \frac{P_1}{S_1}$	`F_PF`
Power Factor of a Harmonic Component	$pf_n = \mathrm{sgn}(Q_n) \cdot \frac{P_n}{S_n}$, n = 2, 3,…, 12	`Hnn_PF`
Harmonic Distortion of a Harmonic Component	$HD_{V_n} = \frac{V_n}{V_1}$, $HD_{I_n} = \frac{I_n}{I_1}$, n = 2, 3,…, 12	`Hnn_VHDN`, `Hnn_IHDN`

Configuring Harmonic Calculations Update Rate

The harmonic engine functions at an 8 kHz rate. From the moment the `HAE_CFG2` register is initialized, and the harmonic indexes are set in the `HAE_H[nn]_INDX` index registers, the HAE calculations take typically 750 mSec to settle within the specification parameters.

The HAE module uses the `HAE_CFG2.UPDATE` bits to manage the update rate of the output registers for the harmonic engine. It manages the update rate independent of the calculations rate of 8 kHz for the engine. The default value of `000` means that the registers are updated every 125 uSec (8 kHz rate). Other update periods are: 250 uSec (`001`), 1 mSec (`010`), 16 mSec (`011`), 128 mSec (`100`), 512 mSec (`101`), 1.024 mSec (`110`). If the `HAE_CFG2.UPDATE` bits are `111`, the harmonic calculations are disabled.

The HAE module provides two ways to manage the harmonic computations. It enables the first approach when bit `HAE_CFG2.MODE` is cleared to its default value of 0. The state sets status bit `HAE_STAT.TXIRQ` to 1 after a certain period and then every time the harmonic calculations are updated at `HAE_CFG2.UPDATE` frequency. This functionality allows an external microcontroller to access the harmonic calculations only after they have settled. The HAE uses the state of bits `HAE_CFG2.SETTLE` to determine the time period. The possible values of settling time of the harmonic calculations are 512 mSec (00), 768 mSec(01), 1024 mSec (10), and 1280 mSec (11).

The HAE module enables the second approach when bit `HAE_CFG2.MODE` is set to 1. The state sets the status bit `HAE_STAT.TXIRQ` to 1 every time the harmonic calculations are updated at the `HAE_CFG2.UPDATE` frequency, without waiting for the harmonic calculations to settle. This functionality allows an external microcontroller to access the harmonic calculations immediately after starting. A write to the `HAE_STAT` register clears the status bit. The corresponding bit (`HAE_STAT.TXIRQ`) is set to 1.

ADSP-SC58x HAE Register Descriptions

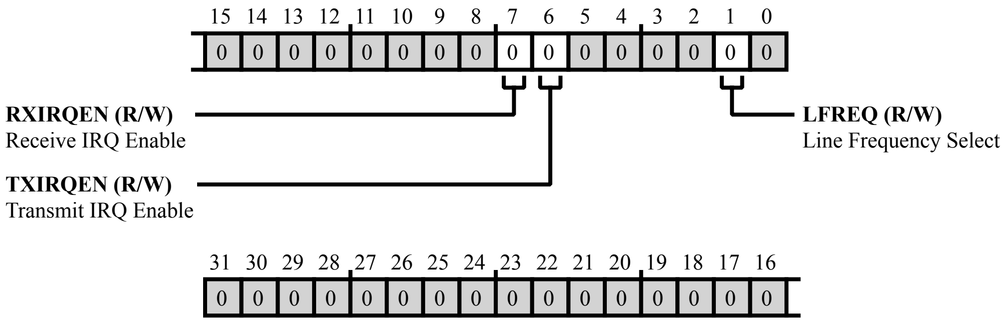
Harmonic Analysis Engine (HAE) contains the following registers.

Table 49-7: ADSP-SC58x HAE Register List

Name	Description
`HAE_CFG0`	Configuration 0 Register
`HAE_CFG1`	Configuration 1 Register
`HAE_CFG2`	Configuration 2 Register
`HAE_CFG3`	Configuration 3 Register
`HAE_CFG4`	Configuration 4 Register
`HAE_DIDT_COEF`	DIDT Coefficient Register
`HAE_DIDT_GAIN`	DIDT Gain Register
`HAE_H[nn]_INDX`	Harmonic n Index Register
`HAE_ISAMPLE`	I (Current) Sample Register
`HAE_IWAVEFORM`	I (Current) Waveform Register
`HAE_RUN`	Run Register
`HAE_STAT`	Status Register
`HAE_VLEVEL`	Voltage Level Register
`HAE_VSAMPLE`	V (Voltage) Sample Register
`HAE_VWAVEFORM`	V (Voltage) Waveform Register

Configuration 0 Register

The `HAE_CFG0` register configures high-level interrupts and specifies the line frequency for HAE operations.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

		1	768 mSec
		2	1024 mSec
		3	1280 mSec
0 (R/W)	MODE	(Results) Mode Select. The `HAE_CFG2.MODE` bit determines whether the HAE produces results immediately or waits per the `HAE_CFG2.SETTLE` bit field.	
		0	Results after Settle
		1	Results First

Configuration 3 Register

The HAE_CFG3 register configures HAE data transfer operations by selecting the fundamental and potential of twelve additional harmonic channels. The selected harmonics have their data (results) transferred to memory using DMA. First, the fundamental; followed by the selected channel n, in the order from the lowest to the highest numbered channel. Each selected channel has its eight result words transferred.

50 FFT Accelerator (FFTA)

The Fast Fourier Transform Accelerator (FFTA) performs memory to memory FFT/IFFT operations without core software intervention. Additionally, the FFTA architecture allows execution of complex, pipelined, memory to memory algorithms including ping-ponged, windowed frequency domain filtering and very large FFTs. The FFTA may also be used in conjunction with minimal computation support from a core in applications such as the overlap-add operations required for large frequency-domain-based convolutions.

FFTA Features

The following list describes the FFTA features.

- Supports both complex and real FFT and IFFT operations.
- Supports 64, 128, 256, 512, 1024, 2048 points in small FFT mode and 4096, 8192, 16384, 32768, 65536, 131072, 262144, 524288, 1048576, 2097152, 4194304 points in large FFT mode.
- Supports the IEEE-754/854 single-precision floating-point data format, round to even.
- Radix-4 butterfly efficiency at a radix-2 (integer power of two) point granularity.
- Automatic insertion of zeros for real FFTs.
- Supports automatic conjugating of the twiddle factors for IFFT.
- Supports automatic scaling of FFT and IFFT inputs.
- Hardware support for windowing and frequency domain filtering.
- Hardware support for magnitude squared FFT output.
- Hardware support for pipelined data flow.
- Dedicated high speed DMA engines for data load and dump with a data width 64-bit clocked by SYSCLK.
- Supports data and coefficient access from both on-chip (L1/L2) and off-chip memories (L3).
- Optional support for bypassing the compute engine to perform high speed memory-to-memory MDMA transfers.
- Clock division options for power reductions. Supports 1:1, 1:2, 1:4 and 1:8 clock ratio modes.

FFTA Functional Description

The FFTA module provides the following functionality.

Complex and real FFT and IFFT operations

The inputs and outputs for the complex FFT routines are packed arrays of floating point numbers. In a packed array, the real and imaginary parts of each complex number are placed in alternate neighboring elements.

Hardware support for windowing, frequency domain filtering and pipelined data flow

Windowing is a technique used to shape the time portion of measurement data, to minimize edge effects that result in spectral leakage in the FFT spectrum. By using Window functions correctly, the spectral resolution of the frequency-domain result increases. Data pipelining helps to process one set of frames while other is being moved into and out of the accelerator via DMA.

Dedicated high speed DMA engines for data load and dump with a data width 64-bit is clocked by SYSCLK. This enables faster data movement between the memory internal to the accelerator and memories external to the accerator (L1/L2/L3).

Supports data and coefficient access from both on-chip (L1/L2) and off-chip memories (L3)

This functionality helps to process larger data buffers which cannot fit within the limited size of the L1/L2 memories.

FFTA_WCTL	Wrapper Control Register
FFTA_XFRLEFT[nn]	Load/Dump Transfer Left Register

FFTA Definitions

To make the best use of the FFTA, it is useful to understand the following terms.

Small FFT

Small FFT corresponds to the FFT/IFFT operation where number of points are less than or equal to 2048. These operations can be accomplished directly with the local memory supported by the FFTA.

Large FFT

Large FFT corresponds to the FFT/IFFT operation where the number of points is greater than 2048. These operations are not directly supported by the FFTA because of the limited local memory. These are carried out in multiple stages using a divide and conquer approach by performing a number of small FFT operations.

FFTA Block Diagram

The FFTA contains a compute engine that operates in conjunction with a High Speed Distributed DMA Engine (HS-DDE). The compute engine appears as a data sink and data source to the two dedicated DDEs. The DDEs stream data into and out of the engine's FIFOs. To support faster data movement, the HS-DDE engine has a bus width of 64 bits and runs at SYSCLK speed. The compute engine data bus is 256 bits wide. The data transfer between the DMA engines and compute engine happens via data pack and unpack logic.

The FFTA compute engine runs at FFTCLK. The value of FFTCLK can go up to a maximum of SYSCLK. However, to achieve lower power consumption, it is also possible to operate the compute engine at frequencies lower than SYSCLK. This can be done by programming the FFTCLK:SYSCLK frequency ratio in the `FFTA_WCTL.FFTCLKRATIO` bit bield.

The two channel high speed DMA engines can also (optionally) be used for high speed memory to memory DMA (MDMA) transfer if the FFT compute engine is not used in the system.

FFTA Programming Model

A software library containing support for using the FFTA is provided with the CrossCore Embedded Studio. Using this library, C or C++ programs running on an ARM Cortex A5 or SHARC+ ADSP-215xx and ADSP-SC5xx core can access the FFTA to implement various specific use scenarios as discussed in the following sections. Analog Devices Inc. does not support programming the FFTA at register level (except for the optional programming of the `FFTA_WCTL` register). The detailed description of the FFTA registers is provided in this chapter for help with debugging.

FFTA Use Cases

The following section provides the conceptual description of the FFTA use cases supported by the CCES RTL APIs. For exact description on the programming model for using the APIs, refer to the *CrossCore Embedded Studio C/C++ Library Manual for SHARC Processors* manual.

1. Single-Shot FFT
2. Pipelined small FFT
3. Pipelined small interleaved FFT and IFFT operations

Single-Shot FFT

This use case is equivalent to the case where the core calls the CCES RTL's FFT/IFFT core library function. An API is called to perform an FFT/IFFT operation on a set of data and wait for the FFT/IFFT processing to finish. In this case all three units of the FFTA (input, compute, and output) operate in a sequential manner as illustrated by the ***Single-Shot*** figure. Notice how each frame passes through the stages of the FFTA block (input > compute > output) sequentially. The total time required to complete the FFT operation is equal to the time taken to load the input data plus time taken to compute the FFT/IFFT plus the time taken to dump the output data. CCES provides an FFTA version of these functions/APIs and the APIs supporting this use case always operate in synchronous mode.

EXECUTION TIME

Figure 50-2: Single-Shot

Pipelined Small FFT

The piplined small FFT is used where an FFT/IFFT operation with a fixed number of points is performed continuously on more than one set of input data. The FFTA architecture supports pipelining of the input and output data which allows the FFTA to load one set of input data and dump another set of processed output data in parallel while another set of data (fetched in the previous pipeline cycle) is being processed. This helps to suppress the input and output DMA overheads while the FFTA compute engine is busy processing the data. This way, programs can take maximum advantage of the FFT compute engine's performance.

To support such cases, the FFTA APIs provide a mechanism where the FFTA is configured one time to perform the FFT/IFFT operation with a fixed number of points in a continuous pipelined manner. Next, the APIs related to the data transfers (asynchronous) are called to send the input data to and collect the output data from the FFTA. After all the data is processed, the FFTA can be closed. For more details on these APIs, refer to the CCES RTL manual.

The ***Pipelined Small FFT*** figure illustrates this use case. There is large startup latency (Input DMA time + Compute time + Output DMA time) involved to fill the pipeline with three frames. After that, each frame can be processed in a lesser steady state time (maximum of Input DMA time, Compute time, and Output DMA time).

Figure 50-3: Pipelined Small FFT

Pipelined Small Interleaved FFT and IFFT Operations

Pipelined small interleaved FFT and IFFT operations are useful when data is first converted to the frequency domain, processed in the frequency domain and converted back to the time domain. The ***Typical Data Flow***

Frequency Domain Processing figure illustrates this where a particular input data frame N is first converted to the frequency domain (N’) with an FFT operation. This FFT output is then processed in the frequency domain to produce the output frame N”. The processed output frame (N”) is then converted in to time domain output frame (N’”).

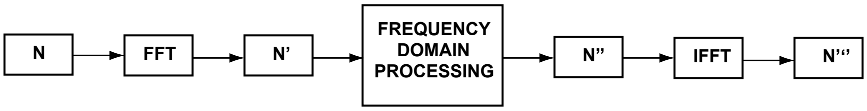

Figure 50-4: Typical Data Flow Frequency Domain Processing

The FFTA can be used to perform the above operation on multiple sets of data in a pipelined manner as shown in the ***Pipelined Interleaved FFT/IFFT*** figure. Unlike in the Pipelined Small FFT section, the compute engine performs both FFT and IFFT operations together in an interleaved manner. Note that the input data for the first valid IFFT operation (1”) is available only when the FFT output of the first frame (1’) is processed by the core. It is necessary to send dummy input data at the start of the pipeline for the initial few IFFT operations as shown in the ***Pipelined Interleaved FFT/IFFT*** figure. The output of these IFFT operations can be ignored. Similarly, dummy data must be sent at the end of the pipeline for the last few FFT operations. The output of these FFT operations can be ignored.

PROCESSING (CORE)	P–2’	P–1’		P’				

Figure 50-5: Pipelined Interleaved FFT/IFFT

Similar to the Pipelined Small FFT section, the FFTA APIs provide a mechanism where the FFTA can be configured once to perform interleaved FFT and IFFT operations with a fixed number of points in a continuous pipelined manner. After that, programs just need to call the APIs related only to the data transfers (asynchronous) to send the input data to and collect the output data from the FFTA. After all the data is processed, the FFTA can be closed. For more details on these APIs, refer to the CCES RTL manual.

Fast Convolution

The FFTA can also be used to perform FIR filtering with the help of fast convolution. In this method, FFTA converts the input data in frequency domain, multiplies it with the FIR coefficients pre-transformed in the frequency domain, and then performs IFFT to return output in the time domain. The core is responsible for maintaining the output delay line and performing overlap-add operation.

For example, the ***FFTA Block Diagram*** shows how a block of 512 input samples is processed with an FIR filter of 8192 taps with the help of fast convolution method.

Extract the 512 output samples from the result and left shift the output delay line by 512 samples.

Figure 50-6: FFTA Block Diagram

The steps involved are as follows:

1. The FIR coefficients are divided in to 16 (=8192/512) sections h(0), h(1), h(2),…..h(15). Each section is padded with 512 zeros to generate hz(0), hz(1), hz(2),….hz(15) and then converted into the frequency domain (1024 point FFT) to generate H(0), H(1), H(2),….H(15).
2. Each time a new block of 512 samples x(n) is received, it is first padded with 512 zeros and the converted to frequency domain (1024 point FFT) to generate X(N).
3. X(N) is then multiplied with each of the 16 sections H(0), H(1), H(2),….H(15) to generate X(N)H(0), X(N)H(1), X(N)H(2),…. X(N)H(15).
4. All the 16 blocks of the result in 3. are then converted in to time domain (1024 point IFFT) to generate the output sections y'(0), y'(1),y'(2)……y'(15) each containing 1024 output samples.

5. The output sections generated in 4. are overlapped and added with the existing output delay line.
6. The left most 512 samples from the output delay line generated in 6. are extracted to generate 512 output samples corresponding to the original 512 input samples.
7. The delay line is then shifted left by 512 samples which is used as an input for the next processing iteration.

ADSP-SC58x FFTA Register Descriptions

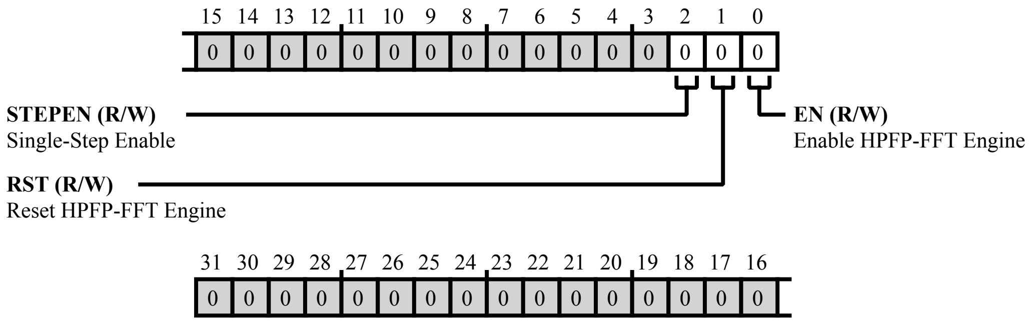
High-Speed FFT Compute Unit (FFTA) contains the following registers.

Table 50-5: ADSP-SC58x FFTA Register List

Name	Description
`FFTA_CTL`	Control Register
`FFTA_INST[nn]`	Instruction Memory Register
`FFTA_LC[nn]`	Loop Counter Value Register
`FFTA_PC`	Program Counter Register
`FFTA_SCALE`	FFT/IFFT Scale Factor Register
`FFTA_STAT`	Status Register
`FFTA_THREADOFFSET`	Thread Count Offset Register
`FFTA_WCTL`	Wrapper Control Register
`FFTA_XFRLEFT[nn]`	Load/Dump Transfer Left Register

Control Register

The FFTA_CTL register is used to reset, start, pause and single step the HPFP-FFT engine.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
STEPEN (R/W)
Single-Step Enable
RST (R/W)
Reset HPFP-FFT Engine
EN (R/W)
Enable HPFP-FFT Engine
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

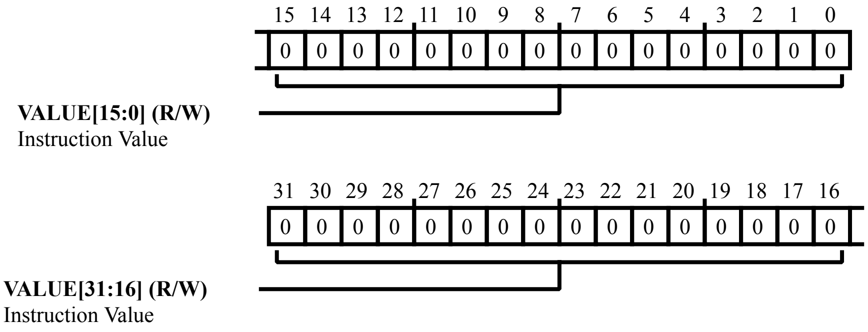
Figure 50-7: FFTA_CTL Register Diagram

Table 50-6: FFTA_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	STEPEN	Single-Step Enable. When the FFTA_CTL.STEPEN and FFTA_CTL.EN bits are set together the engine to release the instruction currently pointed to by the PC to execution, increment the PC then stop execution. The FFTA_CTL.STEPEN and FFTA_CTL.EN bits are automatically cleared when the released instruction completes execution. The FFTA_CTL.EN bit or FFTA_CTL.STEPEN bit can then be read to determine if the instruction step has completed. Note that a single step advances the PC one increment and at least one thread completes execution but one or two other threads may still not have completed execution. The FFTA_CTL.STEPEN control bit is self-clearing.	
		0	Single-Step Disabled
		1	Single-Step Enabled
1 (R/W)	RST	Reset HPFP-FFT Engine. When the FFTA_CTL.RST bit is set all MMRs are cleared. The FFTA_CTL.RST bit is self-clearing.	
		0	Not reset HPFP-FFT engine
		1	Reset HPFP-FFT engine
0 (R/W)	EN	Enable HPFP-FFT Engine. The FFTA_CTL.EN bit must be set for the engine to process instructions. When the FFTA_CTL.EN bit is cleared the engine is in an idle state.	
		0	Disable HPFP-FFT engine
		1	Enable HPFP-FFT engine

Instruction Memory Register

The `FFTA_INST[nn]` MMR registers hold (up to 64) FFT instructions.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[24:16] (R)
Current value of the counter

Figure 50-9: FFTA_LC[nn] Register Diagram

Table 50-8: FFTA_LC[nn] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:0 (R/NW)	VALUE	Current value of the counter.

Program Counter Register

The FFTA_PC register contains the MMR address offset of the current instruction in the instruction queue. The PC advances unless the instruction it points to is not acknowledged. When the instruction pointed to is acknowledged it starts the task and immediately advances. See the rules for instruction acknowledge in the Sequencer section of the Programming reference.

Note that the nop(), jumpCNZ(), load_loop_cntr(), incr_thread_offset() and load_scale() instructions are immediately acknowledged. Also note that only 6 bits are used, which implies that this counter is incremented in the fashion of modulo 64. For example, If the current PC=63, after it is incremented by 1, PC=0.

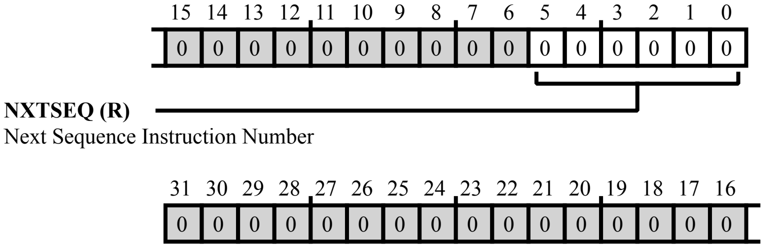

Figure 50-10: FFTA_PC Register Diagram

Table 50-9: FFTA_PC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/NW)	NXTSEQ	Next Sequence Instruction Number. The FFTA_PC.NXTSEQ bits provide the value by which the PC advances unless the instruction it points to is not acknowledged. When the instruction pointed to is acknowledged it starts the task and immediately advances. See the rules for instruction acknowledgement in the Sequencer section. The nop(), jumpCNZ(), load_loop_cntr(), incr_thread_offset() and load_scale() instructions are immediately acknowledged. Note that only 6 bits are used, which implies that this counter is incremented in the fashion of modulo 64. For example, If the current PC=63, after it is incremented by 1, PC=0.

FFT/IFFT Scale Factor Register

The FFTA_SCALE register is loaded using the load_scale() instruction. The scale factor is in a single-precision IEEE format. On reset the SCALE is set to 1.0 (floating point).

Table 50-11: FFTA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	VLDOUT	Data Available State. The `FFTA_STAT.VLDOUT` bit indicates that data is available in the OFIFO to be read out (reflects state of fft.valid_o).	
		0	Data Not Available
		1	Data Available
4 (R/NW)	RDYOUT	Ready for Data State. The `FFTA_STAT.RDYOUT` bit indicates that the IFIFO is ready to receive data (reflects state of fft.ready_o).	
		0	Data Out Not Ready
		1	Data Out Ready
3 (R/NW)	INVLDINST	An Invalid Instruction Was Executed. The `FFTA_STAT.INVLDINST` bit indicates an invalid instruction was executed. Asserts a FFT_I interrupt output when the INVALIDINST flag is first set. This INVAILIDINST flag is sticky.	
		0	No Invalid Instruction
		1	An Invalid Instruction Was Executed
2 (R/NW)	OVR	Math Result Is Greater Than The Maximum Normalized Number. The `FFTA_STAT.OVR` bit indicates a math result after rounding has a magnitude greater than the maximum normalized number. Asserts a FFT_I interrupt output when the OFLOW flag is first set. This OFLOW flag is sticky.	
		0	No Overflow
		1	Overflow
1 (R/NW)	UNDR	Math Result Is Smaller Than The Minimum Normalized Number, But Not A Zero. The `FFTA_STAT.UNDR` bit indicates a math result after rounding has a magnitude less than the minimum normalized number, and it is not an exact zero. Asserts a FFT_I interrupt output when the UFLOW flag is first set. This UFLOW flag is sticky.	
		0	No Underflow
		1	Underflow
0 (R/NW)	INVLDIN	NAN Input Data or Invalid Math Operation. The `FFTA_STAT.INVLDIN` bit indicates a NAN input data or invalid math operation: (0 x infinity, infinity - infinity). Asserts FFT_I interrupt output when the INVALIDIN flag is first set. This INVALIDIN flag is sticky.	
		0	Input And Math Opererations Are Valid
		1	Input And/Or Math Opererations Are Invalid

Thread Count Offset Register

The FFTA_THREADOFFSET register is a modulo 3 added to an instruction's specified thread number to create the actual thread assignment. The incr_thread_offset() instruction will modulo 3 increment the thread offset register.

		0	FFTCLK:SYSCLK_0 = 1:1
		1	FFTCLK:SYSCLK_0 = 1:2
		2	FFTCLK:SYSCLK_0= 1:4
		3	FFTCLK:SYSCLK_0 = 1:8
0 (R/W)	EN	FFT Engine Enable. The `FFTA_WCTL.EN` bit, when set (=1) enables the FFT engine.	
		0	Disable FFT engine and enable MDMA
		1	Enable FFT engine and Disable MDMA

Load/Dump Transfer Left Register

The three `FFTA_XFRLEFT[nn]` registers, one for each thread, contain the number of 64-bit data or coefficient loads or data dumps remaining if a load or dump instruction is executing in that thread. The value of each register ranges from 0 to 1023, which means (Load/dump transfers remaining for thread)/8. So load/dump remaining can cover the range of [0, 1023*8]=[0, 8184]. If no load or dump is executing in that thread then the value is 0. The values reflect the count at the start of the pipeline (stage N0).

51 FIR Accelerator (FIR)

Finite Impulse Response (FIR) filters are frequently used in DSP applications. The FIR accelerator is a dedicated hardware interface used to perform filter processing to reduce the instruction processing load on the core. FIR filters are used in a wide array of applications including multi-rate processing with an interpolator or decimator.

Features

This hardware module can perform FIR filters without core intervention. This feature gives programs freedom to use the core to implement complex algorithms, effectively adding more bandwidth to the processor. The FIR supports the following features:

- Fixed-point and 32-bit IEEE floating-point format
- Four MAC units that operate in parallel
- Various rounding modes
- Single rate or multi-rate window processing
- Programmable rates with decimation or interpolation mode
- Up to 32 filter channels available in TDM

NOTE: The FIR accelerator module has local memory that the core cannot access during regular operation. Unlike previous SHARC processors, the FIR accelerator modules each have access to the system memory (on-chip or off-chip).

Also, unlike in previous SHARC processors, where only one of the FIR or IIR accelerators can be used at a time, the SHARC+ processor can use both of these accelerators simultaneously.

Clocking

The FIR accelerator runs at the maximum speed of the system clock frequency (SCLK0).

Functional Description

The ***FIR Block Diagram*** shows the block diagram of the 1024-TAP FIR hardware accelerator. The accelerator consists of a 1024 word coefficient memory, a 1024 deep delay line for data, and four MAC units. The accelerator runs at the *SCLK0* frequency.

Figure 51-1: FIR Block Diagram

The FIR accelerator has the following logical sub blocks:

1. A datapath unit that consists of:
    - A 1024 deep coefficient memory
    - A 1024 deep delay line for the data
    - Four 32-bit floating-point and fixed-point multiplier and adder units
    - One 32-bit prefetch buffer to operate in a pipelined fashion
    - One 32-bit buffer to hold previous partial sum
    - One 32-bit buffer to hold the output
2. Configuration registers for the number of TAPs, number of channels, filter enable, interrupt control, DMA enable, up sample or down sample control, and ratios.
3. Core access interface for writing to the DMA and filter configuration registers and reading the status register.
4. DMA bus interface for transferring data and coefficients to and from the accelerator.
5. DMA configuration registers including chain pointer, input, output, and coefficient registers.

ADSP-SC58x FIR Register List

The FIR accelerator is a dedicated hardware interface used to perform filter processing to reduce the instruction processing load on the core.

Table 51-1: ADSP-SC58x FIR Register List

Name	Description
`FIR_CHNPTR`	FIR Chain Pointer Register
`FIR_COEFCNT`	FIR Coefficient Count Register
`FIR_COEFIDX`	FIR Coefficient Index Register
`FIR_COEFMOD`	FIR Coefficient Modifier Register
`FIR_CTL1`	FIR Global Control Register
`FIR_CTL2`	FIR Channel Control Register

Compute Block

The MAC unit, shown in the ***FIR MAC Unit*** figure, has four multiply accumulators. The accumulators operate simultaneously on a single filter as described as follows:

- The MAC unit operates on the data and coefficient fetched from the data and coefficient RAMs
- Each MAC can perform 32-bit floating-point or 32-bit fixed-point MAC operations
- Floating-point format is IEEE-compliant
- Multiply and accumulation operation (addition) are pipelined
- A 32-bit floating-point MAC operation generates 32-bit multiply results
- A 32-bit fixed-point operation generates 80-bit results (64-bit result + 16 guard bits)

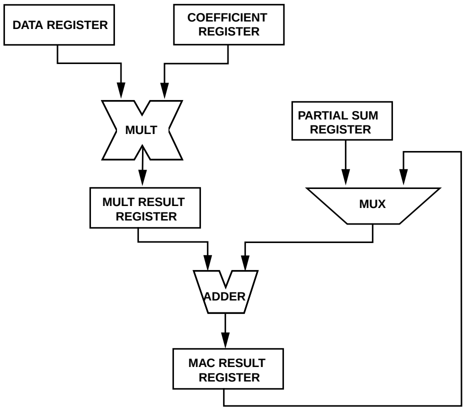

Figure 51-2: FIR MAC Unit

Partial Sum Register

The partial sum register is useful for Floating-point Multi-Iteration mode. For a particular channel, the intermediate MAC result is written to the output buffer of the system (on-chip or off-chip) memory. If the same channel is requested again, the partial result register is updated with the intermediate MAC result through DMA from output buffer of the system memory. The result is added to the current MAC result after each iteration. This process repeats until all iterations complete (the entire soft filter length is processed).

Delay Line Memory

The accelerator has a 1024 TAP delay line to hold the data locally. The DMA controller fetches the data from system memory and loads it into the delay line. Four read accesses can be made to the delay line simultaneously.

Coefficient Memory

The accelerator has a 1024 deep coefficient memory to store the coefficients. The DMA controller loads the coefficients from system memory into coefficient memory. Four coefficients can be fetched from the coefficient memory simultaneously. If the soft filter length is more than 1024, processing happens in multi-iteration mode.

Prefetch Data Buffer

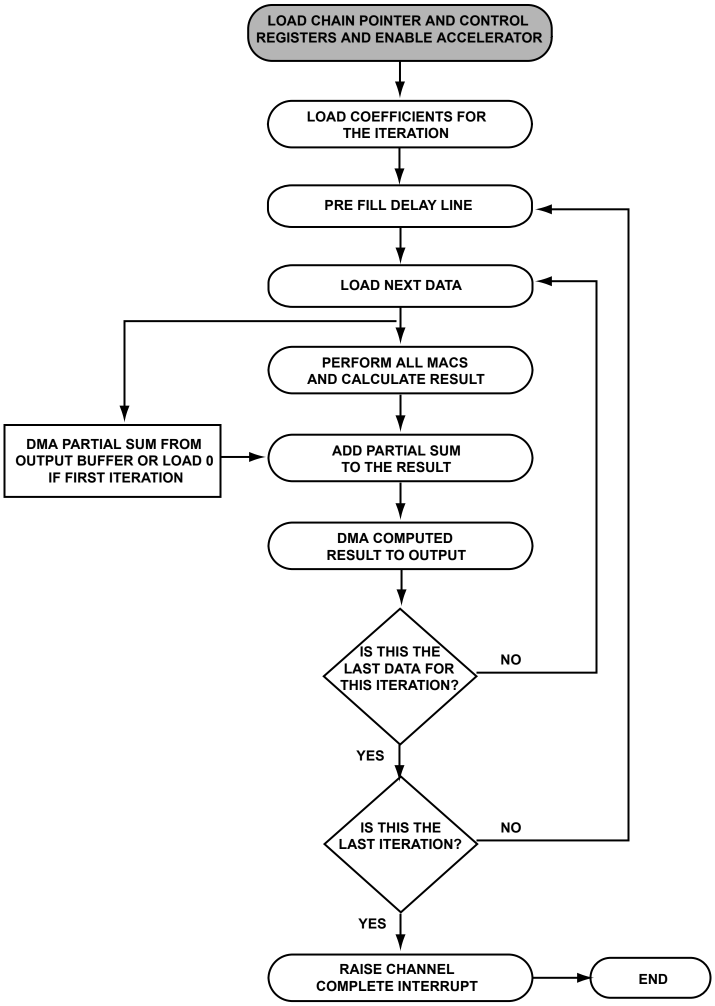
The prefetch data buffer enables pipeline operation. One data sample is prefetched when the compute unit is operating on the delay line corresponding to the current sample. The data prefetched in this buffer is later used to update the delay line for the next sample. This operation happens in parallel again when the compute unit is not accessing the delay line. In other words, it happens when the compute unit is adding the output from the four MACs and the partial sum register.

Table 51-5: Pipeline Operation for Window Size = 1

Cycles	1	2	3	4	5	6
Output DMA			N	N1	N2	N3
Compute		N	N1	N2	N3	
Input DMA	N	prefetch N1	prefetch N2	prefetch N3		

Processing Output

The accelerator uses all four MACs simultaneously to calculate one output sample as shown in the ***Multi-Iteration Filtering Flow*** figure and the following procedure.



LOAD CHAIN POINTER AND CONTROL REGISTERS AND ENABLE ACCELERATOR
LOAD COEFFICIENTS FOR THE ITERATION
PRE FILL DELAY LINE
LOAD NEXT DATA
PERFORM ALL MACS AND CALCULATE RESULT
DMA PARTIAL SUM FROM OUTPUT BUFFER OR LOAD 0 IF FIRST ITERATION
ADD PARTIAL SUM TO THE RESULT
DMA COMPUTED RESULT TO OUTPUT
IS THIS THE LAST DATA FOR THIS ITERATION?
NO
YES
IS THIS THE LAST ITERATION?
NO
YES
RAISE CHANNEL COMPLETE INTERRUPT
END

Figure 51-3: Multi-Iteration Filtering Flow

1. The accelerator fetches four input data from the delay line and four corresponding coefficients from the coefficient memory and feeds them to the MAC units for multiply and accumulation operations.
2. The accelerator repeats the procedure with the next four input data and coefficients until all the TAPs complete. For example, this procedure happens N/4 times for an N TAP filter.
3. When all the TAPs are complete, the accelerator adds the four MAC outputs together to the previous partial sum (if any) to calculate the final result.
4. Finally, that output sample is stored back in system memory.

System Memory Storage

The following sections describe the storage format for the accelerator.

CAUTION: Store all data in memory aligned to the word address boundaries. Any other programmed addresses do not flag an error.

Coefficients and Input Buffer Storage

For any N TAP filter with coefficients:

```
C[i] i = 0,1,
...
N - 1
```

store the coefficients in system memory buffer in the order:

```
C[N - 1], C[N - 2]
...
C[1],C[0]
```

and CI should point to `C(N - 1)`.

Single Rate Input Filtering

The total size of the input buffer must at least be equal to `N - 1 + W`. If the input buffer that needs to be processed is:

```
 x[n],x[n+1],x[n+2]
 ...
 x[n+W-1]
```

store it in the memory as

```
x[n-(N-1)], x[n-(N-2)]
...
x[n-1], x[n], x[n+1]
...
x[n+W-1]
```

and the `FIR_INIDX` register value should point to `x[n - (N - 1)]`

Decimation

Assuming M = decimation ratio, the total size of the input buffer should at least be equal to `N - 1 + W x M`. If the input buffer that needs to be processed is:

```
x[n],x[n+1],x[n+2]....x[n+WxM-1],
```

store it in the memory as:

```
x[n-(N-1)], x[n-(N-2)]....x[n-1],
x[n], x[n+1]....x[n+WxM-1]
```

and the `FIR_INIDX` register value should point to `x[n-(N-1)]`.

Interpolation

Assuming L= interpolation ratio, the total size of the input buffer should be at least equal to Ceil `((N-1)/L)` `+W/L`.

If the input buffer that needs to be processed is:

```
x[n], x[n+1], x[n+2]....x[n+W/L-1],
and K= Ceil((N-1)/L)
```

store it in the memory as:

```
x[n-k], x[n-(K-1)], x[n-(K-2)]....x[n-1],
x[n], x[n+1].... x[n+W/L-1]
```

and the `FIR_INIDX` register value should point to `x[n-K]`.

Operating Modes

The FIR core performs a sum-of-products operation to compute the convolution sum. It supports single-rate, decimation, and interpolation functions.

Single Rate Processing

In a single-rate filter, the output result rate is equal to the input sample rate. The filter output Y(n) is computed according to following equation where N is the number of filter coefficients: c(k) k = 0 to N – 1 are the filter coefficients and x(n) represents the input time-series.

$$Y(n)= \sum_{k=0}^{N-1} c(k) \cdot x(n-k)$$

Figure 51-4: Filter Output Calculation

Single Iteration

Results are computed in a single iteration when the soft filter length is less than or equal to 1024.

Floating-point Multi-Iteration

Results are computed in multiple iterations when the soft filter length is greater than 1024 (for example, 2048 TAPs on a 1024 hard filter length). In this mode, the controller implements two iterations of 1024 TAPs.

NOTE: If the soft filter length is not a multiple of the hard filter length, the controller iterates until the soft filter length is satisfied.

Example: 550 taps on a 256 tap filter. In this example, the FIR controller implements two iterations of 256 taps and one iteration of 38 taps.

NOTE: Multi-iteration mode is not supported in fixed-point format.

Window Processing

Configure the window size to 1 to select sample-based processing mode. In this mode, one sample from a particular channel is processed through all the biquads of that channel and the final output sample is calculated.

In window-based mode, multiple output samples (up to 1024) equal to the window size of that channel are calculated. After these calculations are complete, the accelerator begins processing the next channel. A configurable window size parameter is provided to specify the length of the window.

Multi-Rate Processing

Multi-rate filters change the sampling rate of a signal—they convert the input samples of a signal to a different set of data that represents the same signal sampled at a different rate.

Decimation

A decimation filter provides a single output result for every M input samples, where M is the decimation ratio. The output rate is 1/M'th of the input rate. The filter implementation exploits the low output sample rate by not starting a computation until a new set of M input samples is available.

In this mode, after low-pass filtering (for anti-aliasing), FIR logic discards the ratio – 1 samples of output data. For performance optimization, FIR logic skips the computation of output samples, which are discarded.

The input buffer size for decimation filters is N – 1 + (W × M) where:

- N is the number of taps
- W is the window size
- M is the decimation ratio

The window size (`FIR_CTL2.WINDOW` bits) must be programmed with the number of output samples.

To start this mode, programs set the `FIR_CTL2.RATIO` and `FIR_CTL2.UPSAMP` bits (along with normal filter setting). Also, the `FIR_CTL2.TAPLEN` bit field value should be greater than or equal to the `FIR_CTL2.RATIO` bit field value for the decimation filter.

Interpolation

An interpolation filter provides L output results for each new input sample, where L is the interpolation ratio. The output rate is L times the input rate.

In this mode, according to the ratio specified in configuration register, FIR logic inserts L – 1 zeros between any two input samples (upsampling). It then performs the interpolation (through the FIR filter).

Both upsampling and downsampling do not support multi-iteration mode. Therefore, the filtering operation only happens on up to 1024 TAPs and the ratio of up and downsampling can only be an integer value.

In an interpolation filter, FIR logic inserts L – 1 zeros between each sample. The program has to make sure that these zeros fully shift out of the delay line before moving on to the next channel. This operation puts a restriction on window size in terms of L – *the sample ratio* as showing in the expression:

WINDOWSIZE = *n* × *SAMPLERATIO*, where *n* is the number of input samples.

The input buffer size is smallest integer greater than or equal to (N – 1 + W)/L for interpolation filters where:

- N is the number of taps
- W is the window size
- L is the interpolation ratio

To start the mode, programs configure the `FIR_CTL2.RATIO` and `FIR_CTL2.UPSAMP` bits (along with filter settings).

Channel Processing

The ***Single Channel Filtering Flow*** figure shows the flow diagram for processing a single channel. Channels are processed in TDM format by setting the `FIR_CTL1.CH` bits to a value greater than one. In the time slot corresponding to a particular channel, the corresponding TCB is loaded from system memory.

1. The `FIR_CTL2` register value is fetched from system memory and is used to configure the filter parameters for that channel.
2. The accelerator fetches the coefficients using the `FIR_COEFIDX` register as the pointer and loads them into coefficient memory.
3. The delay line is pre-filled using the `FIR_INIDX` register as the pointer.
4. The accelerator calculates the first output and stores the result back into the output buffer using the `FIR_OUTIDX` register as the pointer.
5. While calculating the output, the accelerator fetches the next data in parallel. After one window of data is processed, the index registers in the system memory TCB are updated. In the next time slot of the same channel, processing can continue from where it stopped.
6. Processing moves to the next channel and repeats the procedure. If the soft filter length is more than the hard filter length, multiple iterations occur to process the window.

Figure 51-5: Single Channel Filtering Flow

Floating-Point Data Format

The FIR accelerator treats data and coefficients in 32-bit floating-point format as the default functional mode.

Fixed-Point Data Format

In fixed-point mode, the 32-bit input data or coefficient is treated as fixed point. A 32-bit fixed-point MAC operation generates an 80-bit result. Fixed-point data or coefficients can be unsigned integer, unsigned fractional and signed integer.

NOTE: In fixed-point mode, the entire 80-bit result register is always written back in bursts of 3 × 32 bits. The first word is the LSW, the second word is the MSW, and the third word is a 16-bit overflow. The remaining 16 bits are padded with zeros. Therefore, for fixed-point mode: WINDOWSIZE = WINDOWSIZE × 3.

If the signed fractional format is used, the output must be scaled by 2. The MAC does not right shift to remove the redundant sign bit. A final routine must decimate the output buffer to the desired samples.

Multi-iteration mode is not supported in this format. Therefore, the maximum TAP length is 1024.

Data Transfer

The FIR filter works exclusively through DMA.

Chain Assignment

The structure of a TCB is conceptually the same as a traditional linked-list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB can point to itself to continuously re-run the same DMA. The FIR accelerator reads each word of the TCB and loads it into the corresponding register. The end of the chain (no further TCBs are loaded) is indicated by a TCB with a chain pointer register value of zero.

The FIR accelerator DMA supports circular buffer chained DMA. The FIR accelerator does not support circular buffering for the coefficient buffer. The ***TCBs for Chained DMA*** table shows the required TCBs for chained DMA.

Table 51-6: TCBs for Chained DMA

Address	Register
TCB	`FIR_CHNPTR`
TCB + 0x1	`FIR_COEFCNT`
TCB + 0x2	`FIR_COEFMOD`
TCB + 0x3	`FIR_COEFIDX`
TCB + 0x4	`FIR_OUTBASE`
TCB + 0x5	`FIR_OUTCNT`
TCB + 0x6	`FIR_OUTMOD`
TCB + 0x7	`FIR_OUTIDX`
TCB + 0x8	`FIR_INBASE`
TCB + 0x9	`FIR_INCNT`
TCB + 0xA	`FIR_INMOD`
TCB + 0xB	`FIR_INIDX`
TCB + 0xC	`FIR_CTL2`

The `FIR_COEFCNT` register is loaded with the values in the `FIR_COEFCNT` TCB field and is decremented from that value onwards. However, coefficient loading continues until the number of coefficients, equal to the tap length, are read. This condition is true even if the `FIR_COEFCNT` register reaches zero as in the case of a tap length = 10, and the `FIR_COEFCNT` field in the TCB is initialized to 0. The value in the `FIR_COEFCNT` register is –10 after all coefficients are loaded.

NOTE: Initialize `FIR_CHNPTR` to TCB + 12.

DMA Access

The FIR accelerator has two DMA channels (accelerator input and output) to connect to the system memory. The DMA controller fetches the data and coefficients from memory and stores the result.

Accelerator TCB

The location of the DMA parameters for the next sequence comes from the chain pointer register that points to the next set of DMA parameters stored in the internal memory of the processor. In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Pointer DMA

The DMA controller supports circular buffer chain pointer DMA. One transfer control block (TCB) must be configured for each channel. The TCB contains:

- A control register value to configure the filter parameters (such as filter tap length, window size, sample rate conversion settings) for each channel
- DMA parameter register values for the input data (delay line)
- DMA parameter register values for coefficient load
- DMA parameter register values for output data

Intermediate results in multi-iteration mode are saved in the output buffer.

As shown in the ***Circular Buffer Addressing*** figure, the accelerator loads the TCB into its internal registers and uses these values to fetch coefficients and data and to store results. After processing a window of data for any channel, the accelerator writes back the appropriate values to the `FIR_INIDX` and `FIR_OUTIDX` bit fields of the TCB in memory. Then, data processing can begin from where it left off during the next time slot of that channel.

The write-back value for input buffer is:

- `FIR_INIDX` + W for single rate filtering
- `FIR_INIDX` + W × M for decimation (M = decimation ratio)
- `FIR_INIDX` + W/L for interpolation (L = interpolation ratio)
- The write-back value for output buffer in floating point mode is: `FIR_OUTIDX` + W
- The write-back value for output buffer in fixed-point mode is: `FIR_OUTIDX` + 3 × W

NOTE: The `FIR_CTL2` register is part of the FIR TCB. This configuration allows programming individual FIR channels with different control attributes.

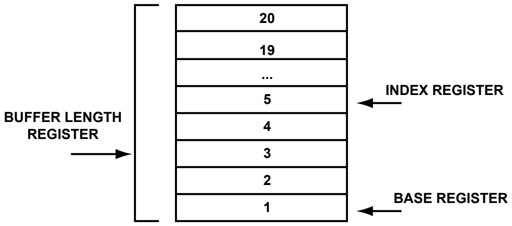

Figure 51-6: Circular Buffer Addressing

Programming Model

The following sections provide general programming information for the FIR accelerator.

Single Channel Processing

1. Create input, coefficient, and output buffers in system memory.

   For input and coefficient buffer storage format, see Coefficients and Input Buffer Storage.

2. Create the TCBs in system memory. Each TCB corresponds to a particular channel.

   TCBs hold the `FIR_CTL2` register which allows programming the window size and tap size along with up or down sample enable, sample rate conversion enable, and the conversion ratio for decimation and interpolation filters.

3. Configure the index, modifier and length entries in the TCBs to point to the corresponding channels' data buffer, coefficient buffer, and output data buffer.

   The output index register must point to the start of the output buffer. However, initialize the value of the input index register based on the explanation provided in Coefficients and Input Buffer Storage.

4. The core configures the `FIR_CTL1` register with the number of channels (one channel), fixed- or floating-point format.

5. Set the enable bit to start the accelerator operation in the modes configured (in `FIR_CTL1` and `FIR_CTL2` registers) by loading the TCB of the first channel. Once the first channel window is calculated, the input and output index registers are written back to internal memory corresponding to the first channel. Once the write-back is complete the accelerator moves into idle.

NOTE: All the addresses programmed in the TCB correspond to 32-bit address boundaries and should not contain the lower 2 bits (assumed as zeros).

Multichannel Processing

The *Wait for Core Intervention ≥ Idle (if auto channel iterate bit = 0)* figure shows the diagram for multichannel filtering. Multiple channels are processed in a time division multiplexed (TDM) format. After completing all the channels, the accelerator can either repeat the slots or wait for core intervention.

For multichannel filtering, use the following steps.

1. Program the number of channels using the `FIR_CTL1.CH` bits.
2. Configure the TCBs in system memory with one channel's TCB pointing to the next channel's TCB.
3. Write the first TCB value into the `FIR_CHNPTR` register and enable the accelerator.

   The accelerator fetches the first channel's TCB and, using it as pointer, prefills the delay line and coefficient memory and loads the `FIR_CTL2` register to configure the filter parameters corresponding to that channel.

   The accelerator then calculates output samples corresponding to one window and stores the data back in internal memory.

   At the end of the window the accelerator updates the `FIR_INIDX` and `FIR_OUTIDX` registers in the TCB of system memory and moves to the next channel.

   When all the channels are finished and the auto channel iterate bit (`FIR_CTL1.CAI`) =1, the accelerator processes the first channel again and iterates through the channels. If the `FIR_CTL1.CAI` bit =0, the accelerator waits for core intervention.

NO
YES
AUTO CHANNEL ITERATE?
YES
NO
WAIT FOR CORE INTERVENTION

Figure 51-7: Wait for Core Intervention ≥ Idle (if auto channel iterate bit = 0)

Dynamic Coefficient Processing Notes

1. The dynamic update of the coefficients can be useful for the FIR accelerator. The FIR accelerator reloads the coefficients for each iteration (if the `FIR_CTL1.CAI` bit is set) before the start of processing of each channel.
2. The dynamic coefficient update is possible for single iteration mode (tap length ≤1024). Ensure that the new coefficients are updated after the accelerator loads the coefficients for current processing and before the next processing starts. The expression for the maximum time available for the coefficient memory update should be equal to 49 +N × 11 + W × (N/4 + 2) SCLK cycles.

3. For multi-iteration mode, dynamic updates are not supported. Programs must finish current processing, disable the accelerator, update the coefficients, and reenable the accelerator.

Debug Mode

The next sections show the steps required for reading and writing local memory in debug mode.

Write to Local Memory

1. Clear the `FIR_CTL1.DMAEN` bit.
2. Set the `FIR_DBG_CTL.EN`, `FIR_DBG_CTL.MEM`, and `FIR_DBG_CTL.HLD` bits.
3. Set the `FIR_DBG_CTL.ADRINC` bit for address auto increment.
4. Write the start address to the `FIR_DBG_ADDR` register.

   NOTE: If the bit 11 in the `FIR_DBG_ADDR` register is set, coefficient memory is selected.

5. Write data to the `FIR_DBG_WRDAT` register.

Read from Local Memory

1. Clear the `FIR_CTL1.DMAEN` bit.
2. Set the `FIR_DBG_CTL.EN`, `FIR_DBG_CTL.MEM`, and `FIR_DBG_CTL.HLD` bits.
3. Set the `FIR_DBG_CTL.ADRINC` bit for address auto increment.
4. Write the start address to the `FIR_DBG_ADDR` register.

   NOTE: If bit 11 in the `FIR_DBG_ADDR` register is set, coefficient memory is selected.

5. Read data from the `FIR_DBG_RDDAT` register.

Single-Step Mode

Single-step mode can be used for debug purposes. An extra debug register is used in this mode.

1. Enable stop DMA during breakpoint hit in the emulator settings.
2. Clear the `FIR_DBG_CTL.HLD` bit and enable `FIR_DBG_CTL.EN` and `FIR_DBG_CTL.RUN` bits.
3. Program the FIR module according to the application.
4. In single-step mode, each iteration is updated in the emulator session.

FIR Programming Example

In this example the application requires the FIR to filter six channels of data. The first four channels require a 256 TAP filter and the last two channels require a 1024 TAP filter. The window size for all the channels is 128.

1. Create a circular data buffer in system memory for each channel.

The buffer should be large enough to avoid overwriting data before the accelerator processes it. Ideally, the input buffer size for a channel is *tap length* + *window size* – 1 for that channel. The 256 coefficients of each of the first four channels and the 1024 coefficients each of the last two channels are also configured in system memory buffers. The output buffer size is equal to the window size.

2. Create six TCBs in system memory with each channel's chain pointer (CP) entry pointing to the next channel's and the sixth channel's CP entry pointing back to the first channel's in a circular manner.
3. Configure the `FIR_CTL2` register for the first four channels' TCBs to 256 TAPs and a window size of 128, and the next two channels for 1024 TAPs and a window size of 128, respectively.
4. Configure the index, modifier, length entries in the TCBs to point to the corresponding channel's data buffer, coefficient buffer, and output data buffer. The location of the first channel's TCB is written to the `FIR_CHNPTR` register. The `FIR_CTL1.CH` bit field is then programmed with a value that corresponds to six channels.
    a. The accelerator iterates through six channels once and then waits for core intervention (the `FIR_CTL1.CAI` bit is not set, the DMA is enabled, and the `FIR_CTL1.EN` bit is set).
    b. The accelerator loads the TCB of the first channel, then loads the coefficient and data, and processes one window.
    c. After saving the index values to memory, the accelerator moves to the next channel.
    d. After all six channels are complete, the accelerator halts and waits for core intervention.

Computing FIR Output, Tap Length Greater than 4096

With little core intervention, the FIR accelerator can also be used to calculate output for a tap length greater than 4096 taps. The section demonstrates the calculation with an example of 8192 taps.

1. Divide the transfer function of an 8192 FIR filter into two 4096 FIR filters:

$$H(Z) = b_0 + b_1\mathrm{Z}^{-1} + b_2Z^{-2} + \ldots\ldots\ldots\ldots b_{4095}Z^{-4095} + b_{4096}Z^{-4096}\mathrm{b}_{4097}Z^{-4097} + \ldots\ldots\ldots b_{8191}Z^{-8191}$$

$$= b_0 + b_1\mathrm{Z}^{-1} + b_2Z^{-2} + \ldots\ldots\ldots\ldots b_{4095}Z^{-4095} + Z^{-4096}(b_{4096} + b_{4097} + \ldots\ldots\ldots b_{8191}Z^{-4096})$$

2. Divide the filter coefficients of an 8192 tap filter among two 4096 tap FIR filters:

    Filter 1

    Coefficients = b0, b1, b2,……, b4095

    Input data = x[n], x [n – 1],……….x[n – 4095]

    Filter 2

    Coefficients = b4096, b4097,…………..,b8191

    Input data = x[n – 4096], x[n – 4097],……x[n – 8191]

The accelerator can be used in two-channel mode where channel 1 operates on x[n]...x[n – 4095] input data with the filter coefficients of filter 1 and channel 2 operates on x[n – 4096]...x[n – 8191] with the filter coefficients of filter 2.

Once both the channels are processed, add the partial sum output of both the channels can to get the final output. Implement this approach (tap length = TAPS = 8192, window size = WINDOW) using the following programming steps.

1. Create a circular input data buffer in system memory (IBUF). The buffer must be large enough to avoid overwriting data before the accelerator processes it. Ideally, the input buffer size for a channel is TAPS + WINDOW – 1.
2. Create a coefficient buffer of size TAPS (8192) (CBUF).
3. Create one output buffer of size WINDOW (OBUF) and another temporary output buffer (OBUF1) to store the partial sum.
4. Create two TCBs in system memory with first TCB chained to the second and second one chained to the first in circular manner.
    a. The `FIR_COEFIDX` bit field of the first TCB should point to the start address of the coefficient buffer (CBUF) and that of the second TCB should point to 4096 offset from the start of the coefficient buffer (CBUF + 4096).
    b. The `FIR_OUTBASE` and `FIR_OUTIDX` bit field of the first TCB should point to the start address of OBUF and that of the second TCB should point to the start address of OBUF1.
    c. The `FIR_INIDX` bit field of the first TCB should point to the start address of IBUF and that of the second TCB should point to 4096 offset from the start address of IBUF.
    d. Configure the `FIR_CTL2` bit field of both the TCB for tap length = TAP/2 = 4096 and window size = WINDOW.
5. Initialize the `FIR_CHNPTR` register pointing to the first TCB.
6. Program the `FIR_CTL1` register to initiate the accelerator processing now by setting the `FIR_CTL1.EN` and `FIR_CTL1.DMAEN` bits and the number of channels configured as 2.
7. Wait for the FIR all channel done interrupt (`FIR_DMASTAT.ACDONE`) to occur. Inside the ISR, add the partial sum results using the core from both the output buffers (OBUF and OBUF1) to get the final output. To save memory, replace the contents of the buffer OBUF with the final output result.

Debug Features

The following sections provide information for debugging the FIR accelerator.

Local Memory Access

The contents of FIR delay line and coefficient memories are made observable for debug by setting the `FIR_DBG_CTL.EN`/`FIR_DBG_CTL.MEM` and `FIR_DBG_CTL.HLD` bits. The debug address register (`FIR_DBG_ADDR`) and two data registers are provided for debug operations. Bit 11 of the `FIR_DBG_ADDR` register selects coefficient memory when set (=1) and selects delay line memory when cleared (=0).

In the debug mode, the read data register (`FIR_DBG_RDDAT`) returns the contents of the memory location pointed to by the address register. Data can be written into any memory location using `FIR_DBG_WRDAT` register writes. If the address auto-increment bit (`FIR_DBG_CTL.ADRINC`) is set, the address register auto-increments on `FIR_DBG_WRDAT` writes and `FIR_DBG_RDDAT` reads. During auto-increment the `FIR_DBG_ADDR` register cannot cross the data memory or coefficient memory boundary.

Single-Step Mode

Programs can single step through the MAC operations and observe the memory contents after each step. The `FIR_DBG_CTL.EN`, `FIR_DBG_CTL.HLD`, and `FIR_DBG_CTL.MEM` bits control the FIR MAC units.

Emulation Considerations

In FIR debug mode, the DMA operations are not observable.

Interrupts

The ***FIR Interrupt Overview*** table provides the source of interrupt and service instructions for the FIR interrupts.

Table 51-7: FIR Interrupt Overview

Default Programmable Interrupt	Sources	Masking	Service
FIR_DMA FIR_STAT	Input DMA complete Output DMA complete Window complete All channels complete	N/A	ROC from `FIR_DMASTAT` + RTI instruction
	MAC IEEE floating-point exceptions MAC fixed-point overflow		ROC from `FIR_MACSTAT` + RTI instruction

Sources

The FIR module drives two interrupt signals: `FIR_DMA` for the DMA status and `FIR_STAT` for the MAC status. The FIR module generates interrupts as described in the following sections.

Window Complete

This interrupt is generated at the end of each channel when all the output samples are calculated corresponding to a window and updated index values are written back.

All Channels Complete

This interrupt is generated when all the channels are complete or when one iteration of time slots completes. Note that the interrupt follows the access completion rule, where the interrupt is generated when all data are written back to system memory.

MAC Status

A MAC status interrupt is generated under the following conditions and is reflected in the `FIR_MACSTAT` register.

- Multiplier result zero – Set if multiplier result is zero
- Multiplier result infinity – Set if multiplier result is infinity
- Multiply invalid – Set if multiply operation is invalid
- Adder result zero – Set if adder result is zero
- Adder result infinity – Set if adder result is infinity
- Adder invalid – Set if addition is invalid
- Adder overflow – for fixed-point operation

Service

When a DMA interrupt occurs, programs can find whether the input or output DMA interrupt occurred by reading the DMA status register (`FIR_DMASTAT`). The DMA interrupt status bits are sticky and are cleared when the DMA status register is read. When a MAC status interrupt occurs, programs can find this state by reading the MAC status register (`FIR_MACSTAT`). The read of the register clears the (sticky) MAC interrupt status bits.

The status interrupt sources are derived from the `FIR_MACSTAT` register. A status interrupt can occur due to the last set of MAC operations of a processing iteration that correspond to a particular channel. The interrupt is generated continuously and cannot be stopped, even after disabling the accelerator. The interrupt can only be stopped when another processing iteration results in a non-zero or valid multiply or add result. However, in this situation, it is difficult to isolate whether the interrupt corresponds to the previous processing iteration or the current one. This functionality makes using status interrupts impractical.

Another option is to poll the status bits of the `FIR_MACSTAT` register inside the DMA interrupt service routine. However, consider the behavior of the status bits. The status bits in the `FIR_MACSTAT` registers are sticky. Once a status bit is set, it gets cleared only when the `FIR_MACSTAT` register is read and the previous set of MAC operations resulted in a non-zero, valid output. Therefore, if the last set of MAC operations of a processing iteration results in a zero, non-valid output, the corresponding status bit are not cleared, even after reading the `FIR_MACSTAT` register. To avoid a false indication in the next processing iteration, ensure that all the status bits are cleared after the current iteration finishes.

The solution is to read the `FIR_MACSTAT` register twice inside the DMA interrupt service routine. The first read identifies which status bits are set. The second read is used to discover if the status bit was set because of the last set of MAC operations. If the status bit was not set because of the last set of MAC operations, it provides a zero result.

If the bit was set because of the last set of MAC operations, clear the status bit by performing a simple dummy FIR processing iteration (tap length = 4 and window size = 1). Choose the appropriate `FIR_MACSTAT` register after the processing is complete.

For more information, see the "FIR MAC Status Register" section.

Effect Latency

The total effect latency is a combination of the write effect latency (core access) plus the peripheral effect latency (peripheral-specific).

Write Effect Latency

For details on write effect latency, see the *SHARC Processor Programming Reference*.

FIR Throughput

Accelerator input and output channels are used to connect to internal memory. Data throughput is one 32-bit data word per SCLK cycle for writes to memory, provided there are no conflicts. Read throughput from memory, throughput is one 32-bit data word per two SCLK clock cycles.

The following information describes the performance of the FIR accelerator in SCLK cycles. The total number of SCLK cycles for a single channel single rate filtering N <= 1024 is the sum of the cycles taken for the following operations.

- TCB load (SCLK cycles) = $13 \times 11 + 3$
- Coefficient Load (SCLK cycles)= $N \times 11 + 3$
- Data Load (SCLK cycles)= $N \times 11 + 3$
- Calculation (SCLK cycles)= $(N/4 + 2) \times W + 16$
- Write Back (SCLK Cycles) = 27

Total number of SCLK cycles for a single rate filtering $N <= 1024$ is:

$(195 + 2 \times N \times 11 + W \times (N/4+2)) \times C$ SCLK cycles

where:

- N is the Number of taps
- W is the Window size
- C is the Number of channels

ADSP-SC58x FIR Register Descriptions

The FIR accelerator (FIR) contains the following registers.

Table 51-8: ADSP-SC58x FIR Register List

Name	Description
FIR_CHNPTR	FIR Chain Pointer Register
FIR_COEFCNT	FIR Coefficient Count Register
FIR_COEFIDX	FIR Coefficient Index Register
FIR_COEFMOD	FIR Coefficient Modifier Register
FIR_CTL1	FIR Global Control Register
FIR_CTL2	FIR Channel Control Register
FIR_DBG_ADDR	Debug Address Register
FIR_DBG_CTL	FIR Debug Control Register
FIR_DBG_RDDAT	FIR Debug Data Read Register
FIR_DBG_WRDAT	FIR Debug Data Write Register
FIR_DMASTAT	FIR DMA Status Register
FIR_INBASE	FIR Input Data Base Register
FIR_INCNT	FIR Input Data Count Register
FIR_INIDX	FIR Input Data Index Register
FIR_INMOD	FIR Input Data Modifier Register
FIR_MACSTAT	FIR MAC Status Register
FIR_OUTBASE	FIR Output Data Base Register
FIR_OUTCNT	FIR Output Data Count Register
FIR_OUTIDX	FIR Output Data Index Register
FIR_OUTMOD	FIR Output Data Modifier Register

FIR Chain Pointer Register

The `FIR_CHNPTR` register contains the chain pointer address.

Bit No. (Access)	Bit Name	Description/Enumeration
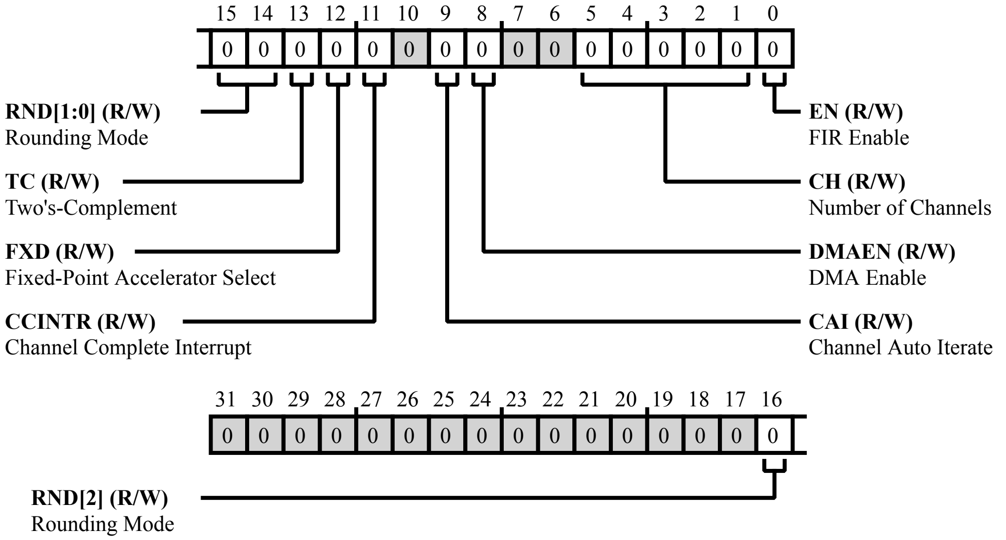
15:0 (R/W)	VALUE	16-bit Coefficient Index Modifier. The FIR_COEFMOD.VALUE bit field contains the 16-bit coefficient index modifier.

FIR Global Control Register

The `FIR_CTL1` register is used to configure the global parameters for the accelerator. These parameters include the number of channels, channel auto iterate, DMA enable, and accelerator enable.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

RND[2] (R/W)
Rounding Mode

Figure 51-12: FIR_CTL1 Register Diagram

Table 51-13: FIR_CTL1 Register Fields

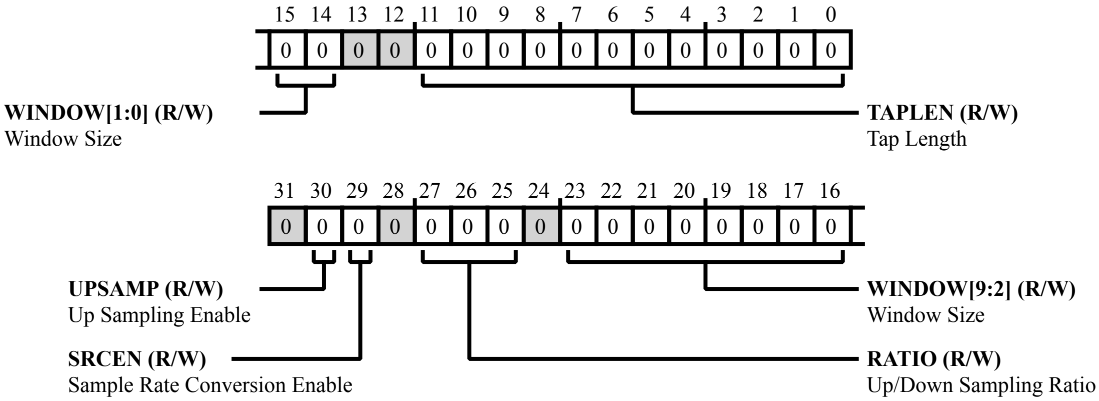
Bit No. (Access)	Bit Name	Description/Enumeration	
16:14 (R/W)	RND	Rounding Mode. The `FIR_CTL1.RND` bit configures the accelerator to use one of the following rounding modes.	
		0	Round to Nearest
		1	Truncate (Round away from zero)
13 (R/W)	TC	Two's-Complement. The `FIR_CTL1.TC` bit configures the accelerator to use either unsigned integer or signed integer	
		0	Unsigned integer
		1	Signed integer
12 (R/W)	FXD	Fixed-Point Accelerator Select. The `FIR_CTL1.FXD` bit configures the accelerator to use either 32-bit IEEE floating-point or 32-bit fixed-point.	
		0	32-bit IEEE floating-point
		1	32-bit fixed point

Table 51-13: FIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	CCINTR	Channel Complete Interrupt. The `FIR_CTL1.CCINTR` bit configures the accelerator to generate an interrupt when each or all channels are done.	
		0	Interrupt is generated only when all channels are done
		1	Interrupt is generated after each channel is done
9 (R/W)	CAI	Channel Auto Iterate. The `FIR_CTL1.CAI` bit, if cleared, causes the TDM processing to stop (idle) once all channels are done. If set, processing moves to the first channel and continues TDM processing in a loop when all channels are done.	
		0	TDM processing stops (idle) once all channels are done
		1	Moves to first channel and continues TDM processing in a loop when all channels are done
8 (R/W)	DMAEN	DMA Enable. The `FIR_CTL1.DMAEN` bit enables and disables DMA on the FIR accelerator.	
		0	DMA disabled
		1	DMA enabled
5:1 (R/W)	CH	Number of Channels. The `FIR_CTL1.CH` bit field configures the number of channels and is programmable from 0 to 31.	
		0	Channel 1
		1-30	Channel 2-31
		31	Channel 32
0 (R/W)	EN	FIR Enable. The `FIR_CTL1.EN` bit enables and disables the FIR accelerator.	
		0	Disable FIR
		1	Enable FIR

FIR Channel Control Register

The `FIR_CTL2` register is used to configure the channel specific parameters such as filter TAP length, window size, sample rate conversion, up/down sampling and ratio.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Window Size
RATIO (R/W)
Up/Down Sampling Ratio

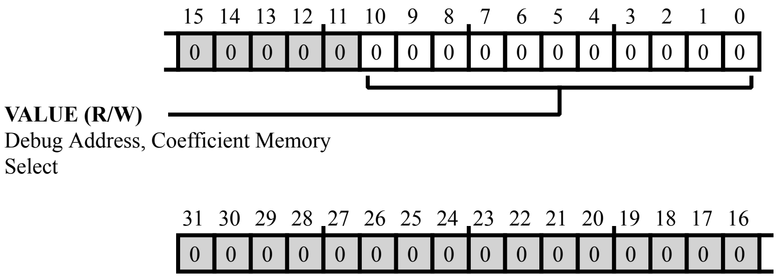
Figure 51-13: FIR_CTL2 Register Diagram

Table 51-14: FIR_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	UPSAMP	Up Sampling Enable. The `FIR_CTL2.UPSAMP` bit enables up sampling.	
		0	Down sampling
		1	Up sampling
29 (R/W)	SRCEN	Sample Rate Conversion Enable. The `FIR_CTL2.SRCEN` bit field enables sample rate conversion.	
		0	Disabled
		1	Enabled
27:25 (R/W)	RATIO	Up/Down Sampling Ratio. The `FIR_CTL2.RATIO` bit field sets the sampling ratio (`FIR_CTL2.RATIO` + 1).	
23:14 (R/W)	WINDOW	Window Size. The `FIR_CTL2.WINDOW` bit field sets the window size which specifies the number of sample/block to process (sample based processing = window size of 0).	
11:0 (R/W)	TAPLEN	Tap Length. The `FIR_CTL2.TAPLEN` bit field sets the tap length which is programmable between 0-4095 (Tap Length = `FIR_CTL2.TAPLEN` + 1).	

Debug Address Register

The FIR_DBG_ADDR register holds the debug address.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

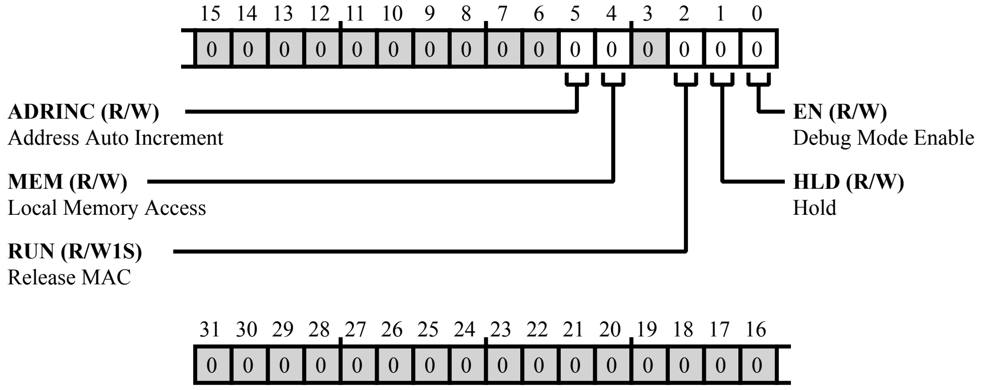
Figure 51-14: FIR_DBG_ADDR Register Diagram

Table 51-15: FIR_DBG_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Debug Address, Coefficient Memory Select. The `FIR_DBG_ADDR.VALUE` bit field holds the debug address (bits 0-10). Bit 11 configures whether the memory access is to coefficient memory (=0) or to delay line memory (=1).

FIR Debug Control Register

The `FIR_DBG_CTL` register controls debugging operations such as enabling debug mode running, hold or single stepping.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

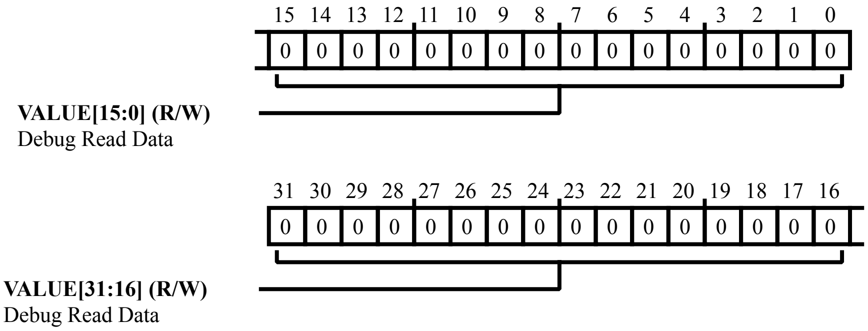
Figure 51-15: FIR_DBG_CTL Register Diagram

Table 51-16: FIR_DBG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	ADRINC	Address Auto Increment. The `FIR_DBG_CTL.ADRINC` bit bit allows the address register to auto-increment on `FIR_DBG_WRDAT` writes and `FIR_DBG_RDDAT` reads.
4 (R/W)	MEM	Local Memory Access. When the `FIR_DBG_CTL.MEM` bit is set, the data and coefficients memory can be indirectly accessed.
2 (R/W1S)	RUN	Release MAC. The `FIR_DBG_CTL.RUN` bit releases the MAC. This bit is self-clearing after one FIR clock cycle.
1 (R/W)	HLD	Hold. The `FIR_DBG_CTL.HLD` bit holds or single-steps through the FIR. 0 Hold 1 Single-step
0 (R/W)	EN	Debug Mode Enable. The `FIR_DBG_CTL.EN` bit enables debug mode. For local memory access, the `FIR_CTL1` register can be cleared. 0 Disable debug mode 1 Enable debug mode

FIR Debug Data Read Register

The `FIR_DBG_RDDAT` register hold the debug read data.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

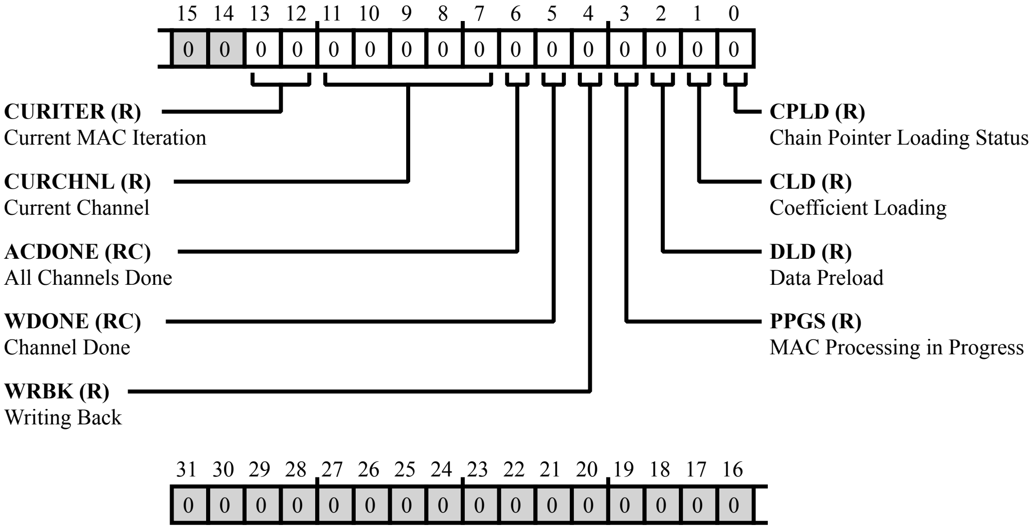
Table 51-18: FIR_DBG_WRDAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Debug Write Data. The `FIR_DBG_WRDAT.VALUE` bit field holds the debug write data.

FIR DMA Status Register

The `FIR_DMASTAT` register provides information about chain pointer loading, coefficient DMA, data preload DMA, processing in progress, window complete, all channels complete.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 51-18: FIR_DMASTAT Register Diagram

Table 51-19: FIR_DMASTAT Register Fields

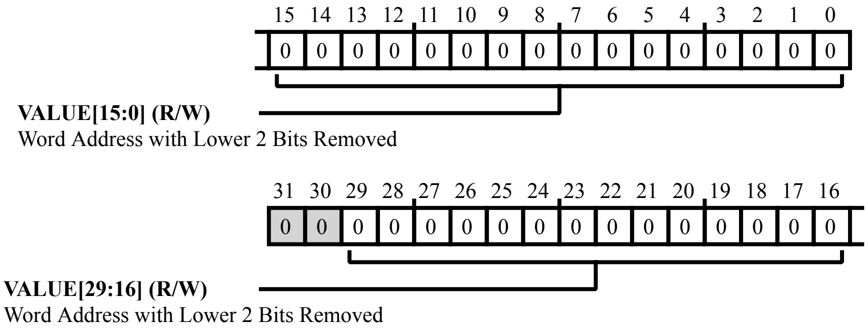
Bit No. (Access)	Bit Name	Description/Enumeration
13:12 (R/NW)	CURITER	Current MAC Iteration. The `FIR_DMASTAT.CURITER` bit indicates the current MAC iteration in multi-iteration mode. Zero indicates the final iteration.
11:7 (R/NW)	CURCHNL	Current Channel. The `FIR_DMASTAT.CURCHNL` bit indicates the channel that is being processed in the TDM slot. Zero indicates the last slot.
6 (RC/NW)	ACDONE	All Channels Done. The `FIR_DMASTAT.ACDONE` bit indicates the accelerator that processing all channels is complete. This is a sticky bit and is cleared on a register read. The `FIR_CTL1.CCINTR` bit does not affect the `FIR_DMASTAT.ACDONE` bit.
5 (RC/NW)	WDONE	Channel Done. The `FIR_DMASTAT.WDONE` bit indicates the accelerator that processing the current channel is complete. This is a sticky bit and is cleared on a register read. The `FIR_CTL1.CCINTR` bit does not affect the `FIR_DMASTAT.WDONE` bit.
4 (R/NW)	WRBK	Writing Back. The `FIR_DMASTAT.WRBK` bit indicates the accelerator is writing back the updated index registers.

Table 51-19: FIR_DMASTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/NW)	PPGS	MAC Processing in Progress. The `FIR_DMASTAT.PPGS` bit indicates MAC processing in progress.
2 (R/NW)	DLD	Data Preload. The `FIR_DMASTAT.DLD` bit indicates data preloading.
1 (R/NW)	CLD	Coefficient Loading. The `FIR_DMASTAT.CLD` bit indicates coefficient loading.
0 (R/NW)	CPLD	Chain Pointer Loading Status. The `FIR_DMASTAT.CPLD` bit indicates the state machine is in chain pointer load state.

FIR Input Data Base Register

The `FIR_INBASE` register contains the input word base address with the lower two bits removed.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

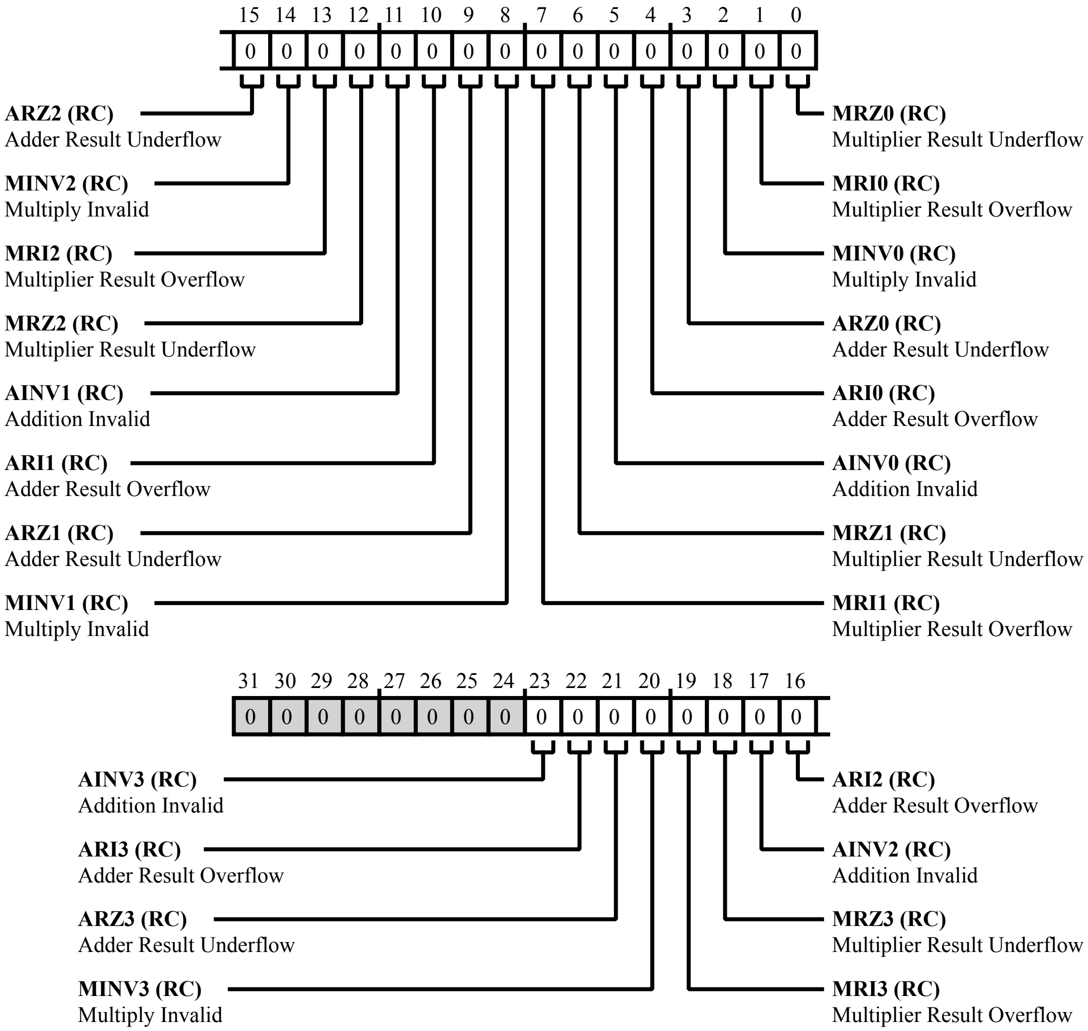
15:0 (R/W)	VALUE	16-bit Input Data Buffer Modifier. The `FIR_INMOD.VALUE` bit field contains the 16-bit input data buffer modifier.

FIR MAC Status Register

The `FIR_MACSTAT` register provides the status of MAC operations. The status of all four multipliers/adders are available separately for programs to poll. In fixed-point mode only, the ARIx bits are used (all other bits are reserved).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 51-24: FIR_MACSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23 (RC/NW)	AINV3	Addition Invalid. The `FIR_MACSTAT.AINV3` bit is set if the adder 3 addition is invalid.

Table 51-24: FIR_MACSTAT Register Fields (Continued)

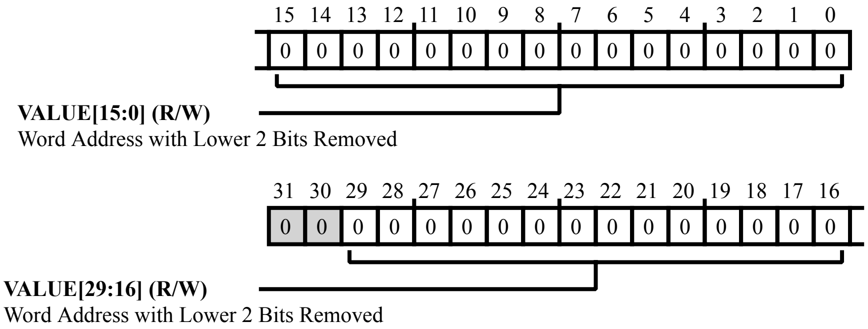
Bit No. (Access)	Bit Name	Description/Enumeration
22 (RC/NW)	ARI3	Adder Result Overflow. The `FIR_MACSTAT.ARI3` bit is set if the adder 3 result is infinity. Indicates overflow in fixed-point mode.
21 (RC/NW)	ARZ3	Adder Result Underflow. The `FIR_MACSTAT.ARZ3` bit is set if the adder 3 result is zero.
20 (RC/NW)	MINV3	Multiply Invalid. The `FIR_MACSTAT.MINV3` bit is set if the multiplier 3 multiply operation is invalid.
19 (RC/NW)	MRI3	Multiplier Result Overflow. The `FIR_MACSTAT.MRI3` bit is set if the multiplier 3 result is infinity.
18 (RC/NW)	MRZ3	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ3` bit is set if the multiplier 3 result is zero.
17 (RC/NW)	AINV2	Addition Invalid. The `FIR_MACSTAT.AINV2` bit is set if the adder 2 addition is invalid.
16 (RC/NW)	ARI2	Adder Result Overflow. The `FIR_MACSTAT.ARI2` bit is set if the adder 2 result is infinity. Indicates overflow in fixed-point mode.
15 (RC/NW)	ARZ2	Adder Result Underflow. The `FIR_MACSTAT.ARZ2` bit is set if the adder 2 result is zero.
14 (RC/NW)	MINV2	Multiply Invalid. The `FIR_MACSTAT.MINV2` bit is set if the multiplier 2 multiply operation is invalid.
13 (RC/NW)	MRI2	Multiplier Result Overflow. The `FIR_MACSTAT.MRI2` bit is set if the multiplier 2 result is infinity.
12 (RC/NW)	MRZ2	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ2` bit is set if the multiplier 2 result is zero.
11 (RC/NW)	AINV1	Addition Invalid. The `FIR_MACSTAT.AINV1` bit is set if the adder 1 addition is invalid.
10 (RC/NW)	ARI1	Adder Result Overflow. The `FIR_MACSTAT.ARI1` bit is set if the adder 1 result is infinity. Indicates overflow in fixed-point mode.
9 (RC/NW)	ARZ1	Adder Result Underflow. The `FIR_MACSTAT.ARZ1` bit is set if the adder 1 result is zero.

Table 51-24: FIR_MACSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
8 (RC/NW)	MINV1	Multiply Invalid. The `FIR_MACSTAT.MINV1` bit is set if the multiplier 1 multiply operation is invalid.
7 (RC/NW)	MRI1	Multiplier Result Overflow. The `FIR_MACSTAT.MRI1` bit is set if the multiplier 1 result is infinity.
6 (RC/NW)	MRZ1	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ1` bit is set if the multiplier 1 result is zero.
5 (RC/NW)	AINV0	Addition Invalid. The `FIR_MACSTAT.AINV0` bit is set if the adder 0 addition is invalid.
4 (RC/NW)	ARI0	Adder Result Overflow. The `FIR_MACSTAT.ARI0` bit is set if the adder 0 result is infinity. Indicates overflow in fixed-point mode.
3 (RC/NW)	ARZ0	Adder Result Underflow. The `FIR_MACSTAT.ARZ0` bit is set if the adder 0 result is zero.
2 (RC/NW)	MINV0	Multiply Invalid. The `FIR_MACSTAT.MINV0` bit is set if the multiplier 0 multiply operation is invalid.
1 (RC/NW)	MRI0	Multiplier Result Overflow. The `FIR_MACSTAT.MRI0` bit is set if the multiplier 0 result is infinity.
0 (RC/NW)	MRZ0	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ0` bit is set if multiplier 0 result is zero.

FIR Output Data Base Register

The `FIR_OUTBASE` register contains the output word base address with the lower two bits removed



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

52 IIR Accelerator (IIR)

The processor includes an Infinite Impulse Response (IIR) filter accelerator implemented in hardware that reduces the processing load on the core, freeing it up for other tasks.

Features

The accelerator supports a maximum of 24 channels. There is support for up to 12 cascaded biquads per channel. The accelerator locally stores all the biquad coefficients of 24 channels. Window size can be configured from 1 (sample based) to 1024. The IIR has the following features.

- Supports IEEE floating point format 32/40-bit
- Supports various rounding modes
- Sample-based or window-based processing
- Up to 12 cascaded biquads per channel
- Up to 24 filter channels available in TDM
- Allows biquad save state storage

NOTE: The IIR accelerator module has local memory which is not accessible by the core during regular operation mode. Unlike previous SHARC processors, the IIR accelerator modules each have access to the system memory (on-chip or off-chip).

Unlike in previous SHARC processors, where only one of the IIR or FIR accelerator can be enabled at a time, the processor can use both the IIR and the FIR accelerators at the same time.

Clocking

The IIR accelerator runs at the maximum speed of SCLK0.

Functional Description

The ***IIR Accelerator Block Diagram*** shows the various blocks of the IIR hardware accelerator. The accelerator has:

- a coefficient memory size of 1440 × 40 bits (12 biquads × 24 channels × 5 coefficients)
- a data memory size of 576 × 40 bits (12 biquads × 24 channels × 2 states)
- one MAC unit with an input data buffer to supply data to the MAC

Figure 52-2: Transposed Direct Form II Biquad

The accelerator has the following logical subblocks.

- A datapath unit with the following elements:
    - 32/40-bit coefficient memory (Ak, Bk) for storing biquad coefficients
    - 32/40-bit input data (Xk) and state (Dk)
    - One 40/32-bit floating-point multiplier and adder (MAC) unit
    - An input data buffer to efficiently supply data to MAC
    - One 40-bit result register to hold result of biquad

- Configuration registers for controlling various parameters such as the number of biquads, the number of channels, interrupt control, and DMA control
- A core access interface for writing the DMA/filter configuration registers and for reading the status registers
- A DMA bus interface for transferring data to and from the accelerator. This interface is also used to preload the coefficients (Ak, Bk) and state (Dk) at startup.
- DMA configuration registers for the transfer of input data, output data, and coefficients

ADSP-SC58x IIR Register List

The IIR module reduces the processing load on the core. For more information on IIR functionality, see the IIR register descriptions.

Table 52-1: ADSP-SC58x IIR Register List

Multiply and Accumulate (MAC) Unit

The ***IIR MAC Unit*** figure shows a pipelined multiplier and accumulator unit that operates on the data and coefficient fetched from the data and coefficient memory. The MAC can perform either 32-bit floating-point or 40-bit floating-point MAC operations. 32-bit floating-point operations generate 32-bit results and 40-bit floating-point operations generate 40-bit results.

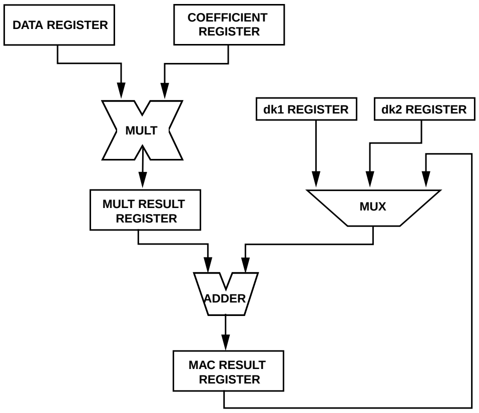

Figure 52-3: IIR MAC Unit

Input Data and Biquad State

The size of data memory is 576 × 40 bits and is used to hold the dk1 and dk2 state of all the biquads locally. The DMA controller fetches the sample data from internal memory and calculates the output as well as the dk1 and dk2 values for each biquad and stores them in local data memory.

Coefficient Memory

The size of coefficient memory is 1440 × 40 bits and is used to store all the coefficients of all the biquads. At start-up, DMA loads the coefficients from system memory into local coefficient memory.

Internal Memory Storage

This section describes the required storage model for the IIR accelerator.

Coefficient Memory Storage

Coefficients and Dk values for a particular biquad BQD[k] should be stored in internal memory in the order: Ak0, Ak1, Bk1, Ak2, Bk2, Dk2, Dk1.

NOTE: The naming convention for the filter coefficients used here is different from the one used in MATLAB. The following conversion should be used when using MATLAB generated coefficients:

(Akx = bx and Bkx = -ax).

Store the coefficients for each biquad in the order:

```
b0, b1, -a1, b2, -a2, dk2, dk1
```

For N biquad stages, store the coefficients in the order:

```
b01, b11, -a11, b21, -a21, dk21, dk11,
b02, b12, -a12, b22, -a22, dk22, dk12,
,......
b0N, b1N, -a1N, b2N, -a2N, dk2N, dk1N.
```

where bxN and axN are the coefficients ([b, a]) for the Nth biquad stage.

Operating Modes

The accelerator operates in Window Processing Mode, 40-Bit Floating-Point Mode and Save Biquad State Mode.

Window Processing Mode

Sample-based processing mode is selected by configuring window size to 1. In this mode, one sample from a particular channel is processed through all the biquads of that channel and the final output sample is calculated.

In window-based mode, multiple output samples (up to 1024) equal to the window size of that channel are calculated. After these calculations are complete, the accelerator begins processing the next channel. A configurable window size parameter is provided to specify the length of the window.

40-Bit Floating-Point Mode

In 40-bit floating-point mode, the input data/coefficient is treated as a 40-bit floating-point number. 40-bit floating-point MAC operations generate 40-bit results. This mode can be selected by setting the `IIR_CTL1.FORTYBIT` bit.

Since the DMA bus width is 32 bits, in 40-bit mode the IIR accelerator performs two packed 32-bit accesses to the memory to:

- fetch one 40-bit input or coefficient data, or
- to store one 40-bit output word

The first 32-bit word provides the lower 32 bits and the 8 LSBs of the second 32-bit word provides rest of the upper 8 bits of the complete 40-bit word. The ***32-Bit to 40-Bit Packing*** figure shows the 32–40 bit packing used by accelerator.

NOTE: Overheads could be required to pack the input 40-bit data into the format acceptable by the IIR accelerator and for unpacking the output of accelerator to the format acceptable by the rest of the application.

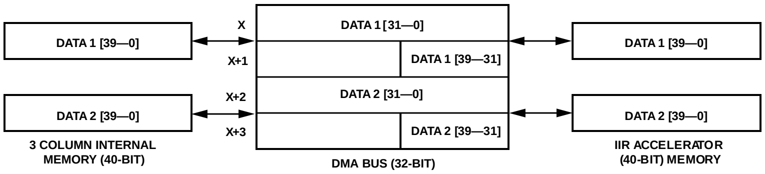

Figure 52-4: 32-Bit to 40-Bit Packing

Save Biquad State Mode

The `IIR_CTL1.SS` bit completely stores the current biquad states in local memory (writes all the DK1 and DK2 states back into the system memory states). This functionality is useful in applications that require fast switching to another high-priority accelerator task—a required IIR to FIR processing transition for example. After resuming, these states can be reloaded and IIR processing can be continued. Note that the DMA status is automatically stored after each iteration.

NOTE: The save state operation cannot be stopped after it starts, even by clearing the `IIR_CTL1.EN` `IIR_CTL1.EN` or `IIR_CTL1.DMAEN` bits. Although the bits would clear on the core side, settings take effect only after the save state operation completes. Therefore, before trying to disable the IIR accelerator, poll the corresponding status bits in the `IIR_DMASTAT` register to ensure the save state operation completed successfully. The following expressions provide the latency due to the save state operation, assuming no higher priority DMA is ON:

- For 32-bit mode: 14 × N + ((8 × M) + 2) × N)
- For 40-bit mode: 14 × N + ((15 × M) + 2) × N)

where N is the number of channels and M is the number of biquads per channel.

NOTE: Write access to any of the IIR accelerator registers loaded by chaining is not allowed while the save state operation is in progress. Attempted writes to these registers could result in the blocking of IOP core reads until the save state operation completes.

Data Transfers

The IIR filter works exclusively through DMA.

IIR Accelerator TCB

The location of the DMA parameters for the next sequence comes from the chain pointer register. This register points to the next set of DMA parameters stored in the system memory of the processor known as TCB. In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Assignment

The structure of a TCB is conceptually the same as the structure of a traditional linked-list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB can point to itself to rerun the same DMA continuously. The FIR accelerator reads each word of the TCB and loads it into the corresponding register. A TCB with a chain pointer register value of zero indicates the end of the chain (no further TCBs are loaded). The IIR accelerator supports circular buffer chained DMA. The ***IIR TCBs for Chained DMA*** table shows the required TCBs for chained DMA. In the table, TCB refers to the start address of the TCB array.

NOTE: In the IIR accelerator DMA, two different TCB loading sequences are available: one TCB loads five parameters for the coefficients (`IIR_CTL2`, `IIR_COEFIDX`, `IIR_COEFMOD`, `IIR_COEFLEN`, and `IIR_CHNPTR`). The second loads 10 parameters for the data (`IIR_CTL2`, `IIR_INIDX`, `IIR_INMOD`, `IIR_INLEN`, `IIR_INBASE`, `IIR_OUTIDX`, `IIR_OUTMOD`, `IIR_OUTLEN`, `IIR_OUTBASE`, and `IIR_CHNPTR`).

Initialize `IIR_CHNPTR` to TCB+12.

Table 52-5: IIR TCBs for Chained DMA

Address	Register
TCB	`IIR_CHNPTR`
TCB + 0x1	`IIR_COEFLEN`
TCB + 0x2	`IIR_COEFMOD`
TCB + 0x3	`IIR_COEFIDX`
TCB + 0x4	`IIR_OUTBASE`
TCB + 0x5	`IIR_OUTLEN`
TCB + 0x6	`IIR_OUTMOD`
TCB + 0x7	`IIR_OUTIDX`
TCB + 0x8	`IIR_INBASE`
TCB + 0x9	`IIR_INLEN`
TCB + 0xA	`IIR_INMOD`
TCB + 0xB	`IIR_INIDX`
TCB + 0xC	`IIR_CTL2`

DMA Access

The IIR accelerator has two DMA channels (accelerator input and output) to connect to the system memory. The DMA controller fetches the data and coefficients from memory and stores the result.

Chain Pointer DMA

The DMA controller supports circular buffer chain pointer DMA. One transfer control block (TCB) must be configured for each channel. The TCB contains:

- A control register value to configure the filter parameters (such as number of biquads, window size) for each channel
- DMA parameter register values for the input data
- DMA parameter register values for coefficient load
- DMA parameter register values for output data

NOTE: The chain pointer (`IIR_CHNPTR`) field of the last channel's TCB should point to the first channel's TCB. This configuration exists so that when the IIR accelerator is enabled, the module:

1. Loads the coefficients (Ak, Bk) and state variables (Dk) for all the channels into the local coefficient memory of the FIR, and
2. Loops back to the first channel again to start fetching the input data for processing.

The accelerator loads the TCB into its internal registers and uses these values to fetch coefficients and data and to store results. After processing a window of data for any channel, the accelerator writes back the `IIR_INIDX` (input index register) and `IIR_OUTIDX` (output index register) values to the TCB in memory. Then, data processing can begin from where it left off during the next time slot of that channel.

For 32-bit mode, the write-back values for the index registers are equal to `IIRII` + W and `IIROI` + W.

For 40-bit mode, the write-back values are: `IIR_INIDX` + 2 × W and `IIR_OUTIDX` + 2 × W.

Accelerator input and output channels connect to system memory.

NOTE: The `IIR_CTL2` register is part of the IIR TCB. This configuration allows software to program individual IIR channels having different control attributes.

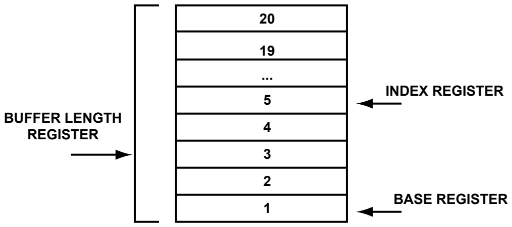

Figure 52-5: Circular Buffer Addressing

Effect Latency

The total effect latency is a combination of the write effect latency (core access) plus the peripheral effect latency (peripheral specific).

Write Effect Latency

For details on write effect latency, see the *SHARC+ Processor Programming Reference*.

IIR Throughput

Data throughput is one 32-bit data word per SCLK cycle for writes to memory, provided there are no conflicts. Read throughput from memory, throughput is one 32-bit data word per two peripheral clock cycles.

IIR throughput is calculated as follows:

Total number of SCLK cycles = (13 × 11 + 5 × B × W) C + B × 11 × 8 × C where:

- B is the number of biquads
- W is the window size
- C is the number of channels
- TCB load = 36 cycles for 32-bit mode and 38 PCLK cycles for 40-bit mode
- 5 × B is the number of cycles to calculate B biquads (This expression does not include the coefficient loading cycles because coefficients need to be loaded only once.)

The loading of input data and writing of output data is pipelined with the computation operation. The expression 5 × B × W includes input data loading, compute, and output data write back operations. This expression does not include the first input data loading, last output data write back, and write back of the updated input and output index registers, the latency of which is included in the TCB load.

NOTE: 14 PCLK cycles are required for TCB loading for coefficients and save state operation.

Interrupts

The ***IIR Interrupt Overview*** table provides the source of interrupt and service instructions for the IIR interrupts.

Table 52-6: IIR Interrupt Overview

Interrupt	Sources	Masking	Service
IIR_DMA IIR_STAT	Input DMA complete Output DMA complete	N/A	ROC from `IIR_DMASTAT`+ RTI instruction
	MAC IEEE floating point exceptions		ROC from `IIR_MACSTAT`+ RTI instruction

Sources

The IIR module drives two interrupt signals, `IIR_DMA` for the DMA status and `IIR_STAT` for the MAC status. The IIR module generates interrupts as described in the following sections.

Window Complete

This interrupt is generated at the end of each channel when all the output samples are calculated corresponding to a window and updated index values are written back.

All Channels Complete

This interrupt is generated when all the channels are complete or when one iteration of time slots completes. The interrupt follows the access completion rule, where the interrupt is generated when all data are written back to system memory.

Chained DMA

For chained DMA, if the `PCI` bit is cleared (= 0), the DMA complete interrupt is generated only after the entire chained DMA access is complete. If the `PCI` bit is set (= 1), then a DMA interrupt is generated for each TCB.

MAC Status

A MAC status interrupt is generated under these conditions:

- Multiplier result zero - Set if multiplier result is zero
- Multiplier result infinity - Set if multiplier result is infinity
- Multiply invalid - Set if multiply operation is invalid

- Adder result zero - Set if adder result is zero
- Adder result infinity - Set if adder result is infinity
- Adder invalid - Set if addition is invalid

Service

When a DMA interrupt occurs, programs can find whether the input or output DMA interrupt occurred by reading the DMA status register (`IIR_DMASTAT`). The DMA interrupt status bits are sticky and are cleared when the DMA status register is read. When a MAC status interrupt occurs, programs can find this state (and clear) by reading the MAC status register (`IIR_MACSTAT`). The MAC interrupt status bits are sticky.

The status interrupt sources are derived from the `IIR_MACSTAT` register. A status interrupt can occur due to the last set of MAC operations of a processing iteration that correspond to a particular channel. The interrupt is generated continuously and cannot be stopped, even after disabling the accelerator. The interrupt can only be stopped when another processing iteration results in a non-zero or valid multiply or add result. However, in this situation it is difficult to isolate whether the interrupt corresponds to the previous processing iteration or that of the current one. This functionality makes using status interrupts impractical.

An alternate way is to poll status bits of the `IIR_MACSTAT` register inside the DMA interrupt service routine. However, consider the behavior of the status bits. The status bits in the `IIR_MACSTAT` registers are sticky. Once a status bit is set, it gets cleared only when the `IIR_MACSTAT` register is read and the previous set of MAC operations resulted in a non-zero, valid output. Therefore, if the last set of MAC operations of a particular processing iteration results in a zero, non-valid output, the corresponding status bit is not cleared, even after reading the `IIR_MACSTAT` register. To avoid a false indication in the next processing iteration, it is necessary to ensure that all the status bits are cleared after the current iteration finishes.

The solution is to read the `IIR_MACSTAT` register twice inside the DMA interrupt service routine. The first read is used to identify which status bits are set. The second read is used to discover if the status bit was set because of the last set of MAC operations. If the status bit was not set because of the last set of MAC operations, it provides a zero result.

If the bit was set because of the last set of MAC operations, clear the status bit by performing a simple dummy FIR processing iteration (biquads = 1 and window size = 1). Choose the appropriate coefficients and input buffer and reading the `IIR_MACSTAT` register after the processing is complete.

Programming Model

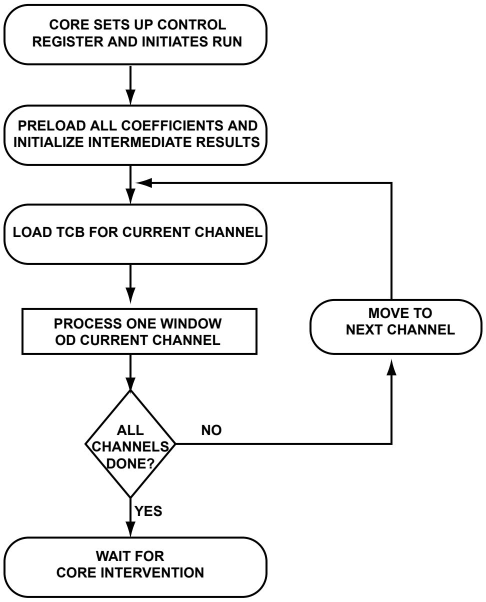
The IIR supports up to 24 channels which are time division multiplexed (TDM). Each channel can have a maximum of 12 cascaded biquads. The window size for each channel is configurable using control registers. A window size of 1 corresponds to sample based operation and the maximum window size is 64.

The coefficients are initially stored in system memory and one TCB per channel is created in system memory with each channels' TCB pointing to the next channels'. The TCB also contains channel specific control registers, input data buffer parameters and output data buffer parameters.

NOTE: The TCB of the last channel should point to the TCB of first channel.

The total number of channels is configured using the `IIR_CTL1` register and DMA is enabled.

The procedure that the accelerator uses to process biquads is shown in the ***Biquad Processing Program Flow*** figure and described in the following procedure.



CORE SETS UP CONTROL REGISTER AND INITIATES RUN
PRELOAD ALL COEFFICIENTS AND INITIALIZE INTERMEDIATE RESULTS
LOAD TCB FOR CURRENT CHANNEL
PROCESS ONE WINDOW OD CURRENT CHANNEL
MOVE TO NEXT CHANNEL
ALL CHANNELS DONE?
NO
YES
WAIT FOR CORE INTERVENTION

Figure 52-6: Biquad Processing Program Flow

1. The controller loads all coefficients of all the channels into local storage.
2. Once all the coefficients are loaded, the controller goes to the first biquad of the first channel and calculates the output of the first biquad and updates the intermediate results for that biquad.
3. Then, the accelerator moves to the next biquad of that channel and repeats the process until all the biquads for that channel are completed and the results are stored to memory.
4. This process is repeated with next sample until one window of the corresponding channel is processed.
5. After one window of the channel accelerator is processed, the accelerator moves to the next channel and computes the results.

NOTE: All the addresses programmed in the TCB should correspond to 32-bit address boundaries and shouldn't contain the lower 2 bits (which are assumed to be zeros).

Dynamic Coefficient Processing Notes

The IIR accelerator loads the coefficients for all the channels only once when the IIR accelerator is enabled. In order to re-load the new coefficients, the accelerator has to be disabled and re-enabled.

Writing to Local Memory

1. Clear the `IIR_CTL1.DMAEN` bit.
2. Set the `IIR_DBG_CTL.EN`, `IIR_DBG_CTL.MEM` and `IIR_DBG_CTL.HLD` bits.
3. Set the `IIR_DBG_CTL.ADRINC` bit for address auto increment.
4. Write start address to the `IIR_DBG_ADDR` register. If bit 11 is set, coefficient memory is selected.
5. Wait at least 4 *CCLK* cycles.
6. Write data to the `IIR_DBG_WRDAT_LO` register.
7. Write data to the `IIR_DBG_WRDAT_HI` register.

Reading from Local Memory

1. Clear the `IIR_CTL1.DMAEN` bit.
2. Set the `IIR_DBG_CTL.EN`, `IIR_DBG_CTL.MEM` and `IIR_DBG_CTL.HLD` bits.
3. Set the `IIR_DBG_CTL.ADRINC` bit for address auto increment.
4. Write start address to the `IIR_DBG_ADDR` register. If bit 11 is set, coefficient memory is selected.
5. Wait at least 4 *CCLK* cycles.
6. Read data from the `IIR_DBG_RDDAT_LO` register.
7. Read data from the `IIR_DBG_RDDAT_HI` register.

Single Step Mode

Single step mode can be used for debug purposes. An additional debug register is used in this mode.

1. Enable stop DMA during breakpoint hit in the emulator settings.
2. Clear the `IIR_DBG_CTL.HLD` bit and enable the `IIR_DBG_CTL.EN` and `IIR_DBG_CTL.RUN` bits.
3. Program the IIR module according to the application.
4. In single step each iteration is updated in the emulator session.

Save Biquad State of the IIR

The following steps are required to resume IIR processing after being interrupted by another accelerator module.

1. When starting the accelerator for the first time, set the `IIR_CTL1.EN`, `IIR_CTL1.DMAEN` and `IIR_CTL1.SS` bits.
2. The core waits for the first set of IIR processing to conclude or performs some other task.

3. The accelerator writes back the updated DMA index registers and the updated Dk values after the processing completes.
4. Disable the accelerator by clearing the `IIR_CTL1.EN` bit. Optionally, clear the `IIR_CTL1.DMAEN` bit.
5. The core and accelerator wait for the next set of data to be ready. (The FIR/FFT accelerator can be used for a completely different purpose during this time.)
6. Once the next block is ready for processing, enable the IIR accelerator again by setting the `IIR_CTL1.EN` and `IIR_CTL1.DMAEN` bits. The coefficients and the Dk values are re-loaded back into the local memory.
7. The core waits for the current set of IIR processing to conclude or performs some other task.

Programming Example

In this example, an application needs IIR filtering for two channels of data; channel 1 has six biquads and channel 2 has eight biquads. The window size for all channels is 32.

1. Create a circular buffer in system memory for each channel's data. The buffer should be large enough to avoid overwriting data before it is processed by the accelerator.
2. Configure system memory buffers containing the 6 × 5 coefficients and the 6 × 2 Dk values for the channel 1 biquads, and the 8 × 5 coefficients and 8 × 2 Dk values of the channel 2 biquads.
3. Configure two TCBs in system memory with each channel's chain pointer entry pointing to the next channel's and the last channel's chain pointer entry pointing to the first in a circular fashion.
4. Program the `IIR_CTL2` register to use channel 1 TCB for 6 biquads and a window size of 32, and channel 2 for 8 biquads and a window size of 32.
5. Configure the index, modifier, and length entries in the TCBs to point to the corresponding channel's data buffer, coefficient buffer and output data buffer.

   The location of the first channel's TCB is written to the chain pointer register in the accelerator.
6. Program the global control register `IIR_CTL1.CH` bit for 2 channels.
   a. The accelerator starts and loads the first channel's TCB, loads coefficients and Dk values of all the 6 biquads into local storage, then loads the TCB of the second channel, and finally loads coefficients and Dk values of all the 8 biquads.
   b. Once all the coefficients and Dk values are loaded, the controller loads the TCB of first channel and fetches the input sample. It then starts calculating the first biquad of the first channel.
   c. The accelerator calculates the output of the first biquad and then updates the intermediate results for that biquad. Then it moves to the next biquad of that channel and repeats the biquad processing until all the biquads for that channel are done and the final result is stored to memory.
   d. The accelerator repeats this process with next sample until one window of the corresponding channel is processed. Once the window is done, the accelerator saves the index values to memory and moves to the next channel. After both channels are done, the accelerator waits for core intervention.

ADSP-SC58x IIR Register Descriptions

The IIR filter accelerator (IIR) contains the following registers.

Table 52-7: ADSP-SC58x IIR Register List

Name	Description
`IIR_CHNPTR`	Chain Pointer Register
`IIR_COEFIDX`	Coefficient Buffer Index Register
`IIR_COEFLEN`	Coefficient Buffer Length Register
`IIR_COEFMOD`	Coefficient Index Modifier Register
`IIR_CTL1`	Global Control Register

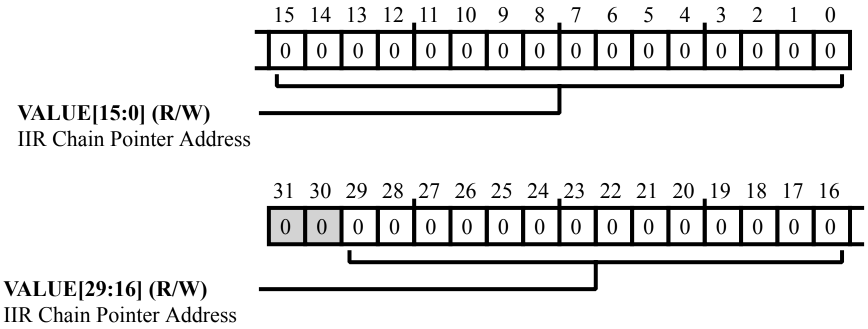
`IIR_OUTLEN`	IIR Output Data Buffer Length Register
`IIR_OUTMOD`	IIR Output Data Index Modifier Register

Chain Pointer Register

The `IIR_CHNPTR` register should be written with word address without the lower 2 bits.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
IIR Chain Pointer Address
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[29:16] (R/W)
IIR Chain Pointer Address

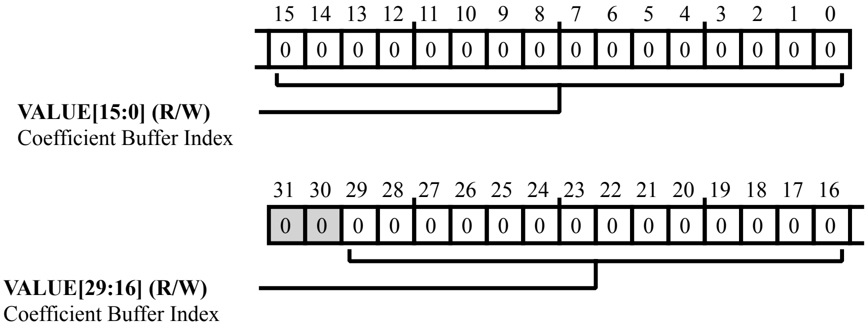
Figure 52-7: IIR_CHNPTR Register Diagram

Table 52-8: IIR_CHNPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	IIR Chain Pointer Address. The `IIR_CHNPTR.VALUE` bit field contains the chain pointer address.

Coefficient Buffer Index Register

The `IIR_COEFIDX` register contains the word address with the lower 2 bits removed.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Coefficient Buffer Index
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[29:16] (R/W)
Coefficient Buffer Index

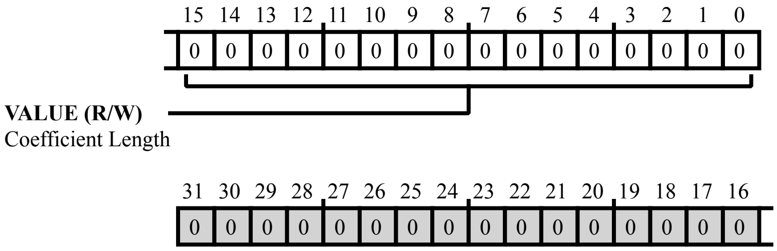
Figure 52-8: IIR_COEFIDX Register Diagram

Table 52-9: IIR_COEFIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Coefficient Buffer Index. The `IIR_COEFIDX.VALUE` bit field provides the coefficient buffer index.

Coefficient Buffer Length Register

The `IIR_COEFLEN` register provides the coefficient buffer length.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R/W)
Coefficient Length
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

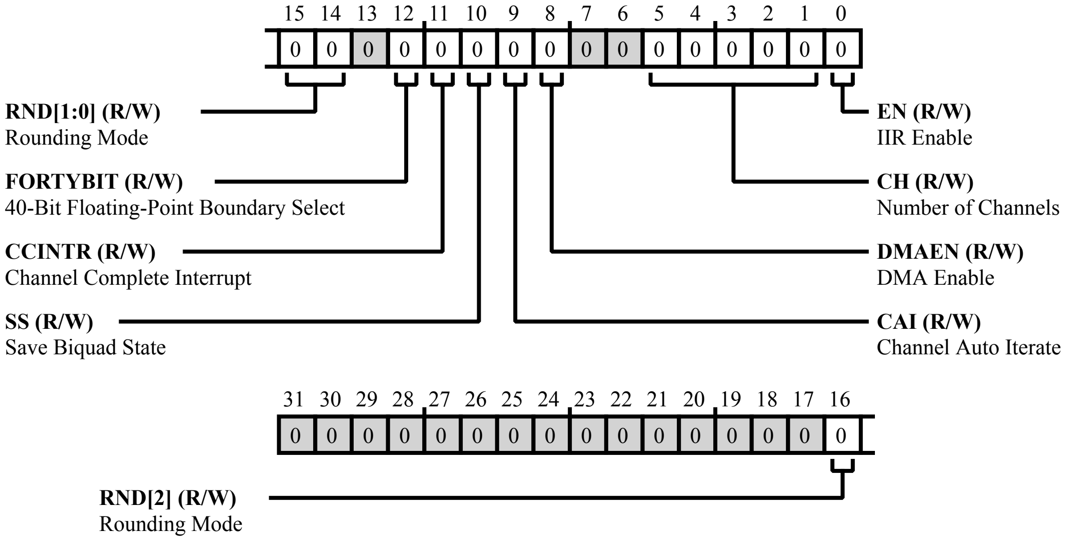
Table 52-11: IIR_COEFMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Coefficient Modifier. The `IIR_COEFMOD.VALUE` bit field provides the coefficient modifier.

Global Control Register

The IIR_CTL1 register is used to configure the global parameters for the accelerator. These parameters include the number of channels, channel auto iterate, DMA enable, and accelerator enable.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RND[1:0] (R/W)
Rounding Mode
FORTYBIT (R/W)
40-Bit Floating-Point Boundary Select
CCINTR (R/W)
Channel Complete Interrupt
SS (R/W)

EN (R/W)
IIR Enable
CH (R/W)
Number of Channels
DMAEN (R/W)
DMA Enable
CAI (R/W)
Channel Auto Iterate
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RND[2] (R/W)
Rounding Mode

Figure 52-11: IIR_CTL1 Register Diagram

Table 52-12: IIR_CTL1 Register Fields

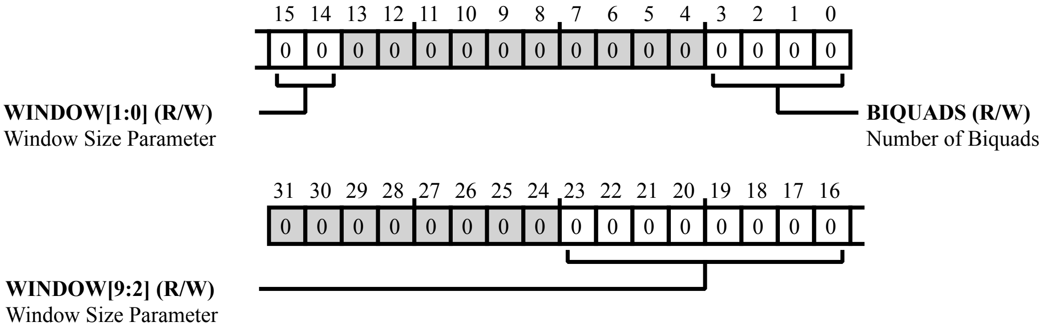
Bit No. (Access)	Bit Name	Description/Enumeration	
16:14 (R/W)	RND	Rounding Mode. The `IIR_CTL1.RND` bit field selects the rounding mode for floating-point format.	
		0	IEEE round to nearest (even)
		1	IEEE round to zero 010 = IEEE round to +ve infinity 011 = IEEE round to -ve infinity 100 = Round to nearest Up 101 = Round away from zero 110 = Reserved 111 = Reserved
12 (R/W)	FORTYBIT	40-Bit Floating-Point Boundary Select. The `IIR_CTL1.FORTYBIT` bit selects between 32-bit IEEE floating-point format or 40-bit IEEE floating-point format.	
		0	32-bit IEEE floating-point
		1	40-bit IEEE floating-point

Table 52-12: IIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	CCINTR	Channel Complete Interrupt. The `IIR_CTL1.CCINTR` bit configures the channel complete interrupt to generate when all channels are done or after each channel is done.	
		0	Interrupt is generated only when all channels are done (default)
		1	Interrupt is generated after each channels is done (default)
10 (R/W)	SS	Save Biquad State. The `IIR_CTL1.SS` bit configures the accelerator to store the Dk register settings into the internal memory. This can be used to save the biquad states before switching to another high priority accelerator task.	
9 (R/W)	CAI	Channel Auto Iterate. The `IIR_CTL1.CAI` bit sets whether TDM processing stops (idle) once all channels complete processing or moves to first channel and continues TDM processing in a loop when all channels complete processing.	
		0	TDM processing stops (idle) once all channels complete processing
		1	Moves to first channel and continues TDM processing in a loop when all channels complete processing
8 (R/W)	DMAEN	DMA Enable. The `IIR_CTL1.DMAEN` bit enables DMA on the accelerator.	
		0	Disable
		1	Enable
5:1 (R/W)	CH	Number of Channels. The `IIR_CTL1.CH` bit field configures the number of channels and is programmable between 0-23 (channels = NCH + 1).	
0 (R/W)	EN	IIR Enable. The `IIR_CTL1.EN` bit enables or disables the IIR accelerator.	
		0	IIR disabled
		1	IIR enabled

Channel Control Register

The `IIR_CTL2` register is used to configure the channel specific parameters. These parameters include the number of biquads and window size.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
WINDOW[1:0] (R/W)
Window Size Parameter
BIQUADS (R/W)
Number of Biquads
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
WINDOW[9:2] (R/W)
Window Size Parameter

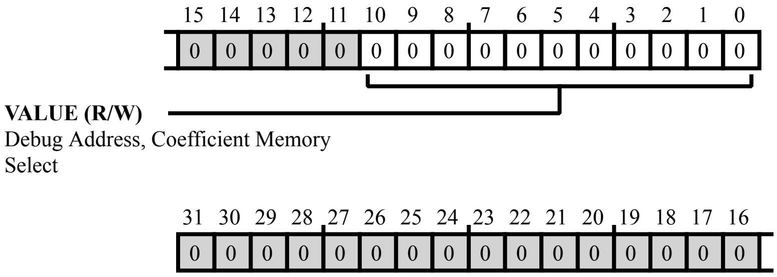
Figure 52-12: IIR_CTL2 Register Diagram

Table 52-13: IIR_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:14 (R/W)	WINDOW	Window Size Parameter. The `IIR_CTL2.WINDOW` bit field configures the window size which specifies the number of sample/block to process (sample based processing = window size of 1). This bit field should be programmed to "actual window size required -1". For example, for sample based processing this bit field should be programmed to 0.
3:0 (R/W)	BIQUADS	Number of Biquads. The `IIR_CTL2.BIQUADS` bit field configures the number of biquads and is programmable between 0-11 (number of Biquads = BIQUADS + 1).

IIR Debug Address Register

The `IIR_DBG_ADDR` register holds the debug address. If bit 11 is set, coefficient memory is selected.



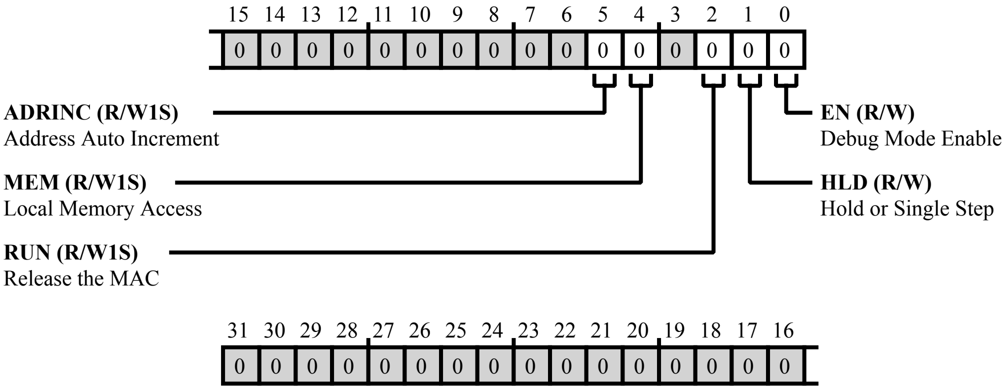
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R/W)
Debug Address, Coefficient Memory Select
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 52-13: IIR_DBG_ADDR Register Diagram

Table 52-14: IIR_DBG_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Debug Address, Coefficient Memory Select. The `IIR_DBG_ADDR.VALUE` bit field holds the debug address (bits 0-10). Bit 11 configures whether the memory access is to coefficient memory (=0) or to delay line memory (=1).

IIR Debug Control Register



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADRINC (R/W1S)
Address Auto Increment
MEM (R/W1S)
Local Memory Access
RUN (R/W1S)
Release the MAC
EN (R/W)
Debug Mode Enable
HLD (R/W)
Hold or Single Step
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

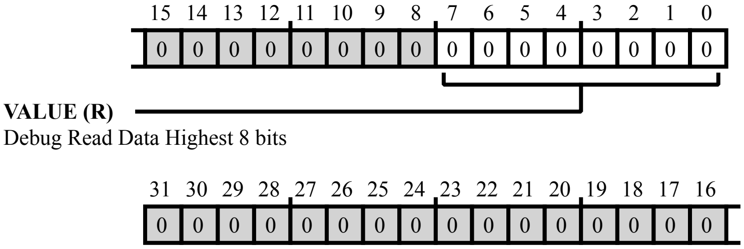
Figure 52-14: IIR_DBG_CTL Register Diagram

Table 52-15: IIR_DBG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1S)	ADRINC	Address Auto Increment. The `IIR_DBG_CTL.ADRINC` bit allows the address register to auto increment on `IIR_DBG_WRDAT_HI`/`IIR_DBG_WRDAT_LO` writes and `IIR_DBG_RDDAT_HI`/`IIR_DBG_RDDAT_LO` reads.	
4 (R/W1S)	MEM	Local Memory Access. The `IIR_DBG_CTL.MEM` bit allows the data and coefficients memory to be indirectly accessed.	
2 (R/W1S)	RUN	Release the MAC. The `IIR_DBG_CTL.RUN` bit releases the MAC and is is self clearing after one IIR clock cycle.	
1 (R/W)	HLD	Hold or Single Step. The `IIR_DBG_CTL.HLD` bit function is based on the `IIR_DBG_CTL.MEM` bit setting. For `IIR_DBG_CTL.MEM` = 0 this bit sets single step. For `IIR_DBG_CTL.MEM` = 1 this bit sets hold data.	
		0	No effect
		1	Single step (IIR_DBGMEM=0) or Hold data (IIR_DBGMEM=1)
0 (R/W)	EN	Debug Mode Enable. The `IIR_DBG_CTL.EN` bit enables debug mode. For local memory access, the `IIR_CTL1` register can be cleared.	
		0	Disable
		1	Enable

IIR Debug Read Data High Register

The `IIR_DBG_RDDAT_HI` register is part of the 40-bit wide debug mode read data register and holds the upper 8 bits.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R)
Debug Read Data Highest 8 bits
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

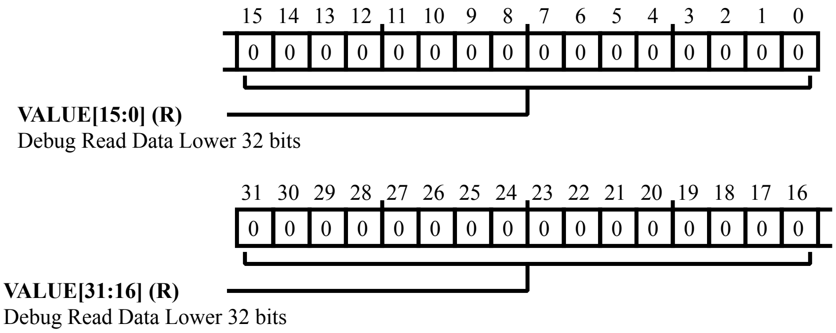
Figure 52-15: IIR_DBG_RDDAT_HI Register Diagram

Table 52-16: IIR_DBG_RDDAT_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	VALUE	Debug Read Data Highest 8 bits. The `IIR_DBG_RDDAT_HI.VALUE` bit field holds the upper 8-bit read data.

IIR Debug Read Data Low Register

The `IIR_DBG_RDDAT_LO` register is part of the 40-bit wide debug mode read data register and holds the lower 32 bits.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Write Back
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 52-19: IIR_DMASTAT Register Diagram

Table 52-20: IIR_DMASTAT Register Fields

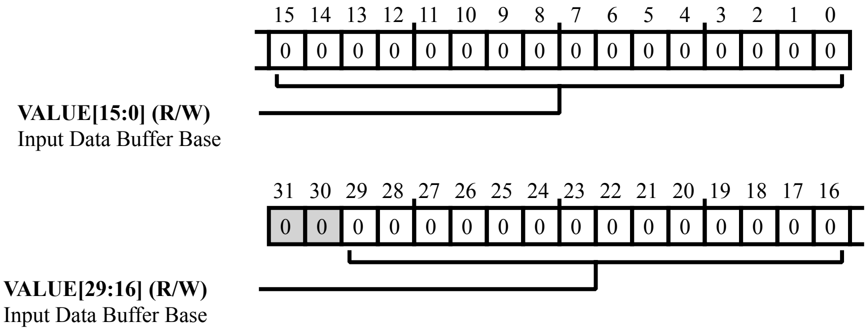
Bit No. (Access)	Bit Name	Description/Enumeration
11:7 (RC/NW)	CURCHNL	Current Channel. The IIR_DMASTAT.CURCHNL bit field indicates the channel that is being processed in the TDM slot. Zero indicates the last slot.
6 (RC/NW)	ACDONE	All Channels Done. The IIR_DMASTAT.ACDONE bit indicates all channels are done processing. Note that the IIR_CTL1.CCINTR bit does not affect this status bit. This bit is sticky and is cleared on register read.
5 (RC/NW)	WDONE	Current Channel Done. The IIR_DMASTAT.WDONE bit indicates the processing of the current channel is complete. Note that the IIR_CTL1.CCINTR bit does not affect this status bit. This bit is sticky and is cleared on register read.

Table 52-20: IIR_DMASTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	SVDK	Save Updated Dk State. If there is more than one channel (`IIR_CTL1.CH`>0), the `IIR_DMASTAT.SVDK` bit toggles between 0 and 1 as it starts and completes the save state operation on one channel at a time. Therefore, this bit is not a reliable indicator of completion of the save state operation for all channels. To ensure graceful completion of the save state operation, programs must poll both the `IIR_DMASTAT.CPLD` and `IIR_DMASTAT.SVDK` bits and ensure (`IIR_DMASTAT.CPLD` OR `IIR_DMASTAT.SVDK`) = 0 after the `IIR_DMASTAT.ACDONE` bit is set. The recommended method for minimizing core intervention is to configure the accelerator to generate an interrupt when the processing of all the channels is complete (the `IIR_CTL1.CCINTR` bit is set), then poll to ensure (`IIR_DMASTAT.CPLD` OR `IIR_DMASTAT.SVDK`) = 0 inside the interrupt service routine. To minimize the interrupt service time, the core can perform unrelated tasks before it starts polling for save state operation completion.
3 (R/NW)	WRBK	Write Back. The `IIR_DMASTAT.WRBK` bit indicates the accelerator is writing back updated index registers.
2 (R/NW)	PPGS	MAC Processing In Progress. The `IIR_DMASTAT.PPGS` bit indicates MAC processing is in progress.
1 (R/NW)	CDKLD	Coefficient and Dk Loading. The `IIR_DMASTAT.CDKLD` bit indicates the coefficient and Dk are loading.
0 (R/NW)	CPLD	Chain Pointer Loading Status. The `IIR_DMASTAT.CPLD` bit indicates the IIR is in the chain pointer load state. 0 State machine not in chain pointer load state 1 State machine in chain pointer load state

Input Buffer Base Register

The `IIR_INBASE` register contains the word address with the lower 2 bits removed.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
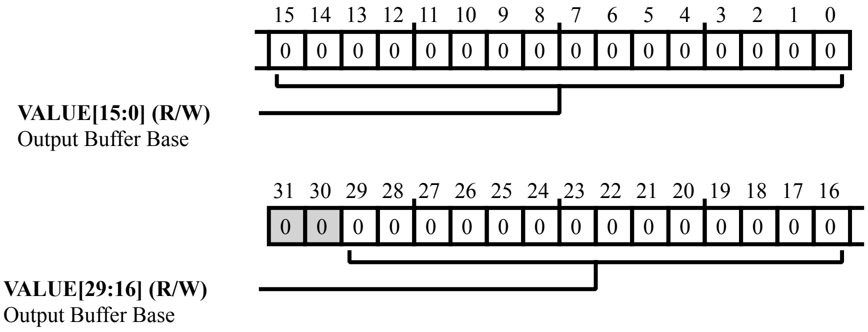
5 (R/NW)	AINV	Addition Invalid. The `IIR_MACSTAT.AINV` bit indicates the addition is invalid.
4 (R/NW)	ARI	Adder Result Infinity. The `IIR_MACSTAT.ARI` bit indicates the adder result is infinity.
3 (R/NW)	ARZ	Adder Result Zero. The `IIR_MACSTAT.ARZ` bit indicates the adder result is zero.
2 (R/NW)	MINV	Multiply Invalid. The `IIR_MACSTAT.MINV` bit indicates the multiply operation is invalid.
1 (R/NW)	MRI	Multiplier Result Infinity. The `IIR_MACSTAT.MRI` bit indicates the multiplier result is infinity.
0 (R/NW)	MRZ	Multiplier Result Zero. The `IIR_MACSTAT.MRZ` bit indicates the multiplier result is zero.

Output Buffer Base Register

The `IIR_OUTBASE` register contains the word address with the lower 2 bits removed.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Output Buffer Base
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

53 Boot ROM and Booting the Processor

Bootstrapping or booting is the series of events that occur when the system applies power to the processor or when the processor enters a hardware reset state. This section gives an in-depth description of these events and how to integrate an application effectively.

On reset, the processor begins fetching instruction from an internal ROM. The boot code contained within the ROM is designed to facilitate loading an application. The boot code can automatically initialize certain peripherals for communication based on a chosen boot mode, then load an application. For more information on what boot modes are available, see the Boot Modes section. The boot code can efficiently load an entire application, code, and data, into appropriate locations after the development tools repackage the application into a boot stream.

A boot stream is an application or data that the boot-loader tool splits into blocks. A 16-byte header in each block provides instruction to the boot code for processing the associated data. The processor can perform several boot functions, depending on the flags set in the header. For more details on what options are available and a description of the stream format, refer to the Boot Loader Stream section.

The boot ROM provides a mechanism through available non-volatile programmable memory (OTP on this processor) to customize different aspects of the boot process. These customizations include: overriding default boot-peripheral instance, overriding default peripheral-timing parameters and disabling boot modes.

Many of the utilities of the boot code are also available to the application. These utilities include features such as copying memory, comparing memory, or loading another boot stream at run time. The APIs may be used to help ensure that application code is more compatible with future products. For more details on available APIs, see the API Reference section.

In addition to APIs, the boot code provides the ability to define a custom boot mode. This capability helps when support is not available for a desired boot mode. It allows second stage boot loaders for unsupported boot peripherals to leverage a significant amount of the existing boot ROM functionality.

SRAM Requirements

The boot process reserves 8KB of L2 ECC Protected SRAM for dedicated use. This topic describes how the reserved memory region is utilized during boot.

The boot process requires SRAM resources for stack usage and for storage of various data items that require read write access during the boot process. 8KB of L2 ECC protected SRAM is reserved for this purpose. The table below describes the various items stored in this memory region.

Table 53-1: Boot Process SRAM Requirements

Address	Size (Bytes)	Item	Description
0x200BE000	4	Reserved	
0x200BE004	4	Pointer to the `ADI_ROM_BOOT_CONFIG` object	Pointer to the boot configuration structure that is located on the stack. This location can be used to find the location of the boot structure on the stack for debug purposes.
0x200BE008	8	Reserved	
0x200BE010	1024	Internal Intermediate Buffer 0	The first of two internal buffers used for intermediate storage of boot content when using indirect and page mode accesses and for secure boot operations. Two buffers are used to allow SHA-224 and AES-128 operations to be performed on one buffer while simultaneously loading the other buffer.
0x200BE410	1024	Internal Intermediate Buffer 1	The second of two internal buffers used for intermediate storage of boot content when using indirect and page mode accesses and for secure boot operations. Two buffers are used to allow SHA-224 and AES-128 operations to be performed on one buffer while simultaneously loading the other buffer.
0x200BE810	16	`ADI_ROM_BOOT_HEADER` object	Storage location for all the block headers of the boot stream.
0x200BE820	2912	Storage for Secure Boot related descriptors	Contains a number of buffers for the various descriptors used by the Cryptographic Accelerators as well as providing storage for the secure header of a secure boot stream.
0x200BF380	128	Cortex-A5 IRQ, FIQ, ABT and UND stacks	Exception handler stacks for the IRQ, FIQ, ABT and UND exceptions.
0x200BF400	3072	Stack for the boot process	The primary booting cores stack. Any processor core that is mastering a boot operation should locate the stack in this region in order to preserve security in secure boot operations.

NOTE: In order to preserve the security of the product the 8KB region described here is not a bootable region of memory. If the boot process determines that a block of data in the boot stream is targeted towards this memory region the boot process will terminate and enter either the default error handler or if applicable a user defined error handler if installed. This reserved memory region is free for use after the boot process completes. In order to preserve security when using the boot API to boot a secure boot stream, the stack used during the execution of the boot API must be located to the default location in this reserved 8KB region of memory.

Preboot Operations

Preboot is responsible for configuration of all system resources prior to executing the required boot operation.

The steps performed by the preboot process are described here in the order of execution. Numerous stages of the preboot process are conditional based upon the content of `RCU_BCODE`.

NOTE: Upon completion of a power on reset, hard reset and software triggered system reset events the processor is initially running by default in PLL Bypass mode. Partway through the preboot sequence the processor will be brought into full-on mode at the default settings unless the user has provisioned custom CGU settings in the OTP. The Oscillator Watchdog Fault, enabled by default upon reset completion will be disabled at this stage unless Oscillator Watchdogs settings are also supplied.

Start-up Sequence

This section describes the initial start-up sequence of all cores in the processor.

Upon completion of a power-on reset, hardware reset or system reset event, only a single core is released from reset and is responsible for managing the boot process. The following sections describe in detail the sequence of events that occur for each of the cores on the various product derivatives.

Core Reset Sequencing

System and Hardware reset events result in the processor state being reset and the boot sequence is executed. Only a single core is initially released from reset and starts execution of the preboot software from the boot ROM. The sequencing between the RCU and the various cores is shown for each of the product derivatives.

For the ADSP-SC583, ADSP-SC584, ADSP-SC587 and ADSP-SC589 derivatives, Core 0 is responsible for mastering the boot process. Cores 1 and 2 are held in reset until Core 0 releases them from reset during the preboot phase of the boot process. The initial sequence of events after the completion of the reset sequence are shown.

Core 0 Start-up

Describes the initial operations performed by Core 0 immediately after being released from reset and soft vector processing has completed. This topic is only applicable to the ADSP-SC58x processors.

Upon initial release from the reset event the soft vectoring process results in Core 0 executing the boot process as long as the `RCU_SVECT0` register contained the default reset value during the soft vector processing. The core performs the following initial operations:

- Set `VBAR` register to 0x00000020. This step installs a second vector table that is located in the boot ROM that has a reset vector pointing directly to the start of the boot process as opposed to the soft vector routine.
- Disable ECC in all 8 banks via `L2CTL_CTL` of `L2CTL1` and `L2CTL2` controllers that interface to the on-chip ROM memories
- Disable the MMU
- Disable L1 Cache
- Invalidate the TLB
- Disable Branch Prediction
- Read and store the contents of `RCU_STAT`
- Install the stack for the IRQ exception
- Install the stack for the FIQ exception
- Install the stack for the ABORT exception
- Install the stack for the UND exception
- Install the stack for the SVC mode of operation. The boot process runs in SVC mode and the stack installed is the main stack used for the complete boot process.

- Initialize the top 1024 bytes of the stack to initialize the corresponding ECC parity to allow for read access to the initial stack space. This step is bypassed if `RCU_BCODE.NOMEMINIT` is set.
- Call the preboot function passing the previously read `RCU_STAT` contents as an argument

NOTE: The USR and SYS modes of operation are never entered during the boot process and as such their stack are not configured during boot. The boot process runs entirely in SVC mode. User application software is required to install USR and SYS stacks in the secure mode of operation. For systems requiring security, user application software should also install a secure monitor and implement any additional security configuration before transitioning to the non-secure mode of operation.

Core 1 Start-up

Describes the initial operations performed by Core 1 immediately after being released from reset and soft vector processing has completed.

Upon initial release from reset the soft vectoring process results in Core 1 executing from the boot ROM as long as the `RCU_SVECT1` register contained the default reset value during the soft vector processing. The operations the core performs varies depending on the product.

ADSP-SC58x Processors

The following steps apply only to the ADSP-SC58x processors. Core 1 is not responsible for the booting of the processor from reset and thus enters a safe IDLE state allowing access to the cores L1 resources by any other core.

- Disable Software Return feature in the BTB
- Disable the BTB
- Disable ECC in all 8 banks via `L2CTL_CTL` of `L2CTL1` and `L2CTL2` controllers that interface to the on-chip ROM memories
- Set `RCU_MSG.C1IDLE`
- Enter and endless `IDLE` loop

ADSP-2158x Processors

The following steps only apply to the ADSP-2158x processors. Core 1 is responsible for mastering the boot process and the following actions are performed:

- Disable Software Return feature in the `BTB`
- Disable the `BTB`
- Disable ECC in all 8 banks via `L2CTL_CTL` of `L2CTL1` and `L2CTL2` controllers that interface to the on-chip ROM memories
- Disable cache via `MODE2` register
- Flush cache

- Set `IRPTL` to 0x00000000
- Configure primary and secondary DAG configurations to setup the C run-time environment
- Clear `CBUFEN`, `SRD1H`, `SRD1L`, `SRD2H`, `SRD2L`, `ALUSAT`, `TRUNCATE` in the `MODE1` register
- Set `IRPTEN`, `IPERREN`, `DPERREN`, `SPERREN`, in the `MODE1` register
- Set `MMASK` to 0x00000000
- Set `IMASK` to 0x00000000
- Initialize the top 1024 bytes of the stack to initialize the corresponding ECC parity to allow for read access to the initial stack space. This step is bypassed if `RCU_BCODE.NOMEMINIT` is set.
- Call the preboot function passing the contents of `RCU_STAT` as an argument

Table 53-2: Primary/Secondary DAG Configuration for C Run-Time Setup

Primary/Secondary DAG register	Value	Description
`M7, M15`	-1	Dedicated registers must always be set to -1
`M6, M14`	1	Dedicated registers must always be set to 1
`M5, M13`	0	Dedicated registers must always be set to 0
`L0-L5`	0	Preserved registers set initially to 0
`L6, L7`	0	Stack Length Register set initially to 0
`L8 - L15`	0	Preserved registers set initially to 0
`B6, B7`	0x200BF400	Stack Base Registers
`I7`	0x200BFFFC	Stack Pointer
`L6, L7`	0x00000BFD	Stack Length Registers
`I6`	0x200BFFFC	Frame Pointer

Core 2 Start-up

Describes the initial operations performed by Core 2 immediately after being released from reset and soft vector processing has completed. This topic applies to all derivatives except the ADSP-SC582.

Upon initial release from reset the soft vectoring process results in Core 2 executing from the boot ROM as long as the `RCU_SVECT2` register contained the default reset value during the soft vector processing. The operations the core performs varies depending on the product.

The following steps apply only to the ADSP-SC58x processors. Core 1 is not responsible for the booting of the processor from reset and thus enters a safe IDLE state allowing access to the cores L1 resources by any other core.

- Disable Software Return feature in the BTB
- Disable the BTB

- Disable ECC in all 8 banks via `L2CTL_CTL` of `L2CTL1` and `L2CTL2` controllers that interface to the on-chip ROM memories
- Set `RCU_MSG.C2IDLE`
- Enter and endless `IDLE` loop

Idle On Entry

The Idle On Entry implementation allows a means for a debugger to perform a system of the processor and halt the boot code before continuing with any further preboot operations.

When this feature is enabled the processor will execute a WFI/IDLE instruction and then continue once an event such as an emulator exception is serviced.

NOTE: Idle On Entry processing is disabled by default and may be optionally enabled by setting `RCU_BCODE.IDLEONENTRY` prior to performing a system reset operation.

Fault Configuration

Describes the initial fault sources that are enabled allowing the processor to signal a fault to the system.

The following faults are enabled via the `SEC`. Please note that only the faults are enabled, the boot process does not install any `SEC` interrupts.

Table 53-3: Initial Faults installed during Preboot

SEC Fault ID	SEC Fault Name	Description
1	`INTR_SEC0_ERR`	SEC Error
3	`INTR_WDOG0_EXP`	WDOG Expire
4	`INTR_WDOG1_EXP`	WDOG Expire
178	`INTR_CRC0_ERR`	CRC Error
179	`INTR_CRC1_ERR`	CRC Error
5	`INTR_OTPC0_ERR`	OTPC Error
47	`INTR_SOFT3_INT`	`Software Driven Interrupt 3`. This is raised in the boot rom error handler should it be entered.

The SEC is configured to have a fault delay of 0x100 via `SEC_FDLY.COUNT` and `SEC_FSRDLY.COUNT`. This allows for a delay to be implemented before assertion of the fault should a customer error handler be installed and any SEC interrupts enabled and handled for more advanced second stage boot scenarios.

The `SYS_FAULT`pins are configured via the SEC to support both incoming and out going faults by enabling both `SEC_FCTL.FIEN` and `SEC_FCTL.FOEN`. This allows the boot process to capture an incoming fault if asserted by the external system upon handover to the user application after boot.

NOTE: The installation of the fault sources is enabled by default and may be optionally bypassed via `RCU_BCODE.NOFAULTS`.

Faults are also disabled when the `NOBOOT` boot mode is enabled.

SPU Configuration

The SPU is configured differently depending upon the detected security state of the device. The first operation clears any existing security violations that may be indicated via `SPU_STAT`.

For an open device, a device that has not had the locked bit set in OTP. The boot process makes all peripherals ignore security signals by setting `SPU_SECURECTL.SSECCLR`.

If the security state of the processor is locked then none of the peripherals are configured to ignore security signals and only the following masters are configured to generate secure transactions.

Table 53-4: Locked Processor SPU Secure Masters During Boot

SPU Endpoint ID	Master Name
88	MDMA0 Source DMA Channel
89	MDMA0 Destination DMA Channel
90	MDMA1 Source DMA Channel
91	MDMA1 Destination DMA channel
10	CRC0
11	CRC1
162	PKTE

SMPU Configuration

The SMPU is used to restrict access to various memory regions in the processor. The configuration applied during boot differs depending on the locked state of the processor.

By default the SMPU instances only allow secure read and write transactions. The tables below describe the configurations for the different security states.

Table 53-5: SMPU Configuration

SMPU Instance	SMPU Instance	Open `SMPU_SECURECTL` Value	Locked `SMPU_SECURECTL` Value
SMC	0	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)
Core_L2_RAM_Boot_ROM0	2	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)
DMA_L2_RAM_Boot_ROM0	3	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)

Table 53-5: SMPU Configuration (Continued)

SMPU Instance	SMPU Instance	Open `SMPU_SECURECTL` Value	Locked `SMPU_SECURECTL` Value
Core_L2_ROM1_Boot_ROM1	4	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)
DMA_L2_ROM1_Boot_ROM1	5	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)
Core_L2_ROM2_Boot_ROM2	6	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)
DMA_L2_ROM2_Boot_ROM2	7	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)
DMC0	9	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)
DMC1	10	`SMPU_SECURECTL.WNSEN` | `SMPU_SECURECTL.RNSEN`	0x00000000 (Default Reset Value)

Speculative reads are also disabled by setting `SMPU_CTL.RSDIS`.

Secure Debug Key Processing

In the event the processor is locked, a secure debug key is required to be submitted via the debug tools and matched with a key on the processor. A 128-bit Secure Debug Key must be provisioned by user prior to locking the device.

The secure debug key is read from the OTP memory and then written to the corresponding register in the TAPC. After the key has been written the `TAPC_SDBGKEY_CTL.VALID` bit is set then allowing for a key compare operation to be performed once the debug tools then submit their key.

It is important that the debug tools wait for the boot software to load the key then set the `TAPC_SDBGKEY_CTL.VALID` before submitting the key for comparison.

The 128-bit Secure Debug Key is loaded as follows from the storage area in OTP.

Table 53-6: Secure Debug Key Load Procedure

Secure Debug Key[127:0]	Register
Secure Debug Key[31:0]	`TAPC_SDBGKEY0`
Secure Debug Key[63:32]	`TAPC_SDBGKEY1`
Secure Debug Key[95:94]	`TAPC_SDBGKEY2`
Secure Debug Key[127:96]	`TAPC_SDBGKEY3`

CAUTION: A key of 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF provisioned in OTP will result in the boot code bypassing the key load operation entirely. If debug access is then ever required the key must be loaded to the TAPC by user software. If the processor fails to boot perhaps due to corrupted firmware then the user will have no debug access. The only way to gain access would be to load an authenticated boot image that can then load the required keys prior to attempting to connect with a debugger.

CGU Configuration

Reconfigures the internal clocks on the processor for improved boot performance.

The boot process can optionally configure the CGU in order to improve boot performance. The settings to be applied to the CGU are located within the `ADI_ROM_OTP_BOOT_CGU_INFO` structure that has storage allocated in the OTP as part of the `ADI_ROM_OTP_BOOT_INFO` structure.

Typically, CGU configuration would be performed through the use of an Init Block in the boot stream. This provides greatest flexibility. In situations where boot time must be kept to a minimum, provide settings in the OTP that can be applied at this stage of preboot as opposed to during the boot process itself. When a processor is locked, the boot process does not support an Init Block in the boot stream. For a locked processor users must use the OTP in order to reconfigure the clocks without adopting a multi-stage boot strategy.

When the processor is initially released from reset, the CGU is configured for PLL Bypass mode. In order to improve boot performance the boot software reconfigures the CGUsuch that Full-On mode is entered with the default CGU settings. If the user has not supplied settings in OTP to configure the Oscillator Watchdog then the Oscillator watchdog fault, enabled by default after reset, is disabled prior to reconfiguring the CGU. If settings are provisioned in the OTP to configure the Oscillator Watchdog the fault is left enabled and if applicable the CGU is configured per the provided settings. The remainder of the boot process completes in Full-On mode.

Table 53-7: ADI_ROM_OTP_BOOT_CGU_INFO Members

Type	Name	Description
`uint32_t`	`ctl_WEN:1` (bitfield)	Enable write to the `CGU_CTL` register
`uint32_t`	`div_WEN:1` (bitfield)	Enable write to the `CGU_DIV` register
`uint32_t`	`reserved0:1` (bitfield)	Reserved
`uint32_t`	`div_DSEL:5` (bitfield)	`CGU_DIV.DSEL` value
`uint32_t`	`div_CSEL:5` (bitfield)	`CGU_DIV.CSEL` value
`uint32_t`	`div_S0SEL:3` (bitfield)	`CGU_DIV.S0SEL` value

`uint32_t`	`oscwctl1_HODF:6` (bitfield)	`CGU_OSCWDCTL.HODF` value
`uint32_t`	`oscwctl1_HODEN:1` (bitfield)	`CGU_OSCWDCTL.HODEN` value
`uint32_t`	`oscwctl1_CNGEN:1` (bitfield)	`CGU_OSCWDCTL.CNGEN` value
`uint32_t`	`oscwctl1_BOUF:5` (bitfield)	`CGU_OSCWDCTL.BOUF` value
`uint32_t`	`oscwctl1_BOUEN:1` (bitfield)	`CGU_OSCWDCTL.BOUEN` value
`uint32_t`	`oscwctl1_FAULTEN:1` (bitfield)	`CGU_OSCWDCTL.FAULTEN` value

Table 53-7: ADI_ROM_OTP_BOOT_CGU_INFO Members (Continued)

Type	Name	Description
`uint32_t`	`oscwctl1_MONDIS:1` (bitfield)	`CGU_OSCWDCTL.MONDIS` value
`uint32_t`	`oscwctl1_FAULTPINDIS:1` (bitfield)	`CGU_OSCWDCTL.FAULTPINDIS` value
`uint32_t`	`reserved2:28` (bitfield)	Reserved

If a `CGU_STAT.WDIVERR`, `CGU_STAT.WDFMSERR`, `CGU_STAT.LWERR` or `CGU_STAT.ADDRERR` is either present upon entry to the configuration routine or upon completion of the configuration then the default error handler is called and the boot process terminates.

NOTE: The configuration of the CGU will be bypassed if `RCU_BCODE.NOPREBOOT` is set when this part of the boot process is reached.

Releasing All Cores From Reset

The master booting core releases all other cores from reset allowing them to then run by default into a safe endless loop state. By releasing all other cores from reset any dedicated core L1 memories then become accessible to all cores via the system address space.

In order for one core to load or read data from another cores dedicated L1 memory. The core must be released from the reset state. By default the other cores in the processor execute a safe endless loop in the boot ROM.

L1/L2 Memory Initialization

The processor initializes all parity and ECC protected memories allowing for subsequent read operations to be performed without generation of an ECC or parity error.

The table below describes the methods used to initialize the various parity and ECC supported memories on the processor.

Table 53-8: L1/L2 Memory Initialization

Resource To Fill Memory	Memory Type	Address	Count	Fill Value	Flag Set Upon Completion
Core 1	Core 1 L1 Bank 0	0x00048000	0x5000 (LW)	0x00000000	`RCU_MSG.C1L1INIT`
Core 1	Core 1 L1 Bank 1	0x00058000	0x5000 (LW)	0x00000000	
Core 1	Core 1 L1 Bank 2	0x00060000	0x4000 (LW)	0x00000000	
Core 1	Core 1 L1 Bank 3	0x00070000	0x4000 (LW)	0x00000000	

Table 53-8: L1/L2 Memory Initialization (Continued)

Resource To Fill Memory	Memory Type	Address	Count	Fill Value	Flag Set Upon Completion
Core 2	Core 2 L1 Bank 0	0x00048000	0x5000 (LW)	0x00000000	`RCU_MSG.C2L1INIT`
Core 2	Core 2 L1 Bank 1	0x00058000	0x5000 (LW)	0x00000000	
Core 2	Core 2 L1 Bank 2	0x00060000	0x4000 (LW)	0x00000000	
Core 2	Core 2 L1 Bank 3	0x00070000	0x4000 (LW)	0x00000000	
MDMA0\CRC0	System L2 RAM	0x20080000	0x20000 (BW)	0x00000000	`RCU_MSG.L2INIT`
MDMA1\CRC1	System L2 RAM	0x200A0000	0x1FC00 (BW)	0x00000000	

NOTE: The Memory Initialization process is enabled by default and may be optionally bypassed by setting `RCU_BCODE.NOMEMINIT`.

Default Application Entry Points

The core sets default application entry points for all cores in the processor. This step is performed in the event a boot stream does not contain blocks that specify the application entry point.

The table below defines the default application entry points for each core in the processor.

Table 53-9: RCU_SVECTn Default Application Entry Points

Core ID	Corresponding RCU_SVECTn Register	Application Entry Point
0	`RCU_SVECT0`	0x20080000
1	`RCU_SVECT1`	0x00090004
2	`RCU_SVECT2`	0x00090004

The values defined here get overwritten by First Block located within the boot stream.

NOTE: The initialization of the `RCU_SVECT0` register is enabled by default and may be optionally bypassed by setting `RCU_BCODE.NOVECTINIT`.

Memory Faults Configuration

Describes the memory fault sources that are enabled allowing the processor to signal a fault to the system in the even of a memory error.

The following faults are enabled via the `SEC`. Please note that only the faults are enabled, the boot process does not install any `SEC` interrupts.

Table 53-10: Memory Faults installed during Preboot

SEC Fault ID	SEC Fault Name	Description
8	`INTR_L2CTL0_ECC_ERR`	L2 ECC Error
23	`INTR_C0_L1_PERR`	Core 0 L1 Parity Error

The SEC is configured to have a fault delay of 0x100 via `SEC_FDLY.COUNT` and `SEC_FSRDLY.COUNT`. This allows for a delay to be implemented before assertion of the fault should a customer error handler be installed and any SEC interrupts enabled and handled for more advanced second stage boot scenarios.

The `SYS_FAULT`pins are configured via the SEC to support both incoming and out going faults by enabling both `SEC_FCTL.FIEN` and `SEC_FCTL.FOEN`. This allows the boot process to capture an incoming fault if asserted by the external system upon handover to the user application after boot.

NOTE: The installation of the fault sources is enabled by default and may be optionally bypassed via `RCU_BCODE.NOFAULTS`.

Faults are also disabled when the `NOBOOT` boot mode is enabled.

NO-BOOT Processing

No-Boot mode is executed on supported devices when selected by the `SYS_BMODE[n]` pins. The boot mode is intended as a recovery boot mode or for debug purposes. The core simply executes in an endless loop in the boot ROM thus terminating further execution of the boot process.

This boot mode is primarily intended for debug sessions when no boot source may be configured. It allows for a debugger to safely connect to the device and take control assuming the debugger has been granted access rights as defined by the processor security implementation.

NOTE: NO-BOOT processing is usually only entered as a result of the boot mode pin sampling resulting in execution of the No-Boot boot mode. This processing can also be optionally enabled by setting `RCU_BCODE.HALT`. The setting of `RCU_BCODE.HALT`can be especially useful for debug sessions to force the execution of the NO-BOOT mode regardless of the `SYS_BMODE[n]` state allowing a user application to be loaded via the debug tools without fear of the image being corrupted as a result of attempting to boot through another source.

SYS_RESOUTb Processing

The `SYS_RESOUT` pin can be used to signal to the external system that the processor is now in a state where it is ready boot

In order to signal to the external system that the processor in now in a configured state and ready to start the boot process, the boot software de-asserts the `SYS_RESOUT` pin via `RCU_CTL.RSTOUTDSRT`.

DMC Configuration

Configures the DMC to allow booting directly to external DDR memory. Primarily intended to support booting to external memory when the processor is locked.

In order to boot to external DDR memories the DMC must be configured. Typically DMC configuration would be done with the support of

Typically, DMC configuration would be performed through the use of an Init Block in the boot stream. This provides greatest flexibility. When a processor is locked however, the boot process does not support an Init Block in the boot stream. For a locked processor users must use the OTP in order to configure the DMC without adopting a multi-stage boot strategy.

The table below provides details of the OTP region that is used to store theDMC configuration to be applied. In addition to the settings described in the table below `ADI_ROM_OTP_BOOT_CFG::dmcEn` must be set in order for the settings to be applied.

There is an additional single bit located in OTP, `ADI_ROM_OTP_BOOT_CFG::dmcInv`, allowing users to invalidate the DMC settings stored in OTP.

NOTE: Once `ADI_ROM_OTP_BOOT_CFG::dmcInv` has been set in OTP there is no means to configure the DMC during the preboot phase.

Table 53-11: ADI_ROM_OTP_DMC_CONFIG Members

Type	Name	Description
`uint32_t`	`reserved0:10` (bitfield)	Reserved
`uint32_t`	`ulDDR_DLLCTL:12` (bitfield)	Contents of `DMC_DLLCTL [11:0]`
`uint32_t`	`ulDDR_EMR2:8` (bitfield)	Contents of `DMC_EMR2 [7:0]`
`uint32_t`	`reserved1:2` (bitfield)	Reserved
`uint32_t`	`ulDDR_CFGCTL`	Packed content of `DMC_CTL` Register, `DMC_CFG` registers.
`uint32_t`	`ulDDR_MREMR1`	Packed content of `DMC_EMR1` Register, `DMC_MR` registers.
`uint32_t`	`ulDDR_TR0`	Content of `DMC_TR0`
`uint32_t`	`ulDDR_TR1`	Content of `DMC_TR1`
`uint32_t`	`ulDDR_TR2`	Content of `DMC_TR2`
`uint32_t`	`ulDDR_PHYCTL0`	Content of `DMC_PHY_CTL0`
`uint32_t`	`ulDDR_PHYCTL145`	Packed content of `DMC_PHY_CTL1` , `DMC_PHY_CTL4` and `DMC_PHY_CTL5` registers.
`uint32_t`	`ulDDR_PHYCTL2`	Content of `DMC_PHY_CTL2`
`uint32_t`	`ulDDR_PHYCTL3`	Content of `DMC_PHY_CTL3`

Table 53-11: ADI_ROM_OTP_DMC_CONFIG Members (Continued)

Type	Name	Description
`uint32_t`	`ulDDR_CAL_PADCTL0_PHY_STAT3_0`	Packed content of `DMC_CAL_PADCTL0` , `DMC_PHY_STAT0` , and `DMC_PHY_STAT3` registers.
`uint32_t`	`ulDDR_CAL_PADCTL2`	Content of `DMC_CAL_PADCTL2`

NOTE: The configuration of the DMC will be bypassed if `RCU_BCODE.NOPREBOOT` is set when this part of the boot process is reached.

Bypassing the Boot Process

It is possible to bypass the actual booting process and execute from the address stored in the cores soft vector register. This can be useful when working in emulation sessions as it provides a mechanism to be able to execute directly from an accessible memory that already contains executable code.

The boot process can be bypassed by setting `RCU_BCODE.NOKERNEL` and the core will instead vector to the address stored in the cores corresponding `RCU_SVECT[n]` register instead of calling the required boot mode.

This feature would often be used along with other features such as disabling of memory initialization.

Boot Mode Disable

Specific boot modes can be permanently disabled via OTP resulting in a boot error should the disabled boot mode be enabled via the `SYS_BMODE[n]` pins.

A byte of storage is provided in the OTP allowing for disabling of up to 8 boot modes. The boot mode disable field can be programmed using the `adi_rom_otp_pgm()` routine. The `otp_data::bootModeDisable` member is used in the program operation to disable the various boot modes.

`otp_data::bootModeDisable` Bit Position	Corresponding Boot Mode
0	SPI Master Boot Mode
1	SPI Slave Boot Mode
2	Reserved
3	Reserved
4	Reserved
5	LINKPORT Slave Boot Mode
6	UART Slave Boot Mode
7	Reserved

Boot Command Customization

Boot Command Customization allows for the permanent customization of a particular boot mode. For example it is possible to change the peripheral instance that is used for the boot operation.

Storage is provide in OTP for a `command` item for each of the supported boot modes. The storage is provided in the `ADI_ROM_OTP_BOOT_CMD_INFO` member of `ADI_ROM_OTP_BOOT_INFO` . Refer to the corresponding boot modes boot command description for details on the supported command options.

NOTE: Before programming the boot command to the OTP. It is advisable to thoroughly evaluate the boot command using the `adi_rom_Boot()` API to ensure the boot command provides the desired functionality. Once the command is programmed to OTP there is no means to revert to the original default settings.

Boot Mode Specific SPU Configuration

Prior to performing the actual boot process, the processors SPU resources specific to the boot mode selected are configured. This is performed in the preboot phase as opposed to within the boot mode itself when calling the boot API as it isolates the security functionality of the processor allowing it to be handled specifically by a separate process.

The following additional SPU resources are configured as secure masters according to the boot mode selected.

Table 53-12: Boot Mode Specific SPU Configuration

Boot Mode	SPU Endpoint ID	Master Name
SPI Master Boot (Memory Mapped Mode)	88, 89	MDMA0 Source DMA Channel, MDMA0 Destination DMA Channel
SPI Master Boot (Peripheral Mode)	106, 104, 102	SPI2 Receive DMA, SPI1 Receive DMA, SPI0 Receive DMA
SPI Slave Boot	106, 104, 102	SPI2 Receive DMA, SPI1 Receive DMA, SPI0 Receive DMA
UART Slave Boot	82, 84, 86	UART 0 Receive DMA, UART1 Receive DMA, UART2 Receive DMA
LINKPORT Slave Boot	5, 6	LINKPORT0 DMA, LINKPORT1 DMA

NOTE: Note that for a given boot mode in the table not all the SPU resources are configured. Only a single peripheral instance is enabled according the peripheral instance selected for boot. For example if the boot command for the boot mode indicates boot from UART0 only the UART0 Receive DMA is configured, the other UART Receive DMAs are not configured for secure access.

Executing the Boot Mode

The boot mode is called using the `adi_rom_Boot()` routine resulting in the fetching and processing of the boot stream from the configured boot source.

The table below provides default parameters passed to each of the supported boot modes. For details on the API usage please refer to `adi_rom_Boot()`.

Table 53-13: Default Boot ROM API Parameters

Boot Mode	`pAddress`	`flags`	`blockCount`	`pHook`	`command`
No Boot	0x00000000	0x00000000	0x00000000	ARM: 0x00000301 SHARC: 0x00b003e5	0x00000000
SPI Master Boot	0x60000000	0x00040000	0x00000000	ARM: 0x00000301 SHARC: 0x00b003e5	0x00010207
SPI Slave Boot	0x00000000	0x00000000	0x00000000	ARM: 0x00000301 SHARC: 0x00b003e5	0x00000212
Reserved	0x00000000	0x00000000	0x00000000	ARM: 0x00000301 SHARC: 0x00b003e5	0x00000000
Reserved	0x00000000	0x00000000	0x00000000	ARM: 0x00000301 SHARC: 0x00b003e5	0x00000000
Reserved	0x00000000	0x00000000	0x00000000	ARM: 0x00000301 SHARC: 0x00b003e5	0x00000000
LINKPORT Slave Boot	0x00000000	0x00000000	0x00000000	ARM: 0x00000301 SHARC: 0x00b003e5	0x00000014
UART Slave Boot	0x00000000	0x00000000	0x00000000	ARM: 0x00000301 SHARC: 0x00b003e5	0x00000013

The hook function installed via `pHook`on this product performs no additional configuration.

Boot Modes

The boot implementation provides built-in support for booting from various peripherals. The ***Booting Modes*** table describes the supported boot modes.

In *slave* boot modes, the processor functions as a slave to any host device. In these modes, the host device usually controls the processor `SYS_HWRST` input. Typically, the host applies the reset sequence and waits until the processor is ready to boot, depending on the peripheral in use, and transmits the boot stream data to the processor. Handshake signals are most likely used to signal to the host that the processor is ready to accept more data.

In a *master* boot modes, the processor controls the peripheral and requests data via the peripheral as and when required.

Individual boot modes can be disabled. For more information about disabling boot modes, see Boot ROM OTP Customizations.

Table 53-14: Booting Modes

SYS_BMODE[2:0]	Boot Source	Description
000	No Boot	The processor does not boot. Rather the boot kernel executes some of the preboot operations then enters and endless `WFI`/`IDLE`state.
001	SPI Master Boot	Boot from integrated Flash memory through the SPI2 peripheral configured for memory mapped mode.
010	SPI Slave Boot	Boot through the SPI2 peripheral configured as a slave
011	Reserved	
100	Reserved	
101	Reserved	
110	LINKPORT Boot	Boot through LINKPORT0 peripheral configured as a slave receiver
111	UART Boot	Boot through UART0 peripheral configured as a slave receiver

No-Boot Mode

No-Boot mode is intended for device-recovery purposes caused by incorrect programming of the boot source memory allowing for target connection through an emulator. Emulation tools can also leverage the No-Boot functionality allowing for debug sessions to run the preboot software prior to loading an application while preventing the boot process from continuing and clobbering data loaded by the emulator.

This boot mode results in a number of preboot operations being performed before then placing the core into a safe endless loop located in the boot ROM. For a complete list of operations performed when No-Boot is selected please refer to Preboot Operations. The core terminates at the NO-BOOT Processing stage of the preboot process.

SPI Master Boot Mode

The SPI master boot routine provides support for booting the processor from SPI flash memories.

The SPI boot mode utilizes a device auto-detection feature that is enabled by default allowing for the boot stream itself to instruct updates to the SPI configuration and the read command used allowing for more efficient transactions.

Boot From External SPI Flash Devices

The SPI boot mode supports booting from 24-bit addressable flash devices. The boot mode uses the MDMA channels by default and configures the SPI flash for memory mapped functionality. Peripheral DMA mode is also supported when calling the boot mode via `adi_rom_Boot()`. Support for 32-bit addressable flash devices can be achieved by disabling the device auto-detection and supplying the required configuration via the `command` parameter.

When auto-device detection is enabled, the SPI memory is initially read using the standard 0x03 SPI read command with a reduced clocking frequency for maximum compatibility. The first nibble of the boot stream is then used to reconfigure the SPI interface and possible the SPI flash. Refer to SPI Device Detection Routine.

NOTE: Support for automatic device detection via the first nibble of the boot stream is not supported when booting secure boot streams. Instead when signing the boot image an attribute can be set in the image header that specifies the configuration to use.

For booting, the SPI memory is connected as shown in the ***SPI Memory Connections*** figure.

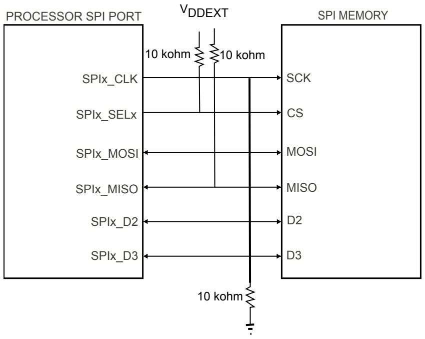

Figure 53-1: SPI Memory Connections

The pull-up resistor on the slave select signal ensures that the memory is deselected when the pin is in a high-impedance mode such as during reset.

Initialization codes are allowed to manipulate `ADI_ROM_BOOT_CONFIG::dBootCommand` to extend the boot mechanism to a second SPI memory connected to another slave select pin. Updating the field that specifies the slave select signal for use allows the boot process to manage larger boot streams than are able to fit in a single SPI device.

NOTE: If modifying the slave select signal used during the boot process, configure the pin multiplexing to enable the correct functionality for the pin. Once the boot process has proceeded past the configuration function and the boot process has actually started, the boot kernel will not perform any further pin multiplexing operations.

For SPI master boot peripheral mode, the `SPE`, `MSTR`, and `SZ` bits are set in the `SPIx_CTL` register. The `TIMOD=2` bits enable the receive DMA mode. The `CPOL` and `CPHA` bits are set by default, resulting in SPI mode 3. The boot kernel does not allow SPIx hardware to control the `SPI_SEL[n]` pin. Instead, software toggles this pin.

SPI Device Detection Routine

Since the boot mode supports booting from various SPI memories, the boot kernel automatically detects what type of memory is connected. To determine whether the SPI memory device requires an 8, 16, 24, or 32-bit addressing scheme, the boot kernel performs a device detection sequence prior to booting. The `SPI_MISO` signal requires a pull-up resistor. The routine relies on the fact that memories do not drive their data outputs unless the right number of address bytes are received.

Initially, the boot kernel transmits the read command on the `SPI_MOSI` line. Once the command has been sent, the boot kernel proceeds to transmit a single address byte and waits until the receive FIFO indicates that the buffer is no longer empty. The first received byte is discarded. The boot code then proceeds to issue another address byte while simultaneously receiving a byte. The process continues until a non-0xFF or 0x00 byte is received or until the full 4 address bytes is sent without any valid data being returned.

The receiving of a non-0x00 or 0xFF byte tells the boot code whether the memory device requires 8, 16, 24, 32 address bits. The lower nibble of the received byte is then used to further customize the boot mode. This nibble is referred to as the `BCODE`. The boot code applies settings to the SPI peripheral according to the ***SPI Master Boot BCODE Descriptions***.

If the received value equals 0x00 or 0xFF, it is assumed that the memory device has not driven its data output thus, another zero byte is transmitted and the received data is tested again.

If the value still equals 0xFF, device detection continues. Device detection aborts immediately when a byte different than 0xFF is received. The boot process continues with normal boot operation and it re-issues a command to re-read from address 0. Two read sequences load the first block header. Separate read sequences load further block headers and block payload fields.

The ***SPI Device Detection Principle*** figure illustrates how individual devices behave.

Table 53-15: SPI Master Boot BCODE Descriptions

BCODE	Mode	Command	Dummy Bytes	Data Lines	Address Lines	SPI Clock	Purpose
0x0	Init	Init	Init	Init	Init	Init	Unused
0x1	STANDARD	0x03	0	1	1	SCLK0/16	Legacy single-bit SPI mode
0x2	STANDARD	0x03	0	1	1	SCLK0/4	Legacy single-bit SPI mode
0x3	FAST READ	0x0B	1	1	1	SCLK0/2	Single bit with dummy address byte

Table 53-15: SPI Master Boot BCODE Descriptions (Continued)

BCODE	Mode	Command	Dummy Bytes	Data Lines	Address Lines	SPI Clock	Purpose
0x4	FAST READ	0x0B	1	1	1	SCLK0/2	Single bit with dummy address byte. `SPI_CTL.FMODE` is enabled for full cycle access.
0x5	STANDARD	0x03	0	1	1	SCLK0/3	Legacy single bit. `SPI_CTL.FMODE` is enabled for full cycle access.
0x6	FAST READ	0x0B	1	2	1	SCLK0/1	Single bit with dummy byte. `SPI_CTL.FMODE` is enabled for full cycle access.
0x7	RAPID-S	0x1B	2	2	2	SCLK0/1	Single bit with dummy bytes. `SPI_CTL.FMODE` is enabled for full cycle access.
0x8	DOR	0x3B	1	2	1	SCLK0/2	Dual bit data. `SPI_CTL.FMODE` is enabled for full cycle access.
0x9	DIOR	0xBB	1	2	2	SCLK0/2	Dual data and address. `SPI_CTL.FMODE` is enabled for full cycle access.
0xA	QOR READ (Quad Mode Method 1)	0x6B	1	4	1	SCLK0/2	Quad bit data mode using quad enable method 1 with `SPI_CTL.FMODE` is enabled for full cycle access.
0xB	QIOR READ (Quad Mode Method 1)	0xEB	3	4	4	SCLK0/2	Quad data and address using quad enable method 1 with `SPI_CTL.FMODE` is enabled for full cycle access.
0xC	QOR READ (Quad Mode Method 2)	0x6B	1	4	1	SCLK0/2	Quad data using quad mode enable method 2. `SPI_CTL.FMODE` is enabled for full cycle access
0xD	QIOR READ (Quad Mode Method 2)	0xEB	3	4	4	SCLK0/2	Quad data and address using quad mode enable method 2. `SPI_CTL.FMODE` is enabled for full cycle access
0xE	QIOR READ (Quad Mode Method 3)	0xEB	3	4	4	SCLK0/2	Quad data and address using quad mode enable method 3. `SPI_CTL.FMODE` is enabled for full cycle access
0xF	Init	Init	Init	Init	Init	Init	Unused

NOTE: For all the above configurations the addressing scheme is also set to a fixed 3-bytes for 24-bit addressable flash support only. The SPI mode byte issued for all the SPI Master peripheral based configurations is 0x00. The mode byte is the first byte transmitted after the address cycles and is used to control the continuous read mode functionality in which the next read operation is not required to issue a command cycle. Continuous read mode is not supported during the boot process.

Supported Quad Mode Enable Methods

The boot rom supports the following methods for enabling quad mode on the SPI flash device

NOTE: Please note that the procedures listed here write to a non-volatile register in the SPI flash. There are typically delays implemented with writes to such registers and these need to be accounted for in the boot time. If the flash supports a non-volatile setting using a different procedure from those supported here then it may be more beneficial to boot initially in dual mode and use an initcode to enable quad mode.

Quad Mode Method 1.

1. Issue the Read Status Register command (0x05) and read in the value of the status register.
2. Issue the Read Configuration Register command (0x3F) and read in the configurations register value.
3. Issue the Write Enable command (0x06).
4. Issue the Read Status Register command (0x05) to verify the write latch status is set.
5. Set bit 7 of the read configuration register value to enable quad mode.
6. Issue the Write Register command (0x3E) and write the value of the configuration register.
7. Issue the Read Status Register command (0x05) until the device is ready and write latch is cleared.
8. Issue the Read Configuration Register command (0x3F) to verify quad mode is enabled.

Quad Mode Method 2.

1. Issue the Read Status Register command (0x05) and read in the value of the status register.
2. Issue the Read Configuration Register command (0x35) and read in the value of the configuration register.
3. Issue the Write Enable command (0x06).
4. Issue the Read Status Register command (0x05) to verify the write latch status is set.
5. Set bit 1 of the read configuration register value to enable quad mode.
6. Issue the Write Register command (0x01) and write the value of the status register and the updated value of the configuration register.
7. Issue the Read Status Register command (0x05) until the device is ready.

Quad Mode Method 3.

1. Issue the Read Status Register command (0x05) and read in the value of the status register.

2. Issue the Write Enable command (0x06).
3. Issue the Read Status Register command (0x05) to verify the write latch status is set.
4. Set bit 6 of the read status register value to enable quad mode.
5. Issue the Write Status command (0x01) and write the value of the status register back to enable quad mode.
6. Issue the Read Status Register command (0x05) until the device is ready.

Run-time API

The following table provides descriptions of the `adi_rom_Boot()` `command` parameter.

Table 53-16: SPI Master Boot `command`Bit Descriptions

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28	ROM_BCMD_SPIM_SPEED	SPI clock divider to be used. The value written to the SPI Peripherals clock divider register.	
26:25	ROM_BCMD_SPIM_IOPROT	SPI I/O protocol. If multiple I/O pins are required, then I/O mode is enabled on the flash device. The number of data bits required for the data transfer determines the I/O mode enabled. This field is only applied if NOAUTO is set to 1. Otherwise, the protocol for enabling the additional pins is defined through the BCODE value supplied.	
		0x0	No protocol required to implement multiple I/O
		0x1	Enable quad functionality using protocol 1
		0x2	Enable quad functionality using protocol 2
		0x3	Enable quad functionality using protocol 3
24:22	ROM_BCMD_SPIM_DUMMY	Number of dummy bytes to be issued. Specifies the number of dummy bytes to be issued after the address bytes are issued for the required read command.	
		0x0	Do not issue dummy bytes
		0x1	Issue 1 dummy byte
		0x2	Issue 2 dummy bytes
		0x3	Issue 3 dummy bytes
		0x4	Issue 4 dummy bytes
		0x5	Issue 5 dummy bytes
		0x6	Issue 6 dummy bytes
		0x7	Issue 7 dummy bytes

Table 53-16: SPI Master Boot `command`Bit Descriptions (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20	ROM_BCMD_SPIM_ADDR	Number of address bytes to be issued. Specifies the number of address bytes that are required to be issued to the SPI flash for the required read command.	
		0x0	Issue 1 address byte
		0x1	Issue 2 address bytes
		0x2	Issue 3 address bytes
		0x3	Issue 4 address bytes
19:16	ROM_BCMD_SPIM_BCODE	Boot mode-specific code. Specifies the boot mode-specific code that can further customize and control the boot process.	
14:12	ROM_BCMD_SPIM_SSEL	SPI Slave select signal. Specifies the SPI slave select signal to be used to enable the SPI Flash. Not all slave selects are available for each SPI port. Refer to the product data sheet for further details.	
		0x0	SEL1
		0x1	SEL2
		0x2	SEL3

Bit No. (Access)	Bit Name	Description/Enumeration	
4	ROM_BCMD_ HOST	Host boot mode enable. When set, this bit indicates that SPI slave boot is to be performed. Otherwise, use the master boot mode.	
3:0	ROM_BCMD_ DEVICE	Boot source device. Specifies the device to boot from.	
		0x2	SPI
		0x7	Memory Mapped SPI (For use with SPI2 only)

NOTE: All bits in the above table that are not defined must be set to zero. Features supported may be limited depending on peripheral instance.

SPI Slave Boot Mode

When using SPI slave mode boot, the processor consumes boot data from an external SPI host device. This mode supports single, dual, and quad-bit modes. The boot kernel always starts in single bit mode and can be changed using the appropriate command. The following figures show the hardware configuration for the modes. As in all slave boot modes, the host device controls the `SYS_HWRST` input of the processor.

NOTE: Secure Boot Stream Padding

For slave boot modes, the host must always send data in multiples of 1024 bytes. This requirement is due to the sizing of internal buffers used for DMA.

Figure 53-5: Connection Between Host (SPI Master) and Processor (SPI Slave) QSPI

The host drives the SPI clock and is responsible for timing. The host must provide an active-low chip select signal that connects to the `SPIx_SS` input of the processor. It can toggle with each byte transferred or remain low during the entire procedure. 8-bit data is expected and 16-bit mode is not supported.

In SPI slave boot mode, the boot kernel sets the `SPI_CTL.CPHA` bit and clears the `SPI_CTL.CPOL` bit in the `SPI_CTL` register. Therefore the `SPI_MISO` pin is latched on the falling edge of the `SPI_MOSI` pin.

The SPI slave processor detects the correct boot mode from the host SPI device by reading the first byte sent, defined as `SPICMD`. The ***SPICMD Descriptions*** table describes the available codes. These additional bytes must be sent prior to transmitting the data to configure the SPI device accordingly.

The table describes two cases, one in which the host starts in single bit mode, and one in which the host starts in a mode other than single bit.

Table 53-17: SPICMD Descriptions

SPICMD	Description
If host Starts in Single bit Mode	
0x3	Keep single-bit mode
0x7	Switch to dual-bit mode
0xB	Switch to quad-bit mode
If host device starts in DIOM or QSPI	

Table 53-17: SPICMD Descriptions (Continued)

SPICMD	Description
0xAA,0xBF	Switch to dual-bit mode
0xEE,0xEE,0xFE,0xFF	Switch to quad-bit mode

In SPI slave boot mode, `SPIx_RDY` functionality is critical. The `SPIx_RDY` output is used for back pressure and requires a pulling resistor. The boot code requires the `SPIx_RDY` signal function as active-low. The host is only permitted to transfer data when `SPIx_RDY` is in the active state. This functionality allows the processor to hold off the host while the processor is in reset or executing the pre-boot and processor initialization sequences. The SPI is configured to de-assert `SPIx_RDY` when the receive FIFO is filled to 75% or more. The ***SPI Program Flow on the Host Side*** figure illustrates the required program flow on the host side.

Run-time API

The SPI Slave Boot mode can be called through the Boot Routine API function at run-time. Initiating a boot through the run-time API allows for extra customization such as disabling automatic device configuration or specifying a different SPI device other than the default.

When `ROM_BCMD_NOCFG` flag is specified, it is necessary to program pin multiplexing and other SPI configuration as required, while keeping the `SPI_CTL.EN` bit cleared.

The `ROM_BCMD_NOAUTO` flag can suppress auto mode detection. In that case, the desired configuration must be passed through the `ROM_BCMD_SPIS_BCODE` bit field, even if the `ROM_BCMD_NOCFG` flag is set.

The following table provides descriptions of the `adi_rom_Boot()` `command` parameter.

Table 53-18: SPI Slave Boot `command` Bit Descriptions

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16	ROM_BCMD_SPIS_BCODE	Boot Mode Specific BCODE. Specifies the boot mode-specific code that can further customize and control the boot process.	
		00xxb	Single bit SPI bus
		01xxb	Dual SPI bus
		10xxb	Quad SPI bus
		11xxb	Reserved
11:8	ROM_BCMD_DEVENUM	Device enumeration. Specifies the SPI device to use.

NOTE: All bits in the above table that are not defined must be set to zero. Features supported may be limited depending on peripheral instance.

Link Port Slave Boot Mode

This section describes booting from the link port with the processor as a slave.

Link port boot is a slave boot mode in which the processor receives boot data from an external link port master through link port 0. The link port is configured for receive mode and all transfers from the link port to memory are performed under the control of DMA. The maximum supported operating frequency of the link port is 66 MHz for which the master boot source is responsible for deriving the clock frequency. The link port receiver operates at an asynchronous frequency up to the maximum supported operating frequency.

The link port protocol supports a way to generate link port transmit and receive service requests. The transmit service request is generated on the processor to transmit data when the transmitter is disabled. The receiver drives the `LACKx` signal high to initiate this activity. The receive service request is generated on a receiver when it is disabled. The transmitter drives the `LCLKx` signal high to initiate this activity.

Because the transmitter and receivers can be enabled at different times, external pull-down resistors are required on both the `LCLKx` and `LACKx` signals to eliminate any false service request assertions.

The link port slave boot mode initialization phase waits for the receive service request before passing control back to the main kernel. Once this initial receive service request has been detected, the receiving link port is enabled and the boot process completes. The receiving link port is not disabled again until after boot is complete. Once the link port is enabled, the receive DMA channel controls all transfers. The load function for the link port receive boot mode can then point to the peripheral DMA routine of the main kernel in a similar way to the SPI slave boot mode.

Run-time API

The LINKPORT slave boot mode can be called through the boot routine API function at run time. The run-time API allows for more customization. Both device auto-detection and device configuration can be disabled, and a device other than the default LINKPORT0 can be specified.

If `ROM_BCMD_NOCFG` flag is specified, it is the programs responsibility to configure pin multiplexing as required.

The following table provides descriptions of the `adi_rom_Boot()` `command` parameter.

Table 53-19: LINKPORT Slave Boot `command` Bit Descriptions

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8	ROM_BCMD_DEVENUM	Device enumeration. Specifies the LINKPORT device to use.	
		0x0	LP0
		0x1	LP1
		0x2 - 0xF	Reserved

NOTE: All bits in the above table that are not defined must be set to zero. Features supported may be limited depending on peripheral instance.

UART Slave Boot Mode

When using UART slave mode boot, the processor receives boot data from a UART host device connected to the UART interface. The device connected to UART0 is initially detected using an autobaud detection sequence. After finishing the UART slave boot process, all control and status registers of the used resources are restored.

Further customization, such as disabling autobaud detection, and changing the device, use the boot routine API.

During the boot operation, the host device usually relies on the `RTS` output of the UART device. At boot time, the processor does not evaluate RTS signals driven by host. Since the RTS is in a high impedance state when the processor is in reset, or while executing a pre-boot, an external pull-up resistor to `VDDEXT` is recommended. The ***Connection Between Host and Processor*** figure shows the interconnection required for booting. The figure does not show physical line drivers and level shifters that are typically required to meet the individual UART-compatible standards.

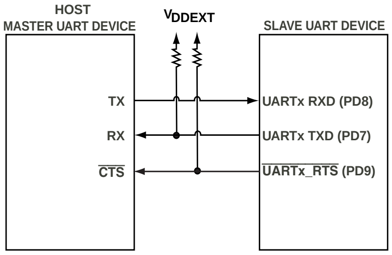

Figure 53-7: Connection Between Host and Processor

When the UART is enabled, the RTS goes immediately low, encouraging the host to send the first boot stream data as shown in the *Host Relying on RTS* figure. For half-duplex UART connections, the host must avoid this action. The host must wait until it has received the 4 bytes from the slave processor before sending any data.

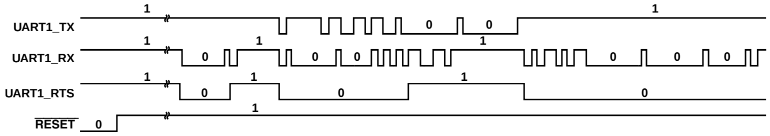

Figure 53-8: Host Relying on RTS

When the boot kernel is processing fill or Initcode blocks, it can require extra processing time and must delay the host from sending more data. This request is signaled using the RTS output.

The *Host Relying on RTS* figure shows RTS timing when an extended Initcode routine executes. Since code execution is distracting from the data loading, the host device must be prevented from sending more data. The timing of the RTS depends on the state of the `RFRT` bit in the UART control register (`UART_CTL`). This bit is cleared during UART slave boot mode when RTS is de-asserted, the UART receive FIFO contains 4 or more data words, and another start bit is detected.

NOTE: Secure Boot Stream Padding

For slave boot modes, the host must always send data in multiples of 1024 bytes. This requirement is due to the sizing of internal buffers used for DMA.

Autobaud Detection

The kernel supports autobaud detection using the '@' character as data. The host is expected to have its clock set to a rate supported in the UART.

To determine the bit rate when performing autobaud detection, use the following steps:

1. The boot kernel expects an '@' character (0x40, eight bits data, one start bit, one stop bit, no parity bit) on the UART RXD input.
2. The `EDBO` and `UART_CLK` register is cleared.
3. The boot kernel acknowledges, and the host then downloads the boot stream. The acknowledgment consists of 4 bytes: 0xBF, `UART_CLK` [15:8], `UART_CLK` [7:0], 0x00.

4. The host is requested to not send further bytes until it has received the complete acknowledge string.
5. Once the 0x00 byte is received, the host can send the entire boot stream.

The host knows the total byte count of the boot stream, but it is not required to know the content of the boot stream.

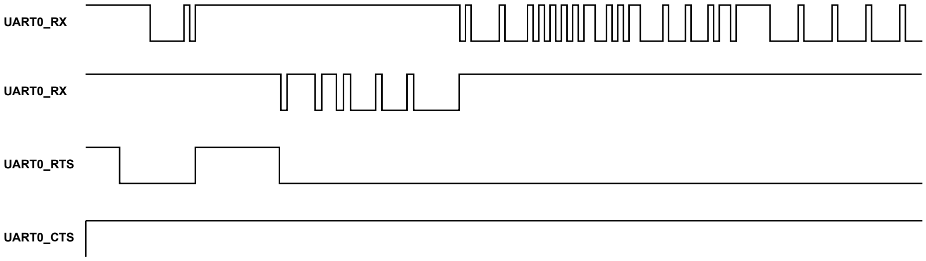

Figure 53-9: UART Autobaud Detection Waveform

The ***UART Autobaud Detection Waveform*** figure provides timing information for UART booting. After the bit rate is known, the UART is enabled and the kernel transmits the 4 acknowledge bytes.

Run-time API

The UART slave boot mode can be called through the boot routine API function at run time. The run-time API allows for more customization. Both autobaud detection and device configuration can be disabled, and a device other than the default UART0 can be specified.

If `ROM_BCMD_NOCFG` flag is specified, it is the programs responsibility to configure pin multiplexing as required.

Autobaud detection can be suppressed using the `ROM_BCMD_NOAUTO` flag. In this case, the desired configuration can be passed through the `ROM_BCMD_UART_CLK` bit field. If the `ROM_BCMD_UART_CLK` bit field is zero, `UART_CLK` is evaluated. If a value of 0xFFFF was present, the default error routine of the boot kernel is called and the booting process is aborted. Otherwise, the value in `UART_CLK` remains untouched.

The following table provides descriptions of the `adi_rom_Boot()` `command` parameter.

Table 53-20: UART Slave Boot `command` Bit Descriptions

Bit No. (Access)	Bit Name	Description/Enumeration
31:16	ROM_BCMD_ UART_CLK	UART Clock Divider. When set to zero this field is ignored.
15	ROM_BCMD_ UART_EDBO	UART Clock Divider Mode When set enables EDBO functionality.

Table 53-20: UART Slave Boot `command` Bit Descriptions (Continued)

		0x0	UART0
		0x1	UART1
		0x2	UART2
		0x3 - 0xF	Reserved
6	ROM_BCMD_ NOAUTO	Automatic device detection disable. When set disables automatic device detection and uses the setting provided in the other fields of this register to configure the boot mode.	
5	ROM_BCMD_ NOCFG	Device configuration disable. When set, this bit disables device configuration. Device configuration includes reconfiguration of the peripherals MMR registers and device pin muxing.	
4	ROM_BCMD_ HOST	Host boot mode enable. When set, this bit indicates that SPI slave boot is to be performed. Otherwise, use the master boot mode.	
3:0	ROM_BCMD_ DEVICE	Boot source device. Specifies the device to boot from.	
		0x3	UART

NOTE: All bits in the above table that are not defined must be set to zero. Features supported may be limited depending on peripheral instance.

Boot Loader Stream

A loader stream is a set of formatted blocks containing instructions for the boot kernel, as well as the application and data for loading to the chip. This section details the different aspects of the stream, its blocks, some common use cases, and the ROM functionality.

Each block begins with a block header which contains attributes of the block as well as flags to control its processing by the boot ROM. On power-up or reset, the processor begins executing the on-chip boot ROM. The boot stream is either read from memory or received from a peripheral, depending on the boot mode specified. Each block in the boot stream instructs the boot kernel to perform an action, most commonly to load data to a specified location. For a complete list of actions, refer to Block Types. Some common actions include:

- running code that initializes a peripheral
- processing data then loading it to a location

As the ***Project Flow*** figure illustrates, a utility is required to process the resulting output from the tool chain to create a valid boot stream. This utility can be in the form of a standalone application or script that parses an application image file, elf output file, or text-based file such as Intel hex. It creates a valid boot stream. A flash programmer utility can format a boot stream internally.

The elfloader utility parses the application data, and creates a set of blocks representing the segmented application. When processing an actual image that must be loaded to a single contiguous memory block, this representation can contain as little as a single header block. The output of the standalone utility is stored in a loader file (.ldr). The loader file contains the boot stream and becomes available to hardware by:

- programming or burning it into non-volatile external memory, or
- sending it through a peripheral such as the UART during boot time

A loader stream must always begin with a first block and end with a final block. The loader file contains the boot stream and becomes available to hardware by:

- programming or burning it into non-volatile external memory, or
- sending it through a peripheral during boot time

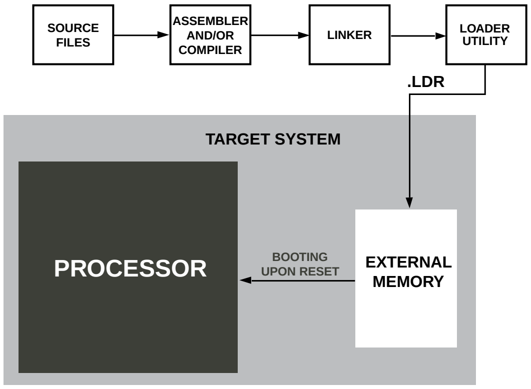

Figure 53-10: Project Flow

The ***Booting Process*** figure shows the parallel or serial boot stream contained in a flash memory device. In host boot scenarios, the non-volatile memory usually connects to the host processor rather than directly to the processor. After reset, the on-chip boot kernel reads and parses the headers and the loader stream is processed block-by-block. Finally, payload data is copied to destination addresses, either in on-chip L1 and L2 memory, or off-chip to SDRAM or SRAM.

Figure 53-11: Booting Process

In some cases (for example, secure boot or when the `BFLAG_INDIRECT` flag for any block is set), the boot kernel uses another memory block for intermediate data storage. In order to preserve the security of the device processors will not allow these storage regions to be initialized with boot data. The boot stream is loaded to the intermediate storage then processed by the kernel and loaded to the final destination. Thge final destination cannot be the intermediate storage location otherwise the boot process will terminate in error.

Figure 53-12: Loader Stream Block Structure

A boot stream consists of multiple boot blocks as shown in the figure. A 16-byte block header begins every block. The 16 bytes are functionally grouped into four 32-bit words:

- the block code
- the target address
- the byte count
- the argument field

This section describes the fields in general. The uses can vary depending on the particular block type and boot mode. Refer to the block type descriptions and boot modes for further information.

Block Code

Table 53-21: Block Code flags

Bit	Name	Description
0–3	`BCODE`	Specific to boot modes (see Boot Modes)
4	`BFLAG_SAVE`	Intended to allow for a user application to mark blocks for saving the memory of this block to off-chip memory in case of power failure . The on-chip boot kernel does not use this flag.
5	`BFLAG_AUX`	When set indicates that the byte address space translation for SHARC core boot blocks requires translation to the 48-bit PM address space. When cleared translation to the 32-bit address space is performed.
6	reserved	
8	`BFLAG_FILL`	Fill the target location with a specified 32-bit value
10	`BFLAG_CALLBACK`	Calls the previously registered callback function
11	`BFLAG_INIT`	Calls function at target address. If the block contains a payload, the payload is loaded prior to the call.
12	`BFLAG_IGNORE`	Block payload is ignored
13	`BFLAG_INDIRECT`	Boots the payload to the intermediate storage location
14	`BFLAG_FIRST`	Indicates the block to be the beginning of a new application
15	`BFLAG_FINAL`	Indicates the last block of a loader stream. Booting will complete after processing the block. This flag does not denote the end of an application in a Multi-Application Boot Streams boot stream.
16–23	`HDRCHK`	A simple 8-bit XOR checksum of the other 24 bits in the boot block header.
24–31	`HDRSIGN`	0xAD, 0xAC or 0xAB. Indicates if the boot block is intended for core 0, core 1 or core 2 respectively.

TARGET_ADDRESS

The `TARGET_ADDRESS` holds the applicable address for the block, (where the code or data is loaded). However, the interpretation of the field differs depending on what specific flags are set in the block code. Refer to the documentation for each block type for details.

The following attributes must be true:

- The target address must be divisible by 4, as the boot kernel uses 32-bit DMA for certain operations.
- The target address must point to valid on-chip or off-chip memory locations.

BYTE_COUNT

The byte count must be divisible by 4, and can also be zero. This 32-bit field generally holds the size of the block. In some cases, it has a different use (such as when `BFLAG_FILL` is set). See the Block Types section for information on the variations.

ARGUMENT

The 32-bit field is a user-variable for most block types. The `Initcode` or the `callback` routine can access this value and use it for optional instructions.

The different block types use the `ARGUMENT` field in various ways. See the Block Types descriptions for further information.

Block Types

A loader stream is a set of linked blocks and each block is responsible for performing a certain function dependent on the block type. The flags in the block header define a block type. Operations include functions such as loading data, filling a memory region with data, and instructing the kernel to stop processing. This section describes each block type and its usage within a boot loader stream.

Normal Block

The primary function of a block is to load data into a specified location of memory. A normal block instructs the boot kernel to load the data contained in its payload to the location specified in the `TARGET_ADDRESS` field. The `BYTE_COUNT` defines the size of the payload. Once the correct amount of data has been loaded, the kernel moves on to process the next block in the stream.

Table 53-22: Flags

Flag	Required Value	Init
`TARGET_ADDRESS`	Y	Address where payload is loaded (must be valid)
`BYTE_COUNT`	Y	Size of block in bytes

First Block

A first block indicates the start of a boot stream and is always needed at the beginning of the boot stream. When a loader stream contains Multi-Application Boot Streams, a first block occurring within the loader stream indicates the beginning of a new application.

When the kernel processes the first block in a loader stream, the boot kernel uses the `TARGET_ADDRESS` to determine the application entry location. For more details, refer to Boot Termination and Application Execution .

NOTE: A first block cannot be combined with a fill block.

Table 53-23: Flags

Flag	Required Value	Init
`BFLAG_FIRST`	Y	1

Table 53-23: Flags (Continued)

Flag	Required Value	Init
`ARGUMENT`	Y	Offset to the next application, or first address following loader stream. Commonly referred to as the `NEXTDXE` field.
`TARGET_ADDRESS`	Y	When the block is the first block in a loader stream, also defines the start address for the application. If the block is not the first in a loader stream, use the target address as in normal operation.

Final Block

The final block marks the last block in a boot stream. After processing a final block, the boot kernel jumps to the start address of the application. For more information on the definition of the start address, refer to Boot Termination and Application Execution .

There is further customization to the kernel behavior available. For example, the kernel can be instructed to return from the boot routine rather than jump to the application using initialization codes or the `adi_rom_Boot()` API.

Before the boot kernel passes program control to the application, it does some housekeeping. Most of the registers in use are set to their default state. However, some register values can differ depending on the boot mode. See Boot Modes for more information.

Table 53-24: Flags

Flag	Required Value	Init
`BFLAG_FINAL`	Y	1

Indirect Block

An indirect block is first loaded to a storage location before being copied to the destination. The following situations motivate this functionality:

- Some boot modes do not use DMA from the boot peripheral. The core is not always able to access some memory locations directly or efficiently. An intermediate load to a different location improves overall efficiency.
- In some booting scenarios, the data in the payload must be operated-on or analyzed before it is fully loaded (such as decryption or checksum calculation). By using an intermediate location, such scenarios are simplified and can be more efficient when loading to off-chip memories (see Callback Block).

In some cases, a boot block does not fit into temporary storage memory. Having a larger buffer can improve boot performance. If an entire block cannot fit into the buffer, it is processed in pieces. Initialization code or callback functions can alter the temporary buffer region, including its location and size, by modifying `ADI_ROM_BOOT_CONFIG::pTempBuffer` and `ADI_ROM_BOOT_CONFIG::dTempByteCount` variables in the `ADI_ROM_BOOT_CONFIG` structure.

Table 53-25: Flags

Flag	Required Value	Init
`BFLAG_INDIRECT`	Y	1
`BFLAG_CALLBACK`	N	Defines a callback function to operate on intermediate data. These 2 flags are often used together.

Ignore Block

An ignore block is a block that is (in most cases) ignored by the loader stream. Ignore blocks are useful when it is not possible to pass information in another block header. For example, if the first block contains data such as a firmware revision rather than application code, then `BFLAG_IGNORE` can be set with the correct application start address. This step ensures that the loader stream uses the correct start address. Since this block has no other function, identify it as an ignore block. Then, the kernel does not attempt to process any payload.

Ignore blocks result in the clearing of the following flags, disabling the corresponding blocks from being processed if set along with `BFLAG_IGNORE`:

- `BFLAG_INIT`
- `BFLAG_CALLBACK`
- `BFLAG_FINAL`
- `BFLAG_AUX`

NOTE: When `BFLAG_IGNORE` is set along with `BFLAG_FIRST`, only the payload associated with the first block is ignored. The application entry point retrieved from the first block is always processed.

Table 53-26: Flags

Flag	Required Value	Init
`BFLAG_IGNORE`	Y	1
`BYTE_COUNT`	Y	Size of block to ignore; can be zero

Fill Block

A fill block instructs the boot kernel to perform a 32-bit memory fill of the memory region. Fill blocks help minimize the size of a boot stream when an application contains large arrays of data that need to be initialized upon startup. Zero fill is the most common fill block type. However, any 32-bit fill value is supported.

Table 53-27: Flags

Flag	Required Value	Init
`BFLAG_FILL`	Y	1
`TARGET_ADDRESS`	Y	Address where payload is loaded (must be valid)
`BYTE_COUNT`	Y	Size of block in bytes (must be multiple of 4)
`ARGUMENT`	Y	32-bit fill value

AUX Block

The AUX block is used to indicate whether addresses not within the system wide byte address space for the processor are to be converted using the regular 32-bit address space translation or 48-bit program memory space conversion. When this flag is cleared, 32-bit address conversion is used. When set, 48-bit address conversion is used to obtain the byte address to load the payload.

This flag is only required to be used when the utility used for generating the boot stream does not automatically convert payload addresses to the byte address space. When the boot kernel detects that an address in the block header is already targeted towards the byte address space, this flag has no purpose.

It should also be noted that the converted address is only used for the loading of the payload via the DMA channels. If a block such a callback block or an init block is required to execute from SHARC L1 48-bit PM space, the address is converted for the load operation. However, the call is performed to the original 48-bit PM address.

Init Block

An initialization block instructs the boot kernel to do a function call to the target address after the entire block has loaded. The function called is referred to as the *initialization code (Initcode) routine*. Refer to the API reference `initcode()` for full details.

If the Initcode routine has been previously loaded, the block can declare a zero-size and have no payload.

Initcode routines can be used to speed up and customize booting mechanisms exposed by the boot kernel. Traditionally, an Initcode routine is used to setup system PLL, bit rates, wait states, and the external memory controllers. If executed early in the boot process, the boot time can be significantly reduced.

Initcode routines are required to follow the C language calling conventions. The expected C prototype is:

```
void initcode(ADI_ROM_BOOT_CONFIG * pBootConfig)
```

NOTE: When programming in assembly, use a return from subroutine instruction for returns.

The structure provided to the Initcode routine by the boot kernel contains various information about the block being processed. It includes header information, locations of temporary block data (for indirect blocks), target address, and byte count. See `ADI_ROM_BOOT_CONFIG` for a full list and details on the provided data.

In the simplest case, an Initcode routine consists of only a single block in which the `BFLAG_INIT` flag is set. For larger routines, a sequence of blocks can incrementally load the routine, and only the last block sets the `BFLAG_INIT` flag. In the latter case, the last block has no payload attached, and simply instructs the boot kernel to issue a call to subroutine instruction.

An Initcode routine can be overwritten by a successive block when it is no longer needed. Otherwise, the routine can be called at multiple points during the boot process, and even remain in memory after the application completes booting.

NOTE: The following list provides requirements for Initcode that is written in C or C++.

- Ensure that the Initcode routine does not contain calls to the run-time libraries
- Do not assume that parts of the run-time environment, such as the heap, are fully functional
- Ensure that all run-time components are loaded and initialized before the routine executes

The `loader` utility and tool set provide mechanisms to aid in implementing initialization codes and organizing them properly within the boot loader stream. A special project type is provided to allow the creation of Initcode routines as separate projects. Options are available to assign particular pieces of the application to be Initcode routines. For details and more information on the utility, see to the *Loader and Utilities manual*.

Table 53-28: Flags

Flag	Required Value	Init
`BFLAG_INIT`	Y	1
`TARGET_ADDRESS`	Y	Location to load payload data. Call to subroutine issued to the same location.
`ARGUMENT`	N	Can be used to supply block specific arguments
`BYTE_COUNT`	Y	Size of payload; can be zero

NOTE: Init blocks result in execution of software not located in the boot rom during the boot process. In the case of a secure boot scenrio, initcode routines are not supported. The secure boot authentication process is performed at the end of the boot process. Execution of any user software prior to the authentication process would violate the secure boot requirements.

Callback Block

A callback block instructs the boot kernel to call a pre-registered function upon completion of loading the payload of the block. The purpose of a callback routine is to apply standard processing to the block payload. The callback routine is registered through an Initcode routine prior to loading a block using the routine. Typically, callback routines contain checksum, decryption, decompression or hash algorithms. Please refer to `callback()` API reference.

To register a callback, create an Init Block whose Initcode modifies `ADI_ROM_BOOT_CONFIG::pCallBackFunction` with the address of the callback function to execute. A callback function must be registered prior to processing a callback block.

Since callback routines require access to the payload data of the boot blocks, load the block data before processing. Often an Indirect Block block is used in combination with a callback block. Indirect blocks in combination with callback blocks can allow for post processing of the loaded data before it is then transferred to the final destination.

Callback routines are expected to meet the C language calling conventions. The prototype is as follows:

```
ROM_BOOT_RESULT callback(
                         ADI_ROM_BOOT_CONFIG * pBootConfig,
                         ADI_ROM_BOOT_BUFFER * pBuffer,
                         uint32_t nFlags
                        )
```

The `pBootConfig` argument contains a pointer to the `ADI_ROM_BOOT_CONFIG` information, and `pBuffer` provides access to the address and size of the block (can vary when using indirect). The `nFlags` parameter is specifically used when `BFLAG_INDIRECT` is also used. `CBFLAG_DIRECT` flag indicates that the `BFLAG_INDIRECT` bit is not active and so that the program only calls the callback routine once per block. When the `CBFLAG_DIRECT` is set, `CBFLAG_FIRST` and `CBFLAG_FINAL` are also set.

NOTE: Callback blocks result in execution of software not located in the boot rom during the boot process. In the case of a secure boot scenario callback routines are not supported as the secure boot authentication process is performed at the end of the boot process and execution of any user software prior to the authentication process would violate the secure boot requirements.

Callback Block Used in Conjunction with Indirect Block

When a block using a callback routine is also loaded indirectly, there are slight behavior differences. The procedure for loading is:

1. Load data into the temporary buffer defined by `ADI_ROM_BOOT_CONFIG::pTempBuffer`.
2. Issue a call to `ADI_ROM_BOOT_CONFIG::pCallBackFunction`.
3. After the callback routine returns, if the return value is zero, the memory DMA copies data to the destination.

When a block does not fit entirely into the temporary buffer, loading is performed similar to indirect blocks. The software calls the callback function after each chunk is loaded into the temporary storage. The `nFlags` parameter gives information on the specific iteration.

When a block does not fit entirely into the temporary storage area, the `nFlags` tells the callback routine whether it is invoked for the first time (`CBFLAG_FIRST`) or called the last time (`CBFLAG_FINAL`) for a specific block.

When the software invokes DMA to copy the data, it relies on the supplied `pBuffer` data, not the `ADI_ROM_BOOT_CONFIG::pTempBuffer` and `ADI_ROM_BOOT_CONFIG::dTempByteCount` members of the boot structure. The callback routine can control the source of the memory DMA by altering the content of the `pBuffer` structure. This alteration can be necessary when the callback routine performs data manipulation such as decompression.

When the software uses an indirect block, the return value of the callback routine determines whether the DMA transfer occurs. If the value is non-zero, then the transfer does not occur.

Table 53-29: Flags

Flag	Required Value	Init
`BFLAG_CALLBACK`	Y	1

NOTE: Callback blocks result in execution of software not located in the boot rom during the boot process. In the case of a secure boot scenrio callback routines are not supported as the secure boot authentication process is performed at the end of the boot process and execution of any user software prior to the authentication process would violate the secure boot requirements.

Quick Boot Block

There are some booting scenarios in which not all memories are required to be reinitialized during the boot process and as a result the boot kernel supports conditional processing of boot blocks in specific circumstances. Dynamic RAM is also not always impacted if it was put into a self-refresh mode before the processor powered down.

The processing of a quick boot block is determined by the state of the `BFLAG_WAKEUP`, `BFLAG_QUICKBOOT` and `BFLAG_IGNORE` flags.

Table 53-30: Quick Boot Block Processing

BFLAG_WAKEUP	**BFLAG_QUICKBOOT**	**BFLAG_IGNORE**	Block Processed
0	0	0	Yes
0	0	1	No
0	1	0	Yes
0	1	1	No
1	0	0	Yes
1	0	1	No
1	1	0	No
1	1	1	Yes

The `BFLAG_WAKEUP` flag is applied to the entire boot process when calling the boot kernel. Refer to `adi_rom_Boot()` for further details on the global flags available that can be applied to the boot process.

When the boot process is triggered via a hard reset or a software triggered system reset event the boot kernel is always called with `BFLAG_WAKEUP` cleared. Processors not supporting the wakeup from hibernate feature would generally not have this quickboot feature available for typical boot events. However, when using `adi_rom_Boot()` or `adi_rom_BootKernel()` from the user application to boot the processor, the quick-boot feature and selective processing of boot blocks is fully available .

NOTE: When `BFLAG_WAKEUP` is set and a block also has `BFLAG_QUICKBOOT` set, `BFLAG_IGNORE` flag is toggled within the boot kernel. This event occurs before the processing of an Ignore Block and as such also has an influence on the processing of blocks that are disabled as a result of `BFLAG_IGNORE` being set.

NOTE: If an initcode contains an implementation that requires some operations to be performed for wakeup type events, do not set `BFLAG_QUICKBOOT` in the initblock, disabling it completely. Instead, ensure `BFLAG_QUICKBOOT` is clear and perform any conditional processing based on the state of the `BFLAG_WAKEUP` flag.

Table 53-31: Flags

Flag	Required Value	Init
`BFLAG_QUICKBOOT`	Y	1

Save Block

A save block is intended to mark blocks in a boot stream that are to be saved to off-chip memory. The on-chip boot kernel does not use this flag. A user application can process the boot steam to find address of regions of memory that are to be saved off to external memory. Upon a reboot the user application may then restore the previously saved contents. It provides a means of doing a context restore after a reboot.

Table 53-32: Flags

Flag	Required Value	Init
`BFLAG_SAVE`	Y	1

Single-Block Boot Streams

The simplest boot stream consists of a single block header and one contiguous block of instructions and possibly data. When the appropriate flags are set in the block header, the kernel loads the block to the target address, terminates the boot process, and begins executing from the entry address of the application.

The ***Initial Header for Single-Block Stream*** table shows an example of a single-block boot stream header with settings that can be loaded using any boot mode. The `BFLAG_FIRST` and `BFLAG_FINAL` flags are both set at the same time. The desired location and size of the application determines the target address and byte count.

When using single block boot streams on products with multiple cores, the boot stream must be targeted towards the primary booting core that manages the boot process. If core 0 is the primary booting core, the boot stream must contain code that is intended for execution by that core. It is possible to boot an single block boot stream when using the API to load an application to the non booting core. In this case the `BFLAG_RETURN` flag must be set so the boot process returns to user application on the core mastering the boot process.

Table 53-33: Initial Header for Single-Block Stream

Field	Description of Value
BLOCK_CODE	0xAD000000|XORSUM|`BFLAG_FINAL`|`BFLAG_FIRST`
TARGET_ADDRESS	Start address of block
BYTE_COUNT	Number of bytes in the block
ARGUMENT	Functions as next-application pointer in multi-application boot streams.

Direct Code Execution

Applications can avoid long booting times and execute code from flash or SDRAM memory with minimal processing by the boot kernel. This feature is called direct code execution.

An initial boot block header is required for the processor to fetch and execute program code from the boot device as early as possible. The block uses safety mechanisms of the block to avoid unpredictable processor behavior when boot memory is not yet programmed with valid data. Safety mechanisms include the header signature and the byte-wise XOR checksum. Rather than blindly executing code, the boot kernel first executes the pre-boot routine for system customization. It then loads the first block header and checks it for consistency. If the block header is corrupt, the boot kernel calls the error handler and does not start code execution.

If the initial block header check is good, the boot kernel interrogates the block flags. If the block has the `BFLAG_FINAL` flag set, the boot kernel terminates and executes the sequence as described in the Boot Termination and Application Execution section. To cause the boot kernel to customize the starting address in advance, the first block must also have the `BFLAG_FIRST` flag set. The target address field is then saved as the application start address.

When processing direct code execution blocks, the block instructs the processor executing the boot code to execute from the address specified. It is not possible to have core 0 to boot the block and have it instruct core 1 to immediately start execution from the address provided.

Table 53-34: Example Direct Code Execution Header

Field	Value	Comments
BLOCK_CODE	0xAD7BD006	0xAD000000|XORSUM|`BFLAG_FINAL`|`BFLAG_FIRST`|`BFLAG_IGNORE`|BCODE
TARGET_ADDRESS	0x20000020	Start address of application code. Provided as an example this would be dependent upon the start address required for a given product.
BYTE_COUNT	0x00000010	Ignores 16 bytes to provide space for control data such as version code and build data. This field is optional and can be zero. The payload is ignored due to the `BFLAG_IGNORE` flag being set.
ARGUMENT	0x00000010	Functions as next-application pointer in multi-application boot streams.

Multi-Application Boot Streams

This section describes loader streams that contain multiple applications.

A boot stream is typically generated from an application file. It is therefore common to refer to loader streams with more than one application (multi-application) booting. A loader utility often accepts multiple application files as input parameters and generates a contiguous boot image. The subsequent applications are appended to the first.

The loader utility must also update the argument field of all `BFLAG_FIRST` blocks. The argument field of a `BFLAG_FINAL` block is called the *next-application* pointer.

The next-application pointer of the first application boot stream points relatively to the start address of the second application boot stream. A multi-application boot image can be seen as a linked list of boot streams. The next-application pointer of the last application boot stream points relatively to the next free address. The ***Multi-Application Boot Stream Example*** figure illustrates an example.

Figure 53-14: Multi-Application Direct Code Execution Example

CRC32 Protection

This section describes the CRC32 protection provisions.

The boot kernel provides mechanisms to allow verification of each blocks payload using a 32-bit CRC. The boot rom contains a function in the rom that can be called as an initcode to register the CRC callback and initialize the CRC peripheral with a user specified polynomial. The utilities provided by the supporting toolchain for the processor allow for generation of CRC32 protected loader streams.

To enable this feature an Init Block must be located in the boot stream with a `TARGET_ADDRESS` that points to the function in the ROM. The `ARGUMENT` field contains the CRC32 checksum polynomial to be used to initialize the CRC lookup table. Once this CRC initcode function in the ROM has been executed CRC verification is enabled for all subsequent blocks except:

- Ignore
- First

NOTE: Due to the fact that the enabling of the CRC functionality is dependent upon the use of an Initblock. The feature is not supported in secure boot situations.

Secure Boot

The secure boot process provides a means of integrating security in the processor boot sequence. A chain of trust is established within the system by ensuring the integrity and authenticity of the boot image. Confidentially support is also supported.

Secure boot increases protection against malicious, unsecured accesses to critical and confidential resources of the processor. The boot stream application code and data must be digitally signed in order to build up a chain of trust in the system. This allows the processor to distinguish between authentic and trusted code from non-authentic and untrusted code.

Secure boot also provides confidentiality support. The digitally signed boot image can be optionally encrypted as well. When loading an encrypted image, the ROM decrypts while loading, then authenticates, before any application code is executed.

Secure boot is an optional feature of the processor and is disabled by default. The feature is enabled using the OTP lock API, and secure boot cannot be disabled after it has been enabled. When security is enabled, developers are not dependent upon on Analog Devices to provision the devices, sign code or provide security certificates. The required tools for signing and encrypting the boot images are provided with the development tools for the processor.

Integrity and Authenticity Protection

Integrity protection is based on the secure hash SHA-2 224 bit algorithm. Authenticity protection is based on the ECDSA algorithm.

ECDSA uses public key cryptography consisting of two keys, a private key and a public key. The public key is stored in OTP memory on the processor so that the secure boot process can verify the authenticity of the signed boot image. Only parties in possession of the private key are able to sign the images.

Confidentiality Protection

Confidentiality protection uses the AES algorithm. Two variants are supported, wrapped and unwrapped.

The wrapped variant utilizes a 128-bit Key Encryption Key (KEK) stored on the processor to decrypt the 128-bit AES decryption key embedded in the secure header. The unwrapped variant stores the AES description key on the processor and utilizes it to decrypt the entire image.

The privacy of the key stored on the device (whether AES or KEK) is paramount to the security of the system. Disclosure of this key compromises security of the entire system.

Anti-Cloning Protection

Anti-cloning protection is based on the confidentiality protection. If each processor uses a unique private key for the confidentiality protection, then cloning between these devices can be prevented. The boot image is incompatible with devices using a different private key for the decryption.

Anti-Rollback Protection

The secure boot process supports anti-rollback protection through a 32-bit counter in the OTP memory. A value of `0x00000000` in the OTP results in anti-rollback being disabled by default. If anti-rollback protection is required, then the user may set the Rollback ID when signing the boot image. Upon successful authentication of the boot image, the secure boot software then updates the counter in the OTP. The software updates the counter if the rollback ID in the boot image is greater than the value currently stored in the OTP counter.

The rollback ID stored in the secure boot image header is integrity-protected preventing altering of the rollback ID.

NOTE: In order to initially enable anti-rollback protection for secure boot operations, a non-zero must be written to the 32-bit counter in the OTP memory. As long as this register filed remains at the default value of zero anti-rollback protections will not be enabled regardless of the rollback ID located in a secure boot stream.

CAUTION: As the rollback ID is implemented in the OTP module, there are a number of restrictions for its use. It is therefore recommended to only use the OTP boot program ROM API to set the counter. Refer to the OTP counters section for information detailing the implementation strategy.

Secure Boot Image Signing

All boot images must be digitally signed to create secure boot images. The boot image is processed by the security utilities included with the development tools to sign and optionally encrypt the boot image. The security utilities operate with key-pairs consisting of a private and a public key. The private key is used for signing the images, and the public key is used to validate an image being loaded into the processor.

CAUTION: The private key generated from the singing utility, used for signing images, is never required by the processor for successful secure boot. The private key is only ever required by the signing utility and should be made available only within the system responsible for the image signing process.

The image signing utility provides the following functionality:

- Signing and encrypting of images
- Generation of ECDSA key pairs
- Generation of random encryption keys
- Extraction of the public key from an ECDSA key pair
- Setting Secure Boot Image Attributes

For more information on the use of the signing utility, refer to the Loader and Utilities manual.

Secure Boot Image Types

This section provides an overview of the different image types supported, as well as supporting information on how to use them.

Plaintext Format (BLp)

Provides integrity plus authentication protection of the boot image. The boot image is produced using a 224-bit Elliptical Curve Digital Signature Algorithm (ECDSA) private key. To authenticate the image, program the corresponding public key into the OTP `public_key` field using the OTP boot program API.

SBH	Boot Loader Stream

Wrapped Format (BLw)

Provides the highest level of protection: integrity plus authentication, confidentiality, and anti-cloning protection. The image contains an ECDSA wrapped image encryption key (denoted by [K]) within the secure header. The image data is encrypted with the wrapped key, preventing cloning. An extra key is required to unwrap the header, program this key into OTP `pvt_128key` field using the OTP boot program API.

SBH [K]	Encrypted Boot Loader Stream

Keyless Format (BLx)

Similar to the BLw format except that the image does not contain the key at all. This format provides anti-cloning protection only if the secure key is unique per device. Program the decryption key for the data into OTP `pvt_128key` field using the OTP boot program API.

SBH	Encrypted Boot Loader Stream

Secure Boot Image Format

Secure Boot images provide authenticity and integrity protection during the boot process. A secure boot image is comprised of a secure boot header and an optionally encrypted loader stream.

Signed images consist of the following sections to comprise a complete secure boot image:

- Secure Boot Header
- Image Attributes
- Image Section

The Figure 53-15 Secure Boot Image figure shows that the image attributes are encapsulated within the secure boot header. The image attributes are actually integrity protected along with the image section. The image section contains a standard Boot Loader Stream. Some block types are not allowed as described in Unsupported Boot Stream Blocks.

Secure Boot Header

Table 53-35: Secure Boot Header

Bytes	Name	Description	Values		
			Keyless Format (BLx)	Wrapped Format (BLw)	Plaintext Format (BLp)
3:0	Type	Format and version of the image. Upper 24 bits is the image format and lower 8 bits is the image version	0x424c7801	0x424c7701	0x424c7001
67:4	Signature	The ECDSA signature of the image	Two 256-bit numbers		
91:68	Key	Confidentiality (only applicable for certain formats)	Reserved	192-bit AES-WRAP data holding a 128-bit AES key	Reserved
107:92	IV	Initialization Vector (only applicable for certain formats)	Reserved	16-byte IV generated during signing process	
111:108	Length	The length of the image section in bytes	Maximum supported byte count 0x10000000 bytes		
175:112	Attributes	Image attributes	Support for up to 8 image attributes		
179:176	Reserved	Reserved	Reserved		

Overview of Secure Boot Processing

The ***Secure Boot Processing*** figure illustrates how the block is processed regarding secure features. The figure does not detail all the block header type handling when processing the 16-byte block headers of the image section. For details on the various block types and their functionality, refer to Block Types. Some image types are decrypted. [Decrypt] indicates that the data is decrypted when applicable to the Secure Boot Image Types at that particular stage.

Figure 53-16: Secure Boot Processing

Unsupported Boot Stream Blocks

To ensure the security of the processor, the following block types are not supported in a secure boot image. If the boot kernel finds one of these block types, the boot process terminates.

- Init Block

  Init blocks require a call to user application code prior to the authentication of the boot image, and, therefore, cannot be supported. If customizations or optimizations are necessary to improve the load performance, use a second stage loader style implementation. The first application will contain only the custom code. Issue a call using to boot using the desired device.

- Callback Block

  Callback blocks require a call to a user-defined address prior to the authentication of the boot image, and therefore cannot be supported.

NOTE: Secure boot streams use double buffer Page Mode to optimize the boot process. This functionality allows for the performance of decrypt and hash operations on received data while new data is fetched from the boot source. This host in slave boot mode must ensure that more data is sent after the boot stream to ensure that the temp buffer is filled completely. The size of the secure boot stream minus the size of the secure boot header must be a multiple of the size of the temp buffer. The temp buffer default size is 1024 bytes.

Secure Boot Image Attributes

Secure boot image attributes form part of the secure boot header . The attributes provide more information about the content of the secure boot image.

All image attributes are integrity protected using the same algorithm as the image section. When the image authentication process completes and the image is successfully authenticated, the image attributes are known to be trustworthy.

Attributes are specified as type value pairs with both the type and value being a 32-bit value. The boot code supports the following image attributes.

Table 53-36: Secure Boot Image Attributes

ID	Name	Description	Values	
0x00000000	Unused	Unused attribute	Value must be 0x00000000	
0x00000001	Version	Version of the attribute format	Value must be 0x00000000	
0x00000002	Rollback ID	Current value of the rollback counter	0x00000000	Rollback disabled
			0x00000001 - 0x0000001F	Current firmware revision. Must be greater than or equal to the value retrieved from OTP Refer to Anti-Rollback Protection and the OTP chapter for details on the counter implementation.
0x80000001	NoRestore	Controls whether the boot process restored registers back to default values and clears sensitive security related information from the stack and dedicated structures.	0x1	Do not restore registers and clear security information from the stack and dedicated structures
			other	Restore registers and clear security sensitive information from the stack and dedicated structures
0x80000002	BCODE	Used by the boot mode drivers that support auto-detection to configure the device from a range of pre-configured settings	Values between 0x00000000 and 0x0000000F supported. Please refer to the boot mode specific documentation for details on a boot modes supported BCODE.	

Secure Boot Streams

The secure boot image sections contain the code and data for loading to the various memory regions of the processor. The content is in the form of a boot stream format consisting of block headers that provide a descriptor for the associated block payloads.

The image section within the secure boot stream consists of a standard boot Boot Loader Stream consisting of block headers and payloads as generated by the supporting tools and utilities. Refer to the section describing the format of the boot stream for further details.

The secure boot image section can contain application images for just a single core or for multiple cores allowing for a flexible booting strategy.

A single boot image containing program and data for multiple cores permits a full system boot initializing all internal memories without needing a second stage loader approach. If boot images are required to initialize external memories, then a multi-stage loader approach can be required to configure the memory interfaces. The advantage of a single boot image for multiple cores is that authentication and decryption of the boot image requires only one execution. However, it is over a larger boot image.

Multiple single-core boot images permit one core to boot then execute that core's boot image without booting the other cores. This booting strategy can be needed when a single processor must be brought up quickly to deal with some initial tasks before booting the rest of the system. Or, it can be used to initialize extra peripherals to use for external memory interfaces. The core that has previously booted can then control the boot process for the remaining cores.

Single Core Images

Single core boot images are the result of processing a single core's output from the linker and converting it to a compliant boot stream. The resulting boot stream has a single first block at the beginning of the boot stream and a final block at the end of the boot stream.

The Block Header `HDRSIGN` field of the resulting boot stream is used to identify which core the image is intended for. This identification is required so that the boot code can set the correct `RCU_SVECT[n]` when the first block is read to set the application start address for that core. When the boot image is loaded and authentication is successful, the boot code jumps to the location stored in the cores corresponding `RCU_SVECT[n]` register.

This boot stream must then be Secure Boot Image Signing using the secure boot utilities resulting in the final secure boot image for a single core.

A second stage loader option is also available giving maximum flexibility both in terms of using ROM functionality, or creating a custom booting strategy. The simplest option is to have the application utilize `adi_rom_Boot()` to boot the main application image or indeed a third stage loader when one is required.

The boot stream is generated such that all image contents are in the system address space. Core specific L1 memory sections are converted during the boot stream generation process such that they are loaded through the multiprocessor memory space. The core executing the second stage loader can boot an application image intended for another core.

NOTE: The `ROM_BFLAG_RETURN` flag is set when calling the boot routine for the other cores than the core executing the second stage loader then cleared when loading the cores own image. Failure to do so would result in unintentional behavior.

When a core is used to boot a separately generated boot stream for another core, the `ROM_BFLAG_RETURN` flag should be used when calling `adi_rom_Boot()` instructing the boot kernel to return to the calling application, which in this case is back to the core that was running the second stage loader. Failure to set this flag would result in the core vectoring to the location in its own `RCU_SVECT[n]` register which would not be the intention. In order to allow the core that was just booted to start running the newly loaded application.

By default when implementing a scheme such as previously described where one processor is responsible for booting images for another core, the other cores in the system will remain in their existing idle state that they should be placed in prior to the boot commencing. In order to allows the cores to execute their new application the corew that was responsible for booting the other cores must reset the cores via the `RCU_CRCTL` then release them again from reset. If there is a requirement to release the core from the reset state, then this must be done within the application code of the running core.

Releasing other cores from reset to run application software while other processors are running a boot process requires careful system design. The drivers used by the boot kernel for the boot process assume the various peripheral and infrastructure resources such as MDMA channels and peripherals are available for use, and are not being used by another core. If the boot routine is being executed while other cores are running applications, then those applications must ensure that all the required boot resources are freed up and remain free in order for the boot process to complete on the remaining cores.

Multi-core Boot Images

Multi-core boot images are generated as a result or processing the multiple linker output files for multiple cores together to create a single compliant boot stream. The resulting boot stream has a first header block at the beginning of each core boot stream and a single final block at the end of the boot stream. The boot stream must only have a single final block to allow the boot kernel to continue processing the entire boot stream. A final block results in the boot kernel terminating triggering the final public key authentication sequence.

The block headers `BLOCK_CODE.HDRSIGN` field of the resulting boot stream is used to identify which core the image is intended for. This identification is required such that the boot code can set the correct `RCU_SVECT[n]` when the first block is read to set the application start address for that core. When the boot image is loaded and authentication was successful, the core executing the boot sequence jumps to the location stored in the cores corresponding `RCU_SVECT[n]` register. However, as the boot stream has multiple first blocks present for each of the cores, all other cores `RCU_SVECT[n]` register is set for their applications. Upon the booting core running its application, it must release the other cores from reset in order for them to then start running their loaded applications.

If a product supports three or more cores, it is acceptable to create a dual core boot image and then load the other cores later using single core boot images stored elsewhere in the boot source. There are no restrictions on a multi-core boot stream requiring to contain an application for all the cores in a product.

The resulting multi-core boot stream must then be signed and optionally encrypted resulting in a complaint secure boot stream that can be used to boot a secure device.

Multiple core boot images are advantageous in the fact that applications can be loaded to all cores in the system in a single boot sequence resulting in the requirement to decrypt and authenticate only a single boot image.

NOTE: If there is a requirement for a multi-core boot stream to load code to memory spaces that require a memory controller to be initialized that is not supported by the boot process a multi-stage booting approach is required that can initialize the peripheral. This boot stream is then authenticated, and executed prior to the loading of the boot stream.

Secure Debug Access

The TAPCcontroller provides a means of restricting access to secure resources of the processor. Secure access through the debug port is protected through a 128-bit security key that must match a key that has been loaded into OTP for access.

To access a locked processor, the TAPC must allow access to the part. The TAPC only allows access to the part if it is provided with a matching key to the data loaded into its `TAPC_USERKEYn` registers.

With the processor in a locked state, on initial boot the boot ROM reads the 128-bit `secure_emu_key` from the OTP memory and programs the key into the `TAPC_SDBGKEY0`, `TAPC_SDBGKEY1`, `TAPC_SDBGKEY2`, and `TAPC_SDBGKEY3` registers before then setting the `TAPC_USERKEY_CTL.USERKEY_VALID` bit. Then, the TAPC is able to access a matching outside key to allow access.

CAUTION: A key of 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF provisioned in OTP will result in the boot code bypassing the key load operation entirely. If debug access is then ever required the key must be loaded to the TAPC by user software. If the processor fails to boot perhaps due to corrupted firmware then the user will have no debug access. The only way to gain access would be to load an authenticated boot image that can then load the required keys prior to attempting to connect with a debugger.

The key is set in OTP using the OTP boot program API to program the `secure_emu_key` , this key is read and loaded by the ROM in the following sequence:

1. Bits 31:0 of the key in OTP are stored to `TAPC_SDBGKEY0` bits 31:0
2. Bits 63:32 of the key in OTP are stored to `TAPC_SDBGKEY1` bits 31:0
3. Bits 95:64 of the key in OTP are stored to `TAPC_SDBGKEY2` bits 31:0
4. Bits 127:96 of the key in OTP are stored to `TAPC_SDBGKEY3` bits 31:0

Once the ROM has loaded the user key, a test key can be provided to the TAPC through JTAG. Refer to the Emulator manual for details for providing the key.

A key failure indication can be detected through the `TAPC_SDBGKEY_STAT` register. The boot code does not check the key status, nor does it enable any associated interrupts to signal key failure. The boot code continues to boot upon a key failure in a secure manner. The key failure status remains intact so that the application loaded can check for a failed challenge on the debug port.

The boot code can be configured to bypass the loading of the key during the boot sequence by setting the value of the `otp_data::secure_emu_key` in the OTP to all ones. In this case, the only way to gain access to the secure resources through the debug port is to load an alternate key using the application. The alternative key must always reside in a secure region of memory. Or, if sent remotely, it should be transmitted over a secure connection.

Errors and Failures

Any errors encounters while processing a secure boot image results in the ROM jumping to the Error Handler . This includes decryption failures, authentication failures, and configuration errors.

As the boot process doe no checking for a matched secure debug key, should an incorrect key be supplied during boot, no boot failure will occur and the processor will continue to boot as normal. A user supplying an incorrect key will not be able to gain access to any secure resources of the processor.

Boot ROM Programming Model

This section describes the programming model for booting the processor. The programming model includes booting functions, API calls, and data structures.

Boot Mode Driver API

The kernel provides a mechanism to provide a customization of supported boot modes or for implementation of completely new boot modes as second stage boot loaders. This allows users to customize booting while still taking advantage of the rest of the booting framework. A custom boot mode could provide support for a peripheral that is not supported for boot by the ROM, or it could support one of the same peripherals but with a different configuration.

All the same security features can be supported when using a custom boot mode.

A full boot mode, as perceived by the boot implementation, is a collection of five functions.

- Register - installs the driver functions listed below so they can be accessed by the boot process
- Initialization - initialize the boot source
- Configuration - configure the boot source
- Load - read from the boot source
- Cleanup - called after booting

Of these later four functions the boot kernel is only ever aware and has a requirement to support the Load function. It is this function that is responsible for the fetching of the boot stream from the boot peripheral. The other functions are used prior to executing the kernel or for cleaning up after the kernel has completed processing the boot stream.

To install a custom boot mode:

- Create a first stage boot application to define a Load function

- Use the `adi_rom_BootKernel()` API to call the boot kernel once the boot peripheral and pinmuxing has configured. Ensure all the fields of `ADI_ROM_BOOT_CONFIG` are configured accordingly prior to performing the call.

The boot mode can use the `pModeData` member of `ADI_ROM_BOOT_CONFIG` to preserve and access shared data across the different function calls if required.

All functions have the following prototype:

```
          void apiFunction(
ADI_ROM_BOOT_CONFIG* pBootStruct);
```

Load Function

The load function is required to read data from the source into the specified destination, according to the parameters given through the configuration struct parameter. The structure provides all of the required information read from the block header, or specified by the kernel to read the block header. The load function often makes use of the supplied DMA APIs in order to simplify the load function implementation.

As the kernel processes the stream, it calls the load function to request data. Initially, the request is for the header, then the kernel requests according to the block flags it parses. The load function must only read from the device, and write where requested.

Relevant fields within the `ADI_ROM_BOOT_CONFIG` object for the load function can be (not limited to): `uwDataWidth`, `pSource`, `dByteCount`, `pDestination`, `loadType`.

Custom load functions must meet the following requirements.

- Protect against `dByteCount` values of zero
- Use multiple DMA units if `dByteCount` is greater than 65536 and the peripheral does not support byte count transfers greater than 65536
- The `pSource` and `pDestination` pointers must be properly updated after loading.

In slave boot modes, the boot kernel uses the address of the `dArgument` field in the `pHeader` block as the destination for the required dummy DMAs when payload data is consumed from `ROM_BFLAG_IGNORE` blocks. If the load function requires access to the `ARGUMENT` word of the block, it should be read early in the function.

Initialization/ Configuration Function

The initialization and configuration functions are called in sequence when calling a boot operation using an already supported boot peripheral via the `adi_rom_Boot()` API. These functions are used to configure the boot peripheral prior to calling the boot kernel. Both functions are called in sequence separated only by a call to a user-defined hook function. This hook function is useful when using built-in boot modes to further customize their functionality. The initialization and configuration functions are responsible for applying any required settings to any devices in use. For example, pin multiplexing may need to be applied, and any data or pointers that are used by the load function must be initialized. The specific actions depend on the device and functionality used.

Cleanup Function

The cleanup function is called after the entire boot stream is read, and the kernel has completed its boot mode-specific function. This is only performed when using the `adi_rom_Boot()` API. Resetting of any status registers, or device parameters is done to prepare the environment for the execution of the newly loaded application.

Error Handler

This section describes the default error handler for the ROM including information on how to customize the error handling.

The default error handler eventually puts the core into an idle state. This functionality can be overridden by using an Init Block (see Block Types) to modify the error function point in the `ADI_ROM_BOOT_CONFIG` structure. The error handler has access to the entire boot info structure and receives the instruction address that triggered the error.

When a part is locked, and the boot type has not disabled secure boot, only the default error handler is called.

The expected prototype is:

```
void ErrorFunction(
ADI_ROM_BOOT_CONFIG* pBootStruct, void *pFailingAddress);
```

The error handler saves the failing address to the `ADI_ROM_BOOT_CONFIG` structure then raises the `INTR_SOFT3` fault signaling a fault condition to the system before then entering an endless loop in the boot rom.

NOTE: When using the `adi_rom_Boot()` function to perform a boot action. Users may need to manually configure the `INTR_SOFT3` fault signaling depending on previous application software executed. Calling the boot process via `adi_rom_Boot()` does not result in all the SEC and Fault configuration being reset and installed as described in Preboot Operations.

Page Mode

For the benefit of page oriented boot source devices, and to improve boot performance for secure boot operations, the boot kernel provides support for page operations. Page mode optimizes memory reads for block organized devices by always reading a page, rather than reading data on demand. Two 1024 byte buffers are used in page mode.

Two buffers are used allowing the contents of one buffer to be processed by the boot kernel while DMA is used to load the next data into the second buffer.

The load to the active buffer uses a blocking DMA, forcing the process to pause until the DMA is complete. Loading to the non-active buffer uses non-blocking DMA allowing the active buffer to be processing while loading the new data in parallel.

Page mode can be enabled when calling a boot mode via the `adi_rom_Boot()`. Refer to the API documentation for the various supported by this API. Additionally users can set the flag via `ADI_ROM_BOOT_CONFIG::dFlags` when using hook functions

NOTE: Due to security requirements it is not recommended to customize the page mode settings from the default installed by the boot process.

Boot Hook Function

The boot software allows installation of callback hooks through the use of the `adi_rom_Boot()` APIs hook function parameter. By using this feature, it is possible to alter the state of the processor, at different stages of the boot process and customize the boot structures to alter the behavior of the boot process.

The hook function must adhere to the following prototype:

```
int32_t
hookFunction(
ADI_ROM_BOOT_CONFIG* pBootconfig,
ROM_HOOK_CALL_CAUSE cause);
```

By modifying settings in the `ADI_ROM_BOOT_CONFIG` structure, many alterations of the boot process can be achieved. Much of the same functionality that is available in an Init Block can be provided through the hook function, with even more flexibility for customization. The hook function is called once after executing the boot modes Init routine then once again after executing the boot modes Config routine. A flag passed to the hook function allows software to determine at which point the call took place to allow for conditional processing to occur at different stages of the setup phase.

The hook function must return a zero value in order for normal booting to continue. A non-zero return value will cause the ROM to skip over loading of any data and immediately transfer control according to Boot Termination and Application Execution .

When the hook function is called, a parameter is passed indicating why the hook function was called. Refer to `ROM_HOOK_CALL_CAUSE` for further details.

enum ROM_HOOK_CALL_CAUSE

Enumeration Type Declaration: `ROM_HOOK_CALL_CAUSE`

Passed to a user hook routine to indicate the reason of the call.

When calling a boot mode via adi_rom_Boot, the user may provide an optional hook routine as a callback. This hook routine is called by the boot software firstly after the execution of the boot modes initialization routine then again after execution of the boot modes configuration routine. This parameter allows the users routine to identify at which point the call was made allowing the user to perform different actions for each call.

Table 53-37: ROM_HOOK_CALL_CAUSE Members

Enumerator	Description
	Call was as a result of completion of the boot modes initialization function

Table 53-37: ROM_HOOK_CALL_CAUSE Members (Continued)

Enumerator	Description
`ROM_HOOK_CALL_INIT_COMPLETE`	
`ROM_HOOK_CALL_CONFIG_COMPLETE`	Call was as a result of the completion of the boot modes configuration function

ROM_HOOK_CALL_INIT_COMPLETE

Call was as a result of completion of the boot modes initialization function

ROM_HOOK_CALL_CONFIG_COMPLETE

Call was as a result of the completion of the boot modes configuration function

Boot Return Feature

The `adi_rom_Boot()` API provides a feature to bypass calling of the loaded application upon boot completion, and to simply return to the routine that made the call instead. This can be useful when using the . The boot software returns the next address after the last loaded application block in the boot source when this feature is enabled..

To enable this feature, set the `ROM_BFLAG_RETURN` flag in the `flags` argument when calling the API.

Boot Termination and Application Execution

When the boot kernel completes the processing of the boot stream, a sequence of events is required to then pass control to the loaded application.

When the boot process is complete, the core sis required to vector to the application start address and start executing the newly loaded application. Typically, the first block of a boot stream, which is marked with the `BFLAG_FIRST` flag, contains the address of the application. In a multi-core system there may be multiple first blocks in the boot stream indicating the start address of the application for each core. The application entry point for each core is loaded into the cores corresponding `RCU_SVECTn` register.

Upon boot completion only the core that performed the boot process will vector and start executing the loaded application. This core must then manage the process of resetting then releasing from the reset the other cores in the system in order to make them execute their newly loaded applications.

Execution of the loaded application can be bypassed when calling the boot mode via `adi_rom_Boot()` and setting the `ROM_BFLAG_RETURN` flag.

Table 53-38: Application Entry Point Registers

Core ID	Corresponding RCU_SVECTn Register
0	`RCU_SVECT0`
1	`RCU_SVECT1`

Table 53-38: Application Entry Point Registers (Continued)

Core ID	Corresponding RCU_SVECTn Register
2	RCU_SVECT2

API Reference

The APIs defined in this section are exposed for general use.

adi_rom_Boot()

Provides access to boot an application at run-time through a supported peripheral.

API Details

```
void * adi_rom_Boot(
                    void * pAddress,
                    uint32_t flags,
                    int32_t blockCount,
                    ROM_BOOT_HOOK_FUNC * pHook,
                    uint32_t command
                   )
```

pAddress

Pointer to source address of the boot stream.

flags

contains the global flags to be applied to the entire boot process

blockCount

Number of block to be booted. Zero results in processing until a final block is reached.

pHook

Pointer to user implemented hook function for enabling callbacks during the registering of the boot mode with the boot kernel

command

The boot command defining the boot mode to use, the peripheral instance to boot from as well as some boot mode specific configuration

Returns

The 32-bit address of the next address in the boot source to be processed

Function Description

This function may be used for any kind of second-stage boot for an already supported boot mode. It provides options to boot from any peripheral enumeration and in the case of SPI Master boot using any SPI slave select signal.

Boot modes may support an auto-detection mechanism to identify the type of connected device and the function provides options to bypass such auto-detection and use custom configuration options. Options are also provided to bypass peripheral configuration such as pinmux settings or peripheral configuration if existing peripheral already configured are more appropriate to allow communication with the boot source.

These features are all provided via the command parameter which is specific for each particular boot mode.

The source address of the boot stream is required for master boot modes that require an address to be issued in order to request data from the boot source. Slave boot modes are under full control of the host and use a handshake mechanism to indicate that the processor is ready to receive data. For boot modes such as UART Slave and SPI Slave this parameter is of little value in regards to the boot process itself however it can prove useful in debug to see how far through the boot stream the boot process got in the event of a boot failure.

NOTE: The processor supports both SPI Memory Mapped boot as well as Peripheral Based SPI Boot. When the boot mode is called to boot from the memory mapped boot mode via the command argument the address must coincide with the processors memory mapped SPI address space as defined by the processors internal memory map. When using the peripheral based boot mode the absolute address of the boot stream in flash must be used.

Flags passed via the flags argument are global flags and the functionality gets applied throughout the entire boot process. These must not be confused with the boot block specific flags which are part of the boot stream and indicate how a particular block in the boot stream is processed. Internally the boot kernel will take the global flags supplied via this function call and combine them with a boot blocks local flags to determine all the operations to be performed on a given block. After processing the boot block the local flags get cleared ready to be populated from the next boot block and the global flags remain.

The global flags supported by the product are:

Bit Position	Flag Name	Description
18	ROM_BFLAG_HOOK	Calls the user supplied hook function after execution of bootmode init and config routines
19	ROM_BLAG_PAGEMODE	Enables page mode processing where blocks of data are fetched and processed from internal memory
20	ROM_BFLAG_NOFIRSTHEADER	Set this if calling the boot mode and the first block header has already been fetched and present in the block header storage location
21	ROM_BFLAG_HEADER	Not intended to be set by the user, set by the boot code each time it fetched a block header
22	Reserved	Reserved
23	Reserved	Reserved
24	Reserved	Reserved
25	ROM_BFLAG_PERIPHERAL	Boot mode is a peripheral boot mode as opposed to a memory boot mode

Bit Position	Flag Name	Description
26	ROM_BFLAG_SLAVE	Boot mode is a slave boot mode. This results in different handling of ignore blocks by the kernel
27	ROM_BFLAG_WAKEUP	Set this to enable conditional processing of boot blocks intended for wakeup events but not exclusively
28	ROM_BFLAG_NEXTDXE	Parse stream via Next DXE pointer
29	ROM_BFLAG_RETURN	Return the application after calling the API instead of running the new application
30	Reserved	Reserved
31	ROM_BFLAG_NORESTORE	Do not execute the boot peripherals cleanup routine to restore register contents

The blockCount argument specifies the number of blocks to be processed before terminating the boot process. The default would normally be 0x00000000. A value of 0x00000000 instructs the boot software to continue processing a boot stream until the `ROM_BFLAG_FINAL` flag is set. Should users wish to load only a specified number of blocks they can instruct the boot kernel to do so via this parameter.

When the block count is used in combination with the `ROM_BFLAG_NEXTDXE` flag then the block count is re purposed as a next application count. The boot kernel will navigate the first blocks of multiple boot streams similar to a linked list and upon reaching the requested application count will return the pointer to this application in the boot source. This allows users to use the boot kernel to find a specific application when multiple application boot stream are stored contiguously in the boot source.

The pHook argument is a function pointer to a hook routine. When set along with the `ROM_BFLAG_HOOK` global flag the boot mode will call the hook routine after calling the boot modes `init` and functions in the boot modes driver allowing customization and altering of the configuration performed by the boot software.

This can be used to enabled new features not supported by the boot software and allows for installing of a user defined load function or error handler as an example.

The command argument describes the boot peripheral to boot from, the peripheral instance and contains additional boot mode specific configuration information and flags specific to the boot mode.

NOTE: When calling a boot mode via this API the user must first ensure that the boot peripheral is confirgured accordingly in the SPU as a secure master. The boot software does not configure the peripheral security via this API in order to allow device security to be fully controlled by a dedicated task.

adi_rom_BootKernel()

Calls the boot kernel allowing for implementation of custom boot modes.

API Details

```
void * adi_rom_BootKernel(ADI_ROM_BOOT_CONFIG * pBoot)
```

pBoot

Pointer to the `ADI_ROM_BOOT_CONFIG` boot structure containing the complete context of the boot configuration

Returns

Pointer containing the address of the byte immediately following the end of the boot stream.

Function Description

The boot kernel performs the core processing of the boot stream. The boot kernel calls a load function to load in data from the peripheral to the required destination. The boot kernel itself has no concept of what the boot peripheral is or how that peripheral is configured. The kernel calls the registered load function and the load function must then analyze the boot structure and provide the requested amount of data to the required destination.

The load function called by the kernel is provided via the `ADI_ROM_BOOT_REGISTRY::pLoadFunction` member of `ADI_ROM_BOOT_CONFIG::bootRegistry`.

The boot kernel basically works in a cycle of fetching a boot stream block header then a payload if one exists. The boot kernel takes care of the size of the data being requested and the destination address.

The load function that is registered with the kernel is required to update the `ADI_ROM_BOOT_CONFIG::pSource` member. Keeping this control under the load function as opposed to the boot kernel itself allows load functions to better control where the next block of data is fetched in the event the boot stream is fragmented or split into different areas of the boot source.

This function would typically be used to implement a second stage boot loader for a peripheral in which there is no driver support in the boot rom. The user is responsible for initializing the peripheral prior and the complete `ADI_ROM_BOOT_CONFIG` object prior to calling this function. Upon return form the function the user application is then responsible for performing a vector to the newly loaded application.

NOTE: Users must ensure that a new application being loaded does not clobber the load function and the part of the software responsible for making the core jump to the start of the newly loaded application.

adi_rom_Crc32Init()

The CRC32 Initcode function in the boot rom that is called to enable CRC32 support of boot stream payloads.

API Details

```
ROM_BOOT_RESULT adi_rom_Crc32Init(ADI_ROM_BOOT_CONFIG * pBootConfig)
```

pBootConfig

Pointer to the `ADI_ROM_BOOT_CONFIG` object containing the complete boot configuration

Returns

Returns the following results

- `ROM_BOOT_RESULT::ROM_BOOT_CRC_INITCODE_ERR` when pBootConfig or pBootConfig->pHeader are zero
- `ROM_BOOT_RESULT::ROM_BOOT_SUCCESS` when the callback is registered and lookup table initialized

Function Description

The boot process supports CRC32 protection of all boot block payloads. In order to enable this feature a global callback must be registered with the boot process via `ADI_ROM_BOOT_CONFIG::pCrcFunction` and the CRC peripherals look up table initialized from the users polynomial.

In order to enable the CRC functionality a init block header in which the `ROM_BFLAG_INIT` flag is set must be included in the boot stream. The_ADI_ROM_BOOT_HEADER::pTargetAddress field must be set to the address of this function and the users polynomial is provided via the blocks `ADI_ROM_BOOT_HEADER::dArgument` member.

When the boot kernel processes the init block described the boot kernel calls this function in the boot rom registering the callback with the kernel and performing the look up table initialization.

The CRC functionality is enabled on `MDMA channel 1` interfaced to the `CRC0` peripheral instance

adi_rom_Crc32Poly()

Initializes the CRC peripheral for use with the user supplied polynomial.

API Details

```
ROM_BOOT_RESULT adi_rom_Crc32Poly(
                                  uint32_t CrcPoly,
                                  ROM_BOOT_MDMA_REGS const *const pDma
                                 )
```

CrcPoly

None

pDma

None

Function Description

In order to prepare the CRC peripheral for use, the CRC lookup table must be initialized for the CRC polynomial of choice. Users may perform this task via this function.

adi_rom_GetAddress()

Used to find the location of various look-up tables and data objects used during the boot process.

API Details

```
int32_t adi_rom_GetAddress(ROM_GETADDR_VALUE value)
```

value

The `ROM_GETADDR_VALUE` enumeration specifying the object to retrieve the address of in the ROM memory

Returns

The byte address of the object in memory

Function Description

The function returns the address of the object specified by the enumerator provided as an argument to the function. Using this function cane make software more code compatible with future products and silicon revisions.

Table 53-39: ROM_GETADDR_VALUE Members

Enumerator	Description
`ROM_GETADDR_CONSTANTS`	Retrieve the address of the `ROM_CONSTANTS_TYPE` object
`ROM_GETADDR_BMODE`	Retrieve the address of the lookup table sotring the default adi_rom_boot() parameters for each boot mode
`ROM_GETADDR_MDMAREGS`	Retrieve the address of the `ROM_BOOT_MDMA_REGS` object
`ROM_GETADDR_SPILUT`	Retrieve the address of the lookup table in the rom describing the various SPI master boot BCODE configurations
`ROM_GETADDR_ECDSA_DOMAIN`	Retrieve the address of the domain parameteres used for ECDSA

adi_rom_MemCompare()

Verifies that a block of data is filled with a user supplied 32-bit value.

API Details

```
ROM_BOOT_RESULT adi_rom_MemCompare(
                                   ROM_DMA_MDMA_CONFIG * pDmaCfg,
                                   ROM_BOOT_MDMA_REGS const *const pDma
                                  )
```

pDmaCfg

None

pDma

None

Function Description

The CRC peripheral used in compare mode and a source MDMA channel is used to read data from a buffer and supply each 32-bit value to the CRC. The CRC peripheral checks the incoming 32-bit value matches the 32-bit value to compare against.

adi_rom_MemCopy()

Performs a Memory to Memory DMA (MDMA) operation using a source and destination pair of DMA channels.

API Details

```
ROM_BOOT_RESULT adi_rom_MemCopy(
                                ROM_DMA_MDMA_CONFIG * pDmaCfg,
                                ROM_BOOT_MDMA_REGS const *const pDma
                              )
```

pDmaCfg

Pointer to the `ROM_DMA_PDMA_CONFIG` object containing the peripheral DMA configuration

pDma

Pointer to the `ROM_BOOT_MDMA_REGS` objects that provides access to the DMA channels MMRs and associated CRC peripheral

Returns

Returns the following results

- `ROM_BOOT_RESULT::ROM_BOOT_SUCCESS` for a successful operation or when byte count is 0 as no operation to be performed
- `ROM_BOOT_RESULT::ROM_BOOT_DMA_FAILURE` if a configuration error was detected in the DMA channel prior to configuring the channels for the new operation
- if a configuration error occurred in the source MDMA channel
- if a configuration error occurred in the destination MDMA channel

Function Description

The memory copy routine performs transfers of blocks of data from one memory location to another. The routine takes a basic descriptor providing configuration details of the operation to be performed via the `ROM_DMA_MDMA_CONFIG` object passed as the first argument. The second argument is a descriptor that provides access the DMA channels MMR registers and associated CRC peripheral. When called from the higher level `adi_rom_MemDma()` routine this object is retrieved from the ROM.

NOTE: Users are expected to make use the `adi_rom_MemDma()` routine for all MDMA operations, there is little additional optional configuration that is supported by using this routine.

adi_rom_MemCrc()

Performs CRC32 verification of a block of block of data by reading the contents and comparing with an expected result.

API Details

```
ROM_BOOT_RESULT adi_rom_MemCrc(
                               ROM_DMA_MDMA_CONFIG * pDmaCfg,
                               ROM_BOOT_MDMA_REGS const *const pDma
                              )
```

pDmaCfg

Pointer to the `ROM_DMA_PDMA_CONFIG` object containing the peripheral DMA configuration

pDma

Pointer to the `ROM_BOOT_MDMA_REGS` objects that provides access to the DMA channels MMRs and associated CRC peripheral

Function Description

The routine uses an MDMA channel pairs source DMA channel and the CRC peripheral to calculate a CRC32 result of a data block using a previously supplied polynomial.

The polynomial should be supplied through the `adi_rom_Crc32Poly()` routine in order to ensure consistent CRC peripheral configuration for the look up table initialization that uses the polynomial and the

NOTE: Users are expected to make use the `adi_rom_MemDma()` routine for all MDMA operations, there is little additional optional configuration that is supported by using this routine.

adi_rom_MemDma()

Provides access to all the MDMA operations supported by the boot ROM implementation.

API Details

```
ROM_BOOT_RESULT adi_rom_MemDma(ROM_DMA_MDMA_CONFIG * pDmaCfg)
```

pDmaCfg

Pointer to the `ROM_DMA_MDMA_CONFIG` object containing the MDMA configuration

Returns

Returns the following results

- `ROM_BOOT_RESULT::ROM_BOOT_SUCCESS` for a successful operation or when byte count is 0 as no operation to be performed

- `ROM_BOOT_RESULT::ROM_BOOT_MDMA_ID_ERR` if an MDMA channel ID is provided that is not supported
- `ROM_BOOT_RESULT::ROM_BOOT_CRC_SUPPORTED_ERR` if a CRC operation was attempted on an MDMA channel not supporting CRC
- `ROM_BOOT_RESULT::ROM_BOOT_MDMA_OPERATION_ERR` if the operation to be performed is not supported
- `ROM_BOOT_RESULT::ROM_BOOT_DMA_FAILURE` if a configuration error was detected in the DMA channel prior to configuring the channels for the new operation
- `ROM_BOOT_RESULT::ROM_BOOT_DMA_FAILURE` if a configuration error was detected in the DMA channel and the operation requested involves only a single DMA channel
- if a configuration error occurred in the source MDMA channel
- if a configuration error occurred in the destination MDMA channel
- `ROM_BOOT_RESULT::ROM_BOOT_CRC_COUNT_ERR` if a CRC operation is being requested and the byte count is not a multiple of 4
- `ROM_BOOT_RESULT::ROM_BOOT_CRC_FAILURE` if CRC32 verification fails
- `ROM_BOOT_RESULT::ROM_BOOT_CRC_FAILURE` if 32-bit memory compare fails

Function Description

The MDMA operations supported are:

Table 53-40: ROM_DMA_MDMA_OPERATION Members

Enumerator	Description
`ROM_DMA_MEM_COPY`	Standard MDMA transfer from a source to a destination
`ROM_DMA_MEM_CRC`	Performs a CRC32 MDMA read operation and compares the result with an expected result
`ROM_DMA_MEM_FILL`	Uses the CRC peripheral to perform a fill operation with a 32-bit value
`ROM_DMA_MEM_COMPARE`	Uses the CRC peripheral to compare data with a constant 32-bit value
`ROM_DMA_CRC_LUT_INIT`	Initializes the CRC LUT from the supplied CRC Polynomial

NOTE: While the MDMA and CRC peripherals support on the fly CRC32 calculations during the transfer of data from one location to another, the MDMA functionality of the boot ROM software does not support this. For CRC calculations data is instead read back from its final destination and verified.

While this function is the main entry point for all the MDMA functionality supported by the boot ROM software, the individual functions that are called for each operation type are also exposed via the public API.

NOTE: The recommendation is to use this function for all operations. The lower level functions allow for some basic reconfiguration of default parameters however such modifications should not be required in most cases where these basic MDMA operations are required.

The boot ROM has an MDMA configuration data structure included that is used to specify the overall MDMA configuration of the processor. It provides details on the DMA channel ID associated with each MDMA channels source and destination DMA channels as well as information relating to CRC support and the CRC peripheral instance that is to be used for a given MDMA channel. Please refer to `ROM_BOOT_MDMA` and `ROM_BOOT_MDMA_REGS` for full details of the content stored.

The configuration provided as the only argument to the function is provided below:

Table 53-41: ROM_DMA_MDMA_CONFIG Members

Type	Name	Description
`ROM_DMA_MDMA_OPERATION`	`eOperation`	Type of operation to perform
`ROM_DMA_MDMA_ID`	`eId`	MDMA Channel ID
`void *`	`pSource`	Source Pointer
`void *`	`pDestination`	Destination Pointer
`uint32_t`	`ByteCount`	Byte Count
`ROM_DMA_DONE_DETECT_METHOD`	`eDoneDetect`	DMA Done Detection Method
`uint32_t`	`CrcCtl`	`CRC_CTL` value when CRC operations are required
`uint32_t`	`FillVal`	Fill value for memory fill operations
`uint32_t`	`CrcPoly`	CRC Polynomial for CRC operations
`uint32_t`	`CrcCompare`	Value used for CRC compare operations or for a CRC32 result compare

For a basic MDMA transfer from source to destination the user needs to configure:

- The `ROM_DMA_MDMA_CONFIG::eOperation` type as `ROM_DMA_MDMA_OPERATION::ROM_DMA_MEM_COPY`
- The MDMA channel to use via `ROM_DMA_MDMA_CONFIG::eId` for example
- Set the address of the source data via `ROM_DMA_MDMA_CONFIG::pSource`
- Set the destination address of the source data via `ROM_DMA_MDMA_CONFIG::pDestination`
- Set the byte count via `ROM_DMA_MDMA_CONFIG::ByteCount`
- Set `ROM_DMA_MDMA_CONFIG::eDoneDetect` to `ROM_DMA_DONE_DETECT_METHOD::ROM_DMA_DONE_POLL_IRQDONE` in order to poll for DMA completion

NOTE: The implementation of the MDMA operations does not support interrupt driven data transfers the routines were implemented for the intentions of polling on the DMA status for use during the boot process. Also there are restrictions in regards to the boot stream in regards to byte counts and source and destination address alignment all being a multiple of 4 bytes and as such, compliance to these restrictions must be adhered to when using these MDMA routines.

When wishing to use the CRC32 functionality of the MDMA routines, the user must first of all initialize the CRC lookup table from the user supplied polynomial. This operation can be performed by setting `ROM_DMA_MDMA_CONFIG::eOperation` type as `ROM_DMA_MDMA_OPERATION::ROM_DMA_CRC_LUT_INIT`. If an MDMA channel is specified that does not support CRC functionality an error result is returned.

For further details of the individual operations supported please refer to the following API references:

- `adi_rom_MemCopy()`
- `adi_rom_MemCrc()`
- `adi_rom_MemFill()`
- `adi_rom_MemCompare()`
- `adi_rom_Crc32Poly()`

adi_rom_MemFill()

Fills a block of memory with a 32-bit user supplied value.

API Details

```
ROM_BOOT_RESULT adi_rom_MemFill(
                                ROM_DMA_MDMA_CONFIG * pDmaCfg,
                                ROM_BOOT_MDMA_REGS const *const pDma
                               )
```

pDmaCfg

None

pDma

None

Returns

Returns the following results

- `ROM_BOOT_RESULT::ROM_BOOT_SUCCESS` for a successful operation or when byte count is 0 as no operation to be performed

- ROM_BOOT_RESULT::ROM_BOOT_DMA_FAILURE if a configuration error was detected in the DMA channel prior to configuring the channels for the new operation
- if a configuration error occurred in the source MDMA channel
- if a configuration error occurred in the destination MDMA channel

Function Description

The CRC peripheralis configured for fill mode and the destination MDMA channel is configured to fill a block of memory with a fixed 32-bit value.

adi_rom_PeriphDma()

Provides access to any peripherals dedicated DMA channel for receive operations only.

API Details

```
ROM_BOOT_RESULT adi_rom_PeriphDma(ROM_DMA_PDMA_CONFIG * pDmaCfg)
```

pDmaCfg

Pointer to the ROM_DMA_PDMA_CONFIG object containing the peripheral DMA configuration

Returns

Returns the following results

- ROM_BOOT_RESULT::ROM_BOOT_SUCCESS for a successful operation or when byte count is 0 as no operation to be performed
- ROM_BOOT_RESULT::ROM_BOOT_DMA_ACTIVE if the DMA channel is currently running
- ROM_BOOT_RESULT::ROM_BOOT_DMA_FAILURE if a configuration error was detected in the DMA channel after starting the DMA operation

Function Description

The peripheral DMA routine is used by the load routines of boot peripherals that have dedicated DMA channels and do not support MDMA channel pairs. Examples are the SPI when not configured for memory mapped mode and UART peripherals.

In the boot implementation this routine is called from the peripheral load function to request data from the boot source. The routine supports both polling on DMA completion and non-blocking operation to allow for immediate return after starting the DMA operation and continuing with further processing.

NOTE: The function only supports read operations from the peripheral to memory. Transmit operations from memory to peripheral are not supported

adi_rom_otp_cfg()

Configures the `OTPC` to enable read and program operations to be be performed.

API Details

```
bool adi_rom_otp_cfg(void)
```

Function Description

Users may call this routine to ensure the `OTPC` is configured correctly for read and write access.

NOTE: The preboot process configured the `OTPC` for use and as such there should be no direct requirement to call this function when using the OTP.

adi_rom_otp_get()

Reads the field from `OTP` as defined by the supplied `OTPCMD`.

API Details

```
bool adi_rom_otp_get(
                     OTPCMD cmd,
                     uint32_t data[]
                    )
```

cmd

The `OTPCMD` enumeration describing the OTP content to be read

data[]

Pointer to storage area to store the read OTP contents

Function Description

Users can read the various fields of the OTP via this routine. The supplied `OTPCMD` object is used to specify the object to be read.

Table 53-42: OTPCMD Members

Enumerator	Description
`otpcmd_reserved0`	Reserved
`otpcmd_huk`	Hardware Unique Key
`otpcmd_DTCP_key_ecc`	DTCP Key (ECC Parameters)
`otpcmd_DTCP_key_cont`	DTCP Key (constant for content key)
`otpcmd_DTCP_key_dev`	DTCP Key (device specific keys)

Table 53-42: OTPCMD Members (Continued)

Enumerator	Description
`otpcmd_pvt_128key0`	Customer Private AES Key0
`otpcmd_pvt_128key1`	Customer Private AES Key1
`otpcmd_pvt_128key2`	Customer Private AES Key2
`otpcmd_pvt_128key3`	Customer Private AES Key3
`otpcmd_ek`	Endorsement Key
`otpcmd_secure_emu_key`	Secure Emulation Key
`otpcmd_public_key0`	Customer Public Key0
`otpcmd_public_key1`	Customer Public Key1
`otpcmd_boot_info`	Customer Programmable Boot Information
`otpcmd_otpTiming`	OTP Read timing override
`otpcmd_antiroll_nv_cntr`	AntiRollback NV Counter
`otpcmd_gp1`	General Purpose 1
`otpcmd_bootModeDisable`	Boot Mode Disable Bits
`otpcmd_preboot_ddr_cfg`	User DMC configuration
`otpcmd_stageID`	StageID
`otpcmd_reserved1`	Reserved

adi_rom_otp_lock()

Locks the processor, enabling all security features.

API Details

```
bool adi_rom_otp_lock(void)
```

Function Description

This function si used to lock the processor securing the device from unauthorized access. Once called users must supply a secure debug key in order to gain access to the device with debug tools and the part may only be booted using a secure boot stream.

WARNING: Users must ensure that the OTP secure boot fields are all programmed. Secure boot can be verified prior to locking the processor. Users should also provision a secure debug key.

adi_rom_otp_pgm()

Programs the `OTP` Memory with the contents of the `otp_data` object.

API Details

```
bool adi_rom_otp_pgm(otp_data * data)
```

data

Pointer to the::otp_data object containing the complete OTP contents to program

Function Description

The OTP memory is only programmed with values that are not 0. Any items that are 0 are ignored. Users are expected to use this function for all OTP program operations.

callback()

Callback function for implementing custom callbacks to previously loaded code during boot.

API Details

```
ROM_BOOT_RESULT callback(
                         ADI_ROM_BOOT_CONFIG * pBootConfig,
                         ADI_ROM_BOOT_BUFFER * pBuffer,
                         uint32_t nFlags
                        )
```

pBootConfig

Pointer to the `ADI_ROM_BOOT_CONFIG` object containing the complete context of the boot procedure

pBuffer

Pointer to the `ADI_ROM_BOOT_BUFFER` object containing details of the payload associated with the callback

nFlags

The callback flags as set by the boot kernel

Function Description

A single callback function may be registered with the boot kernel via `ADI_ROM_BOOT_CONFIG::pCallBackFunction`. This functions is then called whenever a block is processed with the `ROM_BFLAG_CALLBACK` flag set. Only a single callback function can be registered for the complete boot process.

Callbacks may typically be used alongside indirect blocks. This would be used if there was a requirement for post processing of the received boot data before sending to the final destination. An example of this would be if compression was applied to block payloads. The compressed payload would be loaded indirectly to the intermediate buffer where it would be decompressed by the callback. The callback can modify the source address and byte count for the final MDMA transfer of the decompressed payload via the supplied pBuffer parameter such that when the callback returns the boot kernel then handles the final transfer of the uncompressed data to the destination.

When dealing with indirect blocks, there are restrictions on the amount of data that can be loaded depending on the size of the intermediate buffer. For this reason the nFlags parameter is used to indicate the status of the callback when handling larger blocks of indirect data. The table below defines the supported flags:

Bit Position	Flag Name	Description
0	`ROM_CBFLAG_DIRECT`	When set indicates the call was from the processing of a block header with the `ROM_BFLAG_CALLBACK` flag set
1	`ROM_CBLAG_PAGESTART`	Indicates the callback was a result of a fetch of a page of data to the intermediate buffers
2	`ROM_CBFLAG_FIRST`	Set if the first fetch of payload data
3	`ROM_CBFLAG_FINAL`	Set if the final fetch of payload data
31:4	Reserved	Reserved

When a callback block header is received by the boot kernel a call to the callback is performed with the `ROM_CBFLAG_DIRECT` flag set. If the `ROM_BFLAG_INDIRECT` flag or the `ROM_BFLAG_PAGEMODE` flags are set indicating the use of indirect or page mode the `ROM_CBFLAG_FIRST` and `ROM_CBFLAG_FINAL` flags are cleared. If the transfer is a direct transfer straight to the final destination and not via the intermediate buffers then the `ROM_CBFLAG_FIRST` and `ROM_CBFLAG_FINAL` flags are also set.

This allows software to identify a callback call based on the processing of a block header with the `ROM_BFLAG_CALLBACK` flag set.

In addition to callbacks being performed on processing of the block header they are also called when processing payloads indirectly or when page mode is enabled. When the callback is called as a result of processing the payload data via the intermediate buffers `ROM_CBFLAG_DIRECT` is cleared. If the callback is being called as a result of fetching the first block of data in the payload the `ROM_CBFLAG_FIRST` flag is set. If the complete block of data fits in the intermediate buffer is also set. If the payload does not fit completely in the intermediate buffers multiple fetches must take place and thus multiple callbacks generated. If no flags are set it indicates a callback on a payload transfer and it is neither the first nor the last block of data in the payload, so there is still further data in the payload to be fetched. If only `ROM_CBFLAG_FINAL` is set then it is the final block in a payload transfer.

The following table provides an overview of the flag states and their meaning for the processing of callbacks.

ROM_CBFLAG_ DIRECT	**ROM_CBFLAG_ PAGESTART**	**ROM_CBFLAG_ FIRST**	**ROM_CBFLAG_ FINAL**	Description
1	0	0	0	Callback as a result of processing a block header with indirect or pagemode enabled
1	0	1	1	Callback as a result of processing a block header with indirect and pagemode disabled
0	1	0	0	Callback as a result of fetching a page of data in pagemode

ROM_CBFLAG_ DIRECT	ROM_CBFLAG_ PAGESTART	ROM_CBFLAG_ FIRST	ROM_CBFLAG_ FINAL	Description
0	1	0	1	Callback as a result of fetching a page of data in pagemode and the final page in the block
0	0	1	0	Callback as a result of fetching the first part of payload in an indirect payload
0	0	0	0	Callback as a result of fetching an indirect payload, not first or last transfer in payload
0	0	0	1	Callback as a result of fetching the final part of payload in an indirect payload
0	0	1	1	Callback as a result of fetching the complete payload in an indirect payload

initcode()

Initcode function for implementing custom callbacks to previously loaded code during boot.

API Details

```
void initcode(ADI_ROM_BOOT_CONFIG * pBootConfig)
```

pBootConfig

Pointer to the `ADI_ROM_BOOT_CONFIG` object containing the complete context of the boot procedure

Function Description

Initcode functions can be embedded into the boot stream to allow for execution of user defined code during the boot phase. This is typically used to allow for optimal configuration of the CGU or any external memory interfaces that may be required to be initialized in order to be able to boot data to those memories.

A boot stream may have any number of initcodes present. The only requirement is that the code to be executed must be loaded prior to the `BFLAG_INIT` block being processed.

The initcode routine is passed the pointer to the complete boot context allowing for initcodes to provide extensive boot customization tasks is so desired.

Data Structures

The programming model for booting the processor uses the data structures defined in this section.

struct ADI_ROM_BOOT_BUFFER

Structure Type Declaration: `ADI_ROM_BOOT_BUFFER`

Boot Buffer.

A basic buffer type consisting of a pointer to the buffer and its size

Table 53-43: ADI_ROM_BOOT_BUFFER Members

Type	Name	Description
`void *`	`pBuffer`	Pointer to the buffer
`int32_t`	`dByteCount`	Size of the buffer

pBuffer

Pointer to the buffer

dByteCount

Size of the buffer

struct ADI_ROM_BOOT_CONFIG

Structure Type Declaration: `ADI_ROM_BOOT_CONFIG`

The Boot Configuration Object that contains all context for the boot process.

This structure contains the complete context for the boot process. A pointer to this object is passed through many of the routines and is presented to routines that are expected to be customized by users such as initcodes, custom initialization, configuration, load and cleanup routines. The object is passed to error handlers and callbacks giving the end user opportunity to significantly customize and adapt the boot process to their specific needs, especially in regards to multi-stage boot loader development.

Table 53-44: ADI_ROM_BOOT_CONFIG Members

Type	Name	Description
`void *`	`pSource`	Source address from where to fetch the next boot data.
`void *`	`pDestination`	Destination address to store the fetched data.
`int32_t`	`dByteCount`	Number of bytes to fetch from the boot source.
`int32_t`	`dFlags`	Control flags related to the boot kernel processing of blocks.
`uint32_t`	`ulBlockCount`	Limit of blocks to be processed during boot.
`uint32_t`	`ulBlockCurrent`	The number of blocks currently processed by the boot kernel
`void *`	`pNextDxe`	Pointer to the next application in the boot stream or the first free location after the boot stream.
`uint32_t`	`uByteAddress`	The destination address converted to the byte address space.
`uint32_t volatile *`	`pControlRegister`	Pointer to the boot peripherals control register.

Table 53-44: ADI_ROM_BOOT_CONFIG Members (Continued)

Type	Name	Description
`int32_t`	`dControlValue`	Storage for the boot peripheral main control value to enable that peripheral in a required configuration.
`uint32_t volatile *`	`pPeripheralBase`	Pointer to the boot peripherals base MMR address
`uint32_t volatile *`	`pAuxControlRegister`	Pointer to any register that may be used for auxiliary operations such as a timer control register for UART autobaud detection
`uint32_t volatile *`	`pAuxPeripheralBase`	Pointer to the base address of any peripheral used for auxiliary operations such as the TIMER block
`uint32_t volatile *`	`pSecControlRegister`	Base MMR address of the SEC SSI instance associated with the boot peripheral should they be required for advanced second stage boot loader development
`ADI_DMA_TypeDef *`	`pDmaBaseRegister`	Base MMR address of the DMA channel associated with the boot peripheral.
`ROM_DMA_DONE_DETECT_METHOD`	`loadType`	Set by the kernel to specify to the boot peripherals load function if it is requesting a blocking or non-blocking DMA
`ROM_DMA_MDMA_CONFIG`	`MdmaCfg`	An MDMA descriptor that is used by the boot kernel for internal MDMA operations.
`uint16_t`	`uwDataWidth`	The maximum data width supported by the boot peripherals DMA channel. Set to 0 for 8-bit, 1 for 16-bit and 2 for 32-bit
`uint16_t`	`uwSrcModifyMult`	The source modify multiplier used to set `DMA_XMOD` for source MDMA operations or peripheral DMA transmit operations
`uint16_t`	`uwDstModifyMult`	The destination modify multiplier used to set `DMA_XMOD` for destination MDMA operations or peripheral DMA receive operations
`uint16_t`	`uwUserShort`	Free to use by the user
`int32_t`	`dUserLong`	Free to use by the user
`int32_t`	`dReserved0`	Reserved for future use
`void *`	`pModeData`	Pointer to the boot mode specific data structure.
`int32_t`	`dBootCommand`	The boot command value supplied during the call to the `adi_rom_Boot()` routine
`ADI_ROM_BOOT_HEADER *`	`pHeader`	Pointer to the boot header storage location where all boot stream block headers eventually reside for processing by the kernel
`void *`	`pTempBuffer`	Pointer to the internal intermediate buffer. Used for processing of indirect blocks
`void`	`dReserved1`	Reserved
`int32_t`	`dTempByteCount`	Size of the internal intermediate buffer in bytes
`void *`	`pTempSource`	Current source address that is being processed in the internal intermediate buffer

Table 53-44: ADI_ROM_BOOT_CONFIG Members (Continued)

Type	Name	Description
int32_t	dPageByteCount	The page size to be used for page mode processing. On this product page size is fixed to 1024 bytes and this member is not used for the load requests
ADI_ROM_BOOT_INTER_BUFFERS	bootBuffers	The internal intermediate buffer descriptors required when using indirect and page mode features
ROM_BOOT_REGISTRY	bootRegistry	The registry object that is used to register a boot peripherals routines with the kernel.
ROM_BOOT_ERROR_FUNC *	pErrorFunction	Pointer to the error handler to be called in the event of an error
ROM_BOOT_CALLBACK_FUNC *	pCallBackFunction	Pointer to the callback function that is called when processing boot blocks with the callback flag set
ROM_BOOT_CALLBACK_FUNC *	pCrcFunction	Pointer to the CRC function that is used to perform CRC validation of the boot stream payload data
ROM_BOOT_CALLBACK_FUNC *	pForwardFunction	Feature not supported on this product
ADI_ROM_BOOT_MODES	bootModes	Access to all boot mode specific resources
void *	pLogBuffer	Pointer to the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines
void *	pLogCurrent	The current position within the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines
int32_t	dLogByteCount	The size of the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines
ADI_ROM_OTP_BOOT_INFO *	pOtpBootInfo	Pointer to the ADI_ROM_OTP_BOOT_INFO boot information block that gets read from OTP and contains boot customization options
ADI_ROM_BOOT_KEY_TYPE	keyType	When set to a specific value allows keys not stored in OTP to be used for secure boot evaluation on an open processor.
ADI_ROM_BOOT_TYPE	bootType	A key to indicate if the boot type is secure or non-secure for open parts
ROM_SB_IMAGE_TYPE	secureBootImageType	The type of secure boot image
SBIF_ECDSA_Header_t *	pSecureHeader	Pointer to the secure boot stream header that is loaded by the boot peripheral from the boot source during the configuration phase
ADI_SBIF_ECDSA_PublicKey_t	publicKey	The public key used for secure boot image authentication
CRYPTO_DESCRIPTORS	cryptoDescriptors	The descriptor items as required for the PKTE operations
SB_StorageArea_t *	pSB_Storage	Storage area reserved for some crypto operations
int32_t	secureBytesRemaining	The number of bytes remaining to be processed in the secure boot stream
uint32_t[4]	aesKey	The 128-bit AES decryption key

Table 53-44: ADI_ROM_BOOT_CONFIG Members (Continued)

Type	Name	Description
`uint32_t[6]`	`aesWrapKey`	The key wrapped key from the `BLw` secure boot image
`uint32_t[4]`	`IV`	The `IV` as read from the secure boot header as required to initialize the PKTE
`uint8_t *`	`pHash`	Pointer to the output destination of the SHA-224 result that is required for authentication of the secure boot stream
`uint32_t`	`errorReturn`	Storage location for the address of the instruction line following a call to the error handler

pSource

Source address from where to fetch the next boot data.

The source address must be maintained by the boot peripherals load function. The kernel does not update the source pointer automatically after requesting data. This allows for load routines to control and change the source address, especially useful for advanced second stage loaders if they have a requirement to change the source address due to a fragmented boot stream or to reset the address if expanding into a second SPI flash device.

During debug it is useful in identifying the block in the boot stream that is currently being processed.

pDestination

Destination address to store the fetched data.

Used by the boot kernel to indicate the destination address for the data to be fetched. Boot peripherals load function must transfer the data to this location before returning back to the kernel. The boot kernel updates this field depending on whether a block header or payload is being fetched. In normal mode of operation the kernel will load this field with the location of the storage area to store a block header then after processing the block header loads it with the `ADI_ROM_BOOT_HEADER::pTargetAddress` contents red from the fetched block header. When using page mode the destination points to the internal buffers and is then updated for transferring data to the final destination.

dByteCount

Number of bytes to fetch from the boot source.

The kernel sets this parameter to indicate to he load function the number of bytes the kernel is requesting. The kernel is responsible for adjusting the byte count for page mode based accesses. The peripherals load function must return the required number of bytes to the destination address provided.

dFlags

Control flags related to the boot kernel processing of blocks.

When calling a boot mode via the `adi_rom_Boot()` routine the `flags` supplied to that routine are used to initialize this item. These become global flags that remain set through the entire boot process. When a block header is received the lower 16-bits of the block header are OR'ed with the global flags. The boot software may clear some flags if it detects some flags are not compatible with some others and then writes the resulting flags back to this member. The boot kernel then processes the block payload as instructed by the combination of global and boot block specific flags. Upon completion of the block processing original set of global flags are restored and the process repeated.

ulBlockCount

Limit of blocks to be processed during boot.

When calling the boot process the `adi_rom_Boot()` routine can accept a block limit for the number of blocks to process before terminating the boot process. If the block count is set to zero then the boot process will continue until a final block reached indicating end of the boot stream. This member holds the user specified limit for the number of blocks to be processed and is used by the boot kernel after processing of each block and compares it against the `ADI_ROM_BOOT_CONFIG::ulBlockCurrent` value. Boot process terminates when `ADI_ROM_BOOT_CONFIG::ulBlockCurrent` equals `ADI_ROM_BOOT_CONFIG::ulBlockCount`

ulBlockCurrent

The number of blocks currently processed by the boot kernel

pNextDxe

Pointer to the next application in the boot stream or the first free location after the boot stream.

This member is initialized when processing a first block in the boot stream. The `ADI_ROM_BOOT_HEADER::dArgument` field of a first block contains the number of bytes left in the boot stream before we reach the end of that boot stream. This allows for the this pointer to be used to point to the next boot stream or to the first empty location after the boot stream. This allows for a feature when using the `adi_rom_Boot()` routine to find the address of an application in a linked list of boot streams or to find the first empty location after the boot stream.

uByteAddress

The destination address converted to the byte address space.

This member is used to store the byte address space equivalent of SHARC L1 memory addresses, allowing any core to load content to any SHARC cores L1 memory. The SHARC core in which the load is targeted is determined by the block header.

pControlRegister

Pointer to the boot peripherals control register.

This can be used by a boot mode peripherals driver in order to gain efficient access to a control MMR register in the boot peripheral.

NOTE: This is not used in this products boot implementation but may be leveraged by developers of second stage boot loaders if required

dControlValue

Storage for the boot peripheral main control value to enable that peripheral in a required configuration.

This can be used by a boot modes peripheral driver in order to store a control value that can be used to enable the peripheral for a required configuration.

pPeripheralBase

Pointer to the boot peripherals base MMR address

pAuxControlRegister

Pointer to any register that may be used for auxiliary operations such as a timer control register for UART autobaud detection

pAuxPeripheralBase

Pointer to the base address of any peripheral used for auxiliary operations such as the TIMER block

pSecControlRegister

Base MMR address of the SEC SSI instance associated with the boot peripheral should they be required for advanced second stage boot loader development

pDmaBaseRegister

Base MMR address of the DMA channel associated with the boot peripheral.

This is used by the boot kernel to gain access to the DMA channels status when using non blocking DMA operations when page mode or secure boot is required, so it must be set when implementing custom boot loaders in order for the kernel to get access to that peripherals DMA status.

NOTE: If a custom boot peripheral does not support the standard DMA instance then the custom driver will be required to set up a DMA instance in SRAM that this location points to and the load function would need to update the status accordingly to indicate when the DMA was running and when the DMA completed.

loadType

Set by the kernel to specify to the boot peripherals load function if it is requesting a blocking or non-blocking DMA

MdmaCfg

An MDMA descriptor that is used by the boot kernel for internal MDMA operations.

The boot kernel may be required to perform internal MDMA operations outside the control of the boot peripheral driver. Such operations include processing of fill blocks CRC callbacks for CRC verification and MDMA operations from the internal intermediate buffers for indirect block and page mode processing.

NOTE: Users must not use this item or reconfigure this item when developing custom boot drivers, it is intended purely for the internal use by the boot kernel

uwDataWidth

The maximum data width supported by the boot peripherals DMA channel. Set to 0 for 8-bit, 1 for 16-bit and 2 for 32-bit

uwSrcModifyMult

The source modify multiplier used to set `DMA_XMOD` for source MDMA operations or peripheral DMA transmit operations

uwDstModifyMult

The destination modify multiplier used to set `DMA_XMOD` for destination MDMA operations or peripheral DMA receive operations

uwUserShort

Free to use by the user

dUserLong

Free to use by the user

pModeData

Pointer to the boot mode specific data structure.

Can be set by a boot peripheral driver to allow for a single point of access to the boot mode specific object containing control and configuration information specific to that single boot mode.

dBootCommand

The boot command value supplied during the call to the `adi_rom_Boot()` routine

pHeader

Pointer to the boot header storage location where all boot stream block headers eventually reside for processing by the kernel

pTempBuffer

Pointer to the internal intermediate buffer. Used for processing of indirect blocks

dTempByteCount

Size of the internal intermediate buffer in bytes

pTempSource

Current source address that is being processed in the internal intermediate buffer

dPageByteCount

The page size to be used for page mode processing. On this product page size is fixed to 1024 bytes and this member is not used for the load requests

bootBuffers

The internal intermediate buffer descriptors required when using indirect and page mode features

bootRegistry

The registry object that is used to register a boot peripherals routines with the kernel.

When using the `adi_rom_Boot()` function the boot software calls a peripherals initialization, configuration, load and cleanup routines from the pointers stored in this object. The kernel itself only makes calls to the load function for the peripheral so when using the `adi_rom_BootKernel()` function the load function that is called by the boot kernel to fetch data from the boot source must be registered via `ADI_ROM_BOOT_REGISTRY::pLoadFunction`.

pErrorFunction

Pointer to the error handler to be called in the event of an error

pCallBackFunction

Pointer to the callback function that is called when processing boot blocks with the callback flag set

pCrcFunction

Pointer to the CRC function that is used to perform CRC validation of the boot stream payload data

pForwardFunction

Feature not supported on this product

bootModes

Access to all boot mode specific resources

pLogBuffer

Pointer to the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines

pLogCurrent

The current position within the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines

dLogByteCount

The size of the log buffer. Logging is disabled by default on this product and thus must be configured from within initcodes or hook routines

pOtpBootInfo

Pointer to the `ADI_ROM_OTP_BOOT_INFO` boot information block that gets read from `OTP` and contains boot customization options

keyType

When set to a specific value allows keys not stored in `OTP` to be used for secure boot evaluation on an open processor.

By default when performing boot on an open part the decryption keys and the public key are fetched from `OTP`. By setting this field to `ADI_ROM_BOOT_KEY_TYPE::ADI_ROM_CUSTOM_SECURITY` users can disable the fetching of the keys from `OTP` and instead provision the keys directly in the `ADI_ROM_BOOT_CONFIG::publicKey` and `ADI_ROM_BOOT_CONFIG::aesKey` members via hook routines when using the `adi_rom_Boot()` function.

bootType

A key to indicate if the boot type is secure or non-secure for open parts

secureBootImageType

The type of secure boot image

pSecureHeader

Pointer to the secure boot stream header that is loaded by the boot peripheral from the boot source during the configuration phase

publicKey

The public key used for secure boot image authentication

cryptoDescriptors

The descriptor items as required for the PKTE operations

pSB_Storage

Storage area reserved for some crypto operations

secureBytesRemaining

The number of bytes remaining to be processed in the secure boot stream

aesKey

The 128-bit AES decryption key

aesWrapKey

The key wrapped key from the `BLw` secure boot image

IV

The `IV` as read from the secure boot header as required to initialize the PKTE

pHash

Pointer to the output destination of the SHA-224 result that is required for authentication of the secure boot stream

errorReturn

Storage location for the address of the instruction line following a call to the error handler

struct ADI_ROM_BOOT_CUSTOM

Structure Type Declaration: `ADI_ROM_BOOT_CUSTOM`

A custom boot structure for storing information relating to a custom boot mode.

This structure is not used by the boot rom software at all but it is included in `ADI_ROM_BOOT_CONFIG::bootModes` in the event storage is required for custom boot loaders. Users can make use of this storage are to register DMA channels and define flags that may be used by a custom load routine.

Table 53-45: ADI_ROM_BOOT_CUSTOM Members

Type	Name	Description
`uint32_t`	`nFlags`	Flags related to the custom boot mode
`void *`	`pRegisters`	Used to store a pointer to the MMR registers for the peripheral
`ADI_DMA_TypeDef *`	`pRxDmaRegisters`	Pointer to the peripherals Tx DMA channel
`ADI_DMA_TypeDef *`	`pTxDmaRegisters`	Pointer to the peripherals Rx DMA channel
`ADI_SEC_Sysblock_TypeDef *`	`pSecSsi`	Pointer to the peripherals SEC SSI block
`void *`	`pModeData`	Void pointer that can be used to access additional boot mode specific resources not originally accessible via this data object
`ADI_ROM_BOOT_REGISTRY`	`registry`	For storage of the custom boot mode registration items, not used in this product, use `ADI_ROM_BOOT_CONFIG::bootRegistry` to register custom functions

nFlags

Flags related to the custom boot mode

pRegisters

Used to store a pointer to the MMR registers for the peripheral

pRxDmaRegisters

Pointer to the peripherals Tx DMA channel

pTxDmaRegisters

Pointer to the peripherals Rx DMA channel

pSecSsi

Pointer to the peripherals SEC SSI block

pModeData

Void pointer that can be used to access additional boot mode specific resources not originally accessible via this data object

registry

For storage of the custom boot mode registration items, not used in this product, use `ADI_ROM_BOOT_CONFIG::bootRegistry` to register custom functions

struct ADI_ROM_BOOT_HEADER

Structure Type Declaration: `ADI_ROM_BOOT_HEADER`

Boot Block Header.

Boot block headers control the loading process of the boot stream, For full details on the contents of the block header and supported flags see Boot Loader Stream .

Table 53-46: ADI_ROM_BOOT_HEADER Members

Type	Name	Description
`int32_t`	`dBlockCode`	Instructs the boot kernel how to process the block.
`void *`	`pTargetAddress`	Destination Address of Payload
`int32_t`	`dByteCount`	Byte Count of the Payload
`int32_t`	`dArgument`	Argument functionality varies depending on operation

dBlockCode

Instructs the boot kernel how to process the block.

Contains a number of fields for verification of the block header and flags to indicate the type of block allowing the kernel to process the block accordingly.

pTargetAddress

Destination Address of Payload

dByteCount

Byte Count of the Payload

dArgument

Argument functionality varies depending on operation

struct ADI_ROM_BOOT_INTER_BUFFER

Structure Type Declaration: `ADI_ROM_BOOT_INTER_BUFFER`

The buffer object for the internal intermediate buffers used for indirect and page mode operations.

Table 53-47: ADI_ROM_BOOT_INTER_BUFFER Members

Type	Name	Description
`uint8_t *`	`pBuffer`	Pointer to the buffer
`uint32_t`	`size`	Size of the buffer
`uint32_t`	`pageSize`	Page size for block based devices.

pBuffer

Pointer to the buffer

size

Size of the buffer

pageSize

Page size for block based devices.

NOTE: On this product this field is not used. A fixed page size of 1024 bytes is used in this product.

struct ADI_ROM_BOOT_INTER_BUFFERS

Structure Type Declaration: `ADI_ROM_BOOT_INTER_BUFFERS`

The boot kernels internal buffer object used to access the intermediate buffers and obtain buffer status.

Table 53-48: ADI_ROM_BOOT_INTER_BUFFERS Members

Type	Name	Description
`ADI_ROM_BOOT_INTER_BUFFER[2]`	`buffer`	The two buffer descriptors
`ADI_ROM_BOOT_BUFFER_STATE`	`state`	Buffer Status Information
`void *`	`pSource`	Original source address pointer of data loaded to active buffer. Not used on this product
`ADI_DMA_TypeDef *`	`pDma`	

buffer

The two buffer descriptors

state

Buffer Status Information

pSource

Original source address pointer of data loaded to active buffer. Not used on this product

struct ADI_ROM_BOOT_LINKPORT

Structure Type Declaration: `ADI_ROM_BOOT_LINKPORT`

The LINKPORT Slave Boot Mode Specific Structure.

This structure contains all the boot context information that is specific to the use for the LINKPORT slave boot mode.

Table 53-49: ADI_ROM_BOOT_LINKPORT Members

Type	Name	Description
`uint32_t`	`nFlags`	Flags related to linkport boot mode
`ADI_LP_TypeDef *`	`pRegisters`	Pointer to the LP peripherals base MMR address, not used on this product
`ADI_DMA_TypeDef *`	`pRxDmaRegisters`	Pointer to the DMA peripherals base MMR address,for receive operations, not used on this product
`ADI_DMA_TypeDef *`	`pTxDmaRegisters`	Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product
`ADI_SEC_Sysblock_TypeDef *`	`pSecSsi`	Pointer to the SEC `SSI` item for interrupt configuration for the peripheral, not used on this product
`ADI_ROM_BOOT_REGISTRY`	`registry`	For storage of the LP Slave boot specific registration items, not used in this product, use `ADI_ROM_BOOT_CONFIG::bootRegistry`

nFlags

Flags related to linkport boot mode

pRegisters

Pointer to the LP peripherals base MMR address, not used on this product

pRxDmaRegisters

Pointer to the DMA peripherals base MMR address,for receive operations, not used on this product

pTxDmaRegisters

Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product

pSecSsi

Pointer to the SEC `SSI` item for interrupt configuration for the peripheral, not used on this product

registry

For storage of the LP Slave boot specific registration items, not used in this product, use `ADI_ROM_BOOT_CONFIG::bootRegistry`

struct ADI_ROM_BOOT_MODES

Structure Type Declaration: `ADI_ROM_BOOT_MODES`

Holds all boot mode specific configuration items.

A boot mode may have requirements for some dedicated storage. This object is used to collect together all those storage items for all the boot modes supported by the boot rom.

Table 53-50: ADI_ROM_BOOT_MODES Members

Type	Name	Description
`ADI_ROM_BOOT_SPI`	`spi`	Access to all SPI boot mode resources
`ADI_ROM_BOOT_UART`	`uart`	Access to all UART boot mode resources
`ADI_ROM_BOOT_LINKPORT`	`linkport`	Access to all LINKPORT boot mode resources
`ADI_ROM_BOOT_CUSTOM`	`custom`	Access to all custom boot mode resources

spi

Access to all SPI boot mode resources

uart

Access to all UART boot mode resources

linkport

Access to all LINKPORT boot mode resources

custom

Access to all custom boot mode resources

struct ADI_ROM_BOOT_REGISTRY

Structure Type Declaration: `ADI_ROM_BOOT_REGISTRY`

Boot Mode Registration.

Used to hold pointers for the boot modes initialization, configuration, load and cleanup functions. By using pointer users can customize the registered content via hook routines or install their own load functions or cleanup functions from within init codes.

When using `adi_rom_Boot()` the boot process will make a call to the initialization function and the configuration function before calling the kernel. The kernel then runs making calls to the load function. Upon reaching the end of the boot stream the cleanup function is then called.

When using the `adi_rom_BootKernel()` function only the load function is called during execution of the software in the boot rom. All the functions here must return a `ROM_BOOT_RESULT::ROM_BOOT_SUCCESS` result in order for the boot process to continue. All functions expect a single argument that is the pointer to the boot structure object `ADI_ROM_BOOT_CONFIG`.

Table 53-51: ADI_ROM_BOOT_REGISTRY Members

Type	Name	Description
`ROM_BOOT_MODE_INIT_FUNC *`	`pInitFunction`	Pointer to the boot modes Initialization function
`ROM_BOOT_MODE_CONFIG_FUNC *`	`pConfigFunction`	Pointer to the boot modes Configuration function
`ROM_BOOT_MODE_LOAD_FUNC *`	`pLoadFunction`	Pointer to the boot modes Load function
`ROM_BOOT_MODE_CLEANUP_FUNC *`	`pCleanUpFunction`	Pointer to the boot modes Cleanup function
`void *`	`pReserved`	Reserved for future use
`int32_t`	`dReserved`	Reserved for future use

pInitFunction

Pointer to the boot modes Initialization function

pConfigFunction

Pointer to the boot modes Configuration function

pLoadFunction

Pointer to the boot modes Load function

pCleanUpFunction

Pointer to the boot modes Cleanup function

struct ADI_ROM_BOOT_SPI

Structure Type Declaration: `ADI_ROM_BOOT_SPI`

The SPI Master Boot Mode Specific Structure.

This structure contains all the boot context information that is specific to the use for the SPI master boot mode. During auto-detection information is copied from the required ::ROM_SPI_LUTENTRY item into this structure and used to configure the SPI peripheral for the mode of operation.

Table 53-52: ADI_ROM_BOOT_SPI Members

Type	Name	Description
`uint8_t`	`ubReadCommand`	Read command to use to read data from the SPI device
`uint8_t`	`ubDummyBytes`	Number of dummy bytes to issue after the read command
`uint8_t`	`ubAddressBytes`	Number of address bytes required to access the device
`uint8_t`	`ubDataBits`	The bus width to be used when reading the data. 0 for single bit, 1 for dual, 2 for quad
`uint16_t`	`uwClkLower`	The SPI clock divider value to be used
`uint16_t`	`uReserved0`	Reserved
`uint32_t`	`nTxCtl`	The value to be written to the `SPI_TXCTL` register that is used for the address transmit operations such as address cycles
`uint32_t`	`nRxCtl`	The value to be written to the `SPI_RXCTL` register that is used for all receive operations
`uint32_t`	`nCmdCtl`	The value to be written to the `SPI_TXCTL` register that is used for sending the read command to the SPI Flash
`ROM_BOOT_SPIM_IO_ENABLE_FUNC *`	`pMIOEnFunction`	Pointer to the function used to enable quad mode on the SPI flash
`uint8_t`	`nDummy`	The Dummy Byte value to be used if dummy byte transfers are required and the bus is not tri-stated
`uint8_t`	`nFlags`	Flags used for some additional SPI configuration processing.
`uint16_t`	`uReserved2`	Reserved
`void *`	`pXIPAddress`	The memory mapped SPI address to boot from
`ADI_SPI_TypeDef *`	`pRegisters`	Pointer to the SPI peripherals base MMR address, not used on this product
`ADI_DMA_TypeDef *`	`pRxDmaRegisters`	Pointer to the DMA peripherals base MMR address,for receive operations, not used on this product
`ADI_DMA_TypeDef *`	`pTxDmaRegisters`	Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product
`ADI_SEC_Sysblock_TypeDef *`	`pSecSsi`	Pointer to the SEC `SSI` item for interrupt configuration for the peripheral, not used on this product
`ADI_ROM_BOOT_REGISTRY`	`registry`	For storage of the SPI Master boot specific registration items, not used in this product, use `ADI_ROM_BOOT_CONFIG::bootRegistry`

ubReadCommand

Read command to use to read data from the SPI device

ubDummyBytes

Number of dummy bytes to issue after the read command

ubAddressBytes

Number of address bytes required to access the device

ubDataBits

The bus width to be used when reading the data. 0 for single bit, 1 for dual, 2 for quad

uwClkLower

The SPI clock divider value to be used

nTxCtl

The value to be written to the `SPI_TXCTL` register that is used for the address transmit operations such as address cycles

nRxCtl

The value to be written to the `SPI_RXCTL` register that is used for all receive operations

nCmdCtl

The value to be written to the `SPI_TXCTL` register that is used for sending the read command to the SPI Flash

pMIOEnFunction

Pointer to the function used to enable quad mode on the SPI flash

nDummy

The Dummy Byte value to be used if dummy byte transfers are required and the bus is not tri-stated

nFlags

Flags used for some additional SPI configuration processing.

The flags supported are defined as follows:

Bit Position	Name	Description
0	`ROM_SPI_FLAGS_CMDSKIP_EN`	When set will result in the configuration routine enabling command skip mode where the SPI will not issue a read command for read operations
1	`ROM_SPI_FLAGS_MULTICMD_EN`	Instructs the configuration routine to enable sending of command cycles over dual or quad bit bus

pXIPAddress

The memory mapped SPI address to boot from

pRegisters

Pointer to the SPI peripherals base MMR address, not used on this product

pRxDmaRegisters

Pointer to the DMA peripherals base MMR address,for receive operations, not used on this product

pTxDmaRegisters

Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product

pSecSsi

Pointer to the SEC `SSI` item for interrupt configuration for the peripheral, not used on this product

registry

For storage of the SPI Master boot specific registration items, not used in this product, use `ADI_ROM_BOOT_CONFIG::bootRegistry`

struct ADI_ROM_BOOT_UART

Structure Type Declaration: `ADI_ROM_BOOT_UART`

The UART Slave Boot Mode Specific Structure.

This structure contains all the boot context information that is specific to the use for the UART slave boot mode.

Table 53-53: ADI_ROM_BOOT_UART Members

Type	Name	Description
`uint32_t`	`nFlags`	Flags related to UART Boot mode
`ADI_UART_TypeDef *`	`pRegisters`	Pointer to the UART peripherals base MMR address, not used on this product
`ADI_DMA_TypeDef *`	`pRxDmaRegisters`	Pointer to the DMA peripherals base MMR address,for receive operations, not used on this product
`ADI_DMA_TypeDef *`	`pTxDmaRegisters`	Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product
`ADI_SEC_Sysblock_TypeDef *`	`pSecSsi`	Pointer to the SEC `SSI` item for interrupt configuration for the peripheral, not used on this product
`ADI_ROM_BOOT_REGISTRY`	`registry`	For storage of the UART Slave boot specific registration items, not used in this product, use `ADI_ROM_BOOT_CONFIG::bootRegistry`

nFlags

Flags related to UART Boot mode

pRegisters

Pointer to the UART peripherals base MMR address, not used on this product

pRxDmaRegisters

Pointer to the DMA peripherals base MMR address,for receive operations, not used on this product

pTxDmaRegisters

Pointer to the DMA peripherals base MMR address,for transmit operations, not used on this product

pSecSsi

Pointer to the SEC `SSI` item for interrupt configuration for the peripheral, not used on this product

registry

For storage of the UART Slave boot specific registration items, not used in this product, use `ADI_ROM_BOOT_CONFIG::bootRegistry`

struct ADI_ROM_OTP_BOOT_CFG

Structure Type Declaration: `ADI_ROM_OTP_BOOT_CFG`

The boot configuration object for storing further boot customization objects.

This is a 160-bit structure that is allocated to one contiguous region in the `OTP` memory array. The functionality provided allows for individual flags to be set to enable or disable specific features of the boot process. Each flag is allocated in a separate 16-bit word so that each flag can be set at different times and the ECC information will not impact the setting of another flag.

Table 53-54: ADI_ROM_OTP_BOOT_CFG Members

Type	Name	Description
`uint32_t`	`cacheDis:1` (bitfield)	Cache Disable.
`uint32_t`	`reserved0:15` (bitfield)	Reserved
`uint32_t`	`decryptOnlyEn:1` (bitfield)	Decrypt Only Enable.
`uint32_t`	`reserved1:15` (bitfield)	Reserved
`uint32_t`	`cacheDisInv:1` (bitfield)	Cache Disable Invalidate.
`uint32_t`	`reserved2:15` (bitfield)	Reserved
`uint32_t`	`decryptOnlyInv:1` (bitfield)	Decrypt Only Invalidate.
`uint32_t`	`reserved3:15` (bitfield)	Reserved
`uint32_t`	`pubkey0Inv:1` (bitfield)	Invalidate Public Key 0, use next public key for secure boot
`uint32_t`	`reserved4:15` (bitfield)	Reserved
`uint32_t`	`pubkey1Inv:1` (bitfield)	Invalidate Public Key 1, Secure boot will no longer be operational as no further public keys
`uint32_t`	`reserved5:15` (bitfield)	Reserved

Table 53-54: ADI_ROM_OTP_BOOT_CFG Members (Continued)

Type	Name	Description
`uint32_t`	`privkey0Inv:1` (bitfield)	Invalidate Decryption Key 0, use next Decryption key for secure boot
`uint32_t`	`reserved6:15` (bitfield)	Reserved
`uint32_t`	`privkey1Inv:1` (bitfield)	Invalidate Decryption Key 1, use next Decryption key for secure boot
`uint32_t`	`reserved7:15` (bitfield)	Reserved
`uint32_t`	`privkey2Inv:1` (bitfield)	Invalidate Decryption Key 2, use next Decryption key for secure boot
`uint32_t`	`reserved8:15` (bitfield)	Reserved
`uint32_t`	`privkey3Inv:1` (bitfield)	Invalidate Decryption Key 3, once invalidated part will no longer be bootable
`uint32_t`	`reserved9:15` (bitfield)	Reserved
`uint32_t`	`dmcEn:1` (bitfield)	Enables configuration of the DMC from values in `OTP` stored in the format of the `ADI_ROM_OTP_DMC_CONFIG` object
`uint32_t`	`reserved10:15` (bitfield)	Reserved
`uint32_t`	`dmcInv:1` (bitfield)	Invalidates the DMC values in the `OTP` resulting is bypassing of DMC configuration
`uint32_t`	`reserved11:15` (bitfield)	Reserved

cacheDis

Cache Disable.

By default the cache is enabled by boot software during preboot. Setting this bit will prevent the boot software from enabling the cache which will result in slower boot performance but allows for the memory regions that are used for cache space to be bootable memory regions for larger application images.

decryptOnlyEn

Decrypt Only Enable.

By default secure boot images that are also encrypted are decrypted then authenticated before the application is executed by the core. Authentication is a time consuming task and in situations where boot time is critical and the security of the device is less important, bypassing the authentication stage is possible by setting this bit. This will compromise security and is not recommended for use without additional security measures being implemented to verify the integrity of the loader software.

cacheDisInv

Cache Disable Invalidate.

Invalidates the Cache Disable bit to allow the boot rom to enable the cache again during preboot

decryptOnlyInv

Decrypt Only Invalidate.

Invalidates the Decrypt Only bit to allow the boot rom to perform full decrypt and authentication of secure boot streams

pubkey0Inv

Invalidate Public Key 0, use next public key for secure boot

pubkey1Inv

Invalidate Public Key 1, Secure boot will no longer be operational as no further public keys

privkey0Inv

Invalidate Decryption Key 0, use next Decryption key for secure boot

privkey1Inv

Invalidate Decryption Key 1, use next Decryption key for secure boot

privkey2Inv

Invalidate Decryption Key 2, use next Decryption key for secure boot

privkey3Inv

Invalidate Decryption Key 3, once invalidated part will no longer be bootable

dmcEn

Enables configuration of the DMC from values in `OTP` stored in the format of the `ADI_ROM_OTP_DMC_CONFIG` object

dmcInv

Invalidates the DMC values in the `OTP` resulting is bypassing of DMC configuration

struct ADI_ROM_OTP_BOOT_CGU_INFO

Structure Type Declaration: `ADI_ROM_OTP_BOOT_CGU_INFO`

The CGU configuration object located in `OTP` for configuration of the CGU by the boot software.

This is a 128-bit structure that is allocated to one contiguous region in the `OTP` memory array. The functionality provided allows the boot software to configure the CGU to allow for a more efficient boot process.

Table 53-55: ADI_ROM_OTP_BOOT_CGU_INFO Members

Type	Name	Description
`uint32_t`	`ctl_WEN:1` (bitfield)	Enable write to the `CGU_CTL` register
`uint32_t`	`div_WEN:1` (bitfield)	Enable write to the `CGU_DIV` register
`uint32_t`	`reserved0:1` (bitfield)	Reserved
`uint32_t`	`div_DSEL:5` (bitfield)	`CGU_DIV.DSEL` value
`uint32_t`	`div_CSEL:5` (bitfield)	`CGU_DIV.CSEL` value
`uint32_t`	`div_S0SEL:3` (bitfield)	`CGU_DIV.S0SEL` value
`uint32_t`	`div_SYSSEL:5` (bitfield)	`CGU_DIV.SYSSEL` value
`uint32_t`	`div_S1SEL:3` (bitfield)	`CGU_DIV.S1SEL` value
`uint32_t`	`div_OSEL:7` (bitfield)	`CGU_DIV.OSEL` value
`uint32_t`	`ctl_DF:1` (bitfield)	`CGU_CTL.DF` value
`uint32_t`	`ctl_MSEL:7` (bitfield)	`CGU_CTL.MSEL` value
`uint32_t`	`auto_disable:1` (bitfield)	disable polling on auto-alignment of clocks, NOT RECOMMENDED!
`uint32_t`	`clkoutsel_USBCLKSEL:6` (bitfield)	`CGU_CLKOUTSEL.USBCLKSEL` value
`uint32_t`	`clkoutsel_CLKOUTSEL:5` (bitfield)	`CGU_CLKOUTSEL.CLKOUTSEL` value
`uint32_t`	`clkoutsel_WEN:1` (bitfield)	Enable write to the `CGU_CLKOUTSEL` register
`uint32_t`	`oscwctl0_WEN:1` (bitfield)	Enable write to the `CGU_OSCWDCTL` instance 0 register
`uint32_t`	`oscwctl0_HODF:6` (bitfield)	`CGU_OSCWDCTL.HODF` value
`uint32_t`	`oscwctl0_HODEN:1` (bitfield)	`CGU_OSCWDCTL.HODEN` value
`uint32_t`	`oscwctl0_CNGEN:1` (bitfield)	`CGU_OSCWDCTL.CNGEN` value
`uint32_t`	`oscwctl0_BOUF:5` (bitfield)	`CGU_OSCWDCTL.BOUF` value
`uint32_t`	`oscwctl0_BOUEN:1` (bitfield)	`CGU_OSCWDCTL.BOUEN` value
`uint32_t`	`oscwctl0_FAULTEN:1` (bitfield)	`CGU_OSCWDCTL.FAULTEN` value
`uint32_t`	`oscwctl0_MONDIS:1` (bitfield)	`CGU_OSCWDCTL.MONDIS` value

Table 53-55: ADI_ROM_OTP_BOOT_CGU_INFO Members (Continued)

Type	Name	Description
`uint32_t`	`oscwctl0_ FAULTPINDIS:1` (bitfield)	`CGU_OSCWDCTL.FAULTPINDIS` value
`uint32_t`	`oscwctl1_WEN:1` (bitfield)	Enable write to the `CGU_OSCWDCTL` instance 0 register
`uint32_t`	`oscwctl1_HODF:6` (bitfield)	`CGU_OSCWDCTL.HODF` value
`uint32_t`	`oscwctl1_HODEN:1` (bitfield)	`CGU_OSCWDCTL.HODEN` value
`uint32_t`	`oscwctl1_CNGEN:1` (bitfield)	`CGU_OSCWDCTL.CNGEN` value
`uint32_t`	`oscwctl1_BOUF:5` (bitfield)	`CGU_OSCWDCTL.BOUF` value
`uint32_t`	`oscwctl1_BOUEN:1` (bitfield)	`CGU_OSCWDCTL.BOUEN` value
`uint32_t`	`oscwctl1_FAULTEN:1` (bitfield)	`CGU_OSCWDCTL.FAULTEN` value
`uint32_t`	`oscwctl1_MONDIS:1` (bitfield)	`CGU_OSCWDCTL.MONDIS` value
`uint32_t`	`oscwctl1_ FAULTPINDIS:1` (bitfield)	`CGU_OSCWDCTL.FAULTPINDIS` value
`uint32_t`	`reserved2:28` (bitfield)	Reserved

ctl_WEN

Enable write to the `CGU_CTL` register

div_WEN

Enable write to the `CGU_DIV` register

div_DSEL

`CGU_DIV.DSEL` value

div_CSEL

`CGU_DIV.CSEL` value

div_S0SEL

`CGU_DIV.S0SEL` value

div_SYSSEL

`CGU_DIV.SYSSEL` value

div_S1SEL

`CGU_DIV.S1SEL` value

div_OSEL

`CGU_DIV.OSEL` value

ctl_DF

`CGU_CTL.DF` value

ctl_MSEL

`CGU_CTL.MSEL` value

auto_disable

disable polling on auto-alignment of clocks, NOT RECOMMENDED!

clkoutsel_USBCLKSEL

`CGU_CLKOUTSEL.USBCLKSEL` value

clkoutsel_CLKOUTSEL

`CGU_CLKOUTSEL.CLKOUTSEL` value

clkoutsel_WEN

Enable write to the `CGU_CLKOUTSEL` register

oscwctl0_WEN

Enable write to the `CGU_OSCWDCTL` instance 0 register

oscwctl0_HODF

`CGU_OSCWDCTL.HODF` value

oscwctl0_HODEN

`CGU_OSCWDCTL.HODEN` value

oscwctl0_CNGEN

`CGU_OSCWDCTL.CNGEN` value

oscwctl0_BOUF

`CGU_OSCWDCTL.BOUF` value

oscwctl0_BOUEN

`CGU_OSCWDCTL.BOUEN` value

oscwctl0_FAULTEN

`CGU_OSCWDCTL.FAULTEN` value

oscwctl0_MONDIS

`CGU_OSCWDCTL.MONDIS` value

oscwctl0_FAULTPINDIS

`CGU_OSCWDCTL.FAULTPINDIS` value

oscwctl1_WEN

Enable write to the `CGU_OSCWDCTL` instance 0 register

oscwctl1_HODF

`CGU_OSCWDCTL.HODF` value

oscwctl1_HODEN

`CGU_OSCWDCTL.HODEN` value

oscwctl1_CNGEN

`CGU_OSCWDCTL.CNGEN` value

oscwctl1_BOUF

`CGU_OSCWDCTL.BOUF` value

oscwctl1_BOUEN

`CGU_OSCWDCTL.BOUEN` value

oscwctl1_FAULTEN

`CGU_OSCWDCTL.FAULTEN` value

oscwctl1_MONDIS

`CGU_OSCWDCTL.MONDIS` value

oscwctl1_FAULTPINDIS

`CGU_OSCWDCTL.FAULTPINDIS` value

struct ADI_ROM_OTP_BOOT_CMD_INFO

Structure Type Declaration: `ADI_ROM_OTP_BOOT_CMD_INFO`

The boot command object for storing a customized boot command for each boot mode within the `OTP` memory array.

This is a 128-bit structure that is allocated to one contiguous region in the `OTP` memory array. The functionality provided allows the boot rom software to pass a custom boot command to a specific boot mode changing the default boot behavior on startup. This can be used for example to change the default UART instance used for a UART boot operation.

Table 53-56: ADI_ROM_OTP_BOOT_CMD_INFO Members

Type	Name	Description
`uint32_t`	`spiMasterBootCmd`	SPI Master Boot Mode
`uint32_t`	`spiSlaveBootCmd`	SPI Slave Boot Mode
`uint32_t`	`lpBootCmd`	Link Port Slave Boot Mode
`uint32_t`	`uartBootCmd`	UART Slave Boot Mode

spiMasterBootCmd

SPI Master Boot Mode

spiSlaveBootCmd

SPI Slave Boot Mode

lpBootCmd

Link Port Slave Boot Mode

uartBootCmd

UART Slave Boot Mode

struct ADI_ROM_OTP_BOOT_INFO

Structure Type Declaration: `ADI_ROM_OTP_BOOT_INFO`

The 512-bit boot info object located in `OTP` for boot customization.

This is a 512 bit structure that is allocated to one contiguous region in the `OTP` memory array. The contented in `OTP` is stored in the format of this structure allowing boot to read the contents directly into this object.

Users can read this object using the `adi_rom_otp_get()` routine supplying the `OTPCMD::otpcmd_boot_info` enumeration

Table 53-57: ADI_ROM_OTP_BOOT_INFO Members

Type	Name	Description
`ADI_ROM_OTP_BOOT_CGU_INFO`	`cgu`	CGU Configuration information
`ADI_ROM_OTP_BOOT_CMD_INFO`	`bcmd`	Boot Command customization for each boot mode allowing for a change of default boot peripheral instance and configuration

Table 53-57: ADI_ROM_OTP_BOOT_INFO Members (Continued)

Type	Name	Description
ADI_ROM_OTP_BOOT_CFG	bcfg	Additional boot configuration flags for key invalidation and for enabling DMC configuration
uint32_t	reserved0	Reserved
uint16_t	reserved1	Reserved
uint16_t	otpReadTiming	Reserved, Must always be zero

cgu

CGU Configuration information

bcmd

Boot Command customization for each boot mode allowing for a change of default boot peripheral instance and configuration

bcfg

Additional boot configuration flags for key invalidation and for enabling DMC configuration

otpReadTiming

Reserved, Must always be zero

struct ADI_ROM_OTP_DMC_CONFIG

Structure Type Declaration: `ADI_ROM_OTP_DMC_CONFIG`

The 384-bit configuration object located in `OTP` for configuration of the DMC during preboot.

If the user wishes to make use of the memories connected to the DMC peripheral during boot without the use of init codes in the boot stream then the settings can be applied to this object in the `OTP` memory. During preboot the boot software reads the object from `OTP` and will configure the peripheral accordingly.

NOTE: When the device is open it advisable to avoid the use of `OTP` and instead use initcodes for DMC initialization as the initcode method is highly customizable. If users wish to lock the device to enable secure boot then in order to boot to memories interfaced to the DMC then the configuration must be provisioned to `OTP` as initcodes are not supported in secure boot.

Table 53-58: ADI_ROM_OTP_DMC_CONFIG Members

Type	Name	Description
uint32_t	reserved0:10 (bitfield)	Reserved

Table 53-58: ADI_ROM_OTP_DMC_CONFIG Members (Continued)

Type	Name	Description
uint32_t	ulDDR_DLLCTL:12 (bitfield)	Contents of DMC_DLLCTL [11:0]
uint32_t	ulDDR_EMR2:8 (bitfield)	Contents of DMC_EMR2 [7:0]
uint32_t	reserved1:2 (bitfield)	Reserved
uint32_t	ulDDR_CFGCTL	Packed content of DMC_CTL Register, DMC_CFG registers.
uint32_t	ulDDR_MREMR1	Packed content of DMC_EMR1 Register, DMC_MR registers.
uint32_t	ulDDR_TR0	Content of DMC_TR0
uint32_t	ulDDR_TR1	Content of DMC_TR1
uint32_t	ulDDR_TR2	Content of DMC_TR2
uint32_t	ulDDR_PHYCTL0	Content of DMC_PHY_CTL0
uint32_t	ulDDR_PHYCTL145	Packed content of DMC_PHY_CTL1 , DMC_PHY_CTL4 and DMC_PHY_CTL5 registers.
uint32_t	ulDDR_PHYCTL2	Content of DMC_PHY_CTL2
uint32_t	ulDDR_PHYCTL3	Content of DMC_PHY_CTL3
uint32_t	ulDDR_CAL_PADCTL0_PHY_STAT3_0	Packed content of DMC_CAL_PADCTL0 , DMC_PHY_STAT0 , and DMC_PHY_STAT3 registers.
uint32_t	ulDDR_CAL_PADCTL2	Content of DMC_CAL_PADCTL2

ulDDR_DLLCTL

Contents of DMC_DLLCTL [11:0]

ulDDR_EMR2

Contents of DMC_EMR2 [7:0]

ulDDR_CFGCTL

Packed content of DMC_CTL Register, DMC_CFG registers.

The contents are packed as follows:

ADI_ROM_OTP_DMC_CONFIG::ulDDR_CFGCTL	Register
[15:0]	DMC_CFG [15:0]
[31:16]	DMC_CTL [15:0]

ulDDR_MREMR1

Packed content of DMC_EMR1 Register, DMC_MR registers.

The contents are packed as follows:

ADI_ROM_OTP_DMC_CONFIG::ulDDR_MREMR1	Register
[15:0]	DMC_EMR1 [15:0]
[31:16]	DMC_MR [15:0]

ulDDR_TR0

Content of DMC_TR0

ulDDR_TR1

Content of DMC_TR1

ulDDR_TR2

Content of DMC_TR2

ulDDR_PHYCTL0

Content of DMC_PHY_CTL0

ulDDR_PHYCTL145

Packed content of DMC_PHY_CTL1 , DMC_PHY_CTL4 and DMC_PHY_CTL5 registers.

The contents are packed as follows:

ADI_ROM_OTP_DMC_CONFIG::ulDDR_PHYCTL145	Register
[7:0]	DMC_PHY_CTL5 [7:0]
[15:8]	DMC_PHY_CTL4 [7:0]
[31:16]	DMC_PHY_CTL1 [31:16]

ulDDR_PHYCTL2

Content of DMC_PHY_CTL2

ulDDR_PHYCTL3

Content of DMC_PHY_CTL3

ulDDR_CAL_PADCTL0_PHY_STAT3_0

Packed content of DMC_CAL_PADCTL0 , DMC_PHY_STAT0 , and DMC_PHY_STAT3 registers.

The contents are packed as follows:

ADI_ROM_OTP_DMC_CONFIG::ulDDR_CAL_PADCTL0_PHY_STAT3_0	Register
[8:0]	DMC_PHY_STAT0[8:0]
[11:9]	DMC_PHY_STAT3[2:0]
[31:12]	DMC_CAL_PADCTL0[31:12]

ulDDR_CAL_PADCTL2

Content of `DMC_CAL_PADCTL2`

struct ROM_BOOT_DMA_INSTANCE

Structure Type Declaration: `ROM_BOOT_DMA_INSTANCE`

DMA Channel Instance.

Specifies the base MMR address of the DMA channel as well as trigger and interrupt IDs

Table 53-59: ROM_BOOT_DMA_INSTANCE Members

Type	Name	Description
ADI_DMA_TypeDef *	pReg	Pointer to the base address of the DMA channel MMR registers
DMA_CHANn_TypeDef	eDmaChannelId	The actual DMA channel ID in the system
uint8_t	TriggerId	The trigger ID associated with the DMA channel
uint8_t	InterruptId	The interrupt ID associated with the DMA channel

pReg

Pointer to the base address of the DMA channel MMR registers

eDmaChannelId

The actual DMA channel ID in the system

TriggerId

The trigger ID associated with the DMA channel

InterruptId

The interrupt ID associated with the DMA channel

struct ROM_BOOT_MDMA

Structure Type Declaration: `ROM_BOOT_MDMA`

MDMA Channels.

Provides access to all the MDMA channels and CRC peripherals supported by the processor

Table 53-60: ROM_BOOT_MDMA Members

Type	Name	Description
`ROM_BOOT_MDMA_REGS[PARAM_SYS0_NUM_MDMA_STREAMS]`	`Stream`	Array of MDMA channel configurations supported by the processor

Stream

Array of MDMA channel configurations supported by the processor

struct ROM_BOOT_MDMA_REGS

Structure Type Declaration: `ROM_BOOT_MDMA_REGS`

MDMA Channel Registers.

Contains the Source and Destination MDMA channel instances for access to the MMRs and interrupt and trigger information. Information is also provided on the CRC support of the MDMA channel and access is provided to the corresponding CRC peripheral.

Table 53-61: ROM_BOOT_MDMA_REGS Members

Type	Name	Description
`ROM_BOOT_DMA_INSTANCE`	`Src`	The source DMA Channel in the MDMA pair
`ROM_BOOT_DMA_INSTANCE`	`Dst`	The destination DMA Channel in the MDMA pair
`ADI_CRC_TypeDef *`	`pCrc`	The base MMR address of the associated CRC peripheral if one exists
`ROM_BOOT_MDMA_CRC_SUPPORT`	`eCrcSupport`	Indicates if the MDMA channel supports CRC or not

Src

The source DMA Channel in the MDMA pair

Dst

The destination DMA Channel in the MDMA pair

pCrc

The base MMR address of the associated CRC peripheral if one exists

eCrcSupport

Indicates if the MDMA channel supports CRC or not

struct ROM_DMA_MDMA_CONFIG

Structure Type Declaration: `ROM_DMA_MDMA_CONFIG`

MDMA Configuration Object.

The user configurable structure for controlling the MDMA operation to be supplied to the `adi_rom_MemDma()` routine.

Table 53-62: ROM_DMA_MDMA_CONFIG Members

Type	Name	Description
`ROM_DMA_MDMA_OPERATION`	`eOperation`	Type of operation to perform
`ROM_DMA_MDMA_ID`	`eId`	MDMA Channel ID
`void *`	`pSource`	Source Pointer
`void *`	`pDestination`	Destination Pointer
`uint32_t`	`ByteCount`	Byte Count
`ROM_DMA_DONE_DETECT_METHOD`	`eDoneDetect`	DMA Done Detection Method
`uint32_t`	`CrcCtl`	`CRC_CTL` value when CRC operations are required
`uint32_t`	`FillVal`	Fill value for memory fill operations
`uint32_t`	`CrcPoly`	CRC Polynomial for CRC operations
`uint32_t`	`CrcCompare`	Value used for CRC compare operations or for a CRC32 result compare

eOperation

Type of operation to perform

eId

MDMA Channel ID

pSource

Source Pointer

pDestination

Destination Pointer

ByteCount

Byte Count

eDoneDetect

DMA Done Detection Method

CrcCtl

`CRC_CTL` value when CRC operations are required

FillVal

Fill value for memory fill operations

CrcPoly

CRC Polynomial for CRC operations

CrcCompare

Value used for CRC compare operations or for a CRC32 result compare

struct ROM_DMA_PDMA_CONFIG

Structure Type Declaration: `ROM_DMA_PDMA_CONFIG`

PDMA Configuration Object.

The user configurable structure for controlling the PDMA operation via the `adi_rom_PeriphDma()` function.

Table 53-63: ROM_DMA_PDMA_CONFIG Members

Type	Name	Description
`ROM_DMA_PDMA_OPERATION`	`eOperation`	Type of operation to perform
`ADI_DMA_TypeDef volatile *`	`pRegs`	Pointer to the base address of the DMA channel MMR registers
`uint16_t`	`dataWidth`	The maximum supported data width of the DMA channel. Used to configure the `DMA_CFG.PSIZE PSIZE` field in `DMA_CFG`
`uint16_t`	`dstModifyMult`	The modify multiplier to be applied, usually set to 1
`void *`	`pSource`	Source Pointer used for transmit operations
`void *`	`pDestination`	Destination Pointer used for receive operations
`uint32_t`	`byteCount`	Number of bytes to transfer
`ROM_DMA_DONE_DETECT_METHOD`	`eDoneDetect`	DMA Done Detection method to be used for the transfer
`uint32_t`	`Reserved`	Reserved

eOperation

Type of operation to perform

pRegs

Pointer to the base address of the DMA channel MMR registers

dataWidth

The maximum supported data width of the DMA channel. Used to configure the `DMA_CFG.PSIZE` `PSIZE` field in `DMA_CFG`

dstModifyMult

The modify multiplier to be applied, usually set to 1

pSource

Source Pointer used for transmit operations

pDestination

Destination Pointer used for receive operations

byteCount

Number of bytes to transfer

eDoneDetect

DMA Done Detection method to be used for the transfer

struct otp_data

Structure Type Declaration: `otp_data`

Container for accessing data to be written to `OTP` via the `adi_rom_otp_pgm()` routine.

Any pointers that are `NULL` will result in the object not being written. Any data values of 0 will not be written.

Table 53-64: otp_data Members

Type	Name	Description
`uint32_t(*) [ROM_OTP_SZ_huk]`	`huk`	Pointer to 256-bit Hardware Unique Key
`uint32_t(*) [ROM_OTP_SZ_DTCP_key_ecc]`	`DTCP_key_ecc`	Pointer to 1280-bit DTCP Key (ECC Parameters)
`uint32_t(*) [ROM_OTP_SZ_DTCP_key_cont]`	`DTCP_key_cont`	Pointer to 320-bit DTCP Key (constant for content key)
`uint32_t(*) [ROM_OTP_SZ_DTCP_key_dev]`	`DTCP_key_dev`	Pointer to 1024-bit DTCP Key (device specific keys)
`uint32_t(*) [ROM_OTP_SZ_pvt_128key0]`	`pvt_128key0`	Pointer to 128-bit AES Key

Table 53-64: otp_data Members (Continued)

Type	Name	Description
`uint32_t(*)[ROM_OTP_SZ_pvt_128key1]`	`pvt_128key1`	Pointer to 128-bit AES Key
`uint32_t(*)[ROM_OTP_SZ_pvt_128key2]`	`pvt_128key2`	Pointer to 128-bit AES Key
`uint32_t(*)[ROM_OTP_SZ_pvt_128key3]`	`pvt_128key3`	Pointer to 128-bit AES Key
`uint32_t(*)[ROM_OTP_SZ_ek]`	`ek`	Pointer to 256-bit endorsement key
`uint32_t(*)[ROM_OTP_SZ_secure_emu_key]`	`secure_emu_key`	Pointer to 128-bit Secure Debug Key
`uint32_t(*)[ROM_OTP_SZ_public_key0]`	`public_key0`	Pointer to 512-bit public key used for boot stream authentication
`uint32_t(*)[ROM_OTP_SZ_public_key1]`	`public_key1`	Pointer to 512-bit public key used for boot stream authentication
`uint32_t(*)[ROM_OTP_SZ_boot_info]`	`boot_info`	Pointer to 512-bit boot customization structure, see also `ADI_ROM_OTP_BOOT_INFO`
`uint8_t`	`antiroll_nv_cntr`	Anti-rollback counter to prevent loading of older firmware during secure boot.
`uint32_t(*)[ROM_OTP_SZ_gp1]`	`gp1`	Pointer to 512-bit General purpose user space
`uint32_t`	`bootModeDisable:8` (bitfield)	Boot mode disable for permanently disabling specific boot modes
`uint32_t(*)[ROM_OTP_SZ_preboot_ddr_cfg]`	`preboot_ddr_cfg`	Pointer to 384-bit DMC Configuration. See also `ADI_ROM_OTP_DMC_CONFIG`
`uint32_t(*)[ROM_OTP_SZ_stageID]`	`stageID`	Pointer to 64-bit staging ID

huk

Pointer to 256-bit Hardware Unique Key

DTCP_key_ecc

Pointer to 1280-bit DTCP Key (ECC Parameters)

DTCP_key_cont

Pointer to 320-bit DTCP Key (constant for content key)

DTCP_key_dev

Pointer to 1024-bit DTCP Key (device specific keys)

pvt_128key0

Pointer to 128-bit AES Key

pvt_128key1

Pointer to 128-bit AES Key

pvt_128key2

Pointer to 128-bit AES Key

pvt_128key3

Pointer to 128-bit AES Key

ek

Pointer to 256-bit endorsement key

secure_emu_key

Pointer to 128-bit Secure Debug Key

public_key0

Pointer to 512-bit public key used for boot stream authentication

public_key1

Pointer to 512-bit public key used for boot stream authentication

boot_info

Pointer to 512-bit boot customization structure, see also `ADI_ROM_OTP_BOOT_INFO`

antiroll_nv_cntr

Anti-rollback counter to prevent loading of older firmware during secure boot.

The counter supports values of 0 through 31. The counter feature is disabled as long as the counter is set initially to 0.

gp1

Pointer to 512-bit General purpose user space

bootModeDisable

Boot mode disable for permanently disabling specific boot modes

preboot_ddr_cfg

Pointer to 384-bit DMC Configuration. See also `ADI_ROM_OTP_DMC_CONFIG`

stageID

Pointer to 64-bit staging ID

Enumerations

The programming model for booting the processor uses the enumerations defined in this section.

enum ADI_ROM_BOOT_KEY_TYPE

Enumeration Type Declaration: `ADI_ROM_BOOT_KEY_TYPE`

Indicates if custom security keys are to be used for evaluation of secure boot.

By default the boot process will fetch all security keys from `OTP` for use during secure boot. Enabling custom security allows for the user to set their own keys in the `ADI_ROM_BOOT_CONFIG` item and not have them taken from `OTP`. Allowing evaluation of secure boot through the use of the `adi_rom_Boot()` function without provisioning keys in `OTP`.

Table 53-65: ADI_ROM_BOOT_KEY_TYPE Members

Enumerator	Description
`ADI_ROM_CUSTOM_SECURITY`	Enable use of custom security keys for authentication and decryption

ADI_ROM_CUSTOM_SECURITY

Enable use of custom security keys for authentication and decryption

enum ADI_ROM_BOOT_TYPE

Enumeration Type Declaration: `ADI_ROM_BOOT_TYPE`

Used to indicate to the boot kernel in an open processor if secure or non secure boot is required.

The boot kernel defaults to a secure boot unless the boot structure has been configured to indicate Non-Secure Boot

Table 53-66: ADI_ROM_BOOT_TYPE Members

Enumerator	Description
`ADI_ROM_SECURE_BOOT_DIS`	Non-Secure Boot
`ADI_ROM_SECURE_BOOT`	Secure Boot

ADI_ROM_SECURE_BOOT_DIS

Non-Secure Boot

ADI_ROM_SECURE_BOOT

Secure Boot

enum OTPCMD

Enumeration Type Declaration: `OTPCMD`

Commands required by the `adi_rom_otp_get()` routine to retrieve specific fields from the `OTP` memory.

Table 53-67: OTPCMD Members

Enumerator	Description
`otpcmd_reserved0`	Reserved
`otpcmd_huk`	Hardware Unique Key
`otpcmd_DTCP_key_ecc`	DTCP Key (ECC Parameters)
`otpcmd_DTCP_key_cont`	DTCP Key (constant for content key)
`otpcmd_DTCP_key_dev`	DTCP Key (device specific keys)
`otpcmd_pvt_128key0`	Customer Private AES Key0
`otpcmd_pvt_128key1`	Customer Private AES Key1
`otpcmd_pvt_128key2`	Customer Private AES Key2
`otpcmd_pvt_128key3`	Customer Private AES Key3
`otpcmd_ek`	Endorsement Key
`otpcmd_secure_emu_key`	Secure Emulation Key
`otpcmd_public_key0`	Customer Public Key0
`otpcmd_public_key1`	Customer Public Key1
`otpcmd_boot_info`	Customer Programmable Boot Information
`otpcmd_otpTiming`	OTP Read timing override
`otpcmd_antiroll_nv_cntr`	AntiRollback NV Counter
`otpcmd_gp1`	General Purpose 1
`otpcmd_bootModeDisable`	Boot Mode Disable Bits
`otpcmd_preboot_ddr_cfg`	User DMC configuration
`otpcmd_stageID`	StageID
`otpcmd_reserved1`	Reserved

otpcmd_reserved0

Reserved

otpcmd_huk

Hardware Unique Key

otpcmd_DTCP_key_ecc

DTCP Key (ECC Parameters)

otpcmd_DTCP_key_cont

DTCP Key (constant for content key)

otpcmd_DTCP_key_dev

DTCP Key (device specific keys)

otpcmd_pvt_128key0

Customer Private AES Key0

otpcmd_pvt_128key1

Customer Private AES Key1

otpcmd_pvt_128key2

Customer Private AES Key2

otpcmd_pvt_128key3

Customer Private AES Key3

otpcmd_ek

Endorsement Key

otpcmd_secure_emu_key

Secure Emulation Key

otpcmd_public_key0

Customer Public Key0

otpcmd_public_key1

Customer Public Key1

otpcmd_boot_info

Customer Programmable Boot Information

otpcmd_otpTiming

OTP Read timing override

otpcmd_antiroll_nv_cntr

AntiRollback NV Counter

otpcmd_gp1

General Purpose 1

otpcmd_bootModeDisable

Boot Mode Disable Bits

otpcmd_preboot_ddr_cfg

User DMC configuration

otpcmd_stageID

StageID

enum ROM_BOOT_MDMA_CRC_SUPPORT

Enumeration Type Declaration: `ROM_BOOT_MDMA_CRC_SUPPORT`

MDMA Channel CRC support.

Specifies whether the MDMA channel supports CRC operations or not

Table 53-68: ROM_BOOT_MDMA_CRC_SUPPORT Members

Enumerator	Description
`ROM_BOOT_DMA_CRC_SUPPORTED`	MDMA Channel supports CRC
`ROM_BOOT_DMA_CRC_NOT_SUPPORTED`	MDMA Channel does not support CRC

ROM_BOOT_DMA_CRC_SUPPORTED

MDMA Channel supports CRC

ROM_BOOT_DMA_CRC_NOT_SUPPORTED

MDMA Channel does not support CRC

enum ROM_BOOT_RESULT

Enumeration Type Declaration: `ROM_BOOT_RESULT`

General Boot ROM Return Types.

Used throughout the boot software to indicate various success and failure events that can occur during boot. General success and failure are used for most operation in which the user likely has no particular general interest in knowing further details.

Table 53-69: ROM_BOOT_RESULT Members

Enumerator	Description
ROM_BOOT_FAILURE	Failure.
ROM_BOOT_SUCCESS	Success.
ROM_BOOT_HDR_CHKSUM_ERR	Boot Stream Block Header Checksum Error.
ROM_BOOT_HDR_SIGN_ERR	Boot Stream Block Header Sign Failure.
ROM_BOOT_HDR_DEST_ERR	Boot Stream Block Payload Destination Error.
RESERVED0	Reserved.
RESERVED1	Reserved.
RESERVED2	Reserved.
RESERVED3	Reserved.
ROM_BOOT_CGU_WRITE_ERR	CGU Write Error
ROM_BOOT_DMA_SUCCESS	DMA operation was successful
ROM_BOOT_DMA_FAILURE	DMA Failure.
ROM_BOOT_DMA_ACTIVE	DMA Channel is Active
ROM_BOOT_DMA_CONFIG_ERR	DMA configuration error
ROM_BOOT_MDMA_ID_ERR	Illegal MDMA Channel ID.
ROM_BOOT_MDMA_OPERATION_ERR	Illegal MDMA operation Specified.
ROM_BOOT_MDMA_CONFIG_ERR	Memory DMA configuration error
ROM_BOOT_MDMA_SRC_ERR	MDMA Source Channel Configuration Error.
ROM_BOOT_MDMA_DST_ERR	MDMA Destination Channel Configuration Error.
ROM_BOOT_MDMA_DONE_DETECT_ERR	Memory DMA Completed with errors
ROM_BOOT_MDMA_SUCCESS	Memory DMA Completed successfully
ROM_BOOT_PDMA_CONFIG_ERR	Peripheral DMA configuration invalid
ROM_BOOT_PDMA_SUCCESS	Peripheral DMA completed successfully
ROM_BOOT_CRC_FAILURE	MDMA CRC32 Failure.
ROM_BOOT_CRC_COUNT_ERR	CRC Byte Count was not a multiple 4.
ROM_BOOT_CRC_SUPPORTED_ERR	CRC Not Supported Error.
ROM_BOOT_CRC_INITCODE_ERR	CRC32 Enable Failure During Boot.
ROM_BOOT_CRC_CALLBACK_ERR	Error in Execution of the CRC Callback.
ROM_BOOT_SB_IMAGE_VERSION_ERR	Secure Boot Header Version Error.
ROM_BOOT_SB_IMAGE_TYPE_ERR	Secure Boot Header Type Error.

Table 53-69: ROM_BOOT_RESULT Members (Continued)

Enumerator	Description
`ROM_BOOT_SB_CERT_COUNT_ERR`	Secure Boot Header Certificate Count Error.
`ROM_BOOT_SB_KEY_UNWRAP_ERR`	Decryption Key Unwrap Error.
`ROM_BOOT_ROLLBACK_ID_ERR`	Secure Boot Anti-Rollback Protection Error.
`ROM_BOOT_OTP_NVCNTR_READ_ERR`	Non-Volatile Counter Read Error.
`ROM_BOOT_OTP_NVCNTR_PGM_ERR`	Non-Volatile Counter Program Error.
`ROM_BOOT_WAKEUP_NO_CGU_INIT`	Wakeup Actions CGU Programming Status.
`ROM_BOOT_WAKEUP_NO_DMC_INIT`	Wakeup Actions DMC Programming Status.
`ROM_BMODE_SPI_SWITCH`	Need to boot from the alternate SPI port
`ROM_BMODE_ILLEGAL_DEVNUM`	Illegal Device Enumeration Error.
`ROM_BMODE_EXIT`	Boot Stream Block Payload Destination Error.
`ROM_BMODE_FAILURE`	Boot Mode Error.
`ROM_DMA_SUCCESS`	The API call succeeded.
`ROM_DMA_FAILURE`	The API call failed.

ROM_BOOT_FAILURE

Failure.

General failure can be used to indicate any general failure throughout the boot process

ROM_BOOT_SUCCESS

Success.

General success can be used to indicate any general functional success for an operation during the boot process.

NOTE: This must be the return result for a boot mode drivers initialization, configuration, load and cleanup routines when overriding their functionality in second stage boot loaders to use custom functions.

ROM_BOOT_HDR_CHKSUM_ERR

Boot Stream Block Header Checksum Error.

Indicates that the 8-bit XOR checksum of the 16-byte block header failed to generated the expected result.

ROM_BOOT_HDR_SIGN_ERR

Boot Stream Block Header Sign Failure.

The 0xAD block required as byte 4 of the boot block header was not found.

ROM_BOOT_HDR_DEST_ERR

Boot Stream Block Payload Destination Error.

The target address field of the block header indicates that the payload for the block is destined towards an address that is not supported. This would typically indicate an attempt to load data to the reserved 8KB region of memory reserved by the boot process as non-bootable.

ROM_BOOT_CGU_WRITE_ERR

CGU Write Error

Returned by the CGU Configuration routine if a CGU error is set during the initialization of the CGU from settings provisioned in the OTP.

ROM_BOOT_DMA_SUCCESS

DMA operation was successful

ROM_BOOT_DMA_FAILURE

DMA Failure.

Returned by the DMA routines if an error was detected in the `DMA_STAT.IRQERR` prior to setting up a new DMA operation with the newly supplied configuration.

ROM_BOOT_DMA_ACTIVE

DMA Channel is Active

Returned only by the peripheral DMA routine when an attempt to run another peripheral DMA operation is attempted and the DMA channel is already running.

NOTE: This is not currently implemented for MDMA operations.

ROM_BOOT_DMA_CONFIG_ERR

DMA configuration error

ROM_BOOT_MDMA_ID_ERR

Illegal MDMA Channel ID.

Returned by `adi_rom_MemDma()` if the MDMA channel ID is not supported. For supported channel IDs, please refer to `ROM_DMA_MDMA_ID`

ROM_BOOT_MDMA_OPERATION_ERR

Illegal MDMA operation Specified.

Returned by `adi_rom_MemDma()` if the MDMA operation to be performed is not supported. For supported operations, please refer to `ROM_DMA_MDMA_OPERATION`

ROM_BOOT_MDMA_CONFIG_ERR

Memory DMA configuration error

ROM_BOOT_MDMA_SRC_ERR

MDMA Source Channel Configuration Error.

Set by the MDMA routines if after configuring the MDMA source channel to start a DMA operation, an error is generated in the source channels `DMA_STAT.IRQERR`

ROM_BOOT_MDMA_DST_ERR

MDMA Destination Channel Configuration Error.

Set by the MDMA routines if after configuring the MDMA source channel to start a DMA operation, an error is generated in the destination channels `DMA_STAT.IRQERR`.

ROM_BOOT_MDMA_DONE_DETECT_ERR

Memory DMA Completed with errors

ROM_BOOT_MDMA_SUCCESS

Memory DMA Completed successfully

ROM_BOOT_PDMA_CONFIG_ERR

Peripheral DMA configuration invalid

ROM_BOOT_PDMA_SUCCESS

Peripheral DMA completed successfully

ROM_BOOT_CRC_FAILURE

MDMA CRC32 Failure.

Returned by the higher level `adi_rom_MemDma()` routine and the underlying `adi_rom_MemCompare()` routine if the CRC32 result of the block of data did not match the expected result.

ROM_BOOT_CRC_COUNT_ERR

CRC Byte Count was not a multiple 4.

The CRC peripheral operates on 32-bit data only and as such all CRC operations must have a byte count that is a multiple of 4. This result is returned by the higher level `adi_rom_MemDma()` routine and the underlying `adi_rom_MemCompare()` and `adi_rom_MemFill()` routines if the byte count is not a multiple of 4 bytes.

ROM_BOOT_CRC_SUPPORTED_ERR

CRC Not Supported Error.

Returned by `adi_rom_MemDma()`, `adi_rom_MemFill()`, `adi_rom_MemCompare()` and `adi_rom_Crc32Poly()` if the supplied DMA configuration specified an MDMA channel that does not support CRC operations.

ROM_BOOT_CRC_INITCODE_ERR

CRC32 Enable Failure During Boot.

Returned by `adi_rom_Crc32Init()` if the boot process cannot enable the CRC32 functionality due to a `NULL` `ADI_ROM_BOOT_CONFIG` pointer or `NULL` `ADI_ROM_BOOT_HEADER` pointer located in `ADI_ROM_BOOT_CONFIG::pHeader`

ROM_BOOT_CRC_CALLBACK_ERR

Error in Execution of the CRC Callback.

Returned by the default CRC callback function located in the boot rom if any of the following conditions are met:

- The `ADI_ROM_BOOT_CONFIG` pointer passed to the callback is a `NULL` pointer
- The `ADI_ROM_BOOT_BUFFER` pointer pointing to the buffer to run CRC validation on is a `NULL` pointer
- The `ROM_CBFLAG_DIRECT` flag is not set in the supplied flags parameter indicating it was a direct callback
- The `ADI_ROM_BOOT_HEADER` pointer located in `ADI_ROM_BOOT_CONFIG::pHeader` is a `NULL` pointer

ROM_BOOT_SB_IMAGE_VERSION_ERR

Secure Boot Header Version Error.

Returned by the routine responsible for verifying the secure boot header if the version field is not the version supported by the processor. The version field is automatically set by the `signtool` utility.

ROM_BOOT_SB_IMAGE_TYPE_ERR

Secure Boot Header Type Error.

Returned by the routine responsible for verifying the secure boot header if the secure boot image type field is not one of the types supported by the processor. The type field is used to indicate if the image is a `BLp`, `BLx`, or `BLw` image secure boot image.

ROM_BOOT_SB_CERT_COUNT_ERR

Secure Boot Header Certificate Count Error.

Returned by the routine responsible for verifying the secure boot header if the number of certificate count is greater than 0 as the processor does not support the use of certificates in the secure boot implementation.

ROM_BOOT_SB_KEY_UNWRAP_ERR

Decryption Key Unwrap Error.

Indicates failure to unwrap the decryption key in `BLw` secure boot images.

ROM_BOOT_ROLLBACK_ID_ERR

Secure Boot Anti-Rollback Protection Error.

Indicates an attempt to boot a secure boot image with a lower firmware version than is currently stored in `OTP` or if the rollback ID read from `OTP` is out of bounds of the supported firmware update limit.

ROM_BOOT_OTP_NVCNTR_READ_ERR

Non-Volatile Counter Read Error.

A failure occurred in the reading of the non-volatile counter in `OTP` that contains the current Anti-Rollback protection value

ROM_BOOT_OTP_NVCNTR_PGM_ERR

Non-Volatile Counter Program Error.

A failure occurred in the programming of the new Anti-Rollback firmware version to the Non-Volatile Counter in `OTP`.

ROM_BOOT_WAKEUP_NO_CGU_INIT

Wakeup Actions CGU Programming Status.

Indicates that the routine responsible for programming the CGU during wakeup events did not perform any CGU configuration as there was no wakeup action request to do so.

ROM_BOOT_WAKEUP_NO_DMC_INIT

Wakeup Actions DMC Programming Status.

Indicates that the routine responsible for programming the DMC during wakeup events did not perform any DMC configuration as there was no wakeup action request to do so.

ROM_BMODE_SPI_SWITCH

Need to boot from the alternate SPI port

ROM_BMODE_ILLEGAL_DEVNUM

Illegal Device Enumeration Error.

Set when the boot process attempts to boot from a peripheral enumeration that is not supported or does not exist on the product. The peripheral enumeration is checked multiple times by all boot mode drivers in the ROM to ensure that peripheral instance to boot from is supported.

ROM_BMODE_EXIT

Boot Stream Block Payload Destination Error.

The target address field of the block header indicates that the payload for the block is destined towards an address that is not supported. This would typically indicate an attempt to load data to the reserved 8KB region of memory reserved by the boot process as non-bootable.

ROM_BMODE_FAILURE

Boot Mode Error.

A general error that can be returned by any of the boot mode drivers functions to indicate an error occurred. If an error occurs during the initialization, configuration or loading of boot data from the boot source then this error result may be used in the event a more concise error is is not available.

ROM_DMA_SUCCESS

The API call succeeded.

ROM_DMA_FAILURE

The API call failed.

enum ROM_CORE_ID

Enumeration Type Declaration: `ROM_CORE_ID`

Core ID.

An enumeration for referencing a particular core

Table 53-70: ROM_CORE_ID Members

Enumerator	Description
`ROM_CORE_ID0`	Core 0
`ROM_CORE_ID1`	Core 1
`ROM_CORE_ID2`	Core 2
`ROM_CORE_NUM_CORES`	Number of Cores

ROM_CORE_ID0

Core 0

ROM_CORE_ID1

Core 1

ROM_CORE_ID2

Core 2

ROM_CORE_NUM_CORES

Number of Cores

enum ROM_DMA_DONE_DETECT_METHOD

Enumeration Type Declaration: `ROM_DMA_DONE_DETECT_METHOD`

DMA Done Detection Method.

Specifies the method to be used for detecting the completion of the requested DMA operation.

When a user requests a non-blocking DMA operation then separate software is required to check the status of the DMA channel. The boot rom does not provide an API for use for this operation.

NOTE: The trigger mode is not supported on this product

Table 53-71: ROM_DMA_DONE_DETECT_METHOD Members

Enumerator	Description
`ROM_DMA_DONE_NON_BLOCKING`	Return without waiting for the DMA to complete
`ROM_DMA_DONE_POLL_IRQDONE`	Poll on the IRQDONE bit in the DMA Status register
`ROM_DMA_DONE_WAKEUP_TRIGGER`	Configure a trigger to wakeup the core on completion

ROM_DMA_DONE_NON_BLOCKING

Return without waiting for the DMA to complete

ROM_DMA_DONE_POLL_IRQDONE

Poll on the IRQDONE bit in the DMA Status register

ROM_DMA_DONE_WAKEUP_TRIGGER

Configure a trigger to wakeup the core on completion

enum ROM_DMA_MDMA_ID

Enumeration Type Declaration: `ROM_DMA_MDMA_ID`

MDMA Channel ID.

The ID of the Memory DMA channel to be used. This item is used in the `ROM_DMA_MDMA_CONFIG` configuration to specify the Memory DMA channel to use for operations accessible via the `adi_rom_MemDma()` routine

Table 53-72: ROM_DMA_MDMA_ID Members

Enumerator	Description
`ROM_DMA_MDMA0`	Memory DMA Stream 0
`ROM_DMA_MDMA1`	Memory DMA Stream 1
`ROM_DMA_MDMA2`	Memory DMA Stream 2
`ROM_DMA_MDMA3`	Memory DMA Stream 3

Table 53-72: ROM_DMA_MDMA_ID Members (Continued)

Enumerator	Description
`ROM_DMA_MEMDMA_END_COUNT`	Number of Memory DMA Streams

ROM_DMA_MDMA0

Memory DMA Stream 0

ROM_DMA_MDMA1

Memory DMA Stream 1

ROM_DMA_MDMA2

Memory DMA Stream 2

ROM_DMA_MDMA3

Memory DMA Stream 3

ROM_DMA_MEMDMA_END_COUNT

Number of Memory DMA Streams

enum ROM_DMA_MDMA_OPERATION

Enumeration Type Declaration: `ROM_DMA_MDMA_OPERATION`

MDMA Operation to be performed.

The operation determines if only an MDMA is required to be configured, or whether a CRC operation must be used in conjunction with the MDMA.

Table 53-73: ROM_DMA_MDMA_OPERATION Members

Enumerator	Description
`ROM_DMA_MEM_COPY`	Standard MDMA transfer from a source to a destination
`ROM_DMA_MEM_CRC`	Performs a CRC32 MDMA read operation and compares the result with an expected result
`ROM_DMA_MEM_FILL`	Uses the CRC peripheral to perform a fill operation with a 32-bit value
`ROM_DMA_MEM_COMPARE`	Uses the CRC peripheral to compare data with a constant 32-bit value
`ROM_DMA_CRC_LUT_INIT`	Initializes the CRC LUT from the supplied CRC Polynomial

ROM_DMA_MEM_COPY

Standard MDMA transfer from a source to a destination

ROM_DMA_MEM_CRC

Performs a CRC32 MDMA read operation and compares the result with an expected result

ROM_DMA_MEM_FILL

Uses the CRC peripheral to perform a fill operation with a 32-bit value

ROM_DMA_MEM_COMPARE

Uses the CRC peripheral to compare data with a constant 32-bit value

ROM_DMA_CRC_LUT_INIT

Initializes the CRC LUT from the supplied CRC Polynomial

enum ROM_DMA_PDMA_OPERATION

Enumeration Type Declaration: `ROM_DMA_PDMA_OPERATION`

Table 53-74: ROM_DMA_PDMA_OPERATION Members

Enumerator	Description
`ROM_DMA_PERI_TX`	Peripheral Transmit Operation
`ROM_DMA_PERI_RX`	Peripheral Receive Operation

ROM_DMA_PERI_TX

Peripheral Transmit Operation

ROM_DMA_PERI_RX

Peripheral Receive Operation

enum ROM_GETADDR_VALUE

Enumeration Type Declaration: `ROM_GETADDR_VALUE`

Parameter for `adi_rom_GetAddress()` function t oretireve the address of a data object stored in the boot rom.

Table 53-75: ROM_GETADDR_VALUE Members

Enumerator	Description
`ROM_GETADDR_CONSTANTS`	Retrieve the address of the `ROM_CONSTANTS_TYPE` object
`ROM_GETADDR_BMODE`	Retrieve the address of the lookup table sotring the default adi_rom_boot() parameters for each boot mode
`ROM_GETADDR_MDMAREGS`	Retrieve the address of the `ROM_BOOT_MDMA_REGS` object
`ROM_GETADDR_SPILUT`	Retrieve the address of the lookup table in the rom describing the various SPI master boot BCODE configurations
`ROM_GETADDR_ECDSA_DOMAIN`	Retrieve the address of the domain parameteres used for ECDSA

ROM_GETADDR_CONSTANTS

Retrieve the address of the `ROM_CONSTANTS_TYPE` object

ROM_GETADDR_BMODE

Retrieve the address of the lookup table sotring the default adi_rom_boot() parameters for each boot mode

ROM_GETADDR_MDMAREGS

Retrieve the address of the `ROM_BOOT_MDMA_REGS` object

ROM_GETADDR_SPILUT

Retrieve the address of the lookup table in the rom describing the various SPI master boot BCODE configurations

ROM_GETADDR_ECDSA_DOMAIN

Retrieve the address of the domain parameteres used for ECDSA

enum ROM_HOOK_CALL_CAUSE

Enumeration Type Declaration: `ROM_HOOK_CALL_CAUSE`

Passed to a user hook routine to indicate the reason of the call.

When calling a boot mode via adi_rom_Boot, the user may provide an optional hook routine as a callback. This hook routine is called by the boot software firstly after the execution of the boot modes initialization routine then again after execution of the boot modes configuration routine. This parameter allows the users routine to identify at which point the call was made allowing the user to perform different actions for each call.

Table 53-76: ROM_HOOK_CALL_CAUSE Members

Enumerator	Description
`ROM_HOOK_CALL_INIT_COMPLETE`	Call was as a result of completion of the boot modes initialization function
`ROM_HOOK_CALL_CONFIG_COMPLETE`	Call was as a result of the completion of the boot modes configuration function

ROM_HOOK_CALL_INIT_COMPLETE

Call was as a result of completion of the boot modes initialization function

ROM_HOOK_CALL_CONFIG_COMPLETE

Call was as a result of the completion of the boot modes configuration function

enum ROM_SB_IMAGE_TYPE

Enumeration Type Declaration: `ROM_SB_IMAGE_TYPE`

Secure Boot Image Types.

The secure boot header contains a type field for the secure boot image type, this enumeration provides a complete list of all image types.

NOTE: The secure boot process does not necessarily support all image types defined.

Table 53-77: ROM_SB_IMAGE_TYPE Members

Enumerator	Description
`ROM_SB_IMAGE_UNKNOWN`	Unknown Secure Boot image type, used by software to initialize the type before detection of boot image type takes place
`ROM_SB_IMAGE_BLP`	Plain text `BLp` secure boot image supporting authentication only with no decryption
`ROM_SB_IMAGE_BLW`	Keywrapped `BLw` secure boot image supporting authentication and decryption, boot stream decryption key wrapped in the secure header
`ROM_SB_IMAGE_BLE`	Not supported by any Secure boot products. Secure boot image with key stored in plain text form in the secure header
`ROM_SB_IMAGE_BLX`	`BLx` Secure boot image supporting authentication and decryption, boot stream decryption key wrapped located in `OTP`
`ROM_SB_IMAGE_UNSUPPORTED`	May be used by software to indicate any other unsupported image type

ROM_SB_IMAGE_UNKNOWN

Unknown Secure Boot image type, used by software to initialize the type before detection of boot image type takes place

ROM_SB_IMAGE_BLP

Plain text `BLp` secure boot image supporting authentication only with no decryption

ROM_SB_IMAGE_BLW

Keywrapped `BLw` secure boot image supporting authentication and decryption, boot stream decryption key wrapped in the secure header

ROM_SB_IMAGE_BLE

Not supported by any Secure boot products. Secure boot image with key stored in plain text form in the secure header

ROM_SB_IMAGE_BLX

`BLx` Secure boot image supporting authentication and decryption, boot stream decryption key wrapped located in `OTP`

ROM_SB_IMAGE_UNSUPPORTED

May be used by software to indicate any other unsupported image type

enum ROM_SPI_PROTOCOL

Enumeration Type Declaration: `ROM_SPI_PROTOCOL`

The SPI Protocol to use.

SPI Flash devices are now capable of supporting multiple protocols for the sending of the command to the SPI flash. Typically the command would be sent over the single bit bus, however a number of newer devices also support the sending of the command over the dual or quad bit bus.

WARNING: Enabling of DUALIO or QUADIO protocol for the command cycles runs the risk of the boot process being unable to communicate with the SPI flash, especially in system reset type events where the processor will attempt to reboot and the flash may not have been reset. It is not recommended to enable such features on SPI Flash devices if they are also the primary boot source used for booting from hardware reset and system reset events.

Table 53-78: ROM_SPI_PROTOCOL Members

Enumerator	Description
`ROM_SPI_EXT_PROTOCOL`	Extended protocol where the command cycle is sent on the single bit bus
`ROM_SPI_DUALIO_PROTOCOL`	DualIO protocol where the command cycle is sent on the dual bit bus
`ROM_SPI_QUADIO_PROTOCOL`	QuadIO protocol where the command cycle is sent on the quad bit bus

ROM_SPI_EXT_PROTOCOL

Extended protocol where the command cycle is sent on the single bit bus

ROM_SPI_DUALIO_PROTOCOL

DualIO protocol where the command cycle is sent on the dual bit bus

ROM_SPI_QUADIO_PROTOCOL

QuadIO protocol where the command cycle is sent on the quad bit bus

54 System Crossbars (SCB)

A modern system on a chip (SoCs) contains multi-cores, memory controllers, security blocks, and other high speed peripherals. As system integration increases, SoCs need to provide bus connectivity that allows better throughput to reduce performance bottlenecks. While traditional point-to-point connection buses have performed well in smaller systems, there is a need to use advanced switching based bus architectures for efficient handling of data transfer between multiplicity of data sources and sinks in the system. Additionally, mixing various traffic types in the same SoC (for example control, communication over peripherals and computing) while sharing the same bus resources, create different requirements from the Quality of Service (QoS) perspective.

The system crossbars (SCB) are the fundamental building blocks of a switch-fabric style for (on-chip) system bus interconnection. The SCBs connect system bus masters to system bus slaves, providing concurrent data transfer between multiple bus masters and multiple bus slaves. The SCB architecture addresses the challenges described above. The SCB provides sustainable throughput for simultaneous transactions in the system with configurable quality of service for each type of transaction (traffic) as required. A hierarchical model, built from multiple SCBs, provides a power and area efficient system interconnect, which satisfies the performance and flexibility requirements of a specific system.

SCB Features

The SCBs provide the following features:

- Efficient, pipelined bus transfer protocol for sustained throughput
- Full-duplex bus operation for flexibility and reduced latency
- Concurrent bus transfer support to allow multiple bus masters to access bus slaves simultaneously
- Protection model (privileged or secure) support for selective bus interconnect protection
- Simple priority-based QoS based arbitration model
- Programmable quality of service

SCB Functional Description

The following sections provide a functional description of the SCB.

- SCB Architectural Concepts

ADSP-SC58x SCB0 Register List

This describes the System Crossbar fabric.

Table 54-1: ADSP-SC58x SCB0 Register List

SCB3_DCLK0_WR_TIDE	DCLK0 Interface Block APB WR Tidemark
SCB3_MST00_SYNC	SYNC Mode

SCB Architectural Concepts

This section describes the components of the SCB and the modules connected to it. The basic elements in the SCB are SCB masters, slaves master interfaces, and slave interfaces.

Masters

The controllers in the system that raise the data request in the form of a read/write transaction on the SCB are called masters. The system bus masters include peripheral Direct Memory Access (DMA) channels. These include the Serial Port (SPORT) DMA, and SPI DMAs, among others. Also included are the Memory-to-Memory DMA channels (MDMA), the L1 code fill block, and the processor cores.

Slaves

Slaves are SCB connections that are responding to transfer requests. Slaves include MMR registers, memory units, and various peripherals depending upon individual configurations. Each system slave has its own latencies and response times.

SCB Block Diagrams

The SCB architectural model is illustrated in the ***SCB Overview*** figure. This figure shows a high level representation of a basic SCB connecting n Slaves to x Masters. A variable number of masters connect to a variable number of slaves in each SCB. In this example, all SIs connect to all MIs as indicated by the lines connecting them.

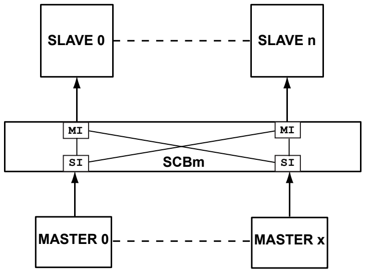

Figure 54-1: SCB Overview

Hierarchy Block Diagram

A system interconnect built from multiple SCBs in a hierarchical model is illustrated in the ***SCB Hierarchy Overview*** figure. The system master node level SCBs master connects multiple SIs to a single MI, which in turn connects to an SI of the system slave level node SCB.

As discussed above, all the masters in the system are distributed across different SCBs. A given SCB at system master node level connects directly to the system masters. These SCBs connect to SCB0 through its SIs forming a hierarchal structure. While a master has to access any slave, its first access goes through the SCB it is connected to, and then through SCB0, to reach its intended slave. This simplifies the connecting hardware in the basic SCB block by limiting the masters. Care must be taken when sharing masters to allow adequate throughput for their individual data transfer requirements.

In this example, all SIs are connected to all MIs.

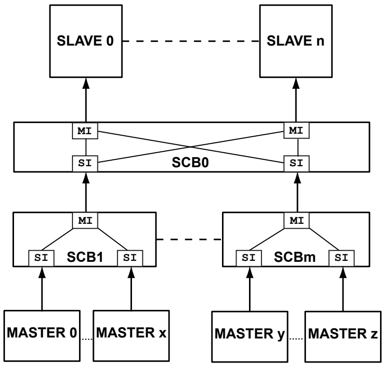

Figure 54-2: SCB Hierarchy Overview

NOTE: For an overall diagram of all SCB interconnections, see the SCB Block Diagram.

SCB Block Diagram

The following figures show the SCB block diagram. For DMA channel assignments for the peripherals shown in the *SCB Block Diagram* figure, see the *DMA Channel Peripherals Controlled by SCBs* table following the figure.

There are two types of peripherals that use DMA. The first have dedicated DMA channels controlled by the Dedicated DMA Engine (DDE) and have the same operating modes (see DMA Operating Modes) and use the same programming model (DMA Channel Programming Model). The second type is not controlled by the DDE. These peripherals have their own operating modes and programming models (see the peripheral chapter for this information). The peripheral types are shown in the following table.

Table 54-4: DMA Channel Peripherals Controlled by SCBs

Figure 54-4: SCB Block Diagram - Interconnections

While this figure is useful just for the overview it provides, it is also useful to observe the following relationships that are highlighted.

- The hierarchy of SCBs manages system bus interconnections, multiplexing, and arbitration among the peripherals on the processor.
- The SCBs connections support DMA channels for some peripherals and support dedicated connections for others (such as USB). The connections also support memory-mapped register access for internal memory (L1 and L2) and for external memory.

  The slave interface of the crossbar (where the masters such as DMA connect to) performs two functions. The first function is arbitration. SCBx handles arbitration. The second function is clock conversion. The programmable QoS registers can be viewed as being associated with the SCBx. For example, the programmable QoS registers for DMA16-17, USB0, GIG-E, SDIO, ACM and SINC can be viewed as residing in SCB3. Whenever a transaction is received at DMA16, the programmed QoS value is associated with that transaction and is arbitrated with the rest of the masters at SCB3.
- Most of the peripherals and their SCBs are in the SCLK0_0 domain. Crypto is also in the SCLK0_0 domain. Enhanced bandwidth MDMA, MDMA0 and MDMA1 streams, MLB, DBG, ETR, PCIe and their SCB are in the SYSCLK_0domain.
- Each peripheral has a latency for access across the SCB. The latency varies with the nature of the peripheral. Also, the number of active peripherals (especially for cases where multiple peripherals are active on a shared

SCB) affects SCB performance. Refer to the L2 System Memory chapter for more details on the L2 memory organization.

MDMA channels are unidirectional. For example, MDMA0 SRC is read-only and MDMA1 is write-only. Access to the MMR space of SCB0 is allowed only in secure mode. The MMR space of SCB0 has registers for programming the QoS of various masters and controlling the clock domain crossing.

The following are definitions of acronyms that appear in the figure:

DMA0-DMA35

Indicate DMA channels for peripherals supporting DMA transfers.

SCB0-8

Indicate SCB interfaces, connecting the system bus masters and slaves.

SCLK0, SCLK1, SYSCLK, LPCLK

Indicate clock domains in which the specific SCBs operate. For more information on clock domains, see the Clock Generation Unit (CGU) chapter and the product data sheet.

CDC

Indicates the clock domain crossing.

C0_D, C1_D

Indicates the SHARC processor (0 or 1) data bus (DM/PM).

C0_I, C1_I

Indicates the SHARC processor (0 or 1) instruction bus (PM).

L2CC

Indicates the system L2 cache.

A5

Indicates the ARM Cortex A5 processor.

L1C0 S1, L1C0 S2, L1C1 S1, L1C1 S2

Indicates the L1 memory for SHARC+ processor (0 or 1) slave port (1 or 2).

DMC0, DMC1

Indicates the dynamic memory controller (DMC) interfaces.

PCIe

Indicates the PCI Express interface.

SP0 A/B, SP1 A/B

Indicates the serial port interfaces and their full-duplex halves.

SPI0, SPI1 - RX/TX

Indicates the serial peripheral interfaces ports with receive or transmit paths.

DBG, ETR

Indicates the Debug Port (DBG) and Embedded Trace Router (ETR) which provide access to debug and trace capabilities.

SMPU

Indicates the system memory protection unit (SMPU).

MDMA0, MDMA1

Indicates the memory DMA 0 through 1 interfaces.

USB

Indicates the universal serial bus (USB) interface.

SMMR

Indicates the system memory-mapped register interface.

System Crossbars

The System Crossbars (SCB) are the fundamental building blocks of the system bus interconnect. The SCB (often referred to as the system interconnect fabric), is a collection of inter-connection units connecting system masters to slave memory spaces. The SCB connects one or more master devices to one or more memory-mapped slave devices. Each connected master can be a core that originates an SCB transaction, or a master interface of an upstream SCB cascaded interconnect. Each connected slave can be the final target of an SCB transaction or a slave interface of a downstream cascaded SCB interconnect (forming a hierarchy of SCBs).

Each SCB that has multiple masters and slaves share the total bandwidth of the SCB. (In a M:N configuration where M masters are connected to N slaves through the SCBx.)

The SCB provides separate channels for reads and writes. Read and write accesses through a given SCB do not share bandwidth. All the SCBs are 32 bits wide and run at SCLK speed, and can provide a bandwidth of up to 400 Mbytes per second for reads and writes separately (when SCLK = 100 MHz). Only SCB0, which is the major SCB in the SCB hierarchy, has the multiple paths between multiple master and slave interfaces.

See the SCB Block Diagram.

All other SCBs in the chip connect to SCB0 through different slave interfaces. Other primary masters (DMAs, cores, and so on) in the system are distributed across these small SCBs. For a given SCB, all the master and slaves share the total bandwidth of the SCB. (Only SCB0 is the exception). Since different DMA channels are scattered across different SCBs (SCB1, SCB2 SCB3, and so on), they do not conflict for the bandwidth as long as they are in different SCB and are accessing different slaves. SCB0 allows for concurrent data transfer between multiple bus masters and multiple bus slaves, providing flexibility, and full-duplex operation. For example, the data transfer between SCB4 (one of the MDMA channels), and SMC controller (accessing SRAM memory) can happen in parallel to SCB2 (SPI RX/TX DMA) accessing memory mapped SPI memory with both the transfers occurring at up to 400 MBPS. If system accesses are carefully architected, SCB has a potential of providing sufficient sustained bandwidth in the end system.

Since the SCBs support burst transfers, it is important to configure the requesting master appropriately to make best use of available SCB bandwidth. For a DMA master, choosing the appropriate `DMA_CFG.MSIZE` value, is important from both a functional and a performance perspective. The value in the `DMA_CFG.PSIZE` bit field determines the width of the peripheral bus in use. It can be configured to 1-byte, 2-bytes, or 4-bytes. The `DMA_CFG.MSIZE` value determines the actual size of the SCB bus in use. It also determines the minimum number of bytes which are transferred from or to memory corresponding to a single DMA request or grant. The transfer can be 1-, 2-, 4-, 8-, 16-, or 32-bytes. If the `DMA_CFG.MSIZE` value is greater than the SCB bus width, the SCB performs burst transfers according to the width defined in `DMA_CFG.MSIZE`. When `DMA_CFG.MSIZE` is less than the SCB bus width, bursting is not supported and partial bus use results.

Each of the SCB unit in the fabric consists of N Slave interfaces (MSTn). Each of these interfaces has controls for read quality of service, write quality of service, and functional mode. A subset of these matrices includes controls for IB (Interface Block) sync mode, and bus functional mode. For more details on IB, see the clock domain synchronization section.

Clock Domain Synchronization

Most of the masters in the system operate at the same clock as the SCB, which is SCLK0_0. There is no need to synchronize. The M4 core and L1 code fill blocks (used for cache fill from SPI flash memory or SMC memory) operate in the CCLK domain. The SCB provides the option to program the different synchronization schemes for these masters through the sync mode registers (`SCB3_MST00_SYNC`, and `SCB1_MST00_SYNC`).

These registers perform clock domain crossing synchronization from CCLK to SCLK. The configuration of these registers depends on the CCLK and SCLK configuration.

SCB Bus Master IDs

The SCB bus master ID tables indicate which masters are connected to each of the slave ports of SCB0. The tables also indicate the precise value of the ID as seen by the slave. These values are useful for SWU programming.

NOTE: For an overall diagram of all SCB interconnections, see the SCB Block Diagram.

Table 54-5: Bus Master IDs

SCB	Masters	Hex ID Values
SCB1	DMA0 (SPORT0, HALF A)	0x0, 0x10 (descriptor fetch)
	DMA1 (SPORT0, HALF B)	0x1, 0x11 (descriptor fetch)
	DMA2 (SPORT1, HALF A)	0x2, 0x12 (descriptor fetch)
	DMA3 (SPORT1, HALF B)	0x3, 0x13 (descriptor fetch)
	DMA4 (SPORT2, HALF A)	0x4, 0x14 (descriptor fetch)
	DMA5 (SPORT2, HALF B)	0x5, 0x15 (descriptor fetch)
	DMA6 (SPORT3, HALF A)	0x6, 0x16 (descriptor fetch)

	PL310 (M1)	There are 32 values. "x" is either a 0 or 1.

SCB Programming Model

The following sections provide information for programming the SCB properly.

Programming SCB Arbitration

Each slave interface has a QoS value (priority) associated with both read and write channels. These values are 4 bits and are located in the `SCB0_MST[n]_RQOS` and `SCB0_MST[n]_WQOS` registers. At the entry point to the infrastructure, all transactions are allocated this programmable local QoS value. The arbitration of the transaction throughout the infrastructure uses this QoS. At any arbitration node, a fixed priority exists for transactions with a different QoS. The highest value has the highest priority.

If there are coincident transactions at an arbitration node with the same QoS that require arbitration, then the network uses a Least Recently Granted (LRG) algorithm. At each switch, the master with the highest QoS acquires access and that switch output takes the QoS value of the winner for that transaction. At the next switch slave interface, the master uses the QoS value of the winner. QoS can have values from 0 (lowest priority) to 15 (highest priority).

For example in the following figure, ***SCB Arbitration***:

1. At SCB1, masters (1, 2, 3) have RQOS values of (6, 4, 2)
2. At SCB2, masters (4, 5, 6) have RQOS values of (12, 13, 1)

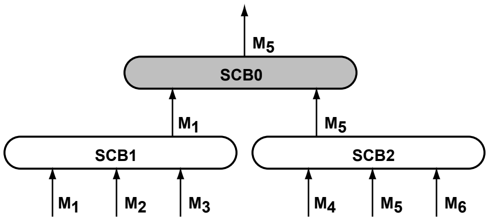

Figure 54-5: SCB Arbitration

In this case, master 1 wins at SCB1, and master 5 wins at SCB2. However, in a perfect competition at SCB0, masters 4 and 5 had the highest overall RQOS values. Masters 4 and 5 would have fought for arbitration directly at SCB0. However, because of the mini-SCBs, master 1, at a much lower RQOS value, is able to win against master 4 and make it all the way to SCB0.

Programming Clock Domain Crossing Registers

In addition to the QoS registers, the interconnect has a set of registers to program the clock domain crossing (CDC) in the interface blocks. The clock domain crossing can be programmed to be one of the following:

- SYNC 1:1
- SYNC 1:n
- SYNC n:1
- ASYNC
- SYNC m:n

The CDC can be programmed at the interface between DCLK and the SYSCLK by writing appropriate bits in the `SCB1_MST00_SYNC` register (address 0x30200020) for DMC0 and the `SCB3_MST00_SYNC` register (address 0x30300020) for DMC1. Refer to the Register Description section for more details.

To change the clock domain crossing mode, follow the actions described in the ***Changing Clock Domain Crossing Modes*** table.

Table 54-6: Changing Clock Domain Crossing Modes

Original Mode	Required Mode	Action
ASYNC	Any other mode	Change the clocks then change the MMR register
Any mode	ASYNC	Change the MMR register then change clocks to ASYNC.
m:n	1:1	Change the clocks, then change the register.

Table 54-6: Changing Clock Domain Crossing Modes (Continued)

Original Mode	Required Mode	Action
1:1	m:n	Change the register, then change the clocks.

The other CDCs are not programmable. The default values are:

- SCLK : SYSCLK CDC – 1: n
- CCLK : SYSCLK CDC – m : 1
- SYSCLK : CCLK CDC – 1 : n
- LPCLK : SYSCLK CDC – ASYNC

SCB Programming Concepts

The SCB arbitration model among master or slave SCBs of the processor is fixed (not programmable). But, each slave does have a quality of service (QoS) programmable feature that affects arbitration.

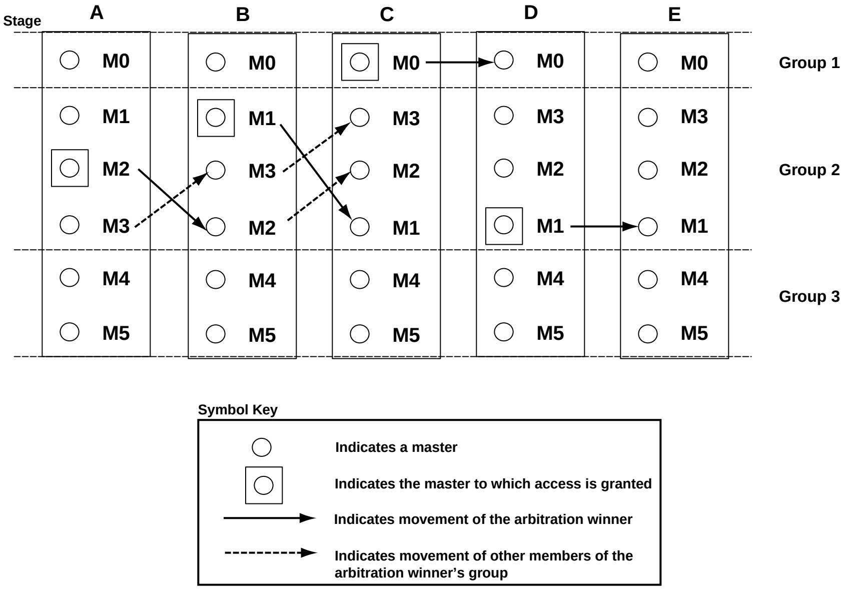
The arbitration of transactions in SCB is based on the QoS value or the priority of the transaction. All masters with the same priority form a priority group. Arbitration is granted to the highest priority group from which a member is trying to win access, and within that group, to the highest master at that time. When a master wins arbitration, it is relegated to the bottom of its group to ensure that it cannot prevent other masters in its group from accessing the slave.

If you configure all master priorities to different levels, the arbiter implements a fixed priority scheme. This scheme occurs because each master is in a group of its own, and therefore, masters maintain their ordering.

The LRG and fixed priority modes concurrently exist when the master priority value registers are programmed with a combination of identical and unique values.

NOTE: The SCB arbitration hierarchy is fixed (for example, SCB1 master to SCB1 slave). However, multiple master inputs to the same slave permit QoS programming.

The *LRG Arbitration Example* figure shows three groups with different QoS values. Masters in the same group share a QoS value. The arbitration occurs using an LRG scheme.



Stage

Indicates the master to which access is granted
Indicates movement of the arbitration winner
Indicates movement of other members of the arbitration winner's group

Figure 54-6: LRG Arbitration Example

The QoS value assigned to a transaction at entry point is carried forward by the transaction as it passes through all arbitration stages in the SCB. QoS for all masters is configured as programmable in system fabric interconnect in ADSP-SC58x.

The priority of the masters fits into three groups:

- Group A – Peripherals without flow control
- Group B – Cores and debug ports
- Group C – Peripherals with flow control or low bandwidth and MDMAs
- Group D – Peripherals with flow control but without bandwidth control

Group A: Peripherals without Flow Control

These masters are assigned the highest priority. Long delays in servicing requests due to losing arbitration could result in underrun or overrun of FIFOs and loss of data. All masters in this group are assigned the QoS reset value of 13. The Group A masters include the following peripherals:

- 10/100/1000 EMAC
- EPPI
- MLB (synchronous mode does not support flow control)
- Serial ports
- 10/100 EMAC

Group B: Cores and Debug Ports

Typically, software running on the cores has the highest priority after the peripherals in Group A. These masters are assigned the QoS reset value of 9.

Group C: Peripherals with Flow Control or Low Bandwidth and MDMAs

This group includes MDMAs and peripherals with flow control or low bandwidth. These masters are assigned the QoS reset value of 5. The Group C masters include the following:

- USB
- SDIO
- Link Ports
- PCIe
- HAE
- SINC
- Standard-BW MDMA
- Enhanced-BW MDMA
- Max-BW MDMA
- FFT-MDMA (Shared Max-BW MDMA)
- SPI
- UART

Although HAE and SINC do not have any flow control, their bandwidth requirement is much less, which places them in this group. MDMAs are given the same QoS as other peripherals with flow control since they can be made to consume lesser bandwidth by using the bandwidth control feature in the DDE.

Group D: Peripherals with Flow Control but without Bandwidth Control

Peripherals with flow control but without bandwidth control are given the lowest priority. This priority prevents them from flooding the system bandwidth. These peripherals can withstand longer latency times without any data loss, but can potentially keep issuing requests continuously. These masters are assigned the reset value of QoS as 1. The Group D masters include the following peripherals:

- EMDMA (delay line DMA)
- FIR
- IIR
- Crypto

NOTE: Although USB, SDIO, SINC, and other peripherals in Group C do not always have bandwidth control mechanisms like MDMAs, their rate of issuing requests is limited by their low bandwidth requirement. The QoS reset values are spaced out as 1, 5, 9 and 13 instead of 0, 1, 2 and 3. These values allows the software to change the priority of a few masters in the system without having to reprogram the QoS of all the masters.

Table 54-7: QoS Register Table

ADSP-SC58x SCB0 Register Descriptions

System Interconnect Fabric (SCB0) contains the following registers.

Table 54-8: ADSP-SC58x SCB0 Register List

Name	Description
`SCB0_MST[n]_RQOS`	Read Quality of Service for Master n
`SCB0_MST[n]_WQOS`	Write Quality of Service for Master n

Read Quality of Service for Master n

The SCB0_MST[n]_RQOS register indicates the read QOS or priority value for the indicated master. This value is used by the SCBs at different levels to arbitrate among different masters requesting read channel accesses. For mapping of master IDs to peripherals, see the SCB Bus Master IDs table.

55 System Watchpoint Unit (SWU)

The system watchpoint unit (SWU) is a single module used for transaction monitoring. The SWU is attached to each system slave through the system crossbar interface and provides ports for all address channel signals for the system crossbar. The SWU does not have ports for the read/write data channel signals or the low-power interface signals.

Each SWU contains four match groups of registers with associated hardware. These four SWU match groups operate independently, but share common event (interrupt and trigger) outputs. Each match group can monitor either the write or read address channel and can operate in either watchpoint mode or bandwidth mode.

SWU Features

The system watchpoint unit has the following features.

- Four independent match groups for each SWU
- Each match group can operate in either bandwidth mode or watchpoint mode
- In addition to the read and write address channels, the SWU monitors read and write ID, VALID and READY signals for data channels.

SWU Functional Description

This section describes the function of the SWU match block, interface block, and MMR block.

ADSP-SC58x SWU Register List

The System Watchpoint Unit (SWU) provides debug and development support through flexible transaction level and bandwidth monitoring and associated event triggering. The SWU can generate events based on monitoring transactions at the system slaves through watchpoint-match groups. The SWU also provides watchpoint event status reporting, a global lock, and processor reset capability. A set of registers governs SWU operations. For more information on SWU functionality, see the SWU register descriptions.

SWU Definitions

The following definitions are helpful when using the SWU module.

Watchpoint Mode

Mode in which transactions are recognized on an exact match. Actions can be configured to be taken after a specified number of matches have occurred.

Bandwidth Mode

Mode in which transactions are recognized and counted inside sampling window.

SWU Architectural Concepts

The information in this section provides basic module design concepts.

SWU-to-SCB Interface

The SWU system crossbar interface block latches all transactions on the system crossbar read and write address channels when the `SWU_GCTL.EN` register enable bit is set.

SWU Block Diagram

The *System Watchpoint Unit Top-Level Block Diagram* figure shows the SWU block diagram.

Figure 55-1: System Watchpoint Unit Top-Level Block Diagram

SCB Interface Block

The SWU system crossbar (SCB) latches all transactions on the SCB read and write address channels when the `SWU_GCTL.EN` bit is set.

MMR Interface Block

The SWU MMR block contains the peripheral bus interface and the SWU MMR registers. It also merges all interrupt requests and events from each match block into common outputs.

SWU Operating Modes

There are two operating modes supported by the SWU: bandwidth mode and watchpoint mode.

Bandwidth Mode

In bandwidth mode, the SWU module counts transactions which match the properties specified in the `SWU_CTL[n]` register during a sampling window determined by the respective `SWU_CNT[n]` register. At the end of the sampling window, the SWU stores results in the `SWU_HIST[n]` register. If the sampled bandwidth falls outside a programmed range, then the programmed action occurs.

Watchpoint Mode

In watchpoint mode, if the `SWU_CTL[n].CNTEN` bit is set, the SWU module decrements the `SWU_CUR[n]` register for each match, until it equals zero, at which point any programmed actions occur. The `SWU_CUR[n]` register is then reloaded from the `SWU_CNT[n]` register (if the `SWU_CTL[n].CNTRPTEN` bit is set), and the cycle repeats. If the `SWU_CTL[n].CNTRPTEN` bit is not set, any programmed actions happen on every match.

Match Block

There are four match blocks for each SWU. Each SWU match block can monitor either the read or write address channel, selected by the `SWU_CTL[n].DIR` bit. The SWU match block can operate in either watchpoint or bandwidth mode, as selected by the `SWU_CTL[n].BWEN` bit.

In either mode, the SWU match block can be programmed to match based on address (exact, inclusive or exclusive range), ID (with masking), security, and lock type. All enabled matches are AND'ed together to determine a match.

Scaling

Scaling allows the SWU to count more transactions by scaling the number of transactions and the number of clock cycles in bandwidth window (CNTn register) by 10,100 or 1000. This functionality is applicable only in bandwidth mode (`SWU_CTL[n].BWEN`==1).

Consider a case where the `SWU_TARG[n].BWMAX` bit field is programmed to 2. In the absence of any scaling, bandwidth overflow occurs when the `SWU_CUR[n].CURBW` bit field value > the `SWU_TARG[n].BWMAX` bit field value (2). With scaling set to 1:100 and after 275 transactions, the `SWU_CUR[n].CURBW` value is still 2 and equal to `SWU_TARG[n].BWMAX`. This event triggers a bandwidth overflow as the actual number of transactions is greater than 200 (2 × 100). The code can be rerun with a smaller scaling selected to analyze the cause for the overflow.

The counter increments after every group of N transactions with scaling enabled, where N is either 10,100 or 1000. (For N = 10, 0–9 transactions == 0 scaled transaction, 10–19 transactions == 1 scaled transaction, 20–29 transactions == 2 scaled transactions, and so on).

Fractional counts with scaling enabled are discarded and not rolled over from one bandwidth window to the next. For example, consider a case where scaling by 1000 is configured and the first window has 1200 transactions. The second window has 2800 transactions. The bandwidth for the first window is read as 1 and the second as 2. The 200 transactions from the first window do not get carried forward to the next window.

Do not use scaling by 10 with the `SWU_CTL[n].BLENINC` bit enabled if any of the masters accessing the slave can launch a transaction of burst length 16.

SWU Event Control

The SWU can generate the following events when a match occurs and when the event is enabled by configuring the proper bits in the control register.

1. Trace Message

2. Trigger
3. Interrupt request
4. Debug

SWU Interrupts

All interrupt requests and events from each match block are merged into common outputs.

SWU Status and Errors

SWU status and errors are reported in the `SWU_GSTAT` register. The SWU records an address error when a write or read attempt is made to the MMR address space of the SWU and the register does not exist. This error is the only one the SWU records. The register contains bits that perform the following functions.

- Indicate whether a particular match group sampled a transaction that is below a minimum target or above a maximum target in bandwidth mode.
- Indicate whether a watchpoint match occurred for each match group.
- Indicate whether an interrupt request was triggered due to a match event from one of the match groups.

Triggers

The SWU can be either a trigger master or a trigger slave depending on the trigger routing unit (TRU) configuration. As a trigger master, programs must set the `SWU_CTL[n].TRGEN` bit so that when a match condition is met, a trigger event is generated. Each SWU in the system can also be a trigger slave when mapped as one in the TRU.

When the SWU is a slave, a trigger event activates the SWU by automatically setting the `SWU_GCTL.EN` bit. Since the SWU can be automatically enabled through a trigger event, programs must pre-configure the SWU before enabling the TRU. Furthermore, although a trigger event can enable the SWU as a slave, to disable the SWU, programs must manually clear the `SWU_GCTL.EN` bit.

SWU Programming Model

Program the appropriate registers to use the SWU. Each control register configures aspects such as:

- The direction of monitoring (reads or writes)
- Whether SWU uses bandwidth mode or watchpoint mode
- The setup of events that are triggered when a condition is met while monitoring using the SWU

Configure supplemental registers such as the lower (`SWU_LA[n]`) and upper (`SWU_UA[n]`) address boundaries before enabling the SWU.

Once the SWU has been enabled and the monitoring conditions are met, events are generated when configured.

The global status register (`SWU_GSTAT`) can be read to observe the status of the units.

The *SWU Logical Flow* diagram shows the logical program flow of the SWU.

SWU Mode Configuration

The following sections show the steps for configuring SWU bandwidth mode and watchpoint mode.

Configuring the SWU for Bandwidth Mode

In bandwidth mode, the SWU counts transactions which match during a sampling window. At the end of the sampling window, the SWU stores the results. An action can be taken if the sampled bandwidth goes above or falls below a programmed range.

1. Configure the `SWU_CTL[n].DIR` bit to test the match on writes or reads.
2. Configure the `SWU_CTL[n].ACMPM` bits to address comparisons, exact match, matches inside a range or matches outside a range.
3. If ID comparison is desired, set the `SWU_CTL[n].IDCMPEN` bit.
4. Set the `SWU_CTL[n].BLENINC` bit to increment by burst length or clear it to increment by 1.

5. Configure the `SWU_CTL[n].MAXACT` and `SWU_CTL[n].MINACT` bits to enable actions taken when the bandwidth goes above the maximum, or falls below the minimum, respectively.
6. Set the `SWU_CTL[n].BWEN`=1 to enable bandwidth mode.
7. Program the lower address register, `SWU_LA[n]`, and upper address register, `SWU_UA[n]`, to define the memory range for comparison.
8. If ID comparison is enabled, program the ID register, `SWU_ID[n]`.
9. Program the count register, `SWU_CNT[n]`, with the number of clock cycles for which the SWU counts the number of matches.
10. If the SWU is set to respond when the bandwidth measurement underflows or overflows, program the min and max values into the `SWU_TARG[n]` register.
11. Enable the SWU

The SWU counts the number of matches in a pre-defined number of clock cycles as programmed. As an option, it can define lower and upper limits. If the matches fall outside the limits, an action can be taken.

Configuring the SWU for Watchpoint Mode

In watchpoint mode, the SWU can trigger a programmed action after every match or after a number of matches. This sequence can be automatically reset.

1. Set the `SWU_CTL[n].DIR` bit to test the match on writes or reads.
2. Configure the `SWU_CTL[n].ACMPM` bits for address comparisons, exact match, matches inside a range or matches outside a range.
3. If ID comparison is desired, set the `SWU_CTL[n].IDCMPEN`.
4. Set the `SWU_CTL[n].CNTEN` bit to enable the events to be triggered when the count decrements to zero.
5. If needed, set the `SWU_CTL[n].CNTRPTEN` bit to automatically reload the counter after it has decremented to zero to start another match sequence.
6. Clear the `SWU_CTL[n].BWEN` = 0 to configure watchpoint mode.
7. Configure the lower address register, `SWU_LA[n]`, and upper address register, `SWU_UA[n]`, to define the memory range for comparison.
8. If ID comparison is enabled, configure the ID register, `SWU_ID[n]`.
9. Configure the count register, `SWU_CNT[n]`, to determine how many matches occur before the watchpoint group responds.
10. Enable the SWU.

The SWU detects and counts down the number of match occurrences. When the counter expires, an action is taken.

ADSP-SC58x SWU Register Descriptions

System Watchpoint Unit (SWU) contains the following registers.

Table 55-5: ADSP-SC58x SWU Register List

Name	Description
SWU_CNT[n]	Count Register n
SWU_CTL[n]	Control Register n
SWU_CUR[n]	Current Register n
SWU_GCTL	Global Control Register
SWU_GSTAT	Global Status Register
SWU_HIST[n]	Bandwidth History Register n
SWU_ID[n]	ID Register n
SWU_LA[n]	Lower Address Register n
SWU_TARG[n]	Target Register n
SWU_UA[n]	Upper Address Register n

Count Register n

The SWU count registers (`SWU_CNT[n]`) contain a 16-bit count field (`SWU_CNT[n].COUNT`) whose usage differs depending on the mode of the watchpoint group. In bandwidth mode, the `SWU_CNT[n].COUNT` field value defines the number of clock cycles in a bandwidth period. In watchpoint mode, when the cycle count is enabled, the `SWU_CNT[n].COUNT` field value determines how many matches occur before the watchpoint group takes action.

Control Register n

The SWU control registers (`SWU_CTL[n]`) contain watchpoint attribute controls for all four watchpoint groups. These controls include enabling watchpoints, selecting the transaction direction for match, selecting address comparison mode, enabling ID comparison, enabling security comparison, enabling locked comparison, enabling cycle count, enabling count repeat, enabling debug events, enabling interrupts, enabling triggers, enabling trace messages, enabling bandwidth mode, selecting the burst length increment, and enabling bandwidth underflow and overflow detection.

Figure 55-4: SWU_CTL[n] Register Diagram

Table 55-7: SWU_CTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	DATACNTMODE	Data Channel Monitor. The `SWU_CTL[n].DATACNTMODE` bit determines whether an address channel or a data channel is monitored. Note that in data channel only ID,READY and VALID signals are monitored and hence other comparisons (Address, Lock, Secure) will be ignored even if enabled. `SWU_CTL[n].STALLCNTMODE` and `SWU_CTL[n].DIR` can be used in conjunction with this bit	
		0	Monitor address channel
		1	Monitor data channel
23:21 (R/W)	SCALE	Scale the number of transactions. The `SWU_CTL[n].SCALE` bit field allows a program to count more transactions by scaling the number of transactions and also the number of clock cycles in the bandwidth window (`SWU_CNT[n]` register) by 10,100 or 1000. This is applicable only in bandwidth mode (`SWU_CTL[n].BWEN`==1).	
		0	No scaling
		1	1:10
		2	1:100
		3	Reserved
		4	1:1000
		5-7	Reserved
20 (R/W)	STALLCNTMODE	Stall Count Mode. The `SWU_CTL[n].STALLCNTMODE` bit determines whether the number of stalls are counted or whether the number of transactions are counted. This feature is only valid in bandwidth mode.	
		0	Count number of transactions
		1	Count number of stalls
19 (R/W)	MAXACT	Action for Bandwidth Above Maximum. Each `SWU_CTL[n].MAXACT` bit determines whether a watchpoint group takes action on bandwidth overflow. This feature is only valid in bandwidth mode.	
		0	No Action
		1	Take Action
18 (R/W)	MINACT	Action for Bandwidth Below Minimum. Each `SWU_CTL[n].MINACT` bit determines whether a watchpoint group takes action on bandwidth underflow. This feature is only valid in bandwidth mode.	
		0	No Action
		1	Take Action

Table 55-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	BLENINC	Increment Bandwidth Count by Burst Length. Each `SWU_CTL[n].BLENINC` bit controls how a watchpoint group's bandwidth count is incremented in the `SWU_CUR[n]` register's `SWU_CUR[n].CURBW` field. If the `SWU_CTL[n].BLENINC` bit is cleared (= 0), the SWU increments the bandwidth count by 1 for each matching transaction. If the `SWU_CTL[n].BLENINC` bit is set (=1), the SWU increments the bandwidth count by the burst length of the transaction for each matching transaction. This feature is only valid for bandwidth mode (`SWU_CTL[n].BWEN` bit == 1). Note that if the address range match is enabled (`SWU_CTL[n].ACMPM` bits) and if any address of a burst falls within the address range, the `SWU_CUR[n].CURBW` field is incremented by the burst length even if some of the burst address fall outside of the range. Also, note that the burst size of the transaction is not included in the increment, only the burst length of the transaction. This increment operation provides an approximate (not exact) number of bus cycles consumed during the bandwidth.	
		0	Increment by 1
		1	Burst Length Increment for Bandwidth Count
16 (R/W)	BWEN	Bandwidth Mode Enable. Each `SWU_CTL[n].BWEN` bit controls whether a watchpoint group operates in watchpoint mode or bandwidth mode. In watchpoint mode, the `SWU_CTL[n].CNTEN` and (optionally) `SWU_CTL[n].CNTRPTEN` registers control usage of the cycle count for watchpoint group operations. In bandwidth mode, the `SWU_CTL[n].BLENINC`, `SWU_TARG[n]`, and `SWU_HIST[n]` registers control usage of watchpoint matches for watchpoint group operations.	
		0	Watchpoint Mode
		1	Bandwidth Mode
14 (R/W)	TRGEN	Trigger Enable. Each `SWU_CTL[n].TRGEN` bit controls whether a match for a watchpoint group generates a trigger event. This feature is valid in both bandwidth and watchpoint modes.	
		0	Disable
		1	Enable
13 (R/W)	INTEN	Interrupt Enable. Each `SWU_CTL[n].INTEN` bit controls whether a match for a watchpoint group generates an interrupt. This feature is valid in both bandwidth and watchpoint modes.	
		0	Disable
		1	Enable

Table 55-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	DBGEN	Debug Event Enable. Each `SWU_CTL[n].DBGEN` bit controls debug event comparison for a watchpoint group, permitting matches based on debug status.	
		0	Disable
		1	Enable
9 (R/W)	CNTRPTEN	Count Repeat Enable. Each `SWU_CTL[n].CNTRPTEN` bit controls whether the watchpoint group's cycle count is reloaded and repeated after cycle countdown. If the `SWU_CTL[n]` register's `SWU_CTL[n].CNTRPTEN` bit is set, the `SWU_CUR[n]` register's `SWU_CUR[n].CURCNT` field is reloaded from `SWU_CNT[n]` register's `SWU_CNT[n].COUNT` field, and the countdown starts again. If `SWU_CTL[n].CNTRPTEN` bit is cleared, the expired count remains zero, and no further events are signalled. (See the `SWU_CTL[n].CNTEN` bit description for information regarding the countdown setup.)	
		0	Disable
		1	Enable
8 (R/W)	CNTEN	Count Enable. Each `SWU_CTL[n].CNTEN` bit controls whether the cycle count in the watchpoint group's `SWU_CNT[n]` register is decremented each cycle until it reaches zero. This feature is only valid in watchpoint mode (`SWU_CTL[n].BWEN` bit == 0).When the count reaches zero, any enabled watchpoint events are triggered. (See the `SWU_CTL[n].CNTRPTEN` bit description for optional actions at that may occur at the end of the countdown.)	
		0	Disable
		1	Enable
6 (R/W)	LCMPEN	Locked Comparison Enable. Each `SWU_CTL[n].LCMPEN` bit controls locked comparison operation of an SWU watchpoint group, permitting matches based on lock status.	
		0	Match on all transaction
		1	Match only locked transactions
5 (R/W)	SCMPEN	Secure Comparison Enable. Each `SWU_CTL[n].SCMPEN` bit controls secure transaction comparison operation of an SWU watchpoint group, permitting matches based on transaction security.	
		0	Match on all transaction
		1	Match only secure transactions

Table 55-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	IDCMPEN	ID Comparison Enable. Each `SWU_CTL[n].IDCMPEN` bit controls the ID comparison operation of an SWU watchpoint group. The ID match is based on comparison with the value in the `SWU_ID[n]` register.
3:2 (R/W)	ACMPM	Address Comparison Mode. Each set of `SWU_CTL[n].ACMPM` bits control the address comparison operation of an SWU watchpoint group. The address within range for comparison is defined as (`SWU_LA[n]` register <= address < `SWU_UA[n]` register). The address outside range for comparison is defined as (address < `SWU_LA[n]`) or (`SWU_UA[n]` <= address). 0 No address comparison 1 Exact match on LAn 2 Match on address within range 3 Match on address outside range
1 (R/W)	DIR	Transaction Direction for Match. Each `SWU_CTL[n].DIR` bit determines whether the SWU check reads or writes for watchpoint matches. 0 Match on reads only 1 Match on writes only
0 (R/W)	EN	Enable Watchpoint. Each `SWU_CTL[n].EN` bit controls the operation of one SWU watchpoint group. Clearing the `SWU_CTL[n].EN` bit halts the execution of watchpoint or bandwidth tracking operations in the watchpoint group without resetting status or configuration registers. Setting the `SWU_CTL[n].EN` bit enables the SWU watchpoint group to begin or resume operation with the current configuration and status. 0 Disable 1 Enable

Current Register n

The SWU current register (`SWU_CUR[n]`) operation varies depending whether the watchpoint group is in bandwidth mode or watchpoint mode. In both modes, the watchpoint count begins when the SWU loads the register's `SWU_CUR[n].CURCNT` field from the `SWU_CNT[n]` register's `SWU_CNT[n].COUNT` field when the watchpoint count is enabled (`SWU_CTL[n]` register, `SWU_CTL[n].CNTEN` bit =1).

In bandwidth mode, the current count field (`SWU_CUR[n].CURCNT`) contains the cycle count remaining within the current watchpoint period. The SWU decrements this value every cycle until the count reaches zero. At that point, the SWU reloads the `SWU_CUR[n].CURCNT` field from `SWU_CNT[n]` register's `SWU_CNT[n].COUNT` field. In bandwidth mode, the current bandwidth field (`SWU_CUR[n].CURBW`) contains the count of watchpoint matches (bandwidth) accumulated in the current watchpoint period.

In watchpoint mode, the current count field (`SWU_CUR[n].CURCNT`) contains the watchpoint match count remaining within the current watchpoint period. The SWU decrements this value with every watchpoint match until the count reaches zero. At that point, the SWU reloads the `SWU_CUR[n].CURCNT` field from `SWU_CNT[n]` register's `SWU_CNT[n].COUNT` field if the `SWU_CTL[n]` register's `SWU_CTL[n].CNTRPTEN` bit is set (=1). In watchpoint mode, the current bandwidth field (`SWU_CUR[n].CURBW`) is undefined.

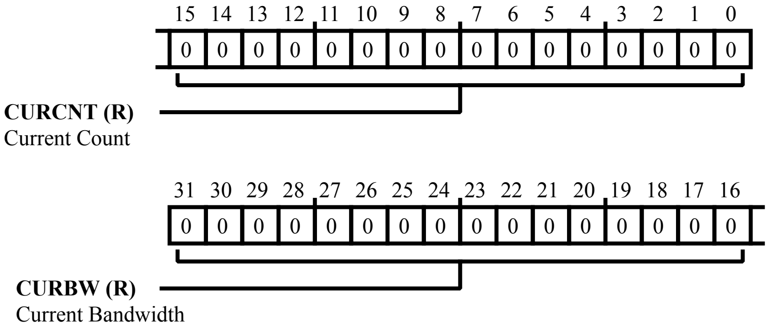

Figure 55-5: SWU_CUR[n] Register Diagram

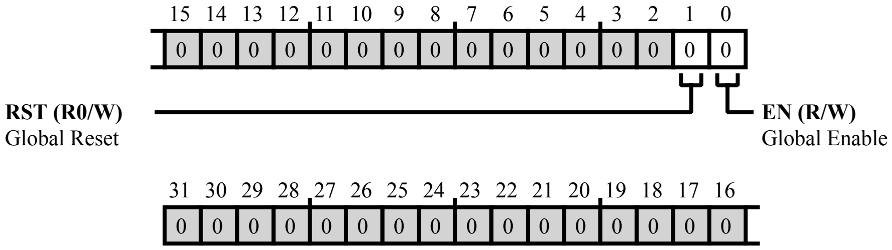
Table 55-8: SWU_CUR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	CURBW	Current Bandwidth.
15:0 (R/NW)	CURCNT	Current Count.

Global Control Register

The SWU global control register (`SWU_GCTL`) provides SWU reset and enable.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 55-6: SWU_GCTL Register Diagram

Table 55-9: SWU_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R0/W)	RST	Global Reset. The `SWU_GCTL.RST`) is write-1-action/read zero and controls the SWU operational state. Setting `SWU_GCTL.RST` resets all SWU registers to their default values and halts all SWU operations. 0: No Action 1: Reset
0 (R/W)	EN	Global Enable. The `SWU_GCTL.EN` controls the SWU operational state. Clearing `SWU_GCTL.EN` halts the execution of all watchpoint and bandwidth tracking operations without resetting status registers or associated signals. Setting `SWU_GCTL.EN` enables the SWU to begin/resume operation with the current configuration and status. 0: Disable 1: Enable

Global Status Register

The SWU global status register (`SWU_GSTAT`) contains status bits for all four watchpoint groups.

		0	Inactive
		1	Active

Table 55-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	OVRBW3	Group 3 Bandwidth Above Maximum Target. See `SWU_GSTAT.OVRBW0` description.	
		0	Group 3 was not above maximum bandwidth
		1	Group 3 was above maximum bandwidth
14 (R/W1C)	UNDRBW3	Group 3 Bandwidth Below Minimum Target. See `SWU_GSTAT.UNDRBW0` description.	
		0	Group 3 was not below minimum bandwitdth
		1	Group 3 was below minimum bandwitdth
13 (R/W1C)	OVRBW2	Group 2 Bandwidth Above Maximum Target. See `SWU_GSTAT.OVRBW0` description.	
		0	Group 2 was not above maximum bandwidth
		1	Group 2 was above maximum bandwidth
12 (R/W1C)	UNDRBW2	Group 2 Bandwidth Below Minimum Target. See `SWU_GSTAT.UNDRBW0` description.	
		0	Group 2 was not below minimum bandwidth
		1	Group 2 was below minimum bandwidth
11 (R/W1C)	OVRBW1	Group 1 Bandwidth Above Maximum Target. See `SWU_GSTAT.OVRBW0` description.	
		0	Group 1 was not above maximum bandwidth
		1	Group 1 was above maximum bandwidth
10 (R/W1C)	UNDRBW1	Group 1 Bandwidth Below Minimum Target. See `SWU_GSTAT.UNDRBW0` description.	
		0	Group 1 was not below minimum bandwidth
		1	Group 1 was below minimum bandwidth
9 (R/W1C)	OVRBW0	Group 0 Bandwidth Above Maximum Target. The `SWU_GSTAT.OVRBW0` - `SWU_GSTAT.OVRBW3` -- Group 0 through 3 watchpoint bandwidth over maximum target bits. Each maximum bandwidth bit indicate (for each group)s that the measured bandwidth over the period defined by the `SWU_CNT[n]` register was over the maximum target. This status bit is sticky; write-1-to-clear it.	
		0	Group 0 was not above maximum bandwidth
		1	Group 0 was above maximum bandwidth

Table 55-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	UNDRBW0	Group 0 Bandwidth Below Minimum Target. The `SWU_GSTAT.UNDRBW0` - `SWU_GSTAT.UNDRBW3` -- Group 0 through 3 watchpoint bandwidth below minimum target bits. Each minimum bandwidth bit indicates (for each group) that the measured bandwidth over the period defined by the `SWU_CNT[n]` register was below the minimum target. This status bit is sticky; write-1-to-clear it.	
		0	Group 0 was not below minimum bandwidth
		1	Group 0 was below minimum bandwidth
7 (R/W1C)	INT3	Group 3 Interrupt Status. See `SWU_GSTAT.INT0` description.	
		0	No Interrupt
		1	Interrupt Occurred
6 (R/W1C)	INT2	Group 2 Interrupt Status. See `SWU_GSTAT.INT0` description.	
		0	No Interrupt
		1	Interrupt Occurred
5 (R/W1C)	INT1	Group 1 Interrupt Status. See `SWU_GSTAT.INT0` description.	
		0	No Interrupt
		1	Interrupt Occurred
4 (R/W1C)	INT0	Group 0 Interrupt Status. The `SWU_GSTAT.INT0` - `SWU_GSTAT.INT3` -- Group 0 through 3 interrupt bits. Each interrupt bit indicates (for each group) whether a watchpoint group is contributing to the SWU's interrupt output. This status bit is sticky; write-1-to-clear it.	
		0	No interrupt
		1	Interrupt Occurred
3 (R/W1C)	MTCH3	Group 3 Match. See `SWU_GSTAT.MTCH0` description.	
		0	No Match
		1	Group 3 Watchpoint Match

Table 55-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	MTCH2	Group 2 Match. See `SWU_GSTAT.MTCH0` description.	
		0	No match
		1	Group 2 Watchpoint Match
1 (R/W1C)	MTCH1	Group 1 Match. See `SWU_GSTAT.MTCH0` description.	
		0	No match
		1	Group 1 Watchpoint Match
0 (R/W1C)	MTCH0	Group 0 Match. The `SWU_GSTAT.MTCH0` - `SWU_GSTAT.MTCH3` -- Group 0 through 3 match bits. Each match bit indicates (for each group) whether a watchpoint match has occurred in a SWU watchpoint group, as controlled by the group's related watchpoint control register (`SWU_CTL[n]`). This status bit is sticky; write-1-to-clear it.	
		0	No match
		1	Group 0 Watchpoint Match

Bandwidth History Register n

The SWU bandwidth history registers (`SWU_HIST[n]`) contain data copied from a watchpoint group's current bandwidth value (`SWU_CUR[n]` register, `SWU_CUR[n].CURBW` bits) at the end of the last two watchpoint periods. At the end of each watchpoint period, the SWU copies the previous bandwidth value from the `SWU_HIST[n].BWHIST0` field to the `SWU_HIST[n].BWHIST1` field and copies the new bandwidth value from the `SWU_CUR[n].CURBW` field to the `SWU_HIST[n].BWHIST0` field.

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BWHIST1 (R)
Bandwidth from Window Before Last

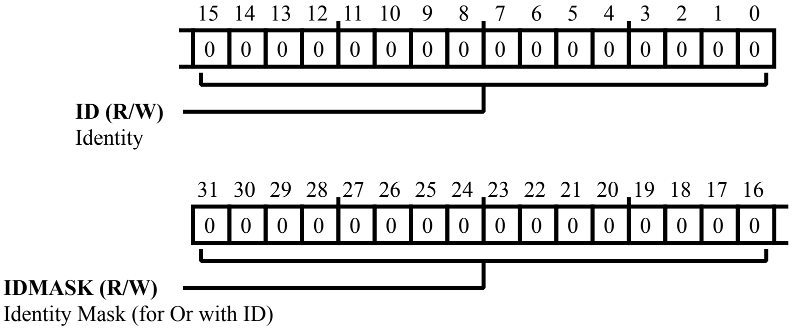
Figure 55-8: SWU_HIST[n] Register Diagram

Table 55-11: SWU_HIST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	BWHIST1	Bandwidth from Window Before Last.
15:0 (R/NW)	BWHIST0	Bandwidth from Last Window.

ID Register n

The SWU ID registers (`SWU_ID[n]`) contain a 16-bit ID field (`SWU_ID[n].ID`) and a 16-bit ID mask field (`SWU_ID[n].IDMASK`) that watchpoint groups use for ID comparison. The ID on the bus is AND'ed with the `SWU_ID[n].IDMASK` field, then the watchpoint group compares the result against the `SWU_ID[n].ID` field.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
IDMASK (R/W)
Identity Mask (for Or with ID)

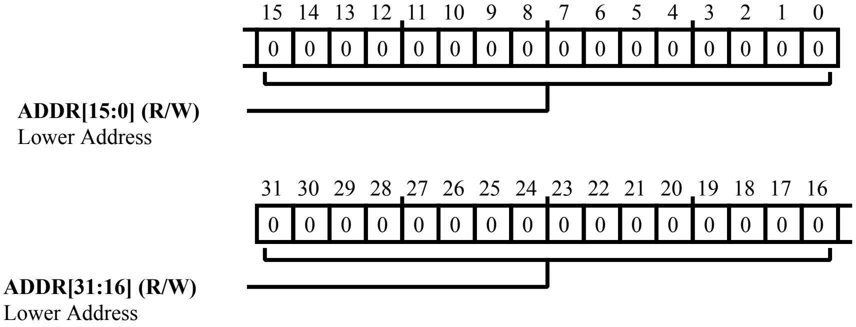
Figure 55-9: SWU_ID[n] Register Diagram

Table 55-12: SWU_ID[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	IDMASK	Identity Mask (for Or with ID).
15:0 (R/W)	ID	Identity.

Lower Address Register n

The SWU lower address registers (`SWU_LA[n]`) contain each watchpoint group's lower address for address match comparison. In exact match on `SWU_LA[n]` address mode (`SWU_CTL[n].ACMPM` bits =01), the watchpoint group uses only this address for match comparison.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDR[31:16] (R/W)
Lower Address

Figure 55-10: SWU_LA[n] Register Diagram

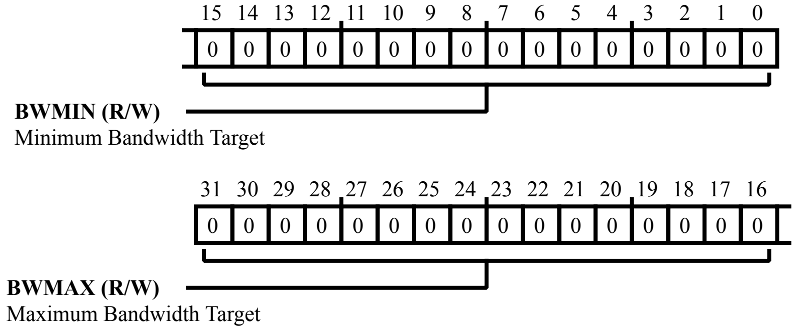
Table 55-13: SWU_LA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Lower Address.

Target Register n

The SWU target registers (`SWU_TARG[n]`) contain a minimum value field (`SWU_TARG[n].BWMIN`) and maximum value field (`SWU_TARG[n].BWMAX`) of bandwidth targets used by watchpoint groups in bandwidth mode. When the bandwidth period expires, if the current bandwidth value (`SWU_CUR[n]` register, `SWU_CUR[n].CURBW` bits) is below the minimum target or above the maximum target, the watchpoint group takes action as enabled by the `SWU_CTL[n]` register's `SWU_CTL[n].MINACT` or `SWU_CTL[n].MAXACT` bits.

In bandwidth mode, note that the watchpoint group increments its count of either data bus transactions or address bus transactions (bursts) as selected by the `SWU_CTL[n].BLENINC` bit. Keep this mode selection in mind when programming the bandwidth target values.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BWMIN (R/W)
Minimum Bandwidth Target

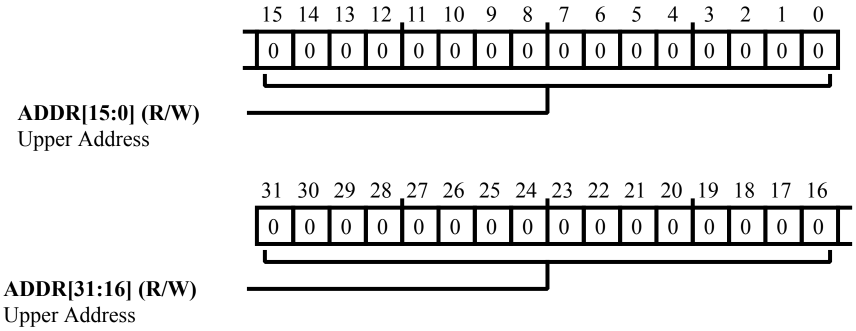
Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	BWMAX	Maximum Bandwidth Target.
15:0 (R/W)	BWMIN	Minimum Bandwidth Target.

Upper Address Register n

The SWU upper address registers (`SWU_UA[n]`) contain each watchpoint group's upper address for address match comparison. In exact match on `SWU_LA[n]` address mode (`SWU_CTL[n].ACMPM` bits =01), the `SWU_UA[n]` is not used for match comparison.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

56 System Debug and Trace Unit (DBG)

The system debug and trace unit is based on ARM Core Sight technology. CoreSight™ is a set of architecture specifications defining debug and trace architecture. The processor uses CoreSight infrastructure to provide industry standard debug and trace capabilities.

http://infocenter.arm.com/help/

The applicable documentation for more details about the ARM CoreSight feature includes:

- CoreSight PFT Architecture Specification , ARM IHI 0035B (PFT)
- System Trace Macrocell, Programmers' Model Architecture Specification, ARM IHI 0054A (STM)
- CoreSight Trace Memory Controller, ARM DDI0461B (TMC)
- CoreSight Components Technical Reference Manual, ARM DDI 0314H (TPIU)
- Embedded Cross Trigger Technical Reference Manual, ARM DDI 0291A
- ETM Architecture Specification, ARM IHI0014Q
- ETM for A5 Technical Reference Manual, DDI0435C

DBG Features

The system debug and trace unit contains the following features.

- System JTAG TAP controller for system debug features, boundary scan, and public JTAG features
- A debug interface to cores, and other system resources
- Direct and run-time access to the memory system and system MMRs
- Direct control over system reset
- Support for debug immediately after reset (boot debug)
- Group halt (debug event immediately halts all specified endpoints)
- Real-time on-chip visibility is made available to all developers, including software developers

DBG Functional Description

The following sections provide functional descriptions of the DBG unit.

DBG Definitions

The following terms are useful when working with the debug features of the processor and programming tools.

Test Access Port Controller (ADI TAPC)

Provides IDCODE and SDBGKEY features.

Debug Access Port (DAP)

Core Sight Interface providing a single port for two debug options: JTAG-DP (JTAP Debug Port), SW-DP (Serial Wire Debug Port)

Embedded Trace Macrocell (ETM)

Provides ARM Core Trace.

Program Trace Macrocell (PTM)

Provides DSP (SHARC +)Core Trace.

Standard Trace Macrocell (STM)

Provides capability to trace up to 32 hardware events and supports 32 software stimulus for data transfer between the user and emulator.

Embedded Cross Trigger (ECT)

The ECTs are responsible managing events and triggers as follows.

- CTI (Cross Trigger Interface) is a CoreSight component for enabling cross triggering of events across a system. From the view of the ECT, it is responsible for combining and mapping trigger requests.
- CTM (Cross Trigger Matrix) is a CoreSight component for connecting multiple CTIs. From the view of the ECT, it is responsible for connecting CTIs and distribution of events.

NOTE: An embedded cross trigger is not the same as the master and slave trigger in the trigger routing unit.

Trace Capture Devices

The trace capture devices capture and format the trace data. There are two trace capture devices in the system:

- ETF - Embedded Trace Funnel - Provides a buffer for burst trace data.
- ETR - Embedded Trace Router - Provides interface for trace data to be stored in system memories.

Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the on-chip trace data, with separate IDs, to a data stream. It encapsulates IDs, when required, that the Trace Port Analyzer (TPA) captures.

Serial Wire Output (SWO)

SWO is a trace data drain that acts as a bridge between the on-chip trace data and a data stream that the Trace Port Analyzer (TPA) captures.

Test Access Port Controller (TAPC)

TAPC is an independent component daisy-chained to the DAP in the JTAG scan path. The TAPC component provides the product IDCODE (Chip ID) and a security feature.

The TAPC component provides security features to the chip using a debug key match features. This feature permits only those components which have the SDBGKEY to connect and debug the chip. Initially, a 128-bits user key is programmed in the SDBGKEY registers (`TAPC_SDBGKEY0`, `TAPC_SDBGKEY1`, `TAPC_SDBGKEY2`, `TAPC_SDBGKEY3`) in TAPC by a secure master. The `TAPC_SDBGKEY_CTL.VALID` bit is set.

Then, a user key is entered through the emulator for a match to the initially programmed-entered user key. On a successful match, the chip connects to the emulator. It can be debugged on a failed user key match. Further attempts at keys matching are disabled. JTAG reset or system reset is required to reenable the user key match logic.

Embedded Trace Macrocell (ETM)

ETM is the standard trace support provided for the A5 processor. For details of programming and functionality, refer to the ARM documentation.

Debug Access Ports

The Debug Access Port (DAP) is an implementation of an ARM Debug Interface version 5 (ADIv5) comprising a number of components supplied in a single configuration. All the supplied components fit into the various architectural components for Debug Ports (DPs). The components are used to access the DAP from an external debugger and APs, to access on-chip system resources.

The DAP provides access to all debug and trace capabilities through a single external interface. DAP has some additions to support BSCA and IDCODE features that Core Sight DAP does not support. The DAP provides a combined single debug interface port called SWJ_DP that includes:

- JTAG Debug Port (JTAG-DP). The JTAG-DP is based on the IEEE 1149.1 Test Access Port (TAP) and Boundary Scan Architecture
- Serial Wire Debug Port (SW-DP). The serial wire debug port provides a bidirectional serial connection to the ARM debug interface

The SWJ-DP is a combined JTAG-DP and SW-DP that allows connections to either a Serial Wire Debug (SWD) or JTAG probe to a target. It is the standard CoreSight debug port, and enables access either to the JTAG-DP or SW-DP blocks. The JTAG-DP is selected by default.

Trace Unit

The trace module provides instruction, data tracing, and system activity tracing for the processor. The program trace module on the processor is similar to the embedded trace macrocell module provided by the ARM processor. System trace is provided using the system trace macrocell as part of the CoreSight debug and trace interface. The trace module uses an interface based on the AMBA Trace Bus (ATB) standard to output its trace data. The trace data can be either exported to an off-chip trace port analyzer or captured on an on-chip buffer. The PFT and STM modules capture information on the processor both before and after a specific event. The modules add no burden to the processor performance when it runs at full speed.

- Programmable Flow Trace (CSPFT)
- System Trace Module (STM)
- Embedded Trace Macrocell (ETM)

Programmable Flow Trace (CSPFT)

When tracing processor execution, trace information can be generated for every instruction the processor executes. This information would be easy to interpret, but would require a prohibitively high trace bandwidth to get the trace data off the chip. With program flow tracing, only branch points are traced. The debugger uses the source code to infer the rest of the executed code.

Certain instructions in the program and events are identified as waypoints. A waypoint is a point where instruction execution involves a change of program flow. The CSPFT only traces those waypoints. These waypoints are:

- All indirect branches
- All direct branches
- Exceptions or interrupts
- Emulator debug entry and exit

When a waypoint occurs, trace data is generated to describe it. From this data and the source code, a trace decompressor can determine what instructions were executed and recreate the instruction flow. To allow the decompressor to calculate where it is in the source code, conditional instructions are marked as waypoints, regardless of whether they pass or fail their condition test. Events like interrupts or debug entry and exit can be promoted from non-waypoint instructions to waypoints to trace the interrupted program flow.

Tracing a waypoint implies the execution of all instructions from the target address of the previous waypoint up to the current waypoint. Non-waypoint instructions are not explicitly traced but the debugger must infer them using the source code. The concept of an instruction block is used throughout this manual and refers to the contiguous block of instructions between two waypoints.

The programming model and function is a subset of the PTM (Programmable Trace Module) of ARM.

System Trace Module (STM)

The STM is a trace source that is integrated into a CoreSight system, and is designed primarily for high-bandwidth trace of instrumentation embedded into software. The STM enables tracing of system activity from various sources:

- Instrumented software, using memory-mapped stimulus ports
- Hardware events

The STM supports the following features:

- Multiple software masters writing software instrumentation independently. Each master can use multiple stimulus ports.
- Time stamping of the system activity. The time stamp is a global time stamp which can be shared with other trace sources in the system to enable correlation of activity from multiple trace sources.
- Indication that specific events have occurred, such as a particular hardware event or a piece of software instrumentation. These events are known as triggers and can be indicated in the trace stream, or through signals to other system components.

Thirty-two hardware event resources are connected as output from the TRU which allows monitoring all of the hardware events that can generate a trigger.

Embedded Cross Trigger (ECT)

ECT provides an interface to the CoreSight debug system enabling the subsystems to interact (cross trigger) with each other. ECT provides a mechanism to forward debug events from one connected subsystem to another connected subsystem. The different subsystems connected to the ECT depend on the processor design. For example, in a multiprocessor system, the interface can be connected to each of the cores and one to the trace subsystem. For a uniprocessor system, the interface can include just the core and trace subsystem connection.

- CTI Cross trigger interface. A CoreSight component for enabling cross triggering of events across a system.
- CTM Cross trigger matrix. A CoreSight component for connecting multiple cross trigger interfaces.

The main function of the ECT (CTI and CTM) is to pass debug events from one connected subsystem to another connected subsystem.

For example, the ECT can communicate debug state information from the core to trace subsystem for a single processor system or to another core in a multiprocessor-based system. Program execution on both the subsystem can be stopped at the same time.

The ***Trigger Flow*** figure shows a simple debug trigger flow sequence. On each CTI, there are four channel, eight input, and eight output debug triggers. All the eight inputs and outputs can be mapped to a single channel or different channels based on the debug trigger to channel mapping. When a trigger input occurs, it creates a channel event. The channel event causes all the output debug triggers to be triggered. The embedded cross trigger depends on the debug trigger it connects to.

Figure 56-2: Trigger Flow

Refer to the ***ECT Integration*** figure. There are 5 CTIs in the system that connect to the core, trace, and system module, respectively. The CTIs all interconnect through the CTM. This configuration allows the core to trigger debug events on the trace, on the system and on the core itself. CTI0 handles all the ETM and core0 debug triggers. CTI1 handles all the PFT and core1 debug triggers. CTI2 handles all the PFT and core2 debug triggers. CTI3 handles all the system debug triggers. CTI4 handles all the trace components debug triggers.

Table 56-13: Trigger Descriptions

Signal Name	Description
STM ASYNCOUT	Alignment synchronization output. This signal is asserted for one clock cycle when an ASYNC-VERSION-FREQ sequence is completely output on the ATB, and can be used for cross-triggering.
STM TRIGOUTHETE	Trigger output. This signal is asserted for one clock cycle when a trigger event is detected on match using STMHETER.
STM TRIGOUTSW	Trigger output. This signal is asserted for one clock cycle when a trigger event is generated on writes to a TRIG location in the extended stimulus port registers.
STM TRIGOUTSPTE	Trigger output. This signal is asserted for one clock cycle when a trigger event is detected on match using STMSPTER.
ETR / ETF FULL	This output indicates the value of the full bit in the ETR/ETF status register. A full bit indicates the amount of data in ETF/ETR. An output signal indicating when the circular buffer or FIFO is full, or within a programmable amount of being full.
ETR / ETF ACQCOMP	This output indicates the value of the FtEmpty bit in the ETR/ETF status register. The bit it is set when trace capture has stopped. An output signal indicating when trace capture has stopped, usually following a trigger condition.
ETR/ETF/ TPIU TRIGIN	This input can cause a trigger event (Start /Stop Trigger). An input signal indicating when a trigger condition has occurred.
ETR/ETF /TPIU FLUSHIN	This input can cause a Trace flush. An input signal indicating a flush request
PTM/ETM TRIGGER	Trigger Input. Trigger event specifies the conditions that must be met to generate a trigger.
PTM/ETM EXTOUT[3:0]	PTM Output.
PTM/ETM EXTIN[3:0]	PTM Input
SEC	CTI Interrupt
DBGRESTART	This is an output from the CTI to a processor core or to system to return from debug mode.
DBGTRIGGER	This is a processor core output signal indicating that the core has moved to debug mode. If the CTIs are setup for synchronous halt, it will generate EDBGRQ to everyone else.

Table 56-13: Trigger Descriptions (Continued)

Signal Name	Description
EDBGRQ	This is an output from CTI and an input (as debug halt) to a processor core and to the system in general. It can assert as a result of another core going to emulation space (DBGTRIGGER) or by setting the corresponding bit in the CTI.
SYS_DBGRESTART	This is an output from the CTI to system to return from debug mode.
To TRU	TRU Master Event
From TRU	TRU Slave Event
COMMRX	The COMMRX output signals enable interrupt-driven communications over the DTR
COMMTX	The COMMTX output signals enable interrupt-driven communications over the DTR
PMU IRQ	Performance Monitor Unit on ARM Interrupt Signal

ADSP-SC58x CSPFT Register Descriptions

Program Flow Trace (CSPFT) contains the following registers.

Table 56-14: ADSP-SC58x CSPFT Register List

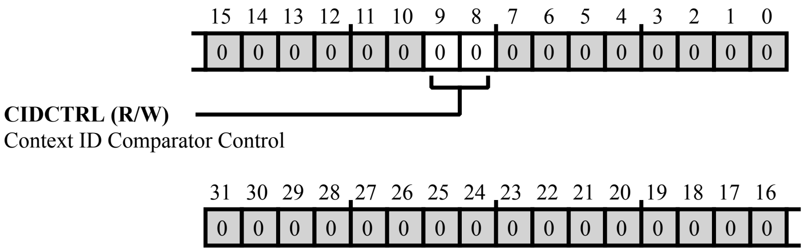
Name	Description
`CSPFT_ACTR[n]`	Address Comparator Access Type Register
`CSPFT_ACVR[n]`	Address Comparator Value Register
`CSPFT_AUTHSTATUS`	Authentication Status Register
`CSPFT_CCER`	Configuration Code Extension Register
`CSPFT_CID0`	Component ID0 Register
`CSPFT_CID1`	Component ID1 Register
`CSPFT_CID2`	Component ID2 Register
`CSPFT_CID3`	Component ID3 Register
`CSPFT_CIDCMR`	Context ID Comparator Mask Register
`CSPFT_CIDCVR[n]`	Context ID Comparator Value
`CSPFT_CLAIMCLR`	Claim Tag Clear Register
`CSPFT_CLAIMSET`	Claim Tag Set Register
`CSPFT_CNTENR[n]`	Counter Enable Event Register
`CSPFT_CNTRLDEVR[n]`	Counter Reload Event Register
`CSPFT_CNTRLDVR[n]`	Counter Reload Value Register
`CSPFT_CNTVR[n]`	Counter Value Register
`CSPFT_CTL`	Main Control Register

Table 56-14: ADSP-SC58x CSPFT Register List (Continued)

Name	Description
CSPFT_DEVTYPE	Device Type Identifier Register
CSPFT_EXTOUTEVR[n]	External Output Event Register
CSPFT_HWFEAT	Hardware Feature Register
CSPFT_LAR	Lock Access Register
CSPFT_LSR	Lock Status Register
CSPFT_PID0	Peripheral ID0 Register
CSPFT_PID1	Peripheral ID1 Register
CSPFT_PID2	Peripheral ID2 Register
CSPFT_PID3	Peripheral ID3 Register
CSPFT_PID4	Peripheral ID4 Register
CSPFT_STAT	Status Register
CSPFT_SYNCFR	Synchronization Frequency Register
CSPFT_TECTL	TraceEnable Control Register
CSPFT_TEEVENT	TraceEnable Event Register
CSPFT_TRACEIDR	CoreSight Trace ID Register
CSPFT_TRIGGER	Trigger Event Register
CSPFT_TSSCTL	TraceEnable Start/Stop Control Register

Address Comparator Access Type Register

The `CSPFT_ACTR[n]` register specifies whether the context ID needs to match.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CIDCTRL (R/W)

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

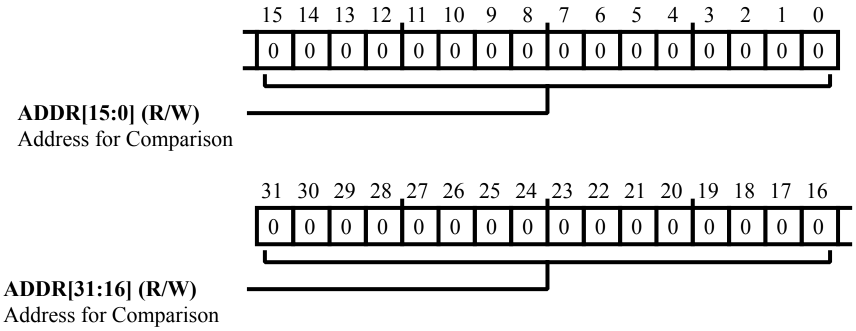
Figure 56-4: CSPFT_ACTR[n] Register Diagram

Table 56-15: CSPFT_ACTR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	CIDCTRL	Context ID Comparator Control. The `CSPFT_ACTR[n].CIDCTRL` contains the ID comparator control value.	
		0	Ignore Context ID
		1	Match if Context ID Comparator 0 Matches
		2	Match if Context ID Comparator 1 Matches
		3	Match if Context ID Comparator 2 Matches

Address Comparator Value Register

The `CSPFT_ACVR[n]` register holds an address for comparison.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDR[15:0] (R/W)
Address for Comparison
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDR[31:16] (R/W)
Address for Comparison

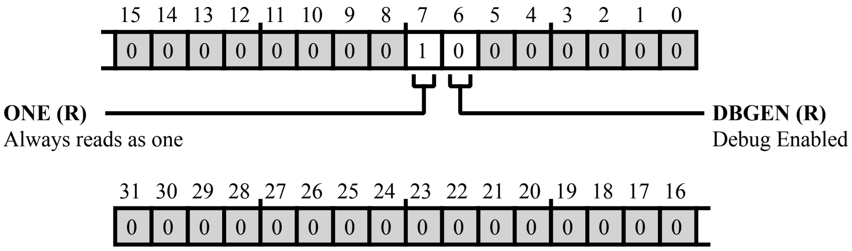
Figure 56-5: CSPFT_ACVR[n] Register Diagram

Table 56-16: CSPFT_ACVR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Address for Comparison. The `CSPFT_ACVR[n].ADDR` bit field contains the address used for comparison.

Authentication Status Register

The `CSPFT_AUTHSTATUS` register reports the level of tracing currently permitted based on the DBGEN signal.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 1 0 0 0 0 0 0 0
ONE (R)
Always reads as one
DBGEN (R)
Debug Enabled
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

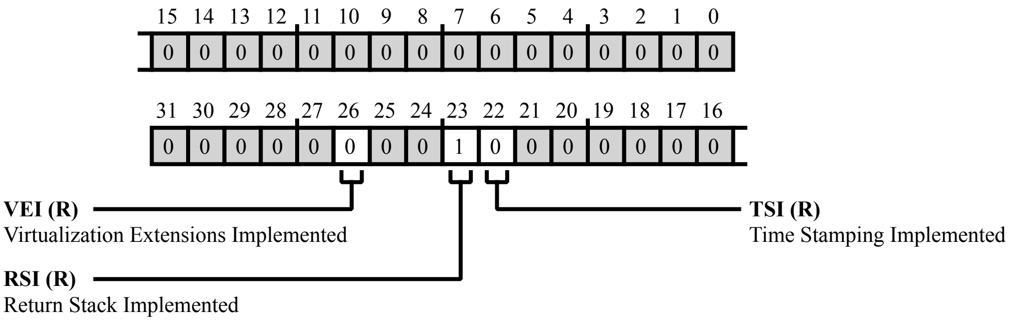
Figure 56-6: CSPFT_AUTHSTATUS Register Diagram

Table 56-17: CSPFT_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	ONE	Always reads as one.
6 (R/NW)	DBGEN	Debug Enabled. The `CSPFT_AUTHSTATUS.DBGEN` bit indicates that invasive debug is enabled. Normally, NIDEN is used in conjunction with a signal that enables invasive debug, DBGEN. Non-invasive debug is disabled only if both NIDEN and DBGEN signals are LOW. In a PTM, typically these signals are ORed together and the result is used to determine whether non-invasive debug is enabled.

Configuration Code Extension Register

The `CSPFT_CCER` register holds extra feature information. (See `CSPFT_HWFEAT`.)



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

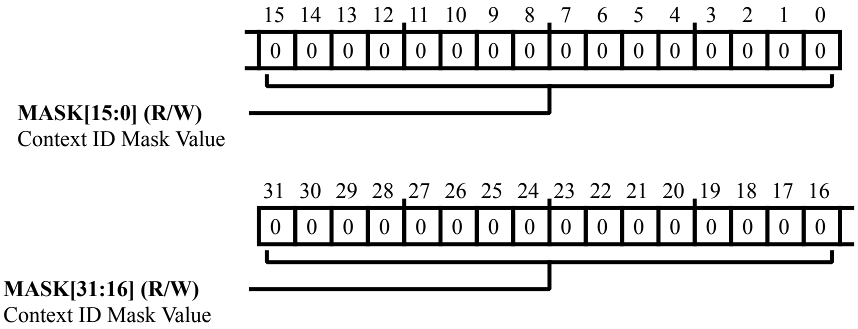
Table 56-22: CSPFT_CID3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	COMPID	Component ID. The `CSPFT_CID3.COMPID` bit field identifies this component as a CoreSight component.

Context ID Comparator Mask Register

The `CSPFT_CIDCMR` register holds a 32-bit mask for use for all context ID comparisons.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit No. (Access)	Bit Name	Description/Enumeration
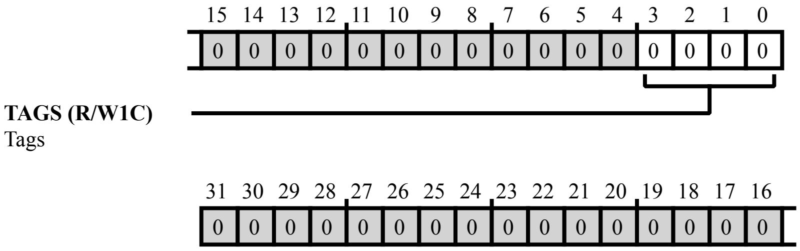
31:0 (R/W)	VALUE	Context ID Comparator Value Register. The `CSPFT_CIDCVR[n].VALUE` bit field holds a context ID value for comparison.

Claim Tag Clear Register

The `CSPFT_CLAIMCLR` register is used to clear bits in the claim tag or get the current value of the claim tag.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0
RSENA (R/W)
Return Stack Enable

Figure 56-20: CSPFT_CTL Register Diagram

Table 56-31: CSPFT_CTL Register Fields

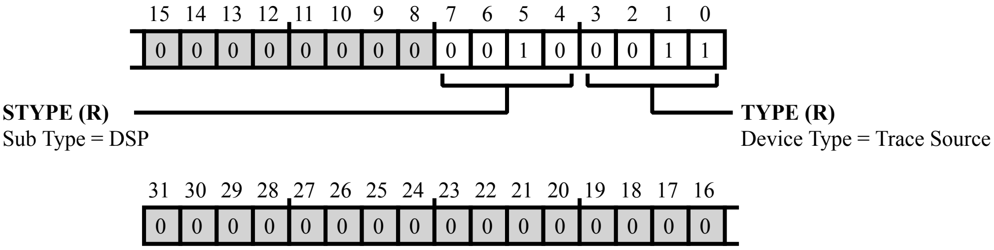
Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	RSENA	Return Stack Enable. When the `CSPFT_CTL.RSENA` bit is set, the first indirect branch back to an address generates a branch without exception packet, and subsequent branches back to the same address generate E Atoms. This compresses inner loops of HW loops and code that indirectly branches back.	
15:14 (R/W)	CIDSZ	Context ID Size. The `CSPFT_CTL.CIDSZ` bit field specifies the byte size to trace. Only the bytes specified are traced, even if the new Context ID value is larger than this.	
		0	No Context ID Tracing
		1	One byte Traced
		2	Two Bytes Traced
		3	Three Bytes Traced

Table 56-31: CSPFT_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	PB	Programming Bit. To program the CSPFT, use the following procedure. 1. Set the `CSPFT_CTL.PB` bit to disable all trace functionality. 2. Poll the `CSPFT_STAT.PB` bit waiting for it to be 1 (FIFO drained, trace halted). 3. Program the trace registers, counter and other registers, as required. 4. Set this bit to 0. 5. Poll the `CSPFT_STAT.PB` bit until it reads 0 (trace status reset, trace restarted). When the `CSPFT_CTL.PB` bit is set, the FIFO is drained and no more trace is produced. All counters are held in their present state and the external outputs are forced low. After the FIFO is drained, the `CSPFT_STAT.PB` is set to reflect that the part is ready to program. When this bit is cleared, the trace status is cleared and trace is restarted. 0 Trace Enabled 1 Trace Disabled
8 (R/W)	BBRAN	Branch Broadcast. Set the `CSPFT_CTL.BBRAN` bit to 1 to enable branch broadcasting. Branch broadcasting traces the address of direct branch instructions rather than producing E atoms.

Device Type Identifier Register

The `CSPFT_DEVTYPE` register is read-only. It provides a debugger with information about the component when the part number field is not recognized. The debugger can then report this information.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

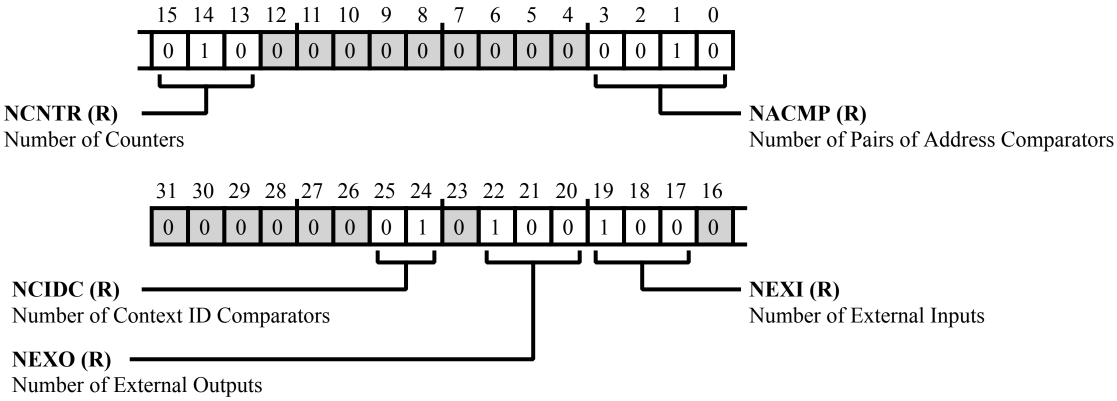
Hardware Feature Register

The `CSPFT_HWFEAT` register enables software to read the implementation defined configuration of the PTM, giving the number of each type of hardware resource. Each field indicates the number of instances of a particular resource, zero indicates that there are no implemented resources of that type.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 0 0 0 0 0 0 0 0 0 0 0 0 1 0
NCNTR (R)
Number of Counters
NACMP (R)

Figure 56-23: CSPFT_HWFEAT Register Diagram

Table 56-34: CSPFT_HWFEAT Register Fields

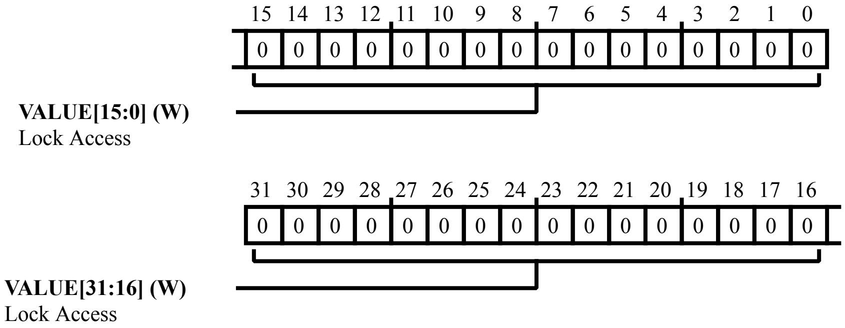
Bit No. (Access)	Bit Name	Description/Enumeration
25:24 (R/NW)	NCIDC	Number of Context ID Comparators. The `CSPFT_HWFEAT.NCIDC` bit field identifies the number of context ID comparators.
22:20 (R/NW)	NEXO	Number of External Outputs. The `CSPFT_HWFEAT.NEXO` bit field identifies the number of external outputs (up to four).
19:17 (R/NW)	NEXI	Number of External Inputs. The `CSPFT_HWFEAT.NEXI` bit field identifies the number of external inputs (up to four).
15:13 (R/NW)	NCNTR	Number of Counters. The `CSPFT_HWFEAT.NCNTR` bit field identifies the number of counters (up to four) that are configured using the counter registers.
3:0 (R/NW)	NACMP	Number of Pairs of Address Comparators. The `CSPFT_HWFEAT.NACMP` bit field identifies the number of pairs of address comparators as address range comparators (ARCs). In this case, two adjacent address comparators form the ARC, so you can use address comparators 1 and 2 to define the first ARC. An ARC matches when any instruction in the specified range is committed for execution, regardless of whether the instruction passes its condition code test.

Table 56-34: CSPFT_HWFEAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	No Address Comparators
		1	1 Pair of Address Comparators
		2	2 Pairs of Address Comparators
		3	3 Pairs of Address Comparators
		4	4 Pairs of Address Comparators
		5	5 Pairs of Address Comparators
		6	6 Pairs of Address Comparators
		7	7 Pairs of Address Comparators
		8	8 Pairs of Address Comparators

Lock Access Register

The `CSPFT_LAR` register is used to provide lock and unlock access to all other CSPFT registers.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

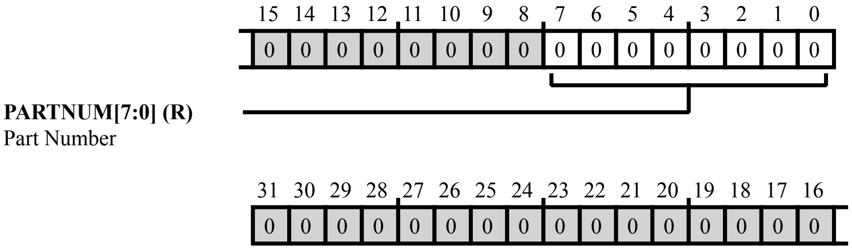
Figure 56-25: CSPFT_LSR Register Diagram

Table 56-36: CSPFT_LSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	LOCKED	Lock Status. The `CSPFT_LSR.LOCKED` bit indicates whether the PFT is locked.	
		0	Writes are permitted
		1	Locked. Writes are ignored
0 (R/NW)	LOCKEN	Locking Supported. The `CSPFT_LSR.LOCKEN` bit indicates whether the lock registers are implemented for this interface.	
		0	Locking is Not Required. This access is from an interface that ignores the lock registers.
		1	Locking is Required. This access is from an interface that requires the PFT to be unlocked.

Peripheral ID0 Register

The `CSPFT_PID0` register holds peripheral identification information.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PARTNUM[7:0] (R)
Part Number
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

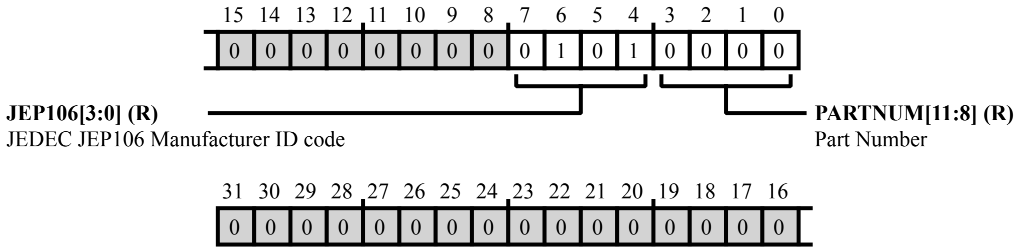
Figure 56-26: CSPFT_PID0 Register Diagram

Table 56-37: CSPFT_PID0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PARTNUM	Part Number. The `CSPFT_PID0.PARTNUM` bit field holds the peripheral identification number.

Peripheral ID1 Register

The `CSPFT_PID1` register holds peripheral identification information.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 1 0 1 0 0 0 0
JEP106[3:0] (R)
JEDEC JEP106 Manufacturer ID code
PARTNUM[11:8] (R)
Part Number
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit No. (Access)	Bit Name	Description/Enumeration
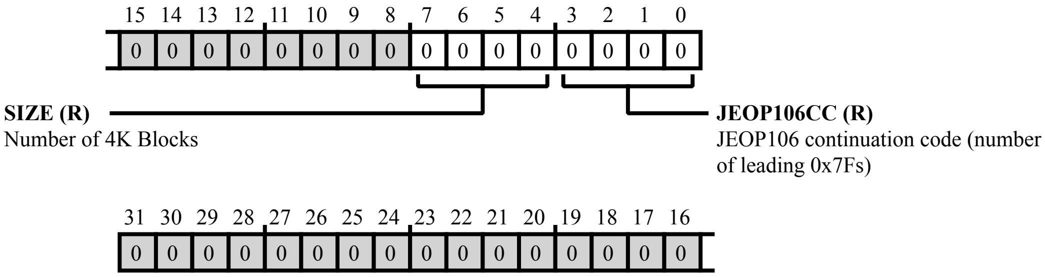
7:4 (R/NW)	REVAND	Field to mark metal fix revision.
3:0 (R/NW)	CUSTMOD	Customer Modified.

Peripheral ID4 Register

The CSPFT_PID4 register holds peripheral identification information.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SIZE (R)
Number of 4K Blocks
JEOP106CC (R)
JEOP106 continuation code (number of leading 0x7Fs)
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

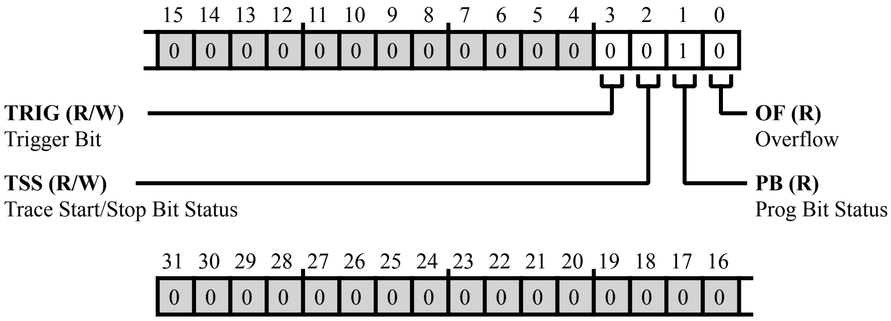
Figure 56-30: CSPFT_PID4 Register Diagram

Table 56-41: CSPFT_PID4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	SIZE	Number of 4K Blocks. The `CSPFT_PID4.SIZE` bit field contains the size of the component in 4K chunks minus 1 (for example 0=4K).
3:0 (R/NW)	JEOP106CC	JEOP106 continuation code (number of leading 0x7Fs).

Status Register

The CSPFT_STAT register provides information about the current status of the trace and trigger logic.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0
TRIG (R/W)
Trigger Bit
TSS (R/W)
Trace Start/Stop Bit Status
OF (R)
Overflow
PB (R)
Prog Bit Status
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

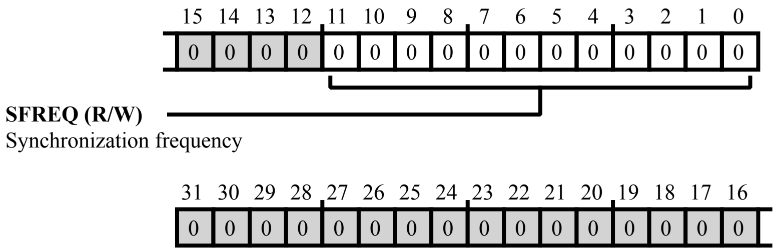
Figure 56-31: CSPFT_STAT Register Diagram

Table 56-42: CSPFT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TRIG	Trigger Bit. The CSPFT_STAT.TRIG bit is set when the trigger occurs, and prevents the trigger from being output until the CSPFT is next programmed. This bit is reset when the CSPFT_CTL.PB bit transitions from 1 to 0.
2 (R/W)	TSS	Trace Start/Stop Bit Status. The CSPFT_STAT.TSS bit holds the current status of the trace start/stop resource. If = 1, it indicates that a trace start address has been matched, without a corresponding trace stop address match. This bit =0 when trace is restarted (the CSPFT_CTL.PB bit transitions from 1 to 0).
1 (R/NW)	PB	Prog Bit Status. The CSPFT_STAT.PB bit indicates the current effective value of the CSPFT_CTL.PB bit. The program must wait for this bit to =1 before programming the CSPFT. (See the CSPFT_CTL.PB bit description).
0 (R/NW)	OF	Overflow. If the CSPFT_STAT.OF bit is =1, there is an overflow. This bit is cleared =0 when the trace is restarted (CSPFT_CTL.PB transitions from 1 to 0)

Synchronization Frequency Register

The `CSPFT_SYNCFR` register holds the trace synchronization frequency value.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SFREQ (R/W)
Synchronization frequency
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

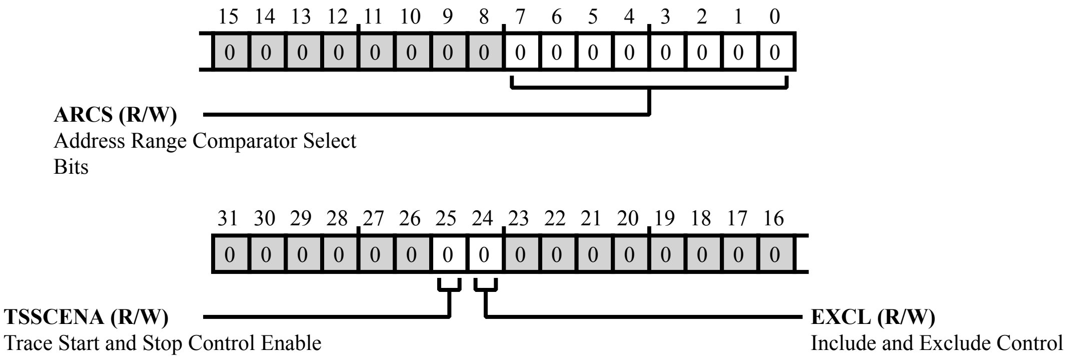
Figure 56-32: CSPFT_SYNCFR Register Diagram

Table 56-43: CSPFT_SYNCFR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	SFREQ	Synchronization frequency. The `CSPFT_SYNCFR.SFREQ` bit field is the number of 128-byte blocks of trace data after which you want to drop an address synchronization packet. If the circular buffer size is 16k, ensure that there are a few A-syncs in the buffer, so setting this to 16 means that every 2k there is an A-Sync packet.

TraceEnable Control Register

The `CSPFT_TECTL` register controls the start stop logic, whether resources specified are used for include or exclude, and specifies the address range comparators to use.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ARCS (R/W)
Address Range Comparator Select Bits
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TSSCENA (R/W)
Trace Start and Stop Control Enable
EXCL (R/W)
Include and Exclude Control

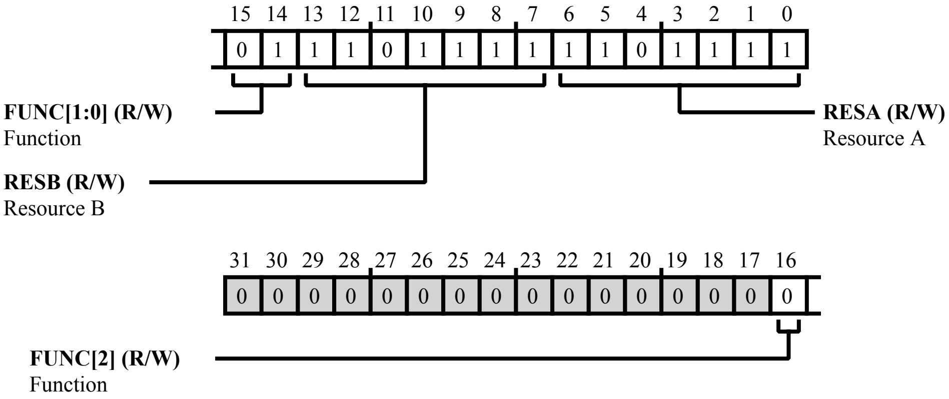
Figure 56-33: CSPFT_TECTL Register Diagram

Table 56-44: CSPFT_TECTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	TSSCENA	Trace Start and Stop Control Enable.	
		0	Tracing is not affected by the trace start/stop logic
		1	Tracing is controlled by the trace on and off address comparators
24 (R/W)	EXCL	Include and Exclude Control.	
		0	Include. The specified address range comparators indicate the regions where tracing can occur. When outside the region trace is prevented.
		1	Exclude. The specified address range comparators indicate regions to be excluded from the trace. When outside the range tracing is enabled.
7:0 (R/W)	ARCS	Address Range Comparator Select Bits. When a bit in the `CSPFT_TECTL.ARCS` bit field is set to 1, it selects an address range comparator, for include/exclude control.	

TraceEnable Event Register

The `CSPFT_TEEVENT` register defines the TraceEnable enabling event.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

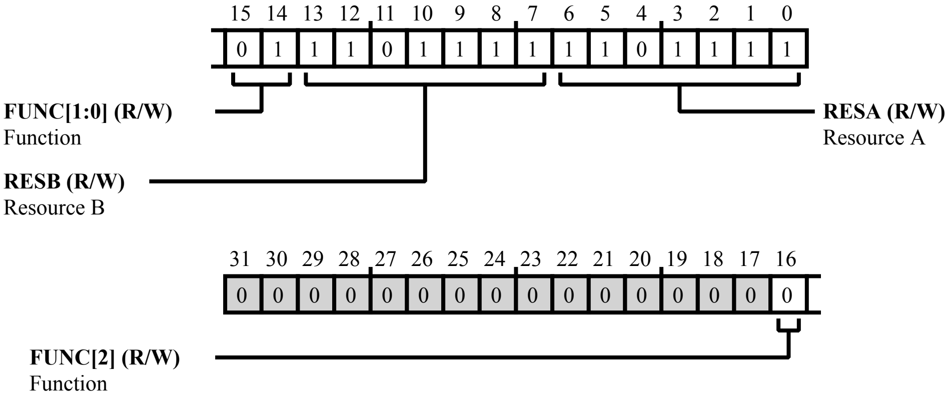
Figure 56-35: CSPFT_TRACEIDR Register Diagram

Table 56-46: CSPFT_TRACEIDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	TID	Trace ID. Defines the 7-bit trace ID, for output to the trace bus. Used in systems where multiple trace sources are present and tracing simultaneously. For example, when outputs trace onto the AMBA 3 Advanced Trace Bus, a unique ID is required for each trace source.

Trigger Event Register

The `CSPFT_TRIGGER` register defines the event that controls the trigger. This event creates the trigger output signal that is in the ATCLK domain.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 (R/W)	SPIDENDAP	SPIDEN for DAP.

IDCODE Register

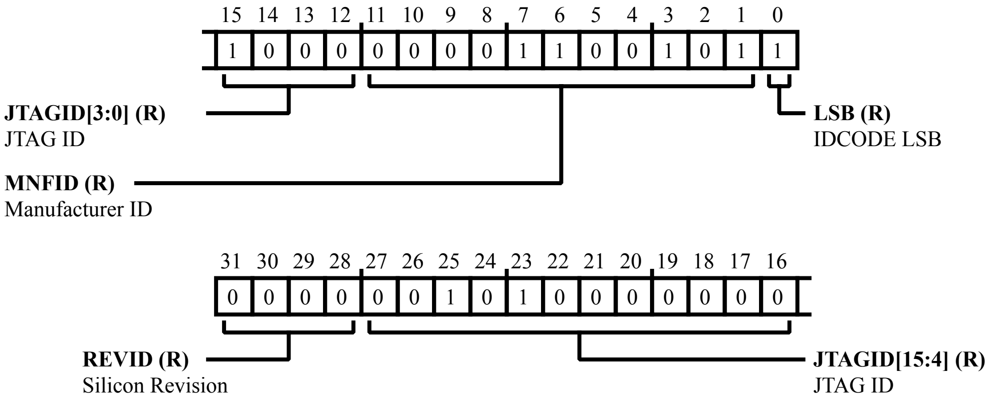
The `TAPC_IDCODE` register holds the IDCODE. The bit field is defined as follows.

IDCODE[31:28] = 0x1* – REVID

IDCODE[27:12] = 0x280B – JTAG ID

IDCODE[11:1] = 0x65 – Manufacturer ID

IDCODE[0] = 0x1



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 0 0 0 0 0 0 0 1 1 0 0 1 0 1 1
JTAGID[3:0] (R)
JTAG ID
MNFID (R)
Manufacturer ID
LSB (R)
IDCODE LSB
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 1 0 1 0 0 0 0 0 0 0
REVID (R)
Silicon Revision
JTAGID[15:4] (R)
JTAG ID

Figure 56-39: TAPC_IDCODE Register Diagram

Table 56-51: TAPC_IDCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/NW)	REVID	Silicon Revision. The `TAPC_IDCODE.REVID` bit field holds the silicon revision. See the processor anomaly list for details.
27:12 (R/NW)	JTAGID	JTAG ID.
11:1 (R/NW)	MNFID	Manufacturer ID.
0 (R/NW)	LSB	IDCODE LSB.

Secure Debug Key 0 Register

The `TAPC_SDBGKEY0` register allows a locked part to unlock debug access through the JTAG or SWD interfaces. A debug key of 128 bits needs to be written into the Secure Debug Key registers (`TAPC_SDBGKEY0`, `TAPC_SDBGKEY1`, `TAPC_SDBGKEY2`, `TAPC_SDBGKEY3`) in the TAPC through the peripheral bus interface.

These registers hold the value of the key against which a matching key provided by the debug user is compared to enable a debug session. The task of writing these registers is performed (initially) by boot ROM code which copies a customer-selected key from the Flash memory info block to these registers.

An SDBGKEY value of all 0's is always an invalid key, a value of all 1's match the default value of the Secure Debug Key Compare registers and requires no entry in these registers. It is recommended programs have a significant number of 0's and 1's in a pseudo-random pattern throughout the 128-bit code for maximum protection.

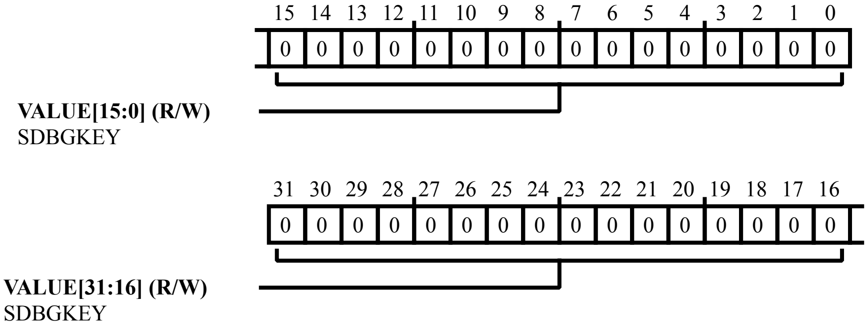


Figure 56-40: TAPC_SDBGKEY0 Register Diagram

Table 56-52: TAPC_SDBGKEY0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SDBGKEY. The `TAPC_SDBGKEY0.VALUE` bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 1 Register

The TAPC_SDBGKEY1 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. See the TAPC_SDBGKEY0 register description for more information.

Table A-23: ADSP-SC58x DMA1 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x3102208C	DMA1_XCNT	DMA1 Inner Loop Count Start Value Register	0x00000000
0x31022090	DMA1_XMOD	DMA1 Inner Loop Address Increment Register	0x00000000
0x31022094	DMA1_YCNT	DMA1 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31022098	DMA1_YMOD	DMA1 Outer Loop Address Increment (2D only) Register	0x00000000
0x310220A4	DMA1_DSCPTR_CUR	DMA1 Current Descriptor Pointer Register	0x00000000
0x310220A8	DMA1_DSCPTR_PRV	DMA1 Previous Initial Descriptor Pointer Register	0x00000000
0x310220AC	DMA1_ADDR_CUR	DMA1 Current Address Register	0x00000000
0x310220B0	DMA1_STAT	DMA1 Status Register	0x00006000
0x310220B4	DMA1_XCNT_CUR	DMA1 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310220B8	DMA1_YCNT_CUR	DMA1 Current Row Count (2D only) Register	0x00000000

Table A-24: ADSP-SC58x DMA10 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31024000	DMA10_DSCPTR_NXT	DMA10 Pointer to Next Initial Descriptor Register	0x00000000
0x31024004	DMA10_ADDRSTART	DMA10 Start Address of Current Buffer Register	0x00000000
0x31024008	DMA10_CFG	DMA10 Configuration Register	0x00000000
0x3102400C	DMA10_XCNT	DMA10 Inner Loop Count Start Value Register	0x00000000
0x31024010	DMA10_XMOD	DMA10 Inner Loop Address Increment Register	0x00000000
0x31024014	DMA10_YCNT	DMA10 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31024018	DMA10_YMOD	DMA10 Outer Loop Address Increment (2D only) Register	0x00000000
0x31024024	DMA10_DSCPTR_CUR	DMA10 Current Descriptor Pointer Register	0x00000000
0x31024028	DMA10_DSCPTR_PRV	DMA10 Previous Initial Descriptor Pointer Register	0x00000000
0x3102402C	DMA10_ADDR_CUR	DMA10 Current Address Register	0x00000000
0x31024030	DMA10_STAT	DMA10 Status Register	0x00006000
0x31024034	DMA10_XCNT_CUR	DMA10 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x31024038	DMA10_YCNT_CUR	DMA10 Current Row Count (2D only) Register	0x00000000

Table A-25: ADSP-SC58x DMA11 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31024080	DMA11_DSCPTR_NXT	DMA11 Pointer to Next Initial Descriptor Register	0x00000000
0x31024084	DMA11_ADDRSTART	DMA11 Start Address of Current Buffer Register	0x00000000
0x31024088	DMA11_CFG	DMA11 Configuration Register	0x00000000
0x3102408C	DMA11_XCNT	DMA11 Inner Loop Count Start Value Register	0x00000000
0x31024090	DMA11_XMOD	DMA11 Inner Loop Address Increment Register	0x00000000
0x31024094	DMA11_YCNT	DMA11 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31024098	DMA11_YMOD	DMA11 Outer Loop Address Increment (2D only) Register	0x00000000
0x310240A4	DMA11_DSCPTR_CUR	DMA11 Current Descriptor Pointer Register	0x00000000
0x310240A8	DMA11_DSCPTR_PRV	DMA11 Previous Initial Descriptor Pointer Register	0x00000000
0x310240AC	DMA11_ADDR_CUR	DMA11 Current Address Register	0x00000000
0x310240B0	DMA11_STAT	DMA11 Status Register	0x00006000
0x310240B4	DMA11_XCNT_CUR	DMA11 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310240B8	DMA11_YCNT_CUR	DMA11 Current Row Count (2D only) Register	0x00000000

Table A-26: ADSP-SC58x DMA12 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31024100	DMA12_DSCPTR_NXT	DMA12 Pointer to Next Initial Descriptor Register	0x00000000
0x31024104	DMA12_ADDRSTART	DMA12 Start Address of Current Buffer Register	0x00000000
0x31024108	DMA12_CFG	DMA12 Configuration Register	0x00000000
0x3102410C	DMA12_XCNT	DMA12 Inner Loop Count Start Value Register	0x00000000
0x31024110	DMA12_XMOD	DMA12 Inner Loop Address Increment Register	0x00000000
0x31024114	DMA12_YCNT	DMA12 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31024118	DMA12_YMOD	DMA12 Outer Loop Address Increment (2D only) Register	0x00000000
0x31024124	DMA12_DSCPTR_CUR	DMA12 Current Descriptor Pointer Register	0x00000000
0x31024128	DMA12_DSCPTR_PRV	DMA12 Previous Initial Descriptor Pointer Register	0x00000000
0x3102412C	DMA12_ADDR_CUR	DMA12 Current Address Register	0x00000000
0x31024130	DMA12_STAT	DMA12 Status Register	0x00006000

Table A-26: ADSP-SC58x DMA12 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x31024134	DMA12_XCNT_CUR	DMA12 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x31024138	DMA12_YCNT_CUR	DMA12 Current Row Count (2D only) Register	0x00000000

Table A-27: ADSP-SC58x DMA13 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31024180	DMA13_DSCPTR_NXT	DMA13 Pointer to Next Initial Descriptor Register	0x00000000
0x31024184	DMA13_ADDRSTART	DMA13 Start Address of Current Buffer Register	0x00000000
0x31024188	DMA13_CFG	DMA13 Configuration Register	0x00000000
0x3102418C	DMA13_XCNT	DMA13 Inner Loop Count Start Value Register	0x00000000
0x31024190	DMA13_XMOD	DMA13 Inner Loop Address Increment Register	0x00000000
0x31024194	DMA13_YCNT	DMA13 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31024198	DMA13_YMOD	DMA13 Outer Loop Address Increment (2D only) Register	0x00000000
0x310241A4	DMA13_DSCPTR_CUR	DMA13 Current Descriptor Pointer Register	0x00000000
0x310241A8	DMA13_DSCPTR_PRV	DMA13 Previous Initial Descriptor Pointer Register	0x00000000
0x310241AC	DMA13_ADDR_CUR	DMA13 Current Address Register	0x00000000
0x310241B0	DMA13_STAT	DMA13 Status Register	0x00006000
0x310241B4	DMA13_XCNT_CUR	DMA13 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310241B8	DMA13_YCNT_CUR	DMA13 Current Row Count (2D only) Register	0x00000000

Table A-28: ADSP-SC58x DMA14 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31024200	DMA14_DSCPTR_NXT	DMA14 Pointer to Next Initial Descriptor Register	0x00000000
0x31024204	DMA14_ADDRSTART	DMA14 Start Address of Current Buffer Register	0x00000000
0x31024208	DMA14_CFG	DMA14 Configuration Register	0x00000000
0x3102420C	DMA14_XCNT	DMA14 Inner Loop Count Start Value Register	0x00000000
0x31024210	DMA14_XMOD	DMA14 Inner Loop Address Increment Register	0x00000000
0x31024214	DMA14_YCNT	DMA14 Outer Loop Count Start Value (2D only) Register	0x00000000

Table A-28: ADSP-SC58x DMA14 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x31024218	DMA14_YMOD	DMA14 Outer Loop Address Increment (2D only) Register	0x00000000
0x31024224	DMA14_DSCPTR_CUR	DMA14 Current Descriptor Pointer Register	0x00000000
0x31024228	DMA14_DSCPTR_PRV	DMA14 Previous Initial Descriptor Pointer Register	0x00000000
0x3102422C	DMA14_ADDR_CUR	DMA14 Current Address Register	0x00000000
0x31024230	DMA14_STAT	DMA14 Status Register	0x00006000
0x31024234	DMA14_XCNT_CUR	DMA14 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x31024238	DMA14_YCNT_CUR	DMA14 Current Row Count (2D only) Register	0x00000000

Table A-29: ADSP-SC58x DMA15 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31024280	DMA15_DSCPTR_NXT	DMA15 Pointer to Next Initial Descriptor Register	0x00000000
0x31024284	DMA15_ADDRSTART	DMA15 Start Address of Current Buffer Register	0x00000000
0x31024288	DMA15_CFG	DMA15 Configuration Register	0x00000000
0x3102428C	DMA15_XCNT	DMA15 Inner Loop Count Start Value Register	0x00000000
0x31024290	DMA15_XMOD	DMA15 Inner Loop Address Increment Register	0x00000000
0x31024294	DMA15_YCNT	DMA15 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31024298	DMA15_YMOD	DMA15 Outer Loop Address Increment (2D only) Register	0x00000000
0x310242A4	DMA15_DSCPTR_CUR	DMA15 Current Descriptor Pointer Register	0x00000000
0x310242A8	DMA15_DSCPTR_PRV	DMA15 Previous Initial Descriptor Pointer Register	0x00000000
0x310242AC	DMA15_ADDR_CUR	DMA15 Current Address Register	0x00000000
0x310242B0	DMA15_STAT	DMA15 Status Register	0x00006000
0x310242B4	DMA15_XCNT_CUR	DMA15 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310242B8	DMA15_YCNT_CUR	DMA15 Current Row Count (2D only) Register	0x00000000

Table A-30: ADSP-SC58x DMA16 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31024300	DMA16_DSCPTR_NXT	DMA16 Pointer to Next Initial Descriptor Register	0x00000000

Table A-30: ADSP-SC58x DMA16 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x31024304	DMA16_ADDRSTART	DMA16 Start Address of Current Buffer Register	0x00000000
0x31024308	DMA16_CFG	DMA16 Configuration Register	0x00000000
0x3102430C	DMA16_XCNT	DMA16 Inner Loop Count Start Value Register	0x00000000
0x31024310	DMA16_XMOD	DMA16 Inner Loop Address Increment Register	0x00000000
0x31024314	DMA16_YCNT	DMA16 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31024318	DMA16_YMOD	DMA16 Outer Loop Address Increment (2D only) Register	0x00000000
0x31024324	DMA16_DSCPTR_CUR	DMA16 Current Descriptor Pointer Register	0x00000000
0x31024328	DMA16_DSCPTR_PRV	DMA16 Previous Initial Descriptor Pointer Register	0x00000000
0x3102432C	DMA16_ADDR_CUR	DMA16 Current Address Register	0x00000000
0x31024330	DMA16_STAT	DMA16 Status Register	0x00006000
0x31024334	DMA16_XCNT_CUR	DMA16 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x31024338	DMA16_YCNT_CUR	DMA16 Current Row Count (2D only) Register	0x00000000

Table A-31: ADSP-SC58x DMA17 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31024380	DMA17_DSCPTR_NXT	DMA17 Pointer to Next Initial Descriptor Register	0x00000000
0x31024384	DMA17_ADDRSTART	DMA17 Start Address of Current Buffer Register	0x00000000
0x31024388	DMA17_CFG	DMA17 Configuration Register	0x00000000
0x3102438C	DMA17_XCNT	DMA17 Inner Loop Count Start Value Register	0x00000000
0x31024390	DMA17_XMOD	DMA17 Inner Loop Address Increment Register	0x00000000
0x31024394	DMA17_YCNT	DMA17 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31024398	DMA17_YMOD	DMA17 Outer Loop Address Increment (2D only) Register	0x00000000
0x310243A4	DMA17_DSCPTR_CUR	DMA17 Current Descriptor Pointer Register	0x00000000
0x310243A8	DMA17_DSCPTR_PRV	DMA17 Previous Initial Descriptor Pointer Register	0x00000000
0x310243AC	DMA17_ADDR_CUR	DMA17 Current Address Register	0x00000000
0x310243B0	DMA17_STAT	DMA17 Status Register	0x00006000

Table A-31: ADSP-SC58x DMA17 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x310243B4	DMA17_XCNT_CUR	DMA17 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x310243B8	DMA17_YCNT_CUR	DMA17 Current Row Count (2D only) Register	0x00000000

Table A-32: ADSP-SC58x DMA18 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31028100	DMA18_DSCPTR_NXT	DMA18 Pointer to Next Initial Descriptor Register	0x00000000
0x31028104	DMA18_ADDRSTART	DMA18 Start Address of Current Buffer Register	0x00000000
0x31028108	DMA18_CFG	DMA18 Configuration Register	0x00000000
0x3102810C	DMA18_XCNT	DMA18 Inner Loop Count Start Value Register	0x00000000
0x31028110	DMA18_XMOD	DMA18 Inner Loop Address Increment Register	0x00000000
0x31028114	DMA18_YCNT	DMA18 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31028118	DMA18_YMOD	DMA18 Outer Loop Address Increment (2D only) Register	0x00000000
0x31028124	DMA18_DSCPTR_CUR	DMA18 Current Descriptor Pointer Register	0x00000000
0x31028128	DMA18_DSCPTR_PRV	DMA18 Previous Initial Descriptor Pointer Register	0x00000000
0x3102812C	DMA18_ADDR_CUR	DMA18 Current Address Register	0x00000000
0x31028130	DMA18_STAT	DMA18 Status Register	0x00006000
0x31028134	DMA18_XCNT_CUR	DMA18 Current Count (1D) or Intra-row XCNT (2D) Register	0x00000000
0x31028138	DMA18_YCNT_CUR	DMA18 Current Row Count (2D only) Register	0x00000000
0x31028140	DMA18_BWLCNT	DMA18 Bandwidth Limit Count Register	0x00000000
0x31028144	DMA18_BWLCNT_CUR	DMA18 Bandwidth Limit Count Current Register	0x00000000
0x31028148	DMA18_BWMCNT	DMA18 Bandwidth Monitor Count Register	0x00000000
0x3102814C	DMA18_BWMCNT_CUR	DMA18 Bandwidth Monitor Count Current Register	0x00000000

Table A-33: ADSP-SC58x DMA19 MMR Register Addresses

Memory Mapped Address	Register Name	Description	Reset Value
0x31028180	DMA19_DSCPTR_NXT	DMA19 Pointer to Next Initial Descriptor Register	0x00000000
0x31028184	DMA19_ADDRSTART	DMA19 Start Address of Current Buffer Register	0x00000000

Table A-33: ADSP-SC58x DMA19 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x31028188	DMA19_CFG	DMA19 Configuration Register	0x00000000
0x3102818C	DMA19_XCNT	DMA19 Inner Loop Count Start Value Register	0x00000000
0x31028190	DMA19_XMOD	DMA19 Inner Loop Address Increment Register	0x00000000
0x31028194	DMA19_YCNT	DMA19 Outer Loop Count Start Value (2D only) Register	0x00000000
0x31028198	DMA19_YMOD	DMA19 Outer Loop Address Increment (2D only) Register	0x00000000

Table A-72: ADSP-SC58x EMAC0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x3100C130	EMAC0_TX256TO511_GB	EMAC0 Tx 256- to 511-Byte Frames (Good/Bad) Register	0x00000000
0x3100C134	EMAC0_TX512TO1023_GB	EMAC0 Tx 512- to 1023-Byte Frames (Good/Bad) Register	0x00000000
0x3100C138	EMAC0_TX1024TOMAX_GB	EMAC0 Tx 1024- to Max-Byte Frames (Good/Bad) Register	0x00000000
0x3100C13C	EMAC0_TXUCASTFRM_GB	EMAC0 Tx Unicast Frames (Good/Bad) Register	0x00000000
0x3100C140	EMAC0_TXMCASTFRM_GB	EMAC0 Tx Multicast Frames (Good/Bad) Register	0x00000000
0x3100C144	EMAC0_TXBCASTFRM_GB	EMAC0 Tx Broadcast Frames (Good/Bad) Register	0x00000000
0x3100C148	EMAC0_TXUNDR_ERR	EMAC0 Tx Underflow Error Register	0x00000000
0x3100C14C	EMAC0_TXSNGCOL_G	EMAC0 Tx Single Collision (Good) Register	0x00000000
0x3100C150	EMAC0_TXMULTCOL_G	EMAC0 Tx Multiple Collision (Good) Register	0x00000000
0x3100C154	EMAC0_TXDEFERRED	EMAC0 Tx Deferred Register	0x00000000
0x3100C158	EMAC0_TXLATECOL	EMAC0 Tx Late Collision Register	0x00000000
0x3100C15C	EMAC0_TXEXCESSCOL	EMAC0 Tx Excess Collision Register	0x00000000
0x3100C160	EMAC0_TXCARR_ERR	EMAC0 Tx Carrier Error Register	0x00000000
0x3100C164	EMAC0_TXOCTCNT_G	EMAC0 Tx Octet Count (Good) Register	0x00000000
0x3100C168	EMAC0_TXFRMCNT_G	EMAC0 Tx Frame Count (Good) Register	0x00000000
0x3100C16C	EMAC0_TXEXCESSDEF	EMAC0 Tx Excess Deferral Register	0x00000000
0x3100C170	EMAC0_TXPAUSEFRM	EMAC0 Tx Pause Frame Register	0x00000000
0x3100C174	EMAC0_TXVLANFRM_G	EMAC0 Tx VLAN Frames (Good) Register	0x00000000
0x3100C178	EMAC0_TXOVRSIZE_G	EMAC0 Number of Tx Frames (Good) greater than maxsize	0x00000000
0x3100C180	EMAC0_RXFRMCNT_GB	EMAC0 Rx Frame Count (Good/Bad) Register	0x00000000
0x3100C184	EMAC0_RXOCTCNT_GB	EMAC0 Rx Octet Count (Good/Bad) Register	0x00000000
0x3100C188	EMAC0_RXOCTCNT_G	EMAC0 Rx Octet Count (Good) Register	0x00000000
0x3100C18C	EMAC0_RXBCASTFRM_G	EMAC0 Rx Broadcast Frames (Good) Register	0x00000000
0x3100C190	EMAC0_RXMCASTFRM_G	EMAC0 Rx Multicast Frames (Good) Register	0x00000000
0x3100C194	EMAC0_RXCRC_ERR	EMAC0 Rx CRC Error Register	0x00000000
0x3100C198	EMAC0_RXALIGN_ERR	EMAC0 Rx alignment Error Register	0x00000000

Table A-72: ADSP-SC58x EMAC0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x3100C19C	EMAC0_RXRUNT_ERR	EMAC0 Rx Runt Error Register	0x00000000
0x3100C1A0	EMAC0_RXJAB_ERR	EMAC0 Rx Jab Error Register	0x00000000
0x3100C1A4	EMAC0_RXUSIZE_G	EMAC0 Rx Undersize (Good) Register	0x00000000
0x3100C1A8	EMAC0_RXOSIZE_G	EMAC0 Rx Oversize (Good) Register	0x00000000
0x3100C1AC	EMAC0_RX64_GB	EMAC0 Rx 64-Byte Frames (Good/Bad) Register	0x00000000
0x3100C1B0	EMAC0_RX65TO127_GB	EMAC0 Rx 65- to 127-Byte Frames (Good/Bad) Register	0x00000000
0x3100C1B4	EMAC0_RX128TO255_GB	EMAC0 Rx 128- to 255-Byte Frames (Good/Bad) Register	0x00000000
0x3100C1B8	EMAC0_RX256TO511_GB	EMAC0 Rx 256- to 511-Byte Frames (Good/Bad) Register	0x00000000
0x3100C1BC	EMAC0_RX512TO1023_GB	EMAC0 Rx 512- to 1023-Byte Frames (Good/Bad) Register	0x00000000
0x3100C1C0	EMAC0_RX1024TOMAX_GB	EMAC0 Rx 1024- to Max-Byte Frames (Good/Bad) Register	0x00000000
0x3100C1C4	EMAC0_RXUCASTFRM_G	EMAC0 Rx Unicast Frames (Good) Register	0x00000000
0x3100C1C8	EMAC0_RXLEN_ERR	EMAC0 Rx Length Error Register	0x00000000
0x3100C1CC	EMAC0_RXOORTYPE	EMAC0 Rx Out Of Range Type Register	0x00000000
0x3100C1D0	EMAC0_RXPAUSEFRM	EMAC0 Rx Pause Frames Register	0x00000000
0x3100C1D4	EMAC0_RXFIFO_OVF	EMAC0 Rx FIFO Overflow Register	0x00000000
0x3100C1D8	EMAC0_RXVLANFRM_GB	EMAC0 Rx VLAN Frames (Good/Bad) Register	0x00000000
0x3100C1DC	EMAC0_RXWDOG_ERR	EMAC0 Rx Watch Dog Error Register	0x00000000
0x3100C1E0	EMAC0_RXRCV_ERR	EMAC0 Rx Error Frames Received Register	0x00000000
0x3100C1E4	EMAC0_RXCTLFRM_G	EMAC0 Rx Good Control Frames Register	0x00000000
0x3100C200	EMAC0_IPC_RXIMSK	EMAC0 MMC IPC Rx Interrupt Mask Register	0x00000000
0x3100C208	EMAC0_IPC_RXINT	EMAC0 MMC IPC Rx Interrupt Register	0x00000000
0x3100C210	EMAC0_RXIPV4_GD_FRM	EMAC0 Rx IPv4 Datagrams (Good) Register	0x00000000
0x3100C214	EMAC0_RXIPV4_HDR_ERR_FRM	EMAC0 Rx IPv4 Datagrams Header Errors Register	0x00000000
0x3100C218	EMAC0_RXIPV4_NOPAY_FRM	EMAC0 Rx IPv4 Datagrams No Payload Frame Register	0x00000000
0x3100C21C	EMAC0_RXIPV4_FRAG_FRM	EMAC0 Rx IPv4 Datagrams Fragmented Frames Register	0x00000000

Table A-72: ADSP-SC58x EMAC0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x3100C220	EMAC0_RXIPV4_UDSBL_FRM	EMAC0 Rx IPv4 UDP Disabled Frames Register	0x00000000
0x3100C224	EMAC0_RXIPV6_GD_FRM	EMAC0 Rx IPv6 Datagrams Good Frames Register	0x00000000
0x3100C228	EMAC0_RXIPV6_HDR_ERR_FRM	EMAC0 Rx IPv6 Datagrams Header Error Frames Register	0x00000000
0x3100C22C	EMAC0_RXIPV6_NOPAY_FRM	EMAC0 Rx IPv6 Datagrams No Payload Frames Register	0x00000000
0x3100C230	EMAC0_RXUDP_GD_FRM	EMAC0 Rx UDP Good Frames Register	0x00000000
0x3100C234	EMAC0_RXUDP_ERR_FRM	EMAC0 Rx UDP Error Frames Register	0x00000000
0x3100C238	EMAC0_RXTCP_GD_FRM	EMAC0 Rx TCP Good Frames Register	0x00000000
0x3100C23C	EMAC0_RXTCP_ERR_FRM	EMAC0 Rx TCP Error Frames Register	0x00000000
0x3100C240	EMAC0_RXICMP_GD_FRM	EMAC0 Rx ICMP Good Frames Register	0x00000000
0x3100C244	EMAC0_RXICMP_ERR_FRM	EMAC0 Rx ICMP Error Frames Register	0x00000000
0x3100C250	EMAC0_RXIPV4_GD_OCT	EMAC0 Rx IPv4 Datagrams Good Octets Register	0x00000000
0x3100C254	EMAC0_RXIPV4_HDR_ERR_OCT	EMAC0 Rx IPv4 Datagrams Header Errors Register	0x00000000
0x3100C258	EMAC0_RXIPV4_NOPAY_OCT	EMAC0 Rx IPv4 Datagrams No Payload Octets Register	0x00000000
0x3100C25C	EMAC0_RXIPV4_FRAG_OCT	EMAC0 Rx IPv4 Datagrams Fragmented Octets Register	0x00000000
0x3100C260	EMAC0_RXIPV4_UDSBL_OCT	EMAC0 Rx IPv4 UDP Disabled Octets Register	0x00000000
0x3100C264	EMAC0_RXIPV6_GD_OCT	EMAC0 Rx IPv6 Good Octets Register	0x00000000
0x3100C268	EMAC0_RXIPV6_HDR_ERR_OCT	EMAC0 Rx IPv6 Header Errors Register	0x00000000
0x3100C26C	EMAC0_RXIPV6_NOPAY_OCT	EMAC0 Rx IPv6 No Payload Octets Register	0x00000000
0x3100C270	EMAC0_RXUDP_GD_OCT	EMAC0 Rx UDP Good Octets Register	0x00000000
0x3100C274	EMAC0_RXUDP_ERR_OCT	EMAC0 Rx UDP Error Octets Register	0x00000000
0x3100C278	EMAC0_RXTCP_GD_OCT	EMAC0 Rx TCP Good Octets Register	0x00000000

Table A-72: ADSP-SC58x EMAC0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x3100C27C	EMAC0_RXTCP_ERR_OCT	EMAC0 Rx TCP Error Octets Register	0x00000000
0x3100C280	EMAC0_RXICMP_GD_OCT	EMAC0 Rx ICMP Good Octets Register	0x00000000
0x3100C284	EMAC0_RXICMP_ERR_OCT	EMAC0 Rx ICMP Error Octets Register	0x00000000
0x3100C400	EMAC0_L3L4_CTL	EMAC0 Layer3 and Layer4 Control Register	0x00000000
0x3100C404	EMAC0_L4_ADDR	EMAC0 Layer 4 Address Register	0x00000000
0x3100C410	EMAC0_L3_ADDR0	EMAC0 Layer 3 Address0 Register	0x00000000
0x3100C414	EMAC0_L3_ADDR1	EMAC0 Layer 3 Address1 Register	0x00000000
0x3100C418	EMAC0_L3_ADDR2	EMAC0 Layer 3 Address2 Register	0x00000000
0x3100C41C	EMAC0_L3_ADDR3	EMAC0 Layer 3 Address3 Register	0x00000000
0x3100C584	EMAC0_VLAN_INCL	EMAC0 VLAN Tag Inclusion or Replacement Register	0x00000000
0x3100C588	EMAC0_VLAN_HSHTBL	EMAC0 VLAN Hash Table Register	0x00000000
0x3100C700	EMAC0_TM_CTL	EMAC0 Time Stamp Control Register	0x00002000
0x3100C704	EMAC0_TM_SUBSEC	EMAC0 Time Stamp Sub Second Increment Register	0x00000000
0x3100C708	EMAC0_TM_SEC	EMAC0 Time Stamp Low Seconds Register	0x00000000
0x3100C70C	EMAC0_TM_NSEC	EMAC0 Time Stamp Nanoseconds Register	0x00000000
0x3100C710	EMAC0_TM_SECUPDT	EMAC0 Time Stamp Seconds Update Register	0x00000000
0x3100C714	EMAC0_TM_NSECUPDT	EMAC0 Time Stamp Nanoseconds Update Register	0x00000000
0x3100C718	EMAC0_TM_ADDEND	EMAC0 Time Stamp Addend Register	0x00000000
0x3100C71C	EMAC0_TM_PPS0TGTM	EMAC0 Time Stamp Target Time Seconds Register	0x00000000
0x3100C720	EMAC0_TM_PPS0NTGTM	EMAC0 Time Stamp Target Time Nanoseconds Register	0x00000000
0x3100C724	EMAC0_TM_HISEC	EMAC0 Time Stamp High Second Register	0x00000000
0x3100C728	EMAC0_TM_STMPSTAT	EMAC0 Time Stamp Status Register	0x00000000
0x3100C72C	EMAC0_TM_PPSCTL	EMAC0 PPS Control Register	0x00000000
0x3100C730	EMAC0_TM_AUXSTMP_NSEC	EMAC0 Time Stamp Auxiliary TS Nano Seconds Register	0x00000000
0x3100C734	EMAC0_TM_AUXSTMP_SEC	EMAC0 Time Stamp Auxiliary TM Seconds Register	0x00000000
0x3100C738	EMAC0_MAC_AVCTL	EMAC0 AV MAC Control Register	0x00000000
0x3100C760	EMAC0_TM_PPS0INTVL	EMAC0 Time Stamp PPS Interval Register	0x00000000

Table A-72: ADSP-SC58x EMAC0 MMR Register Addresses (Continued)

Memory Mapped Address	Register Name	Description	Reset Value
0x3100C764	EMAC0_TM_PPS0WIDTH	EMAC0 PPS Width Register	0x00000000
0x3100C780	EMAC0_TM_PPS1TGTM	EMAC0 PPS 1 Target Time Seconds Register	0x00000000
0x3100C784	EMAC0_TM_PPS1NTGTM	EMAC0 PPS 1 Target Time Nanoseconds Register	0x00000000
