Contents

Introduction

Power and Clock Management (DPM/RCU/CGU/CDU) 1–2

System Interrupts and Triggers (SEC/TRU) 1–3

System Memory (L2CTL/DMC/SMC/OTPC/SMPU) 1–4

Direct Memory Access (DMA/MDMA/EMDMA/CRC) 1–7

Peripherals 1–9

- General-Purpose I/O (GPIO) Peripherals 1–9
- DAI/SRU Peripherals 1–14
- Dedicated Pin Peripherals 1–15

System Accelerators (FFT/FIR/IIR/HAE/SINC) 1–17

Security and Protection (SPU/PKTE/PKIC/PKA/TRNG) 1–19

Safety (WDOG/TMU/VMU) 1–20

Analog Subsystem (HADC) 1–20

System Debug (SCB/SWU/DBG/TAPC/CSPFT/STM) 1–20

ARM Cortex-A5 Sub-System

Cortex A5 Features 2–1

Functional Description 2–2

- A5 Block Diagram 2–2
- Control Co-Processor (CP15) 2–2
- L1 Cache 2–3
- Prefetch Unit (PFU) 2–3
- Memory-Management Unit (MMU) 2–3
- L2 Cache 2–4
- Floating-Point Unit (FPU) 2–5
- NeON 2–6
- Generic Interrupt Controller (GIC) 2–7

A5 Configurations 2–7

Clock Generation Unit (CGU)

CGU Features 3–1
CGU Functional Description 3–1
ADSP-SC58x CGU Register List 3–2
ADSP-SC58x CGU Interrupt List 3–2
ADSP-SC58x CGU Trigger List 3–3
CGU Definitions 3–3
CGU PLL Block Diagram 3–4
CGU Operating Modes 3–6
CGU Power-up Sequence 3–6
CGU Event Control 3–6
Oscillator Watchdog 3–7
CGU Programming Model 3–8
Configuring CGU Modes 3–8
Changing Clock Frequencies 3–9
Changing the PLL Clock Frequency 3–9
Changing the CCLKn or SYSCLK Frequency Without Modifying the PLLCLK Frequency 3–10
Changing the OCLK Frequency 3–11
Aligning All Clocks 3–11
Shutting Off CCLKn From Another Master 3–12
Valid Clock Multiplier Settings 3–12
PLL Bypass and PLL Disable 3–13
ADSP-SC5xx Specific Information 3–13
ADSP-SC58x CGU Register Descriptions 3–13
Core Clock Buffer Disable Register 3–15
Core Clock Buffer Status Register 3–16
CLKOUT Select Register 3–17
Control Register 3–19
Clocks Divisor Register 3–21

Oscillator Watchdog Register 3–24
PLL Control Register 3–26
Revision ID Register 3–28
System Clock Buffer Disable Register 3–29
System Clock Buffer Status Register 3–31
Status Register 3–33
Time Stamp Counter 32 LSB Register 3–36
Time Stamp Counter 32 MSB Register 3–37
Time Stamp Control Register 3–38
Time Stamp Counter Initial 32 LSB Value Register 3–39
Time Stamp Counter Initial MSB Value Register 3–40

Clock Distribution Unit (CDU)

CDU Features 4–1
CDU Functional Description 4–1
CDU Block Diagram 4–1
CDU Definitions 4–2
CDU Clock Configuration Options 4–3
CDU Programming Model 4–6
Changing the PLL and Clock Frequency 4–6
Changing the Clock Frequency 4–7
ADSP-SC58x CDU Register Descriptions 4–8
CDU Configuration 4–9
CLKIN Select 4–10
CDU Revision ID 4–11
CDU Status 4–12

Dynamic Power Management (DPM)

DPM Features 5–1
DPM Functional Description 5–1
ADSP-SC58x DPM Register List 5–1

DPM Definitions 5–1
DPM Operating Modes 5–2
Reset State 5–2
Full-on Mode 5–2
DPM Event Control 5–3
DPM Programming Model 5–3
ADSP-SC58x DPM Register Descriptions 5–5
Control Register 5–6
Peripherals Disable Register 0 5–7
Peripherals Disable Register 1 5–9
Revision ID 5–11
Status Register 5–12

Reset Control Unit (RCU)

RCU Features 6–1
RCU Functional Description 6–2
ADSP-SC58x RCU Register List 6–2
ADSP-SC58x RCU Trigger List 6–3
RCU Definitions 6–3
RCU Architectural Concepts 6–4
RCU Status and Error Signals 6–4
Resetting the ARM Core through Another Core or System Master 6–5
Resetting a SHARC+ Core Through Another Core 6–5
ADSP-SC58x RCU Register Descriptions 6–7
Boot Code Register 6–8
Core Reset Outputs Control Register 6–11
Core Reset Outputs Status Register 6–12
Control Register 6–13
Message Register 6–15
Message Clear Bits Register 6–19

Message Set Bits Register 6–20
System Interface Disable Register 6–21
System Interface Status Register 6–22
Status Register 6–23
Software Vector Register 0 6–25
Software Vector Register 1 6–26
Software Vector Register 2 6–27
SVECT Lock Register 6–28

System Event Controller (SEC) and Generic Interrupt Controller (GIC)

SEC Features 7–1
SEC Functional Description 7–2
ADSP-SC58x SEC Register List 7–2
ADSP-SC58x SEC Interrupt List 7–3
Combined SEC and GIC Interrupt List 7–3
SEC Definitions 7–12
SEC Block Diagram 7–13
SEC Fault Interface (SFI) 7–13
SEC Core Interface (SCI) 7–14
SEC Source Interface (SSI) 7–15
SEC Architectural Concepts 7–15
System Interrupt Acknowledge 7–15
System Interrupt Groups 7–16
System Interrupt Flow 7–16
System Interrupt Priorities 7–17
SEC Error 7–17
SEC Programming Model 7–17
Programming Concepts 7–18
Programming Examples 7–18
Fault Management Interface Programming Model 7–18
Configuring a System Source to Interrupt a Core 7–19

Core/SEC Handshaking Requirements to Ensure Proper Interrupt Handling 7–20

Configuring a System Source as a Fault 7–20

Configuring the WDOG Expiry Event to Issue a System Reset 7–21

SEC Programming Restrictions 7–21

ADSP-SC58x SEC Register Descriptions 7–22

SCI Active Register n 7–24

SCI Control Register n 7–25

SCI Group Mask Register n 7–27

SCI Priority Level Register n 7–29

SCI Priority Mask Register n 7–31

Core Pending Register n 7–32

SCI Source ID Register n 7–33

SCI Status Register n 7–34

Global End Register 7–36

Fault COP Period Register 7–37

Fault COP Period Current Register 7–38

Fault Control Register 7–39

Fault Delay Register 7–42

Fault Delay Current Register 7–43

Fault End Register 7–44

Fault Source ID Register 7–45

Fault System Reset Delay Register 7–46

Fault System Reset Delay Current Register 7–47

Fault Status Register 7–48

Global Control Register 7–50

Global Status Register 7–51

Global Raise Register 7–53

Source Control Register n 7–54

Source Status Register n 7–57

GIC Overview 7–58

GIC Functional Description 7–59

GIC Block Diagram 7–60

ADSP-SC58x GICDST Register List 7–60

ADSP-SC58x GICCPU Register List 7–60

ADSP-SC58x GICDST Register Descriptions 7–61

GIC Port 0 Enable 7–62

Software Generated Interrupt Priority Register 7–63

Shared Peripheral Interrupt Priority Register 7–64

Software Generated Interrupt Active Register 7–65

Software Generated Interrupt Control Register 7–66

Software Generated Interrupt Clear-Pending Register 7–68

Software Generated Interrupt Pending Set Register 7–69

Software Generated Interrupt Security Register 7–70

Shared Peripheral Interrupt Register 7–71

Shared Peripheral Interrupt Active Register 7–72

Shared Peripheral Interrupt Configuration Register 7–73

Shared Peripheral Interrupt Enable Clear Register 7–74

Shared Peripheral Interrupt Enable Set Register 7–75

Shared Peripheral Interrupt Pending Clear Register 7–76

Shared Peripheral Interrupt Pending Set Register 7–77

Shared Peripheral Interrupt Security Register 7–78

Shared Peripheral Interrupt Processor Targets Register 7–79

ADSP-SC58x GICCPU Register Descriptions 7–79

Aliased Binary Point Register (ICCABPR) 7–80

Binary Point Register (ICCBPR) 7–81

CPU Interface Control Register (ICCICR) 7–82

End of Interrupt Register (ICCEOIR) 7–83

Highest Pending Interrupt Register (ICCHPIR) 7–84

Interrupt Acknowledge Register (ICCIAR) 7–85

Priority Mask Register (ICCIPMR) 7–86

Running Priority Register (ICCRPR) 7–87

ADSP-SC58x GICDST Register Descriptions 7–87

GIC Port 0 Enable 7–89
Software Generated Interrupt Priority Register 7–90
Shared Peripheral Interrupt Priority Register 7–91
Software Generated Interrupt Active Register 7–92
Software Generated Interrupt Control Register 7–93
Software Generated Interrupt Clear-Pending Register 7–95
Software Generated Interrupt Pending Set Register 7–96
Software Generated Interrupt Security Register 7–97
Shared Peripheral Interrupt Register 7–98
Shared Peripheral Interrupt Active Register 7–99
Shared Peripheral Interrupt Configuration Register 7–100
Shared Peripheral Interrupt Enable Clear Register 7–101
Shared Peripheral Interrupt Enable Set Register 7–102
Shared Peripheral Interrupt Pending Clear Register 7–103
Shared Peripheral Interrupt Pending Set Register 7–104
Shared Peripheral Interrupt Security Register 7–105
Shared Peripheral Interrupt Processor Targets Register 7–106

Trigger Routing Unit (TRU)

TRU Features 8–1
TRU Functional Description 8–1
  ADSP-SC58x TRU Register List 8–2
  ADSP-SC58x TRU Interrupt List 8–2
  ADSP-SC58x Trigger List 8–3
  TRU Definitions 8–12
  TRU Block Diagram 8–12
TRU Architectural Concepts 8–13
TRU Programming Model 8–13
  Programming Concepts 8–13
  Programming Examples 8–14

Configuring a Simple Trigger Sequence........8–14
Toggle a GPIO on Timer Expiry Event........8–14
TRU Event Control........8–14
TRU Status and Error Signals........8–14
ADSP-SC58x TRU Register Descriptions........8–14
Error Address Register........8–16
Global Control Register........8–17
Master Trigger Register........8–19
Slave Select Register........8–20
Status Information Register........8–21

L2 System Memory

L2 System Memory Features........9–1
L2 System Memory Functional Description........9–1
ADSP-SC58x L2CTL Interrupt List........9–2
ADSP-SC58x L2CTL Register List........9–2
L2 System Memory Block Diagram........9–2
L2 System Memory Architectural Concepts........9–3
Access Characteristics........9–3
Read/Write Latency and Throughput........9–3
L2 Memory Controller Block Diagram (Instance)........9–4
Arbitration and Priority........9–4
Data Integrity........9–6
ECC Algorithm........9–6
ECC Hardware Control........9–8
ECC Error Management........9–9
Memory Refresh........9–9
L2 System Memory Event Control........9–10
ECC Error Interrupt........9–10
ADSP-SC58x L2CTL Register Descriptions........9–10
Control Register........9–12

Error Type 0 Address Register 9–16
Error Type 1 Address Register 9–17
ECC Error Address 0 Register 9–18
ECC Error Address 1 Register 9–19
ECC Error Address 2 Register 9–20
ECC Error Address 3 Register 9–21
ECC Error Address 4 Register 9–22
ECC Error Address 5 Register 9–23
ECC Error Address 6 Register 9–24
ECC Error Address 7 Register 9–25
Error Type 0 Register 9–26
Error Type 1 Register 9–28
Refresh Address Register 9–29
Read Priority Count Register 9–30
Status Register 9–31
Write Priority Count Register 9–34

Dynamic Memory Controller (DMC)

DMC Features 10–1
  Feature Exclusions 10–3
DMC Functional Description 10–3
  ADSP-SC58x DMC Register List 10–3
  ADSP-SC58x DMC Register List 10–4
  Protocol Controller 10–5
  Efficiency Controller 10–5
    Page-Based Scheduling 10–5
    Same Master Transaction Scheduling 10–5
    DMC Read Data Buffer 10–6
    Closed Page Per Bank 10–6
    SCB ID-Based Priority 10–6
    Delaying up to Eight Auto-Refresh Commands 10–7

    - Page and Bank Interleaving 10–7
  - System Crossbar Slave Interface 10–7
    - Read/Write Command and Data Buffers 10–8
  - Peripheral Bus Slave Interface 10–8
  - Architectural Concepts 10–8
    - Controller On Die Termination (ODT) 10–9
    - Mode Register Set and Extended Mode Register Set Command 10–9
    - DDR3 Reset Functionality 10–9
    - DDR3 SDRAM Organization 10–9
    - DDR2 SDRAM Organization 10–10
    - LPDDR SDRAM Organization 10–11
    - DMC Clocking 10–12
    - DMC DMA 10–12
- DMC Operating Modes 10–12
  - Self-Refresh Mode 10–13
- DMC Event Control 10–14
- DMC Programming Model 10–14
  - PHY DLL Calibration 10–17
  - DDR2 OCD Calibration 10–17
  - DDR3 ZQ Calibration Short CMD 10–17
  - DDR3 ZQ Calibration Long CMD 10–17
  - On Die Termination (DDR2/DDR3) 10–18
  - Output Driver Impedance 10–18
  - Initializing the DMC (ADSP-SC58x) 10–19
- ADSP-SC58x DMC Register Descriptions 10–22
  - Configuration Register 10–24
  - Controller to PHY Interface Register 10–26
  - Control Register 10–27
  - DLL Control Register 10–31
  - Data Calibration Address Register 10–32

Data Calibration Data 0 Register 10–33
Data Calibration Data 1 Register 10–34
Efficiency Control Register 10–35
Shadow EMR1 DDR2 Register 10–39
Shadow EMR2 Register (DDR2)/Shadow EMR Register (LPDDR) 10–41
Shadow MR Register (DDR2/LPDDR), Shadow MR0 Register (DDR3) 10–43
Shadow MR1 Register (DDR3) 10–46
Shadow MR2 Register (DDR3) 10–49
Mask (Mode Register Shadow) Register 10–51
Priority ID Register 1 10–53
Priority ID Register 2 10–54
Priority ID Mask Register 1 10–55
Priority ID Mask Register 2 10–56
DMC Read Data Buffer ID Register 1 10–57
DMC Read Data Buffer ID Register 2 10–58
DMC Read Data Buffer Mask Register 1 10–59
DMC Read Data Buffer Mask Register 2 10–60
Status Register 10–61
Timing 0 Register 10–64
Timing 1 Register 10–66
Timing 2 Register 10–67
ADSP-SC58x DMC Register Descriptions 10–68
Calibration PAD Control 0 Register 10–69
Calibration PAD Control 2 Register 10–70
PHY Control 0 Register 10–71
PHY Control 1 Register 10–72
PHY Control 2 Register 10–73
PHY Control 3 Register 10–74
PHY Control 4 Register 10–75

Static Memory Controller (SMC)

SMC Features 11–1

SMC Definitions 11–1

SMC Functional Description 11–3

ADSP-SC58x SMC Register List 11–4

SMC Architectural Concepts 11–4

Avoiding Bus Contention 11–5

ARDY Input Control 11–6

SMC Operating Modes 11–6

Asynchronous Flash Mode 11–7

Asynchronous Page Mode 11–7

SMC Event Control 11–7

SMC Programmable Timing Characteristics 11–7

Asynchronous SRAM Reads and Writes 11–7

Asynchronous SRAM Reads with IDLE Transition Cycles Inserted 11–9

High-Speed Asynchronous SRAM Read Burst 11–9

High-Speed Asynchronous SRAM Writes 11–10

Asynchronous SRAM Reads with ARDY 11–11

Asynchronous Flash Reads 11–12

Asynchronous Flash Writes 11–14

Asynchronous Flash Page Mode Reads 11–15

Asynchronous FIFO Reads and Writes 11–15

SMC Programming Model 11–17

ADSP-SC58x SMC Register Descriptions 11–17

Bank 0 Control Register 11–19

Bank 0 Extended Timing Register 11–22

Bank 0 Timing Register 11–24

Bank 1 Control Register 11–26

Bank 1 Extended Timing Register 11–29

Bank 1 Timing Register 11–31

Bank 2 Control Register 11–33
Bank 2 Extended Timing Register 11–36
Bank 2 Timing Register 11–38
Bank 3 Control Register 11–40
Bank 3 Extended Timing Register 11–43
Bank 3 Timing Register 11–45

One-Time Programmable Memory Controller (OTPC)

OTPC Features 12–1
Error Correction 12–1
OTP Layout 12–1
OTPC Event Control 12–2
OTPC Interrupt Signals 12–3
OTPC Status and Error Signals 12–3
OTP API Overview 12–3
OTP Programming 12–3
OTP Program 12–3
OTP Reading 12–4
OTP Get Field 12–4
OTP Counters 12–6
Lock API 12–6
ADSP-SC58x OTPC Interrupt List 12–7
ADSP-SC58x OTPC Register Descriptions 12–7
OTP Security State Register 12–8
OTP Status Register 12–9

System Memory Protection Unit (SMPU)

SMPU Features 13–1
SMPU Functional Description 13–2
ADSP-SC58x SMPU Register List 13–3
ADSP-SC58x SMPU Interrupts 13–4

Memory Writes 13–4

Memory Reads 13–4

ID Comparison 13–5

Memory Region 13–8

SMPU Definitions 13–9

SMPU Block Diagram 13–10

SMPU Architectural Concepts 13–10

SMPU Operating Modes 13–11

SMPU Interrupt Signals 13–11

SMPU Status and Error Signals 13–12

SMPU Programming Example 13–12

ADSP-SC58x SMPU Register Descriptions 13–13

Bus Error Address Register 13–15

Bus Error Details Register 13–16

SMPU Control Register 13–17

Exclusive Access IDn Address 13–19

Exclusive Access Status 13–20

Interrupt Address Register 13–21

Interrupt Details Register 13–22

Region n Address Register 13–23

Region n Control Register 13–24

SMPU Revision ID Register 13–27

Region n ID A Register 13–28

Region n ID B Register 13–29

Region n ID Mask A Register 13–30

Region n ID Mask B Register 13–31

SMPU Control Secure Accesses Register 13–32

Region n Control Secure Accesses Register 13–34

SMPU Status Register 13–35

General-Purpose Ports (PORT)

PORT Features 14–2

PORT Functional Description 14–2

ADSP-SC58x PORT Register List 14–3

ADSP-SC58x PINT Register List 14–3

ADSP-SC58x PINT Interrupt List 14–4

ADSP-SC58x PINT Trigger List 14–4

ADSP-SC58x PADS Register List 14–5

PORT Architectural Concepts 14–5

Internal Interfaces 14–5

External Interfaces 14–5

GPIO Functionality 14–5

Input Mode 14–5

Output Mode 14–6

Open-Drain Mode 14–6

Port Multiplexing Control 14–6

PORT Event Control 14–7

PORT Interrupt Signals 14–7

PORT Programming Model 14–9

ADSP-SC58x PORT Register Descriptions 14–12

Port x GPIO Data Register 14–14

Port x GPIO Data Clear Register 14–18

Port x GPIO Data Set Register 14–22

Port x GPIO Output Toggle Register 14–25

Port x GPIO Direction Register 14–28

Port x GPIO Direction Clear Register 14–32

Port x GPIO Direction Set Register 14–36

Port x Function Enable Register 14–39

Port x Function Enable Clear Register 14–42

Port x Function Enable Set Register 14–45

Port x GPIO Input Enable Register 14–48
Port x GPIO Input Enable Clear Register 14–51
Port x GPIO Input Enable Set Register 14–54
Port x GPIO Lock Register 14–57
Port x Multiplexer Control Register 14–59
Port x GPIO Polarity Invert Register 14–61
Port x GPIO Polarity Invert Clear Register 14–65
Port x GPIO Polarity Invert Set Register 14–68
ADSP-SC58x PINT Register Descriptions 14–70
PINT Assign Register 14–72
PINT Edge Clear Register 14–73
PINT Edge Set Register 14–76
PINT Invert Clear Register 14–79
PINT Invert Set Register 14–82
PINT Latch Register 14–85
PINT Mask Clear Register 14–89
PINT Mask Set Register 14–92
PINT Pin State Register 14–95
PINT Request Register 14–99
ADSP-SC58x PADS Register Descriptions 14–103
DAI0 Port Input Enable Control Register 14–104
DAI1 Port Input Enable Control Register 14–105
Peripheral PAD Configuration0 Register 14–106

Link Port (LP)

LP Features 15–1
LP Functional Description 15–1
ADSP-SC58x LP Register List 15–1
ADSP-SC58x LP Interrupt List 15–2
ADSP-SC58x LP Trigger List 15–2

ADSP-SC58x LP DMA Channel List 15–3

Block Diagram..... 15–3

External Connections 15–3

Internal Blocks 15–4

Architectural Concepts 15–4

Link Port Protocol..... 15–4

FIFO Buffers 15–7

Handshake for Link Port Enable Process 15–9

Clocking 15–10

Multi-Processor Connectivity 15–10

LP Operating Modes 15–12

LP Data Transfer Modes..... 15–12

Core Data Transfers 15–12

DMA Data Transfers..... 15–12

LP Event Control..... 15–13

Interrupt Signals 15–13

Enabling Link Port Interrupts 15–13

Status and Error Signals..... 15–14

LP Programming Model 15–14

Setting Up a DMA Transmit Operation 15–14

Setting Up a DMA Receive Operation..... 15–15

Setting Up a Core Transmit Operation..... 15–16

Setting Up a Core Receive Operation 15–16

ADSP-SC58x LP Register Descriptions 15–17

Control Register 15–18

Clock Divider Value Register 15–20

Receive Buffer Register 15–21

Status Register 15–22

Transmit Buffer Register 15–24

Shadow Input Transmit Buffer Register 15–25

Shadow Output Transmit Buffer Register 15–26

Serial Peripheral Interface (SPI)

SPI Features 16–1
SPI Functional Description 16–2
ADSP-SC58x SPI Register List 16–2
ADSP-SC58x SPI Interrupt List 16–3
ADSP-SC58x SPI Trigger List 16–4
ADSP-SC58x SPI DMA Channel List 16–5
SPI Block Diagram 16–5
Transfer Protocol 16–6
Clock Considerations 16–7
Controlling Delay Between Frames 16–8
Flow Control 16–9
Slave Select Operation 16–10
Beginning and Ending a Non-DMA SPI Transfer 16–11
Transmit Operation in Non-DMA Mode 16–12
Receive Operation in Non-DMA Mode 16–12
Dual I/O Mode 16–12
Quad I/O Mode (SPI2 only) 16–13
Fast Mode 16–14
Memory-Mapped Mode (SPI2 only) 16–15
Memory-Mapped Description of Operation 16–16
Memory-Mapped Architectural Concepts 16–17
Memory-Mapped Read Accesses 16–19
Memory-Mapped High-Performance Features 16–23
Merged Read Accesses 16–23
Wrap Around Accesses 16–23
Execute-In-Place (XIP, SPI2 only) 16–24
Memory-Mapped Mode Error Status Bits 16–25
Memory-Mapped Programming Guidelines 16–25

SPI Interrupt Signals 16–28

Data Interrupts 16–28

Status Interrupts 16–29

Error Conditions 16–29

SPI Programming Concepts 16–30

Master Operation in Non-DMA Modes 16–30

Slave Operation in Non-DMA Modes 16–31

Configuring DMA Master Mode 16–32

Configuring DMA Slave Mode Operation 16–33

ADSP-SC58x SPI Register Descriptions 16–34

Clock Rate Register 16–36

Control Register 16–37

Delay Register 16–43

Masked Interrupt Condition Register 16–44

Masked Interrupt Clear Register 16–46

Interrupt Mask Register 16–49

Interrupt Mask Clear Register 16–51

Interrupt Mask Set Register 16–54

Memory Mapped Read Header (Only on SPI2) 16–57

SPI Memory Top Address (Only on SPI2) 16–61

Receive FIFO Data Register 16–62

Received Word Count Register 16–63

Received Word Count Reload Register 16–64

Receive Control Register 16–65

Slave Select Register 16–68

Status Register 16–71

Transmit FIFO Data Register 16–76

Transmitted Word Count Register 16–77

Transmitted Word Count Reload Register 16–78

Transmit Control Register 16–79

Universal Asynchronous Receiver/Transmitter (UART)

UART Features 17–1
UART Functional Description 17–2
ADSP-SC58x UART Register List 17–2
ADSP-SC58x UART Interrupt List 17–3
ADSP-SC58x UART Trigger List 17–4
ADSP-SC58x UART DMA Channel List 17–4
UART Block Diagram 17–5
UART Architectural Concepts 17–5
Internal Interface 17–5
External Interface 17–6
Hardware Flow Control 17–6
Bit Rate Generation 17–6
Autobaud Detection 17–7
UART Debug Features 17–9
UART Operating Modes 17–9
UART Mode 17–10
IrDA SIR Mode 17–10
Multi-Drop Bus Mode 17–10
UART Data Transfer Modes 17–12
UART Mode Transmit Operation (Core) 17–12
UART Mode LIN Break Command 17–12
UART Mode Receive Operation (Core) 17–13
IrDA Transmit Operation 17–14
IrDA Receive Operation 17–14
MDB Transmit Operation 17–15
MDB Receive Operation 17–16
DMA Mode 17–16
Mixing DMA and Core Modes 17–17
Setting Up Hardware Flow Control 17–17
UART Event Control 17–18

- Interrupt Masks 17–18
- Interrupt Servicing 17–18
- Transmit Interrupts 17–19
- Receive Interrupts 17–20
- Status Interrupts 17–21
- Multi-Drop Bus Events 17–22

UART Programming Model 17–22

- Detecting Autobaud 17–22
- Using Common Initialization Steps 17–23
- Using Core Transfers 17–23
- Using DMA Transfers 17–23
- Using Interrupts 17–23
- Setting Up Hardware Flow Control 17–23

ADSP-SC58x UART Register Descriptions 17–24

- Clock Rate Register 17–25
- Control Register 17–26
- Interrupt Mask Register 17–32
- Interrupt Mask Clear Register 17–36
- Interrupt Mask Set Register 17–38
- Receive Buffer Register 17–40
- Receive Shift Register 17–41
- Receive Counter Register 17–42
- Scratch Register 17–43
- Status Register 17–44
- Transmit Address/Insert Pulse Register 17–49
- Transmit Hold Register 17–50
- Transmit Shift Register 17–51
- Transmit Counter Register 17–52

Enhanced Parallel Peripheral Interface (EPPI)

ADSP-SC58x Register List

Preface

Thank you for purchasing and developing systems using an ADSP-SC58x SHARC+ processor from Analog Devices, Inc.

The ADSP-SC58x processor features two high-performance, floating-point SHARC+® cores (ADSP-2158x) and one ARM® Cortex-A5 core. The cores deliver 24 GFLOPS performance at under 2W for advanced, real-rime audio and industrial applications. The processor is designed for a wide variety of automotive, consumer, professional audio energy distribution systems, and other computationally intensive real-time applications.

Purpose of This Manual

The *ADSP-SC58x SHARC Processor Hardware Reference* provides architectural information about the ADSP-SC58x processors. This hardware reference provides the main architectural information about these processors. The architectural descriptions cover functional blocks, buses, and ports, including all features and processes that they support. For information about programming the ARM core in the ADSP-SC58x processor, visit the ARM Information Center at:

http://infocenter.arm.com.

For timing, electrical, and package specifications, see the processor data sheet.

Intended Audience

The primary audience for this manual is a programmer who is familiar with Analog Devices processors. The manual assumes the audience has a working knowledge of the appropriate processor architecture and instruction set. Programmers who are unfamiliar with Analog Devices processors can use this manual, but should supplement it with other texts, such as programming reference books and data sheets, that describe their target architecture.

What's New in This Manual

This is the first released to production revision (1.0) of the *ADSP-SC58x SHARC+ Processor Hardware Reference*.

Technical or Customer Support

You can reach customer and technical support for processors from Analog Devices in the following ways:

- Post your questions in the processors and DSP support community at ***EngineerZone***:

  http://ez.analog.com/community/dsp

- Submit your questions to technical support at ***Connect with ADI Specialists***:

http://www.analog.com/support

- E-mail your questions about software/hardware development tools to:

  processor.tools.support@analog.com

- E-mail your questions about processors and DSPs to:

  processor.support@analog.com (world wide support)

  processor.china@analog.com (China support)

- Contact your Analog Devices sales office or authorized distributor. Locate one at:

  http://www.analog.com/adi-sales

- Send questions by mail to:

  Analog Devices, Inc.

  Three Technology Way

  P.O. Box 9106

  Norwood, MA 02062-9106 USA

Product Information

Product information can be obtained from the Analog Devices Web site and CrossCore Embedded Studio online Help system.

Analog Devices Web Site

The Analog Devices Web site, http://www.analog.com, provides information about a broad range of products—analog integrated circuits, amplifiers, converters, and digital signal processors.

To access a complete technical library for each processor family, go to: http://www.analog.com/processors/technical_library The manuals selection opens a list of current manuals related to the product as well as a link to the previous revisions of the manuals. When locating your manual title, note a possible errata check mark next to the title that leads to the current correction report against the manual.

Also note, MyAnalog.com is a free feature of the Analog Devices Web site that allows customization of a Web page to display only the latest information about products you are interested in. You can choose to receive weekly e-mail notifications containing updates to the Web pages that meet your interests, including documentation errata against all manuals. MyAnalog.com provides access to books, application notes, data sheets, code examples, and more.

Visit MyAnalog.com to sign up. If you are a registered user, just log on. Your user name is your e-mail address.

EngineerZone

EngineerZone is a technical support forum from Analog Devices. It allows you direct access to ADI technical support engineers. You can search FAQs and technical information to get quick answers to your embedded processing and DSP design questions.

Use EngineerZone to connect with other DSP developers who face similar design challenges. You can also use this open forum to share knowledge and collaborate with the ADI support team and your peers. Visit http://ez.analog.com to sign up.

Supported Processors

The following is the list of Analog Devices, Inc. processors supported by the CrossCore Embedded Studio® development tools suite.

Blackfin+® (ADSP-BF7xx) Processors

The name *Blackfin+* refers to the enhanced fixed-point Blackfin core architecture featured by the ADSP-BF70x processor product line, which is a family of 16-bit embedded processors.

Blackfin® (ADSP-BF6xx/BF5xx) Processors

The name *Blackfin* refers to the fixed-point core architecture featured on the following processors: ADSP-BF5xx and ADSP-BF6xx.

SHARC® (ADSP-21xxx) Processors

The name *SHARC* refers to the high-performance, 32-bit, floating-point core architecture featured on the following processors: ADSP-2116x, ADSP-2126x, ADSP-213xx, and ADSP-214xx. These processors can be used in speech, sound, graphics, and imaging applications.

SHARC+® (ADSP-SC5xx, ADSP-215xx) Processors

The name *SHARC+* refers to the enhanced high-performance, 32-bit, floating-point core architecture featured on the following processors: ADSP-215xx/ADSP-SC5xx. The connected SHARC+ ADSP-SC5xx processors also contain an ARM® Cortex-A5® core. These products can be used in speech, sound, graphics, and imaging applications.

The following is the list of Analog Devices, Inc. processors supported by the IAR Embedded WorkBench® development tools. For information about the IAR Embedded WorkBench product and software download, go to http://www.iar.com/en/Products/IAR-Embedded-Workbench .

Mixed-Signal Control Processors

The ADSP-CM40x processors are based on the ARM Cortex®-M4 core and are designed for motor control and industrial applications.

The ADSP-CM41x processors are based on the ARM Cortex-M4 and ARM Cortex-M0 cores and are designed for motor control and industrial applications.

How to Use this Manual

This section describes how this manual is organized and where you can find specific types of information.

This manual is organized such that it aligns with the Figure 1-1 ADSP-SC58x Functional Block Diagram. This structure is:

ARM Cortex Overview

Power and Clock Management

- Clock Generation Unit (CGU)
- Dynmic Power Management (DPM)
- Reset Control Unit (RCU)

System Interrupts and Triggers

- System Event Control (SEC)
- Trigger Routing Unit (TRU)

System Memory (L2CTL/DMC/SMC/OTPC/SMPU)

- L2 Controller (L2CTL)
- Dynamic Memory Congtroller (DMC)
- Static Memory Controller (SMC)
- One-Time Programmable Memory Controller (OTPC)
- System Memory Protection Unit (SMPU)

Peripherals:

- GPIO
- Timers and Counters
  - General-Purpose Counter (CNT)
  - General-Purpose Timer (TMR)
  - Watchdog Timer (WDOG)

    - Real-Time Counter (RTC)
- Serial Interfaces
    - Serial Ports (SPORTs)
    - Serial Peripheral Interface (SPI, SPIHP)
    - Universal Asynchronous Receiver/Transmitter (UART)
    - Two-Wire Interface (TWI)
    - Control Area Network (CAN)
    - Universal Serial Bus (USB)
- Parallel Interfaces
    - Enhanced Parallel Peripheral Interface (EPPI)
    - Mobile Storage Interface (MSI)

Direct Memory Access

- Dynamic Memory Controller (DMC)
- Memory DMA Controller (MDMA)
- Cyclic Redundancy Check (CRC)

Analog Subsystem (Housekeeping ADC)

Security and Protection (SPU/PKTE/PKIC/PKA/TRNG)

- System Protection Unit (SPU)
- Security Packet Engine (PKTE)
- Public Key Interrupt Controller (PKIC)
- Public Key Accelerator (PKA)
- True Random Number Generator (TRNG)

Booting

System Debug

- System Crossbars (SCB)
- System Watchpoint Unit (SWU)
- System Debug and Trace Unit (DBG)
- Test Access Port Controller (TAPC)
- Trace Unit (CSPFT)

- System Trace Module (STM)

The following list provides information on the organization and contents of each chapter of this manual. Note that not every chapter follows this organization exactly nor does every chapter contain all of the topics listed.

- ***Overview.*** Provides very general information on what the module does. Also may list relevent industry standards that the modules support or comply with.
- ***Features.*** Provides a list of module features such as modes of operation, clocking options, and throughput.
- ***Functional Description.*** Provides details on how the module functions including descriptions of module blocks, connectivity and a glossary. This section also contains a register list and lists of interrupts, triggers and DMA channels (if applicable).
- ***Operating Modes.*** Describes the available modes of operation, how to configure them and how they work.
- ***Event Control.*** Provides information on interrupt and fault generation and how to manage them.
- ***Programming Model.*** Provides general guidelines on how to configure and enable the module. May also provide specific examples for configuring a mode of operation.
- ***Debug Features.*** Describes debugging operations.
- ***Register Descriptions.*** Provides detailed descriptions of all of the registers and bits used by the module.

This manual also contains a comprehensive appendix of memory-mapped register addresses and names. The modules in this appendix are presented in alphabetical order.

Notation Conventions

Text conventions used in this manual are identified and described as follows. Additional conventions, which apply only to specific chapters, may appear throughout this document.

Example	Description
File > ***Close***	Titles in reference sections indicate the location of an item within the CrossCore Embedded Studio IDE's menu system (for example, the ***Close*** command appears on the ***File*** menu).
`{this | that}`	Alternative required items in syntax descriptions appear within curly brackets and separated by vertical bars; read the example as `this` or `that`. One or the other is required.
`[this | that]`	Optional items in syntax descriptions appear within brackets and separated by vertical bars; read the example as an optional `this` or `that`.
`[this, …]`	Optional item lists in syntax descriptions appear within brackets delimited by commas and terminated with an ellipse; read the example as an optional comma-separated list of `this`.
`.SECTION`	Commands, directives, keywords, and feature names are in text with `Letter Gothic` font.

Example	Description
`filename`	Non-keyword placeholders appear in text with italic style format.
NOTE:	*NOTE:* For correct operation, ... A note provides supplementary information on a related topic. In the online version of this book, the word *NOTE:* appears instead of this symbol.
CAUTION:	*CAUTION:* Incorrect device operation may result if ... *CAUTION:* Device damage may result if ... A caution identifies conditions or inappropriate usage of the product that could lead to undesirable results or product damage. In the online version of this book, the word *CAUTION:* appears instead of this symbol.
ATTENTION:	*ATTENTION:* Injury to device users may result if ... A warning identifies conditions or inappropriate usage of the product that could lead to conditions that are potentially hazardous for devices users. In the online version of this book, the word *ATTENTION:* appears instead of this symbol.
Registers/Bits	All registers and bits in this manual are linked (clickable) to their respective descriptions in the "Register Descriptions" of each chapter.
Miscellaneous Conventions	Interrupt and internal signals are shown in all caps with no other formatting. For example the SPDIFn_RX or SCLK signal or the PKTE0_IRQ interrupt. An overbar denotes an active-low signal as in $\overline{\text{SYS\_FAULT}}$.

Register Documentation Conventions

Register diagrams use the following conventions:

- The descriptive name of the register appears at the top with the short form of the name.
- If a bit has a short name, the short name appears first in the bit description, followed by the long name.
- The reset value appears in binary in the individual bits and in hexadecimal to the left of the register.
- Bits marked *X* have an unknown reset value. Consequently, the reset value of registers that contain such bits is undefined or dependent on pin values at reset.
- Shaded bits are reserved

NOTE: To ensure upward compatibility with future implementations, write back the value that is read for reserved bits in a register, unless otherwise specified.

Register description tables use the following conventions:

- Each bit's or bit field's access type appears beneath the bit number in the table in the form (read-access/write-access). The access types include:
  - R = read, RC = read clear, RS = read set, R0 = read zero, R1 = read one, Rx = read undefined
  - W = write, NW = no write, W1C = write one to clear, W1S = write one to set, W0C = write zero to clear, W0S = write zero to set, WS = write to set, WC = write to clear, W1A = write one action

- Many bit and bit field descriptions include enumerations, identifying bit values and related functionality. Unless otherwise indicated (with a prefix), these enumerations are decimal values.

1 Introduction

The ADSP-SC58x and ADSP-215xx processors are members of the SHARC+ family of products. The ADSP-SC58x processor is based on the SHARC+ dual-core processor and the ARM Cortex-A5 processor cores.

As shown in the ***ADSP-SC58x Functional Block Diagram***, by integrating a rich set of industry-leading system peripherals and memory (see product data sheet), the ARM/SHARC+ processor is the platform of choice for next-generation applications that require RISC-like programmability, multimedia support, and leading-edge signal processing in one integrated package. These applications span a wide array of markets, from automotive and pro-audio to industrial-based applications that require high floating-point performance.

NOTE: For specific product configurations (available cores and peripherals), see the SHARC+ Dual Core DSP with ARM Cortex-A5 ADSP-SC582/SC583/SC584/SC587/SC589/ADSP-21583/21584/21587 data sheet.

Figure 1-1: ADSP-SC58x Functional Block Diagram

ARM Cortex-A5 Processor Core

The ARM Cortex-A5 processor (shown in the Figure 2-1 A5 Sub-System Block Diagram) is a high performance processor with an L1 cache and a virtual Memory Management Unit. This processor is available on the ADSP-SC5xx processors and has a core ID = 0.

SHARC+ Processor Cores

The ADSP-SC58x/ADSP-215xx SHARC+ processors are members of the SIMD SHARC+ family of DSPs that feature Analog Devices Super Harvard Architecture. These 32-bit/40-bit/64-bit floating-point processors are optimized for high performance audio/floating-point applications with their large on-chip SRAM, multiple internal buses to eliminate I/O bottlenecks, and innovative digital audio interfaces (DAI). New enhancements to the SHARC+ core add cache enhancements, branch prediction and other instruction set improvements all while maintaining instruction set compatibility to previous SHARC products.

The ADSP-SC58x/ADSP-2158x processors feature two SHARC+ cores (SHARC1 and SHARC2), which have core IDs of 1 and 2, respectively.

Power and Clock Management (DPM/RCU/CGU/CDU)

The processor contains four modules that control power and clocking.

Dynamic Power Management (DPM)

The Dynamic Power Management (DPM) unit of the processor controls transitions between different power-saving modes.

Reset Control Unit (RCU)

The Reset Control Unit (RCU) controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. The RCU supports separate reset control for various chip sub-systems. For deterministic operation programmers should ensure there is no activity between separate chip sub-systems during reset activity. More global reset options are also supported. Programs must guarantee that none of the reset functions puts the system into an undefined state or causes resources to stall. This functionality is important when only one of the cores is reset (programs must ensure that there is no pending system activity involving the core that is being reset).

Clock Generation Unit (CGU)

The Clock Generation Unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock that runs at a frequency that is a multiple of the SYS_CLKINx input clock frequency. It also generates all on-chip clocks and synchronization signals. The PCU allows the application software to control the PLL module operation. All clocks derived from the CGU are then forwarded to the CDU for distribution.

Figure 1-3: CGU System Diagram

Clock Distribution Unit (CDU)

The Clock Distribution Unit (CDU) consists of an array of software-configurable multiplexors that select clocks originated from up to four different clock sources that are generated from the CGUs. Unused input clocks are grounded internally and never selected. The output clock signal for each multiplexor is assigned to one or more destinations within the processor.

Figure 1-4: CDU System Diagram

System Interrupts and Triggers (SEC/TRU)

The SEC and TRU modules provide interrupt and trigger management functions for the processor.

System Event Controller (SEC)

There are two interrupt controllers— the System Event Controller (SEC) and Generic Interrupt Controller (GIC). The generic interrupt controller is used for the ARM core, and the system event controller is used for the SHARC+ cores.

The SEC manages the configuration of all system event sources and the propagation of system events to all connected cores and the system fault interface. The SEC arbitrates among all pending system interrupt requests and presents the highest priority interrupt to the core(s) for processing.

Hardware Interrupt Assertion (IVG11) to SHARC+ Cores
Software Interrupt Assertion (IVG11) to SHARC+ Cores

Figure 1-5: SEC System Diagram

Trigger Routing Unit (TRU)

The Trigger Routing Unit (TRU) provides system-level sequence control without core intervention. The TRU maps trigger masters (generators of triggers) to trigger slaves (receivers of triggers). Slave endpoints can be configured to respond to triggers in various ways. Multiple TRUs may be provided in a multiprocessor system to create a trigger network. Common applications enabled by the TRU include:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes
- Software triggering
- Synchronization of concurrent activities

System Memory (L2CTL/DMC/SMC/OTPC/SMPU)

The following sections describe the memory architecture of the ADSP-SC58x processors. More information can be found in the processor data sheet.

L2 Memory Controller (L2CTL)

L2 System Memory has significant bandwidth for core accesses, but it is important to note that L2 responds slower to core accesses than L1 memories. L2 SRAM is the ideal storage for multiple processor cores to share data and instruction resources, such as semaphores, shared buffers, and code libraries. Due to sophisticated data integrity protection and write protection, L2 SRAM is also ideal for data and instructions critical for safe operation of the application.

Core/Cache Access Arbitration in SCB0 Only
DMA Access Arbitration Among Numerous SCBs

Figure 1-7: L2CTL System Diagram

Dynamic Memory Controller (DMC)

The Dynamic Memory Controller (DMC) provides a glueless interface between DDR3/DDR2/LPDDR SDRAMs and the system crossbar interface (SCB). The DMC enables execution of instructions from, as well as transfer of data to and from, DDR3, DDR2 SDRAM or LPDDR SDRAM, respectively.

The DMC is partitioned in a manner that allows reconfiguration and maintainability. The memory access protocol state machine along with JEDEC standard specific logic is embedded in the protocol controller. An access and operation reordering mechanism is incorporated as an efficiency controller. An SCB slave interface is provided to interface with the on-chip interconnect. This interface results in an efficient slave implementation owing to its out-of-order transaction capabilities.

The DMC supports access to the external memory by core and DMA accesses.

Figure 1-8: DMC System Diagram

Static Memory Controller (SMC)

The Static Memory Controller (SMC) is a protocol converter and data transfer interface between the internal processor bus and the external L3 memory. It provides a glueless interface to various external memories and peripheral devices, including SRAM, ROM, EPROM, NOR flash memory and FPGA/ASIC devices.

The SMC acts as an SCB slave. The processor SCB interconnect fabric arbitrates accesses to the SMC. The SMC connects to signal pins for memory control (such as read, write, output enable, and memory select lines).

One-Time Programmable Memory Controller (OTPC)

The One-Time Programmable Memory Controller (OTPC) module is a complete system integrating an OTP memory core with a programming controller, charge pump, and voltage regulator. A built-in Hamming Code Error Correction (ECC), and a fully implemented double-redundant program or read scheme protect the OTP data.

System Memory Protection Unit (SMPU)

The System Memory Protection Unit (SMPU) provides a flexible way of protecting memory regions against read or write access from any or all masters in the system. In addition, it can guard against memory access depending on security privileges of the system master.

On the ADSP-SC58x, 10 SMPU instances are available to protect the L2, external memory (DMC/SMC), and memory-mapped I/O (PCIe) interfaces. Six instances are allotted to protect the L2 memory, two instances for DMC0 and DMC1, one instance for SMC and one instance for PCIe.

Direct Memory Access (DMA/MDMA/EMDMA/CRC)

DMA Controller (DMA)

The processors use Direct Memory Access (DMA) to transfer data within memory spaces or between a memory space and a peripheral. The processors can specify data transfer operations and return to normal processing while the fully integrated DMA controller carries out the data transfers independent of processor activity.

DMA transfers can occur between memory and a peripheral or between one memory and another memory. Each Memory-to-memory DMA stream uses two channels, where one channel is the source channel, and the second is the destination channel. Most peripherals have at least one dedicated DMA channel associated with them.

All DMAs can transport data to and from all on-chip and off-chip memories. Programs can use two types of DMA transfers, descriptor-based or register-based. Register-based DMA allows the processors to directly program DMA control registers to initiate a DMA transfer. On completion, the control registers may be automatically updated with their original setup values for continuous transfer. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. Descriptor-based DMA transfers allow multiple DMA sequences to be chained together and a DMA channel can be programmed to automatically set up and start another DMA transfer after the current sequence completes.

Figure 1-12: DMA System Diagram

Memory DMA Controllers (MDMA)

The processor supports a variety of Memory DMA and Triggering memory-to-memory DMA operations which include:

- Two standard memory DMA channels with CRC protection (32-bit bus width, run on SCLK0)
- One enhanced memory DMA channel (32-bit bus width, runs on SYSCLK)
- Two memory DMA channels (64-bit bus width, run on SYSCLK, one channel may be assigned to the FFT accelerator)
- Two EMDMA channels (32-bit bus width, run on SCLK0)

Extended Memory DMA (EMDMA)

The Extended Memory DMA (EMDMA) engine can be used in applications that copy data in a non-sequential manner. This includes delay lines, scatter and gather, and circular access types.

Unlike previous SHARC processors which contained external port DMA, the current EPDMA module can access all memory locations (L1/L2/L3) for source and destination DMA operations.

Cyclic Redundancy Check (CRC)

The Cyclic Redundancy Check (CRC) peripheral performs the cyclic redundancy check (CRC) of the block of data that is presented to the peripheral. The peripheral provides a means to verify periodically the integrity of the system memory, the contents of memory-mapped registers (MMRs), or communication message objects. It is based on a CRC32 engine that computes the signature of 32-bit data presented to the peripheral.

The dedicated hardware compares the calculated signature of the operation to a pre-loaded expected signature. If the two signatures fail to match, the peripheral generates an error. The source channel of the memory-to-memory DMA channels can provide data. The CRC optionally forwards data to memory through the destination DMA channel. Alternatively, the peripheral supports data presented by core write transactions.

The CRC peripheral implements a reduced table-look-up algorithm to compute the signature of the data. The CRC uses a programmable 32-bit CRC polynomial to generate the look-up table (LUT) contents automatically.

More CRC peripheral modes allow for initializing large memory sections with a constant value, or for verifying that sections of memory are equal to a constant value.

Peripherals

The SHARC+ processor contains a rich set of industry leading system peripherals. The processor is the platform of choice for applications that require RISC-like programmability, multimedia support, and leading edge signal processing in one integrated package. These applications span a wide array of markets, including automotive, pro audio, and industrial-based applications that require high floating-point performance. These peripherals are described in the following sections.

- General-Purpose I/O (GPIO) Peripherals
- DAI/SRU Peripherals
- Dedicated Pin Peripherals

General-Purpose I/O (GPIO) Peripherals

The SHARC+ processors feature up to 102 general-purpose I/O pins mapped across up to seven ports (PORT A through PORT G). Each pin can be configured individually to serve as a GPIO pin or as a peripheral-specific pin.

GPIO Ports (PORT)

When configured in the default GPIO mode, the PORT pins allow for the processor to interface to system components to provide handshaking functionality as either inputs or outputs. When in output mode, open-drain output is supported. A single MMR access can be used to sense or set individual pins or a complete port of 16 pins.

Additionally, each GPIO pin can optionally be configured to raise a system interrupt on the processor via a dedicated pin interrupt (PINT) block, and all peripheral functions are controlled via a set of port multiplexing registers, with specific settings defined in the processor data sheet.

Serial Peripheral Interface Ports (SPI)

The Serial Peripheral Interface (SPI) is an industry-standard synchronous serial link that supports communication with multiple SPI-compatible devices. The baseline SPI peripheral is a synchronous, four-wire interface consisting of two data pins, one device select pin, and a gated clock pin. The two data pins allow full-duplex operation to other SPI-compatible devices. Two extra (optional) data pins are provided on specific SPIs to support quad SPI operation. Enhanced modes of operation such as flow control, fast mode, and dual-I/O mode (DIOM) are also supported. In addition, a direct memory access (DMA) mode allows for transferring several words with minimal CPU interaction.

Universal Asynchronous Receiver/Transmitter (UART)

The Universal Asynchronous Receiver/Transmitter (UART) module is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word lengths, stop bits, bit rates, and parity-generation options. The UART includes interrupt-handling hardware. Multiple events can generate interrupts.

The UART is logically compliant to EIA-232E, EIA-422, EIA-485 and LIN standards, but usually requires external transceiver devices to meet electrical requirements. In IrDA (Infrared Data Association) mode, the UART meets the half-duplex IrDA SIR (9.6/115.2 Kbps rate) protocol. In multi-drop bus mode, the UART meets the full-duplex MDB/ICP v2.0 protocol.

Enhanced Parallel Peripheral Interface (EPPI)

The Enhanced Parallel Peripheral Interface (EPPI) is a half-duplex, bidirectional port with a dedicated clock pin and three frame sync (FS) pins. It can support direct connections to active TFT LCDs, parallel A/D and D/A converters, video encoders and decoders, image sensor modules and other general-purpose peripherals. Each EPPI has two DMA channels associated with it. Moreover, in some modes, an EPPI can use an extra DMA channel.

General-Purpose Counter (CNT)

The General-Purpose Counter (CNT) converts pulses from incremental position encoders into data that is representative of the actual position of the pulse. This conversion is done by integrating (counting) pulses on one or two inputs. Since integration provides relative position, some devices also feature a zero-position input (zero marker). The GP counter can use the zero position input feature to establish a reference point for verifying that the acquired position does not drift over time. In addition, the GP counter can use the incremental position information to determine speed, if the time intervals are measured.

DAI/SRU Peripherals

The Digital Audio Interface (DAI) (DAIn) are comprised of groups of identical peripherals and their respective Signal Routing Units (SRUn). The SRU connects inputs and outputs of the DAI peripherals with each other and to the external pins. This configuration allows peripherals to be interconnected to accomodate a wide variety of systems without making external pin connections.

The DAI Routing Capabilities section provides an overview of the different routing capabilities for the DAI unit. An example for the eight SPORTs is shown in the following figure.

The following additional peripherals are connected using the DAI/SRU.

- Eight Asynchronous Sample Rate Converter (ASRC) blocks
- Two Sony/Philips Digital Interface (S/PDIF) transmit/receive blocks
- Four Precision Clock Generators (PCG)

Dedicated Pin Peripherals

The following peripherals have dedicated pins on the processor.

Two-Wire Interface (TWI)

The processor has a Two-Wire Interface (TWI), that provides a simple exchange method of control data between multiple devices. The TWI module is compatible with the widely used I2C bus standard. Additionally, the TWI module is fully compatible with serial camera control bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

Universal Serial Bus (USB)

The Universal Serial Bus (USB) controller provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras, and MP3 players. It allows these devices to transfer data using a point-to-point USB connection without the need for a personal computer host.

The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On-The-Go (OTG) supplement to the USB 2.0 Specification.

Housekeeping ADC (HADC)

The Housekeeping ADC (HADC) is a 12-bit (with 10-bit accuracy), successive approximation ADC. It operates from single supply and features throughput rates up to 1 MSPS. The HADC can be used for the collection of housekeeping parameters like voltages, temperatures in the system or for any general-purpose use as well.

System Accelerators (FFT/FIR/IIR/HAE/SINC)

The following sections provide information about the high-performance acceleration engines on the processor.

FFT Accelerator (FFTA)

The FFT Accelerator (FFTA) performs memory to memory FFT/IFFT operations without core software intervention. Additionally, the FFTA architecture allows execution of complex, pipelined, memory to memory algorithms including ping-ponged, windowed frequency domain filtering and very large FFTs. The FFTA may also be used in conjunction with minimal computation support from a core in applications such as the overlap-add operations required for large frequency domain based convolutions.

Figure 1-35: FFTA System Diagram

FIR Accelerator (FIR)

FIR Accelerator (FIR) filters are frequently used in DSP applications. The FIR accelerator is a dedicated hardware interface used to perform filter processing to reduce the instruction processing load on the core. FIR filters are used in a wide array of applications including multi-rate processing with an interpolator or decimator.

Harmonic Analysis Engine (HAE)

The Harmonic Analysis Engine (HAE) analyzes harmonic frequencies present on the voltage and current input samples. The HAE receives input samples from two source channels whose frequencies are 45–65 Hz. The HAE then processes the input samples and produces output results. The output results consist of power quality measurements of the fundamental and up to 12 more harmonics.

Sinus Cardinalis (SINC) Filter

The Sinus Cardinalis (SINC) Filter module processes four independent sigma-delta bit streams by applying a pair of SINC filters to each stream. A SINC filter converts the bit stream from a sigma-delta front-end modulator into a digital word representing the signal level presented to the modulator.

The filter consists of a set of integration and decimation stages implemented directly in logic for efficient execution. The SINC filter supports capture of current or voltage feedback signals from an isolating analog-to-digital converter (ADC). Each modulator bit stream connects to two SINC filters: a primary filter for controlling feedback; a secondary filter for overcurrent detection. The SINC module includes four filter channels and two modulator clock generators.

Security and Protection (SPU/PKTE/PKIC/PKA/TRNG)

The following modules provide system safety and security.

System Protection Unit (SPU)

In a system with multiple system MMR masters, configurations of peripherals can be changed unintentionally leading to bad data or even system malfunctions. The peripherals are shared resources in the system. The System Protection Unit (SPU) restricts access to certain MMRs, similar to the functionality of a semaphore.

The SPU also protects peripherals based on security settings. It is part of the overall security infrastructure of the processor.

Security Packet Engine (PKTE)

The PKTE is a security packet engine designed to off-load the host processor to improve the speed of applications requiring cryptographic processing. The packet engine contains a set of modules for encryption and decryption, hashing, and pseudo-random number generation.

Public Key Accelerator (PKA)

The Public Key Accelerator (PKA) helps offload computationally-intensive operations commonly found in public key cryptography algorithms. The PKA also contains hardware logic to automatically zero out the PKA RAM buffer to clear out any information that is considered sensitive or secure.

Public Key Interrupt Controller (PKIC)

The Public Key Interrupt Controller (PKIC) is a common interrupt controller shared with the True Random Number Generator. The host processor configures the PKIC to generate interrupts when certain operations are complete or interrupts are caused by errors.

True Random Number Generator (TRNG)

The True Random Number Generator (TRNG) engine provides a true, non-deterministic, noise source for generating keys, Initialization Vectors (IVs), and other random number requirements. Other non-cryptographic purposes include statistical sampling, retry timers for communications protocols and noise generation.

Safety (WDOG/TMU/VMU)

Signal Watchdogs (WDOG)

The eight general-purpose Watchdog Timer (WDOG) timers feature modes to monitor off-chip signals. The Watchdog Period mode monitors whether external signals toggle with a period within an expected range. The Watchdog Width mode monitors whether the pulse widths of external signals are within an expected range. Both modes help to detect undesired toggling (or lack thereof) of system-level signals.

Thermal Monitor Unit (TMU)

The Thermal Monitoring Unit (TMU) unit senses the die temperature during runtime. In cases of weak temp violations an alert (interrupt) is given or in case for severe violations a HW reset is asserted to shut down the system.

Analog Subsystem (HADC)

The Housekeeping ADC (HADC) is a 12-bit (with 10-bit accuracy), successive approximation ADC. It operates from single supply and features throughput rates up to 1 MSPS. The HADC can be used for the collection of housekeeping parameters like voltages, temperatures in the system or for any general-purpose use as well.

Figure 1-40: HADC System Diagram

System Debug (SCB/SWU/DBG/TAPC/CSPFT/STM)

The System Debug and Trace Unit (DBG) is based on ARM Core Sight technology. CoreSight™ is a set of architecture specifications defining debug and trace architecture. The processor uses CoreSight infrastructure to provide industry standard debug and trace capabilities through the following modules.

- Test Access Port Controller (TAPC)
- Trace Unit (CSPFT)
- System Trace Module (STM)

Additional debug resources are provided by the following modules.

- The System Crossbars (SCB) are the fundamental building blocks of a switch-fabric style for (on-chip) system bus interconnection. The SCBs connect system bus masters to system bus slaves, providing concurrent data transfer between multiple bus masters and multiple bus slaves. The SCB provides sustainable throughput for simultaneous transactions in the system with configurable Quality of Service for each type of transaction (traffic) as required. A hierarchical model, built from multiple SCBs, provides a power and area efficient system interconnect, which satisfies the performance and flexibility requirements of a specific system.

- The System Watchpoint Unit (SWU) is a single module used for transaction monitoring. The SWU is attached to each system slave through the system crossbar interface and provides ports for all address channel signals for the system crossbar. The SWU does not have ports for the read/write data channel signals or the low-power interface signals.

2 ARM Cortex-A5 Sub-System

The ADSP-SC589 processor includes an ARM® Cortex-A5® core. The ARM Cortex-A5 processor is the smallest, lowest cost and lowest power ARMv7 application processor. The A5 sub-system in the ADSP-SC589 processor includes a Floating-Point Unit, NEON Media Processing Engine, Generic Interrupt Controller and a Level 2 Cache Controller. The A5 also includes support for a L1-Cache sub-system and a full-fledged Memory Management Unit. The A5 implements the ARMv7 architecture and runs 32-bit ARM instructions, 16-bit and 32-bit Thumb instructions, and 8-bit Java byte-codes in Jazelle state.

This document describes the ARM Cortex-A5 core and memory architecture used on the ADSP-SC58x processor, but does not provide detailed programming information for the ARM processor. For more information about programming the ARM processor, visit the ARM Information Center:

- http://infocenter.arm.com.

The applicable documentation for programming the ARM Cortex-A5 processor include:

- Cortex-A5 Technical Reference Manual, Revision: r0p1
- Cortex-A Series Programmer's Guide, Revision: r0p1
- Cortex-A5 NEON Media Processing Engine Technical Reference Manual, Revision: r0p1
- Cortex-A5 Floating-Point Unit Technical Reference Manual, Revision: r0p1
- CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, Revision: r3p3
- PrimeCell Generic Interrupt Controller (PL390) Technical Reference Manual, Revision: r0p0

Cortex A5 Features

The Cortex-A5 Sub-system has the following features.

- Thumb / ARM Instruction support
- L1- Instruction Cache and L1-Data Cache
- Floating Point Unit (FPU)
- NEON Media Processing Engine (NEON)

- Generic Interrupt Controller (GIC)
- Level 2 Cache Controller (L2CC)
- Memory Management Unit (MMU)

Functional Description

The following sections provide information on the function of the sub-system.

A5 Block Diagram

The following figure shows the primary blocks of the Cortex A5 sub-system. The performance increases with accesses to lower levels of memory as follows:

1. Level 1 – cache on-chip, separate data/code (highest)
2. Level 2 – cache on-chip, unified
3. Level 3 – memory external, (lowest)

Figure 2-1: A5 Sub-System Block Diagram

Control Co-Processor (CP15)

The system control co-processor, CP15, controls and provides status information for the functions implemented in the processor. The main functions of the system control co processor are:

- Overall system control and configuration
- MMU configuration and management
- Cache configuration and management
- System performance monitoring

All system architecture functions are controlled by reading or writing a general purpose processor register (Rt) from or to a set of registers (CRn) located within co-processor 15. The Op1, Op2, and CRm fields of the instruction can also be used to select registers or operations.

- MRC p15, Op1, Rt, CRn, CRm, Op2; read a CP15 register into an ARM register
- MCR p15, Op1, Rt, CRn, CRm, Op2; write a CP15 register from an ARM register

L1 Cache

The Cortex-A5 processor has separate instruction and data caches that run at ARM Core clock speed. The caches have the following features:

- L1-Data Cache size 32 KB
- L1-Instruction Cache size 32 KB
- Each cache can be disabled independently, using the system control coprocessor
- Cache replacement policy is pseudo random
- Data cache is 4-way set-associative
- Instruction cache is 2-way set-associative
- The cache line length is eight words.
- On a cache miss, critical word first filling of the cache is performed.

Prefetch Unit (PFU)

The PFU implements a two-level prediction mechanism, comprising the following:

- A 256 entry branch pattern history table
- A four-entry BTAC
- A four-entry return stack

Memory-Management Unit (MMU)

The ARM MMU is responsible for translating addresses of code and data from the virtual view of memory to the physical addresses in the real system. The translation is carried out by the MMU hardware and is transparent to the application. In addition, the MMU controls such things as memory access permissions, memory ordering and cache policies for each region of memory.

The MMU enables tasks or applications to be written in a way that requires them to have no knowledge of the physical memory map of the system, or about other programs that might be running simultaneously. This enables you to use the same virtual memory address space for each program. It also lets you work with a contiguous virtual memory map, even if the physical memory is fragmented. This virtual address space is separate from the actual physical map of memory in the system. Applications are written, compiled and linked to run in the virtual memory space. Virtual addresses are those used by you, and the compiler and linker, when placing code in memory. Physical addresses are those used by the actual hardware system.

The first level MMU uses a Harvard design with separate micro TLB structures in the PFU for instruction fetches and in the DPU for data read and write requests. A miss in the micro TLB results in a request to the main unified TLB shared between the data and instruction sides of the memory system. The TLB consists of a 128-entry two-way set-associative RAM based structure. The TLB page-walk mechanism supports page descriptors held in the L1 data cache. The caching of page descriptors is configured globally for each translation table base register, TTBRx, in the system coprocessor, CP15.

Page table entries support:

- 16 MB super sections
- 1 MB sections
- 64 KB large pages
- 4 KB small pages

NOTE: Virtual Memory translation tables are typically created by operating systems, and are often dynamically managed by the memory management layer. However, even a bare metal system can enable the MMU. For this, a flat mapping technique is used, where all virtual memory addresses shall be programmed exactly same as the physical memory addresses in the system.

NOTE: In order to utilize L1-Data Cache, application has to enable the MMU, via Co-Processor 15 in the ARM Core. After MMU and L1-Data Cache are enabled via CP15: SCTLR, application can disable / enable cache for individual pages / sections.

L2 Cache

The Level 2 Cache Controller in the ADSP-SC589 is a CoreLink Level 2 Cache Controller (L2C-310) from ARM and is clocked at SYSCLK speed. The addition of an on-chip secondary cache, also referred to as a Level 2 or L2 cache, is a recognized method of improving the performance of ARM-based systems when significant memory traffic is generated by the processor. By definition a secondary cache assumes the presence of a Level 1 or primary cache, closely coupled or internal to the processor. The cache controller is a unified, physically addressed, physically tagged cache. It includes the following features:

- 256 KB total size
- Lockdown by Line / Way / Master
- Fixed line length of 32 bytes, eight words or 256 bits

- Direct mapped to 8-way associativity (fixed)
- Prefetching capability
- Event monitoring
- Software option to enable exclusive cache configuration
- Additional Buffers:
  - Line Fill Buffers (LFBs)
  - Line Read Buffers (LRBs)
  - Eviction Buffers (EBs)
  - Store Buffers (STBs)
- TrustZone support, with the following features:
  - Non-Secure (NS) tag bit added in tag RAM and used for lookup in the same way as an address bit. The NS-tag bit is added in all buffers.
  - NS bit in Tag RAM used to determine security level of evictions to L3.
  - Restrictions for NS accesses for control, configuration, and maintenance registers to restrict access to secure data.
- Parity Support

NOTE: The L2CC Address Filtering registers should not be programmed by user. Not retaining the reset values can give unpredictable results.

Sharing L2 Cache with SHARC+ Cores

The L2CC (PL310) supports two master and two slave ports. The SHARC+ core can access the L2-Cache without bank conflict versus the Cortex A5 core by programming the L2CC registers. The cache access is restricted to the address range: from `CMMR_L2CC_START` [31:0] to `CMMR_L2CC_END` [31:0]. For more information, see the SHARC+ Core Programming Reference.

NOTE: There is no guarantee for the data coherency between A5 and SHARC+ cores.

NOTE: Programs should perform L2 cache write-back invalidation before changing the value of `CMMR_L2CC_START` and `CMMR_L2CC_END`.

Floating-Point Unit (FPU)

The Cortex-A5 FPU is a VFPv4-D16 implementation of the ARMv7 floating-point architecture. It provides low-cost high performance floating-point computation. The FPU supports all addressing modes and operations described in the *ARM Architecture Reference Manual*.

The features in the FPU are as follows.

- Support for single-precision and double-precision floating-point formats
- Support for conversion between half-precision and single-precision
- Support for Fused Multiply Accumulate (FMA) operations
- Normalized and de-normalized data are all handled in hardware
- Trap-less operation enabling fast execution

NeON

The Cortex-A5 NEON MPE extends the Cortex-A5 functionality to provide support for the ARM v7 Advanced SIMD v2 and Vector Floating-Point v4 (VFPv4) instruction sets. The Cortex-A5 NEON MPE supports all addressing modes and data-processing operations described in the *ARM Architecture Reference Manual*.

The Cortex-A5 NEON MPE features are:

- SIMD and scalar single-precision floating-point computation
- scalar double-precision floating-point computation
- SIMD and scalar half-precision floating-point conversion
- SIMD 8, 16, 32, and 64-bit signed and unsigned integer computation
- 8 or 16-bit polynomial computation for single-bit coefficients
- structured data load capabilities
- Large, shared register file, addressable as:
    - 32 32-bit S (single) registers
    - 32 64-bit D (double) registers
    - 16 128-bit Q (quad) registers
- The operations include:
    - Addition and subtraction
    - Multiplication with optional accumulation
    - Maximum or minimum value driven lane selection operations
    - Inverse square-root approximation
    - Comprehensive data-structure load instructions, including register-bank-resident table lookup

See the *ARM Architecture Reference Manual* for details of the extension register set.

Generic Interrupt Controller (GIC)

The GIC is an ARM Architecture compliant System-on-Chip (SoC) peripheral. It is a high-performance, area-optimized interrupt controller. The GIC implements the ARM Generic Interrupt Controller Architecture. The GIC takes interrupts asserted at the system level and signals them to each connected processor as appropriate. The GIC has the following features.

- Registers for managing interrupt sources, interrupt behavior, and interrupt routing to one or more processors
- Support for the ARM architecture Security Extensions
- Support for enabling, disabling, and generating processor interrupts from hardware (peripheral) interrupt sources
- Support for generating software interrupts
- Support for interrupt masking and prioritization

Refer to GIC Overview for more information on the ADSP-SC58x specific configuration of GIC.

Table 2-1: ADSP-SC58x *GIC Interrupt List*

Module	Event/Interrupt	SEC ID	GIC ID	SEC/GIC Interrupt Name

3 Clock Generation Unit (CGU)

The Clock Generation Unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a master clock that runs at a frequency that is a multiple of the CLKIN input clock frequency. The PCU divides down the master clock to generate various system clocks and synchronization signals.

CGU Features

The CGU module supports the following features:

- Provides smooth transitions from the current clock condition to a new condition with PLL logic and executes the changes to clocks due to register programming
- Provides PLL and clock domain status reporting for event management
- Supports the capability to bypass the PLL for power savings
- Manages power dynamically through software, allowing the dynamic control of the core clock frequency (f_{CCLK}) of the processor
- Controls clock gating of core and system clocks

NOTE: For more information about processor-specific CGU features, see the processor data sheet.

CGU Functional Description

The CGU generates all on-chip clocks and synchronization signals based on the programmed PLL multiplication factor and dividers. The CGU provides the following functionality.

Change the PLL clock frequency

The CGU allows programs to change the PLL clock frequency by writing new values to bits in the control register. Any time the PLL relocks, the CGU aligns all core and system clocks.

Change other clock frequencies

The CGU allows programs to change the CCLKn, SYSCLK, SCLKn, DCLK, and OCLK frequencies by writing values to the `CGU_DIV` register. Any time the clock frequency is changed, the OCLK, CCLKn, SYSCLK, DCLK and SCLKn clocks exit the frequency change sequence aligned.

Perform clock alignment

The CGU can align all clocks by writing to the `CGU_DIV` register. This function aligns all PLL-based clocks.

For more information on these functions, see the CGU Programming Model section.

ADSP-SC58x CGU Register List

The clock generation unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock, running at a frequency that is a multiple of the CLKIN input clock's frequency. The CGU also generates all on-chip clocks and synchronization signals. The PCU permits application software control of the PLL's operation. A set of registers govern CGU operations. For more information on CGU functionality, see the CGU register descriptions.

Table 3-1: ADSP-SC58x CGU Register List

Name	Description

CGU Definitions

DPM

The dynamic power management (DPM) works with the CGU to provide flexible power dissipation modes for the processor.

PCU

The PLL control unit (PCU) in the CGU controls PLL operations. All the MMR registers of the CGU are implemented in this unit.

PLL

The phase-locked loop (PLL) operates within the CGU.

RCU

The reset control unit (RCU) provides input to the CGU to manage clocks during processor reset.

CDU

The clock distribution unit distributes the clocks from the CGU to different clock domains

CGU

The clock generation unit (CGU) is comprised of the PLL and PCU. The CGU generates the clocks listed in the *Clock Descriptions* table.

Table 3-5: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0

DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
CCLK1_1	CCLK1 derived from CGU1
SYSCLK_1	SYSCLK derived from CGU1
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1

CGU PLL Block Diagram

The *CGU PLL Block Diagram* provides a top-level block diagram of the phase locked loop (PLL). The main blocks of the PLL are the phase/frequency detector (PFD), the charge pump, the loop filter, and the voltage controlled oscillator (VCO). The VCO multiplies the SYS_CLKINx input to a higher frequency.

NOTE: The processor supports two PLLs (CGU1–0), see the ***CDU Block Diagram*** figure in the Clock Distribution (CDU) chapter. The configuration of CGU0 is mandatory because it provides the clock to the chip infrastructure (Fabric, L2 cache, L2 system, SEC and GIC) and to some high speed peripherals.

CGU Operating Modes

The CGU does not have configurable operating modes, but CGU operations affect the operating modes of other modules. Some CGU operation issues that affect operation of other modules include the following:

- The PLL of the CGU operates in either normal mode (CGU clock divisors applied) or bypass mode (CGU PLL is bypassed and clock divisors ignored).
- The SCB uses the CGU for clock synchronization across clock domains. For more information, see System Crossbars (SCB).
- The DPM uses the CGU for clock management as power state transitions occur. For more information, see the Dynamic Power Management (DPM) chapter.
- The CGU uses clock gating control to obtain flexible low-power modes.

CGU Power-up Sequence

See the product data sheet for exact power-up requirements. The processor is configured to come up in clock bypass mode. The programs is required to configure full speed clocks and safety monitors. CLKIN0 and all supplies should be stable before the `SYS_HWRST` signal is deasserted. CLKIN1 should be stable before operation of OCU safety unit.

CGU Event Control

The CGU generates an event or error for several different reasons.

CGU Events

After a frequency change, a CGU event indicates that the PLL has locked and clocks are synchronized. If a core was idled while changing frequencies, the CGU can use an event interrupt to break the core idle. While in active mode, a CGU event indicates that the PLL has locked.

CGU Errors

A CGU error occurs under following conditions:

- A write access to the `CGU_DIV` register triggers an alignment sequence while the PLL is locked and is still aligning the clocks.

  The `CGU_STAT.WDIVERR` bit state indicates this error. If this error occurs, clear the `CGU_STAT.WDIVERR` bit and rewrite the desired values to the `CGU_DIV` register.
- A change to the `CGU_DIV` register occurs while the PLL is locked and is still aligning the clocks

  The `CGU_STAT.WDIVERR` bit state indicates this error. If this error occurs, clear the `CGU_STAT.WDIVERR` bit and rewrite the desired values to the `CGU_DIV` register.

- A write access to the `CGU_CTL.DF` bit field occurs or a write access to the `CGU_CTL.MSEL` bit field occurs while the PLL is locking.

  The `CGU_STAT.WDFMSERR` bit state indicates this error. If this error occurs, wait until the PLL has finished locking, clear the error, and rewrite the desired value change.

- A clock divisor value error occurs when the *CCLK* divisor is greater than the *SYSCLK* divisor. For example, the `CGU_DIV.CSEL` is greater than `CGU_DIV.SYSSEL`.

  The `CGU_STAT.WDIVERR` bit state indicates this error. If this error occurs, clear it. The CGU writes new values to the `CGU_DIV.CSEL` bit field, so the field is less than or equal to the `CGU_DIV.SYSSEL` bit field value.

The CGU monitors changes to the following fields:

- CCLK Divisor - `CGU_DIV.CSEL`
- SYSCLK Divisor - `CGU_DIV.SYSSEL`

CGU Generated Bus Errors

The CGU generates a bus error when a read or write transaction is attempted to an unused address within the CGU address range. It also generates a bus error when a misaligned access is made to a CGU register. In addition to the bus error, the `CGU_STAT.ADDRERR` bit is set. If a write to a write-protected CGU register is attempted, the CGU generates a bus error. In addition, the `CGU_STAT.LWERR` bit is set.

Oscillator Watchdog

The oscillator watchdog detects the absence of input clock transitions and provides a fault warning through the `SYS_FAULT` pin. To detect harmonic or subharmonic crystal oscillator behavior, the watchdog (under programmable control) also detects and reports input oscillator frequencies above and below the specified limits. Use an internal asynchronous, local 1-MHz oscillator combined with a series of programmable counters for this detection. Set the `CGU_OSCWDCTL.MONDIS` bit and clear the `CGU_OSCWDCTL.FAULTEN` bit in the control register to optionally disable all the input clock monitor and fault detection functions.

Set the `CGU_OSCWDCTL.HODEN` bit to enable harmonic oscillation detection. The CGU uses the `CGU_OSCWDCTL.HODF` bit field to indicate the desired lower fail limit for the harmonic oscillation detection in MHz. The upper limit is always twice the lower limit. The ***HODF Settings for Different Input Clock Frequencies*** table shows an example of the `CGU_OSCWDCTL.HODF` bit settings for different input clock frequencies.

Table 3-6: HODF Settings for Different Input Clock Frequencies

CGU_OSCWDCTL.HODF[5:0]	Subharmonic Frequency (MHz)	Nom. Lower Fail Limit (MHz)	Input Clock Frequency (MHz)	Nom. Upper Fail Limit (MHz)	Second Harmonic Frequency (MHz)
14	10	14	20	28	40
21	15	21	30	42	60

The CGU uses the `CGU_OSCWDCTL.BOUF` asynchronous control bit field to indicate the desired upper fail limit for the bad oscillation detection. Set the `CGU_OSCWDCTL.BOUEN` bit to enable upper-limit bad oscillation detection. A bad oscillation detection condition signals a fault before any processor operations occur. This detection occurs (even in bypass mode) whenever a clock frequency exceeds its specifications.

The `CGU_OSCWDCTL.BOUF` =0 operation starts with a target of 32 MHz and each additional LSB increases the frequency test limit by 2 MHz. For example:

Target Upper Frequency Limit = `CGU_OSCWDCTL.BOUF` × 2 MHz + 32 MHz

The `CGU_STAT.OSCWDSTATFC` status bits indicate the nature of the fault. The ***Fault Map*** table shows the fault values.

Table 3-7: Fault Map

`CGU_STAT.OSCWDSTATFC` Bitfield Values	Fault Type
0	No Fault
1	No Input Clock
2	Subharmonic CLKIN
3	Harmonic CLKIN
4	No AUX_CLK
5	CLKIN > Upper Freq Limit (BOUF)
6	Reserved
7	Multiple Limit Faults

There is a priority to the faults given in the case of multiple fault errors. The highest priority is given to No Input clock followed by No AUX_CLK. The other three fault cases share the lowest priority. Multiple limit faults are asserted if more than one type of subharmonic CLKIN, harmonic CLKIN, or BOUF faults are observed.

NOTE: All the `CGU_STAT.OSCWDSTATFC` faults other than the absence of AUX_CLK (for example, `CGU_STAT.OSCWDSTATFC` =4) are not reliable and used for debug only.

NOTE: Program and enable the OSCWDOG to match the actual crystal, before bringing the PLL out of bypass.

CGU Programming Model

The programming model for the CGU involves the various mode configuration techniques.

Configuring CGU Modes

Use the following procedures to configure the clocks and PLL.

NOTE: The program needs to perform the following sequence only once, after coming out of reset, inside the application, before changing clocks. This sequence clears the `CGU_STAT.CLKSALGN` bit:

```
*pREG_CGU0_PLLCTL |= BITM_CGU_PLLCTL_PLLBPCL; // come out of bypass and enter
Full ON
while( (pADI_CGU0 ->STAT & 0xF) != 0x5 ) { } // poll
// now clocks are running with hardware default divisors.
// now program can change frequencies If desired the program can put the PLL
again into bypass.
```

Changing Clock Frequencies

Applications change clock frequencies in two ways. The first way is modifying the PLL multiplication value by writing to the `CGU_CTL` register and the second is modifying the clock dividers by writing to the `CGU_DIV` register. Both actions have different implications even if the frequencies of the final clock are the same. Write accesses to change the `CGU_CTL.DF` or `CGU_CTL.MSEL` bit fields while the PLL is locking set the `CGU_STAT.WDFMSERR` error bit. The `CGU_STAT.WDIVERR` error bit is set when one of following accesses is attempted while the PLL is locked, but still aligning the clocks:

- A write access to the `CGU_DIV` register to trigger an alignment sequence
- A write access to the `CGU_DIV` register to change the `CGU_DIV.CSEL`, `CGU_DIV.SYSSEL`, `CGU_DIV.S0SEL`, `CGU_DIV.S1SEL`, or `CGU_DIV.DSEL` bits

Read-after-write accesses to these registers return the new value, even if the frequency of the clock change is still in-progress.

Modifying the PLL multiplier requires the PLL to relock. Once the PLL locks, the CGU synchronizes the clocks. Changes to the `CGU_CTL.DF` or `CGU_CTL.MSEL` bit field result in bypassing the PLL. By setting the `CGU_CTL.WFI` bit, programs force the PLL to wait for all the cores to return to their idle or reset states before the frequency changes. If necessary, clear the `CGU_DIV.UPDT` bit to avoid multiple clock alignment sequences. If the `CGU_DIV` register is not updated, the CGU uses the current values to determine the frequencies of the clock. It is the programs responsibility to guarantee that the new `CGU_CTL.DF` or `CGU_CTL.MSEL` and `CGU_DIV` combinations are legal.

Changing the PLL Clock Frequency

To change the phase-locked loop clock (*PLLCLK*) frequency, write new values to the `CGU_CTL.MSEL` field or `CGU_CTL.DF` field. Any time the PLL relocks, all core and system clocks are aligned.

1. Read `CGU_STAT` register and verify that:
    a. The `CGU_STAT.PLLEN` bit =1 (PLL enabled)
    b. The `CGU_STAT.PLOCK` bit =1 (PLL is not locking)
    c. The `CGU_STAT.CLKSALGN` bit =0 (clocks aligned)
2. Write the desired values to the clock divisor select fields of the `CGU_DIV` register with the `CGU_DIV.UPDT` bit =0.
3. Write the desired values to the `CGU_CTL.DF` and `CGU_CTL.MSEL` fields.

a. To change the PLL frequency while the cores are idle, write to the `CGU_CTL` register with the `CGU_CTL.WFI` bit =1.

b. To change the PLL frequency while the cores are active, write to the `CGU_CTL` register with the `CGU_CTL.WFI` bit =0.

This sequence performs these actions:

1. Updates the corresponding CGU registers
2. Bypasses the PLL
3. Makes the PLL lock to the new values in the `CGU_CTL.MSEL` or `CGU_CTL.DF` fields
4. Changes the clock frequencies
5. Exits the PLL bypass with all clocks aligned

When exiting the PLL bypass state, a CGU event occurs.

The `CGU_STAT` register exits this sequence with the `CGU_STAT.PLLEN` bit =1, the `CGU_STAT.PLOCK` bit =1, the `CGU_STAT.PLLBP` bit =0, and the `CGU_STAT.CLKSALGN` bit =0. Poll the `CGU_STAT.PLOCK` bit, `CGU_STAT.PLLBP` bit, and `CGU_STAT.CLKSALGN` bit to discover when the PLL is locked and the clocks are aligned.

Changing the frequency of the PLL is allowed while the PLL is bypassed. But, the new PLLCLK frequency is not used until the PLL is no longer bypassed.

Changing the CCLKn or SYSCLK Frequency Without Modifying the PLLCLK Frequency

To change the clock frequencies, write new values to `CGU_DIV.CSEL` or `CGU_DIV.SYSSEL` bits. The frequency change occurs only when the PLL is not bypassed. Any time the *CCLKn* or *SYSCLK* clock frequencies are changed, they exit the frequency change sequence aligned.

1. Read the `CGU_STAT` register to verify that the `CGU_STAT.CLKSALGN` bit =0 (clocks aligned).
2. Write the desired `CGU_DIV.CSEL`, `CGU_DIV.SYSSEL`, and `CGU_DIV.OSEL` bit field values with the `CGU_DIV.UPDT` bit = 1.

   ADDITIONAL INFORMATION: This write updates the `CGU_DIV` register, changes the *SCLKn* and *SYSCLK* frequencies, and aligns the clocks. When the clocks are aligned, a CGU event occurs.

The `CGU_STAT` register exits this sequence with the `CGU_STAT.CLKSALGN` bit =0. Poll the `CGU_STAT.CLKSALGN` bit to discover when the clocks are aligned. Any write attempt to change the `CGU_DIV.S0SEL` or `CGU_DIV.S1SEL` bit fields while `CGU_STAT.CLKSALGN` bit =1 (clocks alignment in progress) triggers an MMR access bus error and the `CGU_DIV` register is not modified.

Programming the *SYSCLK* frequency to a higher value than *CCLKn* also triggers an MMR access bus error and the `CGU_DIV` register is not modified.

Writing to the `CGU_DIV` register is allowed while the processor is in active (PLL bypassed) mode. But, the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Accessing the DDR memory while changing the *SYSCLK* frequency is not supported and can have unpredictable results.

Changing the OCLK Frequency

To change the *OCLK* clock frequency, write a new `CGU_DIV.OSEL` bit value. Any time the *OCLK* clock frequency is changed, the *OCLK*, *CCLKn*, *SYSCLK*, and *SCLKn* clocks exit the frequency change sequence aligned.

1. Read the `CGU_STAT` register to verify that the `CGU_STAT.CLKSALGN` bit =0 (clocks aligned).
2. Write the desired `CGU_DIV.OSEL` value with the `CGU_DIV.UPDT` bit =1.

   ADDITIONAL INFORMATION: This write updates the `CGU_DIV` register, changes the *OCLK* frequency, and aligns all clocks except *OCLK*.

The `CGU_STAT` register exits this sequence with the `CGU_STAT.CLKSALGN` bit =0. Poll the `CGU_STAT.CLKSALGN` bit to discover when the clocks are aligned. Any write attempt to change the `CGU_DIV.DSEL` field while the `CGU_STAT.CLKSALGN` bit =1 (clock alignment in progress) triggers an MMR access bus error and the `CGU_DIV` register is not modified. When the clocks are aligned, a CGU event occurs.

Writing to the `CGU_DIV.OSEL` bit field is allowed while the processor is in active (PLL bypassed) mode. But, the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Aligning All Clocks

To align the clocks, write 1 to the `CGU_DIV.ALGN` bit. The frequency can be changed, if necessary. The clocks aligned include:

- *CCLKn*
- *SYSCLK*
- *SCLKn*
- *DCLK*
- *OCLK*

1. Read the `CGU_STAT` register to verify that `CGU_STAT.CLKSALGN` bit =0 (clocks aligned).
2. Write 1 to the `CGU_DIV.ALGN` bit. All other fields can change.

   ADDITIONAL INFORMATION: This write does not alter the `CGU_DIV` register unless one of the clock-select fields is modified. When the clocks are aligned, a CGU event occurs.

The `CGU_STAT` register exits this sequence with the `CGU_STAT.CLKSALGN` bit =0. Poll the `CGU_STAT.CLKSALGN` bit to discover when the clocks are aligned. Any write to the `CGU_DIV` register intended to align clocks or to change a clock select field while the `CGU_STAT.CLKSALGN` bit =1 (clocks alignment in progress) triggers an MMR access bus error. And, the `CGU_DIV` register is not modified.

Writing 1 to the `CGU_DIV.ALGN` bit has no effect while the processor is in active (PLL bypassed) mode.

The CGU does not support accessing the DDR memory while changing the *SYSCLK* or *DCLK* frequencies. This type of access can have unpredictable results.

Shutting Off CCLKn From Another Master

CCLKn can be shut off to save power when it is not in use.

1. Disable interrupts to core n.
2. Set the `RCU_SIDIS.SI[n]` bit to disable the interfaces of core n in order to:
    a. Stop DMA accesses to its L1.
    b. Stop accesses to memory to core 0.
    c. Stop accesses to MMRs.
3. Test the `RCU_SISTAT.SI[n]` bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
4. Set the `CGU_CCBF_DIS.CCBF0` bit to disable the *CCLKn* buffer.
5. Check the `CGU_CCBF_STAT.CCBF0` bit.

If the `CGU_CCBF_STAT.CCBF0` bit is set, continue.

Reenable CCLKn From Another Master

1. Clear the `CGU_CCBF_DIS.CCBF0` to enable *CCLKn*.
2. Check the `CGU_CCBF_STAT.CCBF0` bit.
    a. If the `CGU_CCBF_DIS.CCBF0` bit is cleared, continue.
3. Clear the `RCU_SIDIS.SI[n]` bit. The core deasserts its acknowledge signal in response to the `RCU_SYSRST0`signal. This operation clears the `RCU_SISTAT.SI[n]` bit.

Valid Clock Multiplier Settings

Processor operations depend on valid settings in the `CGU_CTL` and `CGU_DIV` registers. These registers control the clock multiplier and divisor values. Set these registers such that the minimum and maximum clocks specified in the data sheet are not violated. All other clock specifications in the data sheet must also be adhered to for correct operation of the processor.

NOTE: The frequency of any processor core clock to the *SYSCLK* is either 1:1 or 2:1 only.

PLL Bypass and PLL Disable

Writing 1 to the `CGU_PLLCTL.PLLBPST` bit tells the PLL to apply OSC_CLKIN clock to *CCLK*, *SYSCLK*, *SCLK0*, *SCLK1*, *DCLK* (PLL Bypass), and *OCLK* outputs. Writing 1 to the `CGU_PLLCTL.PLLBPCL` bit tells the PLL to exit its PLL Bypass state and make all output clocks align and transition to their programmed frequencies.

The PLL can be disabled by clearing `CGU_PLLCTL.PLLEN` bit while in the bypass state. If necessary, clock buffers can be disabled. *CCLK0* and *CCLK1* clocks can be disabled or enabled by writing 1 or 0 to the corresponding bit in the `CGU_CCBF_DIS` register. To know which Core clock buffers are enabled or disabled, software reads the `CGU_CCBF_STAT` register. To know which Core clock buffers were disabled since the last read, software reads the `CGU_CCBF_STAT` register. The *SCLK0*, *SCLK1*, *DCLK* and *OCLK* clocks can be disabled or enabled by writing 1 or 0 to the corresponding bit in the `CGU_SCBF_DIS` register. Software cannot disable *SYSCLK*.

ADSP-SC5xx Specific Information

The processor has two system crystal oscillators and two system CGU units to provide the clocks to the system. Both of the CGUs come up in bypass mode out of reset.

CGU0 is the main CGU which provides the *SYSCLK (SYSCLK_0)*, *SCLK0 (SCLK0_0)*, and *SCLK1 (SCKL1_0)* to the system buses, infrastructure, and most of the peripherals. The rest of the clock outputs from the two CGUs can be routed to a specific peripheral and the cores in the system. For more details, refer to the Clock Distribution Unit (CDU) chapter.

NOTE: Frequency ratios of Core clock to *SYSCLK* are either 2:1 or 1:1.

The processor supports no other frequency ratios. Program the divider/CDU values for the *CLKO0*, *CLKO1*, and *CLKO2* carefully in relation to the divider programming for the *SYSCLK*.

ADSP-SC58x CGU Register Descriptions

Clock Generation Unit (CGU) contains the following registers.

Table 3-8: ADSP-SC58x CGU Register List

Name	Description
`CGU_CCBF_DIS`	Core Clock Buffer Disable Register
`CGU_CCBF_STAT`	Core Clock Buffer Status Register
`CGU_CLKOUTSEL`	CLKOUT Select Register

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If set (=1) the `CGU_CCBF_DIS.LOCK` bit locks the `CGU_CCBF_DIS` register.	
		0	Unlock register
		1	Lock register
1 (R/W)	CCBF1	Core Clock Buffer 1. The `CGU_CCBF_DIS.CCBF1` bit enables (=0) or disables (=1) CCLK1s buffer.	
0 (R/W)	CCBF0	Core Clock Buffer 0. The `CGU_CCBF_DIS.CCBF0` bit enables (=0) or disables (=1) CCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

Core Clock Buffer Status Register

The `CGU_CCBF_STAT` register shows which core clock buffer(s) are disabled. For example clearing the `CGU_CCBF_DIS.CCBF0` bit clears the `CGU_CCBF_STAT.CCBF0` bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

1 (R/NW)	CCBF1	Core Clock Buffer 1. The `CGU_CCBF_STAT.CCBF1` bit reports the status of the `CGU_CCBF_DIS.CCBF1` bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
0 (R/NW)	CCBF0	Core Clock Buffer 0. The `CGU_CCBF_STAT.CCBF0` bit reports the status of the `CGU_CCBF_DIS.CCBF0` bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

CLKOUT Select Register

The `CGU_CLKOUTSEL` selects the signal that the CGU drives through the CLKOUT multiplexer. Also, this register selects the divisor for the USBCLK output.

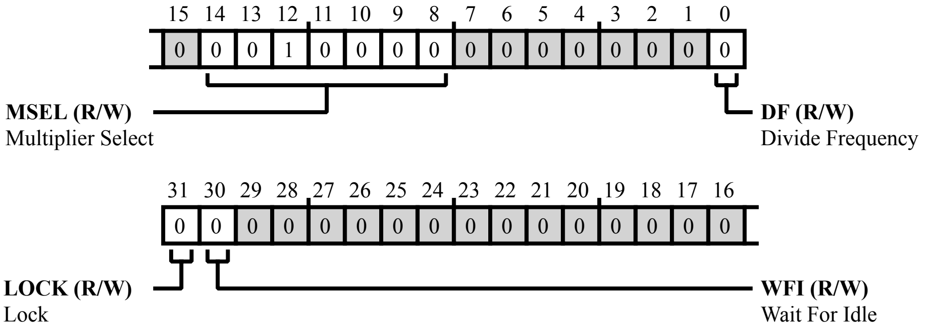
Control Register

The CGU_CTL controls the clock generation divisors for SYS_CLKIN and the PLL. Read after write accesses to the CGU_CTL register returns the new value even if the clock's frequency change is still in progress.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

LOCK (R/W)
Lock
WFI (R/W)
Wait For Idle

Figure 3-6: CGU_CTL Register Diagram

Table 3-12: CGU_CTL Register Fields

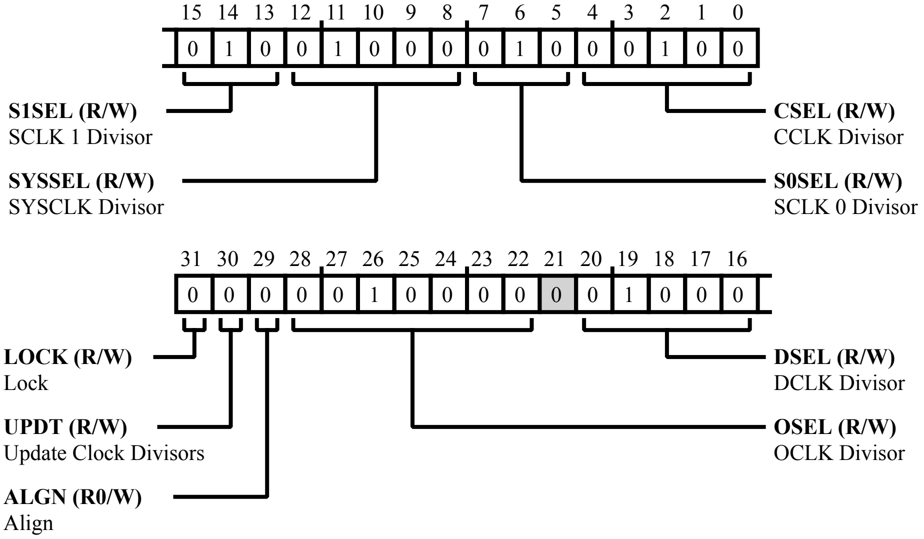
Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (`SPU_CTL.GLCK` bit =1) and the `CGU_CTL.LOCK` bit is set, the `CGU_CTL` register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	WFI	Wait For Idle. Modifying the PLL multiplier requires the PLL to re-lock and once the PLL locks, clocks have to be synchronized. Changes to the `CGU_CTL.MSEL` and the `CGU_CTL.DF` bit values results in bypassing the PLL. The `CGU_CTL.WFI` bit forces the PLL to wait for all processor cores to be in an idle or reset state before changing frequencies as a result of changes to the `CGU_CTL.MSEL` or `CGU_CTL.DF` bits. Write accesses to the `CGU_CTL` to change the `CGU_CTL.DF` or `CGU_CTL.MSEL` bit values while the PLL is locking sets the `CGU_STAT.WDFMSERR` bit.	
		0	Update Immediately
		1	Wait for Idle

Table 3-12: CGU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:8 (R/W)	MSEL	Multiplier Select. The `CGU_CTL.MSEL` bit field selects the multiplier in the PLLCLK equation: PLLCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL Where the value of MSEL is between 1 and 127.	
		0	MSEL = 128
		1-127	MSEL = 1 to 127
0 (R/W)	DF	Divide Frequency. The `CGU_CTL.DF` bit selects whether or not the CLKIN input is divided by two before being passed to the PLL.	
		0	Pass OSC_CLKIN to PLL
		1	Pass OSC_CLKIN/2 to PLL

Clocks Divisor Register

The CGU_DIV register controls clock divisors for core clocks, system clocks, external (off core) memory clocks, and output clock. Read after write accesses to the CGU_DIV register returns the new value even if the clock's frequency change is still in progress.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 3-13: CGU_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_DIV.LOCK bit is set, the CGU_DIV register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	UPDT	Update Clock Divisors. The CGU_DIV.UPDT controls whether the CGU drives new CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and CGU_DIV.OSEL values to PLL after CGU_DIV register update.	
		0	No PLL Update
		1	Drive Updated SEL Values to PLL

Table 3-13: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R0/W)	ALGN	Align. The `CGU_DIV.ALGN` directs the CGU to align the PLL-based clocks. The divisor selections (`CGU_DIV.CSEL`, `CGU_DIV.SYSSEL`, `CGU_DIV.S0SEL`, `CGU_DIV.S1SEL`, `CGU_DIV.DSEL`, and/or `CGU_DIV.OSEL`) do not have to change.	
		0	No Action
		1	Align PLL Clocks
28:22 (R/W)	OSEL	OCLK Divisor. The `CGU_DIV.OSEL` selects the divisor in the OCLK equation: OCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL / `CGU_DIV.OSEL` Where the value of `CGU_DIV.OSEL` is between 1 and 127.	
		0	OSEL = 128
		1-127	OSEL = 1 to 127
20:16 (R/W)	DSEL	DCLK Divisor. The `CGU_DIV.DSEL` selects the divisor in the DCLK equation: DCLK frequency = (SYS_CLKIN frequency/(DF+1)) MSEL/`CGU_DIV.DSEL` Where the value of `CGU_DIV.DSEL` is between 1 and 31.	
		0	DSEL = 32
		1-31	DSEL = 1 to 31
15:13 (R/W)	S1SEL	SCLK 1 Divisor. The `CGU_DIV.S1SEL` selects the divisor in the SCLK1 equation: SCLK1 frequency = (SYSCLK frequency) / `CGU_DIV.S1SEL` Where the value of `CGU_DIV.S1SEL` is between 1 and 7.	
		0	S1SEL = 8
		1-7	S1SEL = 1 to 7
12:8 (R/W)	SYSSEL	SYSCLK Divisor. The `CGU_DIV.SYSSEL` selects the divisor in the SYSCLK equation: SYSCLK frequency = (SYS_CLKIN frequency/(DF+1)) MSEL/`CGU_DIV.SYSSEL` Where the value of `CGU_DIV.SYSSEL` is between 1 and 31.	
		0	SYSSEL = 32
		1-31	SYSSEL = 1 to 31

Table 3-13: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:5 (R/W)	S0SEL	SCLK 0 Divisor. The `CGU_DIV.S0SEL` selects the divisor in the SCLK0 equation: SCLK0 frequency = (SYSCLK frequency) / `CGU_DIV.S0SEL` Where the value of `CGU_DIV.S0SEL` is between 1 and 7.	
		0	S0SEL = 8
		1-7	S0SEL = 1 to 7
4:0 (R/W)	CSEL	CCLK Divisor. The `CGU_DIV.CSEL` selects the divisor in the CCLK equation: CCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL / `CGU_DIV.CSEL` Where the value of `CGU_DIV.CSEL` is between 1 and 31.	
		0	CSEL = 32
		1-31	CSEL= 1 to 31

Oscillator Watchdog Register

The CGU_OSCWDCTL register configures the CGU to allow the detection of the absence of input clock transitions and provides a fault warning via the SYS_FAULT pin. The CGU_OSCWDCTL register also detects and reports input oscillator frequencies above and below specified limits, in order to specifically detect harmonic or sub-harmonic crystal oscillator behavior. This detection is achieved by using an internal asynchronous, local 1 MHz oscillator combined with a series of programmable counters.

Figure 3-13: CGU_STAT Register Diagram

Table 3-19: CGU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W1C)	PCFGERR	PLL Configuration Error. If the `CGU_PLLCTL.PLLBPST` and the `CGU_PLLCTL.PLLBPCL` bits are set (=1) simultaneously or the `CGU_PLLCTL.PLLDIS` bit was set (=1) in full-on mode or while trying to enter full-on mode (`CGU_PLLCTL.PLLBPCL` =1), the `CGU_STAT.PCFGERR` bit triggers the bus error.	
		0	No Error
		1	Configuration Error

Table 3-19: CGU_STAT Register Fields (Continued)

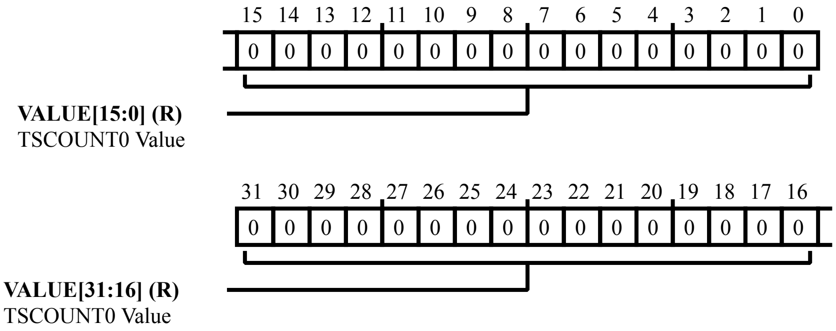
Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W1C)	WDIVERR	Write to DIV Error. The `CGU_STAT.WDIVERR` bit indicates a write access to the `CGU_DIV` register (to trigger an alignment sequence or to change the `CGU_DIV.CSEL`, `CGU_DIV.SYSSEL`, `CGU_DIV.S0SEL`, `CGU_DIV.S1SEL`, or `CGU_DIV.DSEL` bit values) while the PLL is locked, but still aligning the clocks. Read after write accesses to the `CGU_STAT` and `CGU_DIV` registers return the new value even if the clock frequency change is still in progress.	
		0	No Error
		1	Write DIV Error
19 (R/W1C)	WDFMSERR	Write to DF or MSEL Error. The `CGU_STAT.WDFMSERR` bit indicates a write access to the `CGU_CTL` register to change the `CGU_CTL.DF` or `CGU_CTL.MSEL` bit values while the PLL is locking.	
		0	No Error
		1	Write DF/MSEL Error
17 (R/W1C)	LWERR	Lock Write Error. The `CGU_STAT.LWERR` bit indicates an attempt to write to write-protected (locked) CGU registers. The CGU issues a bus error for this condition.	
		0	No Error
		1	Lock Write Error
16 (R/W1C)	ADDRERR	Address Error. The `CGU_STAT.ADDRERR` bit indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The CGU issues a bus error for this condition.	
		0	No Error
		1	Address Error
15 (R/NW)	OSCWDSTATF	Oscillator Watchdog Status Fault. The `CGU_STAT.OSCWDSTATF` bit indicates a fault in the oscillator watchdog (CGU's OSC_WDSTAT[1:0]) input pins.	
		0	No Fault
		1	Fault
14:12 (R/NW)	OSCWDSTATFC	Oscillator Watchdog Status Fault Code. The `CGU_STAT.OSCWDSTATFC` bit field indicates the nature of the fault in the oscillator watchdog (CGU's OSC_WDSTAT[1:0]) input pins.	
		0	No Fault
		1	No Input Clock

Table 3-19: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	Subharmonic CLKIN
		3	Harmonic CLKIN
		4	No AUX_CLK
		5	CLKIN > Upper Frequency Limit (BOUF)
		6	Reserved
		7	Multiple Limit Faults
3 (R/NW)	CLKSALGN	Clock Alignment. The `CGU_STAT.CLKSALGN` bit indicates whether a clock alignment sequence is in progress. This bit is set when clocks alignment is required by changes to `CGU_DIV.CSEL`, `CGU_DIV.S0SEL`, `CGU_DIV.S1SEL`, `CGU_DIV.DSEL`, or `CGU_DIV.OSEL`. The `CGU_STAT.CLKSALGN` bit is cleared when clocks are aligned. Note that (after a PLL frequency change in active state) the `CGU_STAT.CLKSALGN` bit may indicate that clocks are not aligned even though the clocks are aligned (all clocks are aligned and running at CLKIN frequency).	
		0	Clocks are Aligned
		1	Clocks not Aligned (alignment in progress)
2 (R/NW)	PLOCK	PLL Lock. The `CGU_STAT.PLOCK` bit indicates whether the PLL is locked. This bit is set when the PLL locks (PLL lock counter end-of-count). The `CGU_STAT.PLOCK` bit is cleared when requested PLL frequency change (for PLL reset, PLL disable-to-enable transition, or a change to the `CGU_CTL.MSEL` or `CGU_CTL.DF` values) is in progress.	
		0	PLL not Locked (PLL frequency change in progress)
		1	PLL Locked
1 (R/NW)	PLLBP	PLL Bypass. The `CGU_STAT.PLLBP` bit indicates whether the PLL is bypassed. The default value for the `CGU_STAT.PLLBP` bit is determined by the bypass strap pin.	
		0	PLL not Bypassed
		1	PLL Bypassed
0 (R/NW)	PLLEN	PLL Enable. The `CGU_STAT.PLLEN` bit indicates whether the PLL is enabled.	
		0	Disabled
		1	Enabled

Time Stamp Counter 32 LSB Register

The `CGU_TSCOUNT0` register address is used to read the CoreSight time stamp counter LSB 32-bit (bits [31:0]) value.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Counter's 32 LSB Initial Value

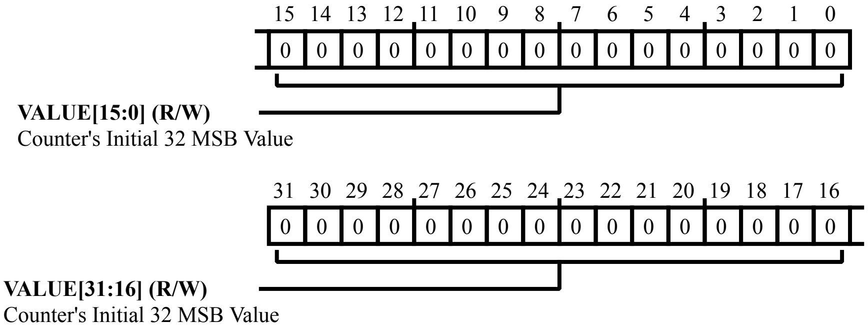
Figure 3-17: CGU_TSVALUE0 Register Diagram

Table 3-23: CGU_TSVALUE0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's 32 LSB Initial Value. The `CGU_TSVALUE0.VALUE` bit field holds the LSBs value that is initially loaded to the CoreSight time stamp counter.

Time Stamp Counter Initial MSB Value Register

The `CGU_TSVALUE1` register holds the most significant bits (bits [63:32]) value that is initially loaded to the CoreSight time stamp counter.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Counter's Initial 32 MSB Value
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Counter's Initial 32 MSB Value

Figure 3-18: CGU_TSVALUE1 Register Diagram

Table 3-24: CGU_TSVALUE1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's Initial 32 MSB Value. The `CGU_TSVALUE1.VALUE` bit field holds the MSBs value that is initially loaded to the CoreSight time stamp counter.

4 Clock Distribution Unit (CDU)

The Clock Distribution Unit (CDU) consists of an array of multiplexors that select clocks originated from up to four different clock sources. These sources are different clocks that are generated from the CGUs. The multiplexors are configured by software. All clocks multiplexors have up to four different sources. Unused input clocks are grounded internally and never selected. The output clock signal for each multiplexor is assigned to one or more destinations within the processor as shown in CDU Clock Configuration Options.

CDU Features

The CDU modules supports the following features:

- Generation of up to 10 output clocks
- Output clock buffers that can be disabled by software
- Each multiplexor has four input clocks
- Multiplexors that are configured by writing to configuration registers (`CDU_CFG[n]`)
- Clocks originated in CGU0 that are selected by default
- A CDU status register (`CDU_STAT`) that indicates a configuration change is in-progress
- The processor supports 2 independent CGUs: CGU0 is used mandatory, CGU1 is used optional

CDU Functional Description

The CDU functions as a set of software-configurable multiplexors that select clocks from different sources.

CDU Block Diagram

The ***CDU Block Diagram*** figure shows the functional blocks within the CDU. As shown in the figure, the CDU takes different clocks generated by the CGU blocks and provides flexibility to route any clock from possible options as shown in CDU Clock Configuration Options to the output CDU clocks. The output clocks from the CDU are connected to specific targets such as the core, DDR, or CAN module. These targets are clocked though the CDU output clocks rather than being directly clocked by CGU clocks.

This configuration provides the flexibility to meet the specific clock requirements of the different modules in the system (core, DDR, or CAN module) without compromising the clocking of other modules. Such a flexibility is not possible with a single CGU in the system. With two CGUs:

- Each CGU has its own set of clock multipliers and dividers, providing a greater number of orthogonal clocks than possible with a single CGU.
- Each CGU can be clocked from a different CLKIN source, providing additional flexibility.
- CGU0 is always clocked by CLKIN0, whereas CGU1 can be clocked either by CLKIN0 or CLKIN1.

CDU Definitions

The *Clock Descriptions* table provides a brief description of the clocks supported by the processor.

Table 4-1: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
CCLK1_1	CCLK1 derived from CGU1

Table 4-1: Clock Descriptions (Continued)

Clock	Description
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1
CDU_CLKOn	Clocks that come out from the CDU that go to different blocks.

CDU Clock Configuration Options

The ***CDU Targets*** table provides information on clock source and destination options.

Table 4-2: CDU Targets

CDU0 Input				CDU0 Output	Target
CCLK0_0	SYSCLK_0	N/A	N/A	CDU_CLKO0	Core1 (SHARC1)
CCLK0_0	SYSCLK_0	N/A	N/A	CDU_CLKO1	Core2 (SHARC2)
CCLK1_0	SYSCLK_0	N/A	N/A	CDU_CLKO2	Core0 (ARM A5)

CDU Programming Model

The `CDU_CFG[n]` registers are a system configuration resource. These registers are accessed by a system configuration routine that also handles the configuration of other system modules. Writes to a `CDU_CFG[n]` register must occur when there is not a CDU_CLKOn configuration change in progress. If a CGUn inputs are selected, that CGUn configuration must be completed first.

Changing the PLL and Clock Frequency

1. Read the `CGU_STAT` register. Verify that:
   - `CGU_STAT.PLLEN` =1 (enabled)
   - `CGU_STAT.PLOCK` =1 (PLL is not locking)
   - `CGU_STAT.CLKSALGN` =0 (clocks aligned)
2. Write the desired values into the `CGU_DIV.CSEL`, `CGU_DIV.S0SEL`, `CGU_DIV.SYSSEL`, `CGU_DIV.S1SEL`, `CGU_DIV.DSEL` and `CGU_DIV.OSEL` bits with the `CGU_DIV.UPDT` bit cleared (= 0).
3. Write the desired values to the `CGU_CTL.DF` and `CGU_CTL.MSEL` bits.

- To change the PLL frequency while all cores are idle, set the `CGU_CTL.WFI` bit (=1).
- To change the PLL frequency while the cores are active, clear the `CGU_CTL.WFI` bit (=0).

4. Read the `CGU_STAT` register. Verify that:
   - `CGU_STAT.PLLEN` = 1 (enabled)
   - `CGU_STAT.PLOCK` = 1 (not locking)
   - `CGU_STAT.CLKSALGN` = 0 (clocks aligned)
5. If clocks switch from CGUm clocks to CGUn input clocks, read the `CGU_SCBF_STAT` and `CGU_CCBF_STAT` registers. The `CGU_CCBF_STAT`[1:0] bit field corresponds to the CCLK1 and CCLK0 clock buffers, respectively. The `CGU_SCBF_STAT`[3:0] bit field corresponds to the OUTCLK, DCLK, SCLK1, and SCLK0 clock buffers, respectively.
6. Read the `CDU_STAT` register. Verify that the `CDU_STAT.CLKO0` through `CDU_STAT.CLKO9` bits =0 (no CLKOn configuration change in progress).
7. Write to the `CDU_CLKINSEL` register to select the CGU's CLKIN input clock.
8. Write to the `CDU_CFG[n].SEL` bit to select the clock source (the `CDU_CFG[n].EN` bit should =1.)
9. Read the `CDU_CFG[n]` register. Verify that the `CDU_CLKINSEL` has the programmed value.
10. Verify that the `CDU_STAT.CLKO0` through `CDU_STAT.CLKO9` bits =0.

CLKOn is reconfigured.

Changing the Clock Frequency

Use the following procedure to change a clock frequency.

1. Read the `CGU_STAT` register to verify that the `CGU_STAT.CLKSALGN` bit =0 (clocks aligned).
2. Write the desired values into the `CGU_DIV.CSEL`, `CGU_DIV.S0SEL`, `CGU_DIV.SYSSEL`, `CGU_DIV.S1SEL`, `CGU_DIV.DSEL` and `CGU_DIV.OSEL` bits with the `CGU_DIV.UPDT` bit =1.
3. Read the `CGU_DIV` registers to verify that the `CGU_DIV.CSEL`, `CGU_DIV.S0SEL`, `CGU_DIV.SYSSEL`, `CGU_DIV.S1SEL`, `CGU_DIV.DSEL` and `CGU_DIV.OSEL` bit values are correct.
4. Read the `CGU_STAT` register to verify that the `CGU_STAT.CLKSALGN` =0 (clocks aligned).
5. If clocks switch from CGUm clocks to CGUn input clocks, read the `CGU_SCBF_STAT` and `CGU_CCBF_STAT` registers. The `CGU_CCBF_STAT`[1:0] bit field corresponds to the CCLK1 and CCLK0 clock buffers, respectively. The `CGU_SCBF_STAT`[3:0] bit field corresponds to the OUTCLK, DCLK, SCLK1, and SCLK0 clock buffers, respectively.
6. Read the `CDU_STAT` register. Verify that the `CDU_STAT.CLKO5` through `CDU_STAT.CLKO9` bits =0 (No CLKOn configuration change in progress).

7. Write to the `CDU_CFG[n].SEL` bit to select the clock source (the `CDU_CFG[n].EN` bit should =1).
8. Read the `CDU_CFG[n]` register. Verify that the `CDU_CLKINSEL` has the programmed value.
9. Verify that the `CDU_STAT.CLKO0` through `CDU_STAT.CLKO9` bits =0.

ADSP-SC58x CDU Register Descriptions

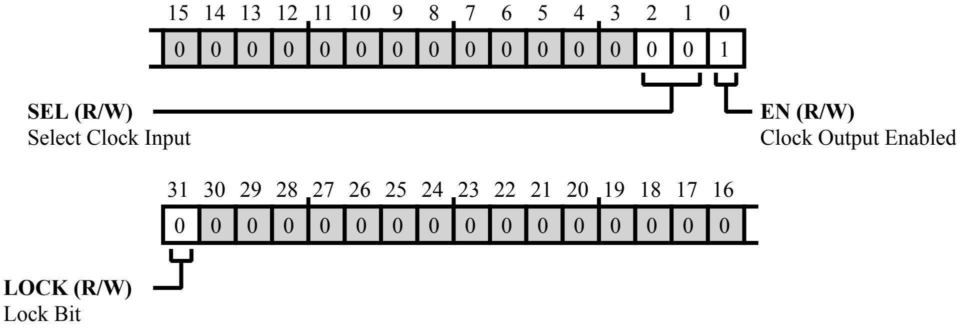
Clock Distribution Unit (CDU) contains the following registers.

Table 4-4: ADSP-SC58x CDU Register List

Name	Description
`CDU_CFG[n]`	CDU Configuration
`CDU_CLKINSEL`	CLKIN Select
`CDU_REVID`	CDU Revision ID
`CDU_STAT`	CDU Status

CDU Configuration

The `CDU_CFG[n]` registers control the configuration of the clock multiplexors. CDU0_CFG[n] corresponds to output clock CDU_CLKO[n].



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

5 Dynamic Power Management (DPM)

The dynamic power management (DPM) unit of the processor controls transitions between different power-saving modes.

DPM Features

The DPM allows programs to control the power mode of the processor as follows.

- Permits operation of multiple, external wake-up sources

DPM Functional Description

The DPM can be programmed to transition between power modes.

ADSP-SC58x DPM Register List

A set of registers govern DPM operations. For more information on DPM functionality, see the DPM register descriptions.

Table 5-1: ADSP-SC58x DPM Register List

Name	Description
DPM_CTL	Control Register
DPM_PER_DIS0	Peripherals Disable Register 0
DPM_PER_DIS1	Peripherals Disable Register 1
DPM_REVID	Revision ID
DPM_STAT	Status Register

DPM Definitions

To make the best use of the DPM, it is useful to understand the following terms.

CGU

Acronym for the clock generation unit (CGU), which is comprised of the PLL and PCU

DPM

Acronym for the dynamic power management (DPM) controller.

Full-on mode

The normal operating mode in which all clock domains are derived from the PLL.

PCU

Acronym for the PLL control unit (PCU).

PLL

Acronym for the phase-locked loop (PLL).

RCU

Acronym for the reset control unit (RCU).

DPM Operating Modes

The DPM includes several operating modes. The modes are:

- Reset
- Full-on

Reset State

Reset is the initial state of the processor and is the result of a hardware or software triggered event. The DPM itself does not trigger entering reset. The external `SYS_HWRST` pin or the RCU triggers entering reset. The DPM responds to reset by transitioning to its default state.

From Reset, the DPM always transitions to PLL Bypassed state.

Full-on Mode

Full-on mode is the default state of the DPM after Reset.

In full-on mode, the processor can reach its maximum clock rate and power dissipation can be at its highest.

DPM Event Control

The DPM event is triggered when an enabled wake-up is asserted. The DPM generates bus errors when a misaligned access to a register occurs. It also generates errors when an attempt is made to access unused DPM address space or a write-protected register.

DPM Events

The DPM event interrupt is triggered when any bit in the `DPM_STAT` register is set, indicating that an enabled wake-up was asserted. The DPM event interrupt stays active until the user clears any bits that are set in the `DPM_STAT` register.

DPM Errors

The DPM generates a bus error when a read or write transaction is attempted to an unused address within the DPM address range. It also generates a bus error when a misaligned access is made to a DPM register. In addition to the bus error, the DPM sets the `DPM_STAT.ADDRERR` bit.

If a write to a write-protected DPM register is attempted, the DPM generates a bus error. In addition, the DPM sets the `DPM_STAT.LWERR` bit.

DPM Programming Model

The ***DPM_PER_DIS0 Register Mapping*** table shows the module clocks and the corresponding peripheral. The `DPM_PER_DIS0` register is used to shut off the clock to each peripheral if it is not required by the application.

NOTE: In the table, SMPU-L2CTL-CL2_x and SMPU-L2CTL-DL2_x correspond to the SMPU modules associated with the core and the DMA ports of L2 respectively. The six instances of SMPU blocks are shown in the Figure 9-1 ADSP-SC58x Complete L2 System Block Diagram – two SMPUs for each L2CLTL, one for the port 0-core and another for the port 1-DMA.

ADSP-SC58x DPM Register Descriptions

Dynamic Power Management (DPM) contains the following registers.

Table 5-4: ADSP-SC58x DPM Register List

Name	Description
`DPM_CTL`	Control Register
`DPM_PER_DIS0`	Peripherals Disable Register 0
`DPM_PER_DIS1`	Peripherals Disable Register 1
`DPM_REVID`	Revision ID
`DPM_STAT`	Status Register

Control Register

The `DPM_CTL` register controls sleep modes selections and PLL operations of the DPM. A write protect feature permits locking out changes to this register.

6 Reset Control Unit (RCU)

Reset is the initial state of the whole processor at power-on or the run-time state of any core, as controlled by another core in the device via the RCU or as a a result of a hardware or software triggered event. In this state, all control registers are set to their default values and functional units are idle. Exiting a full system hardware reset results with only the host core being released from reset and ready to boot (Core 0 on ADSP-SC58x devices, Core 1 on ADSP-215xx devices). The following table shows the cores that are released from reset.

Additional information on reset and booting can be found in Boot ROM and Booting the Processor.

Product	Core Released from Reset by RCU
ADSP-SC58x	Core ID = 0
ADSP-2158x	Core ID = 1

The Reset Control Unit (RCU) controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. Programs must guarantee that none of the reset functions puts the system into an undefined state or causes resources to stall. This functionality is important when only one of the cores is reset (programs must ensure that there is no pending system activity involving the core that is being reset). While core resets and software system resets are controlled directly in the RCU, hardware resets can come from the TRU, the SEC, or the CGU Oscillator Watchdog.

RCU Features

The RCU module supports the following features:

- Hardware reset through the $\overline{\texttt{SYS\_HWRST}}$ pin
- Software system reset through the RCU control (`RCU_CTL`) register
- Hardware system reset through:
    - TRU module
    - SEC module (System Fault Unit)
- A clock not good reset state (safe state of chip under reset) from the Oscillator Watchdog.
- Core reset through RCU Core Reset Output (`RCU_CRCTL`) register

RCU Functional Description

This section provides information on the function of RCU module.

Hardware reset using SYS_HWRST pin

Asserting the `SYS_HWRST` pin resets all functional units, except the real time clock (RTC) (if present).

Hardware reset through RCU

The RCU can perform a full system reset which can be initiated through hardware blocks like the SEC, the TRU, and the oscillator watchdog.

Software reset using RCU registers

Setting the `RCU_STAT.SWRST` bit issues a software reset for all system units except the RTC module and `RCU_BCODE`, `RCU_CRCTL` and `RCU_STAT` registers.

Core reset RCU registers

A core can be individually reset by software, or by setting the `RCU_CRCTL.CR[n]` bit.

ADSP-SC58x RCU Register List

The Reset Control Unit (RCU) controls how all the functional units in the processor enter and exit Reset. Differences in functional requirements and clocking constraints exist (units in different clock domains have to enter reset asynchronously, but units exit reset in a deterministic way), and these differences define how reset signals are generated. Reset signals propagate through all functional units asynchronously. For more information on RCU functionality, see the RCU register descriptions.

Table 6-1: ADSP-SC58x RCU Register List

Name	Description
`RCU_BCODE`	Boot Code Register
`RCU_CRCTL`	Core Reset Outputs Control Register
`RCU_CRSTAT`	Core Reset Outputs Status Register
`RCU_CTL`	Control Register
`RCU_MSG`	Message Register
`RCU_MSG_CLR`	Message Clear Bits Register
`RCU_MSG_SET`	Message Set Bits Register
`RCU_SIDIS`	System Interface Disable Register
`RCU_SISTAT`	System Interface Status Register

Table 6-1: ADSP-SC58x RCU Register List (Continued)

Name	Description
`RCU_STAT`	Status Register
`RCU_SVECT0`	Software Vector Register 0
`RCU_SVECT1`	Software Vector Register 1
`RCU_SVECT2`	Software Vector Register 2
`RCU_SVECT_LCK`	SVECT Lock Register

ADSP-SC58x RCU Trigger List

Table 6-2: ADSP-SC58x RCU Trigger List Masters

Trigger ID	Name	Description	Sensitivity
None			

Table 6-3: ADSP-SC58x RCU Trigger List Slaves

Trigger ID	Name	Description	Sensitivity
50	`RCU0_SYSRST0`	RCU0 System Reset 0	Pulse
51	`RCU0_SYSRST1`	RCU0 System Reset 1	Pulse

RCU Definitions

To make the best use of the RCU, it is useful to understand the terms in this section.

The target or source defines the following are types of resets.

Hardware Reset (by target)

All functional units except a small subsection of debug interfaces are set to their default states. State is lost in all non-volatile storage.

System Reset (by target)

All functional units except the RCU, flash interface, and debug are set to their default states.

Core n Only Reset (by target)

Affects Core n only. The system software must guarantee that a bus master cannot access the core in reset state.

Hardware Reset (by source)

The $\overline{\texttt{SYS\_HWRST}}$ input signal is asserted active (pulled low).

System Reset (by source)

Software can trigger the reset by writing to the `RCU_CTL` register or by another functional unit such as the TRU or any of the generic reset inputs.

RCU Architectural Concepts

To understand the architecture of the RCU, it is important to consider the reset sources and how differing resets affect the functional units of the processor.

The RCU provides the hardware that controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. For example, units in different clock domains must enter reset asynchronously but exit reset in a deterministic way.

The program must guarantee that none of the reset functions put the system in an undefined state or cause resources to stall. This functionality is important when only one of the cores is reset. The program must guarantee that there is no pending system activity involving Core n before it is reset. For example, there must be no pending transactions to core 0 when the core 0 is reset and vice-versa.

The ***RCU Reset Sources*** table defines how reset sources affect the different functional units.

Table 6-4: RCU Reset Sources

Reset Source	Reset Type	Affected Functional Units
$\overline{\texttt{SYS\_HWRST}}$ pin assertion	Hardware Reset	All functional units, except RTC (if present)
SYSCLK clock domain system reset by fault unit (FMU) or TRU master	System Reset	All functional units, except: • RTC (if present), • RCU_STAT, • RCU_BCODE, and • the units on the VDDEXT power domain
`RCU_CTL.SYSRST` bit set (software triggered reset)	System Reset	All functional units, except: • RTC (if present), • RCU_STAT, • RCU_BCODE, and • the units on the VDDEXT power domain
`RCU_CRCTL.CR[n]` bit set (software triggered reset)	Core Only Reset	Core n only, for $(2 \geq n \geq 0)$

RCU Status and Error Signals

The `RCU_STAT` register reflects status and error information. There are three kinds of errors that can occur in the RCU. The reset out error is triggered when `RSTOUT` is both asserted and deasserted at the same time. The lock write error occurs if an attempt is made to write a lock RCU register. The address error occurs if a read-only register is written to or if an attempt is made to a reserved address within the RCU MMR address range.

Resetting the ARM Core through Another Core or System Master

The RCU allows reset of a given core n using another core or system master. Core 0 can be individually reset by software, either setting any of CR0 bit in the `RCU_CRCTL` register. Cores that reset themselves cannot guarantee that all the system transactions to or from it have completed. Although a core n reset can be triggered by core n itself, it is recommended that another core or system master trigger it. Core n can be reset to restore its functionality when it cannot execute software.

The following steps show the suggested programming sequence to reset core n only.

1. Clear the `RCU_CRSTAT.CR[n]` bit.
2. Disable interrupts to core n
3. Set the `RCU_SIDIS.SI[n]` bit to disable the interfaces for core n, to stop DMA accesses to its L1, to stop accesses to memory for core n, and stop accesses to MMRs.
4. Test the `RCU_SISTAT.SI[n]` bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
5. Set the `RCU_CRCTL.CR[n]` bit to reset core n.
6. Poll the `RCU_CRSTAT.CR[n]` bit until core n is in reset.
7. Once the core is in reset, clear the `RCU_SIDIS.SI[n]` bit to reenable the core interfaces.
8. Clear the `RCU_CRCTL.CR[n]` bit to take core n out of reset.
9. Poll the `RCU_CRSTAT.CR[n]` bit until core n is out of reset.

Resetting a SHARC+ Core Through Another Core

Resetting a SHARC+ core involves a software handshake between the Master core which issues a reset to the SHARC+ core. The handshake is done using a core interrupt along with message passing through a variable in shared L2 memory RAM. Each SHARC+ core needs two bits for handshaking.

- Core Reset Request bit (CRR). This bit is set by the master core to indicate to the SHARC+ core that a core reset needs to be done. If the CRR bit is set the SHARC+ core should disable all interrupts, stop all system and memory accesses and enter the IDLE state.
- IDLE acknowledgement (IDLE). Once the SHARC+ core is ready for reset, it sets this bit before entering the IDLE state to inform the master core that it is ready for reset.

Two bits are needed for SHARC0 core and two bits are needed for SHARC1 core. These bits are:

- CCR0 – SHARC0 core reset request bit in shared variable
- IDLE0 – SHARC0 IDLE acknowledgement bit in shared variable
- CCR1 – SHARC1 core reset request bit in shared variable
- IDLE1 – SHARC1 IDLE acknowledgement bit in shared variable

Use the following programming to reset the SHARC+ core.

1. The master core checks the IDLE status bits in shared variable for the corresponding SHARC+ core (`RCU_MSG.C1IDLE` and `RCU_MSG.C0IDLE`).
2. If one of the core idle bits is set then the program jumps to step 10. Otherwise the process continues to step 3.
3. The master core sets the CCRx bit in message register and raises the SOFT0 software interrupt through the SEC to the SHARC+ core (see Programming Examples for more information).
4. The SHARC+ core goes to into the ISR, and checks the “CCRx” status bit in RCU_MSG register to ensure that software interrupt is for core reset.

   ADDITIONAL INFORMATION: The SOFT0 software interrupt handler can be used for other non-reset/ general purposes as well.

   ADDITIONAL INFORMATION: The ISR should be in L1 memory.
5. The core should disable all interrupts before entering IDLE for reset.
6. The core sets the appropriate idle status bit (`RCU_MSG.C1IDLE` and `RCU_MSG.C0IDLE`).
7. Core enters IDLE.
8. Master core polls for the IDLEx status bit
9. The master core keeps a timeout option where if within N number of cycles the SHARC core doesn’t respond then a system reset is initiated.

   ADDITIONAL INFORMATION: N can be decided by the user depending on timing criticality of the application.
10. Once the IDLEx status bit is found set, the master core initiates a core reset though the RCU.
11. Clear the `RCU_CRSTAT.CR[n]` bit.
12. Set the `RCU_SIDIS.SI[n]` bit to disable the interfaces for core n, to stop DMA accesses to its L1, to stop accesses to memory for core n, and stop accesses to MMRs.
13. Test the `RCU_SISTAT.SI[n]` bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
14. Set the `RCU_CRCTL.CR[n]` bit to reset core n.

15. Poll the `RCU_CRSTAT.CR[n]` bit until core n is in reset.
16. Once the core is in reset, clear the `RCU_SIDIS.SI[n]` bit to re-enable the core interfaces.
17. Clear the `RCU_CRCTL.CR[n]` bit to take core n out of reset.
18. Poll the `RCU_CRSTAT.CR[n]` bit until core n is out of reset.

If a core is servicing a higher priority interrupt and gets stuck then it may not respond to the SEC.

ADSP-SC58x RCU Register Descriptions

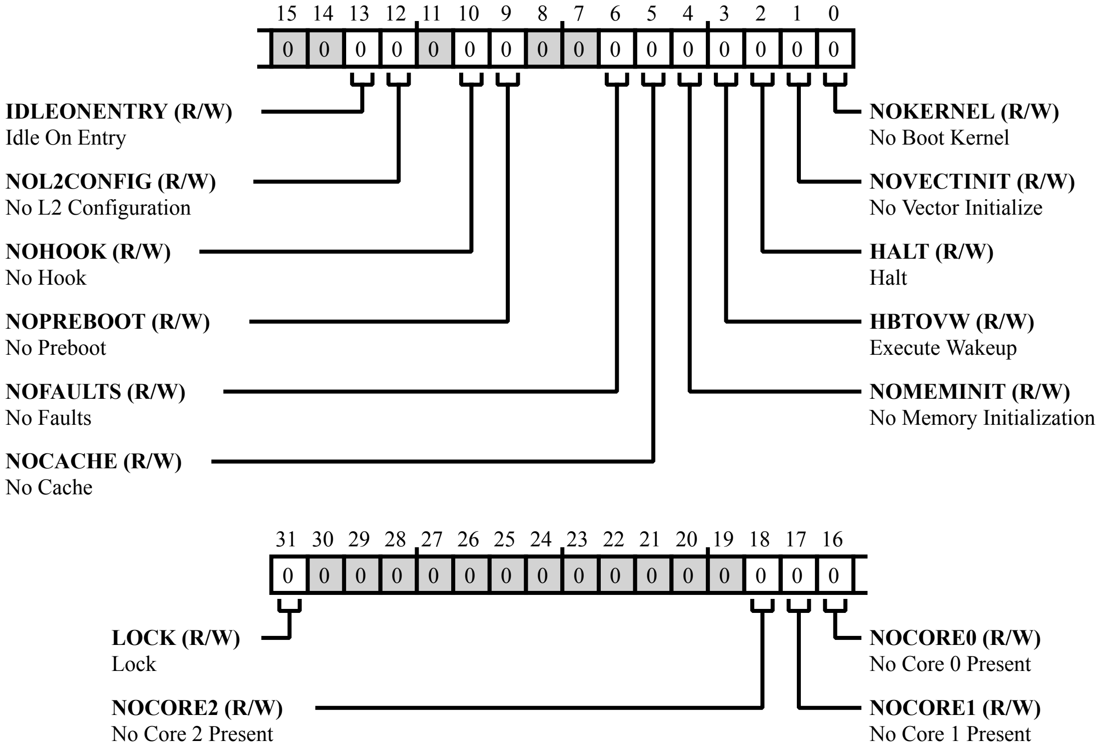
Reset Control Unit (RCU) contains the following registers.

Table 6-5: ADSP-SC58x RCU Register List

Name	Description
`RCU_BCODE`	Boot Code Register
`RCU_CRCTL`	Core Reset Outputs Control Register
`RCU_CRSTAT`	Core Reset Outputs Status Register
`RCU_CTL`	Control Register
`RCU_MSG`	Message Register
`RCU_MSG_CLR`	Message Clear Bits Register
`RCU_MSG_SET`	Message Set Bits Register
`RCU_SIDIS`	System Interface Disable Register
`RCU_SISTAT`	System Interface Status Register
`RCU_STAT`	Status Register
`RCU_SVECT0`	Software Vector Register 0
`RCU_SVECT1`	Software Vector Register 1
`RCU_SVECT2`	Software Vector Register 2
`RCU_SVECT_LCK`	SVECT Lock Register

Boot Code Register

The `RCU_BCODE` register can be used to determine if and how core boots. This register is set to its default values by RESET.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
IDLEONENTRY (R/W)
Idle On Entry
NOL2CONFIG (R/W)
No L2 Configuration
NOHOOK (R/W)
No Hook
NOPREBOOT (R/W)
No Preboot
NOFAULTS (R/W)
No Faults
NOCACHE (R/W)
No Cache
NOKERNEL (R/W)
No Boot Kernel
NOVECTINIT (R/W)
No Vector Initialize
HALT (R/W)
Halt
HBTOVW (R/W)
Execute Wakeup
NOMEMINIT (R/W)
No Memory Initialization
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LOCK (R/W)
Lock
NOCORE2 (R/W)
No Core 2 Present
NOCORE0 (R/W)
No Core 0 Present
NOCORE1 (R/W)
No Core 1 Present

Figure 6-1: RCU_BCODE Register Diagram

Table 6-6: RCU_BCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (`SPU_CTL.GLCK` bit =1) and the `RCU_BCODE.LOCK` bit is set, the `RCU_BCODE` register is read only (locked).	
		0	Unlock
		1	Lock
18 (R/W)	NOCORE2	No Core 2 Present. The `RCU_BCODE.NOCORE2` bit indicates the presence of core 2.	
		0	Core does not exist
		1	Core exists

Table 6-6: RCU_BCODE Register Fields (Continued)

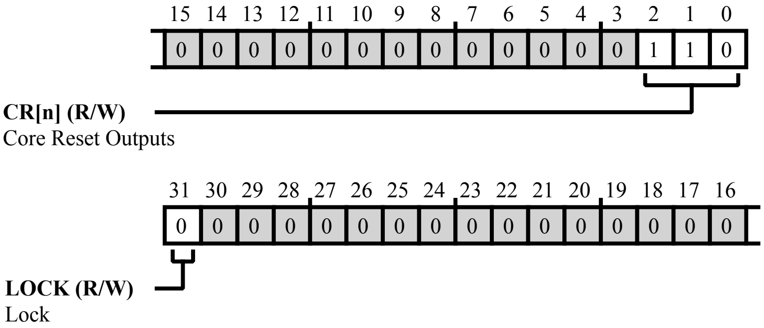
Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	NOCORE1	No Core 1 Present. The `RCU_BCODE.NOCORE1` bit indicates the presence of core 1.	
		0	Core does not exist
		1	Core exists
16 (R/W)	NOCORE0	No Core 0 Present. The `RCU_BCODE.NOCORE0` bit indicates the presence of core 0.	
		0	Core does not exist
		1	Core exists
13 (R/W)	IDLEONENTRY	Idle On Entry. The `RCU_BCODE.IDLEONENTRY` bit configures the RCU to enter the idle state at startup.	
		0	Do not enter idle state
		1	Enter idle state
12 (R/W)	NOL2CONFIG	No L2 Configuration. The `RCU_BCODE.NOL2CONFIG` bit configures the RCU to not perform the L2 memory configuration.	
		0	Configure L2 memory
		1	Do not configure L2 memory
10 (R/W)	NOHOOK	No Hook. The `RCU_BCODE.NOHOOK` bit configures the RCU to not perform the hook routine.	
		0	Perform hook routine
		1	Do not perform hook routine
9 (R/W)	NOPREBOOT	No Preboot. The `RCU_BCODE.NOPREBOOT` bit configures the RCU to not perform the customer preboot routine.	
		0	Perform preboot
		1	Do not perform preboot
6 (R/W)	NOFAULTS	No Faults. The `RCU_BCODE.NOFAULTS` bit configures the RCU to not perform fault initialization.	
		0	Perform fault initialization
		1	Do not perform fault initialization

Table 6-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	NOCACHE	No Cache. The `RCU_BCODE.NOCACHE` bit configures the RCU to not perform a cache initialization and to not enable the cache.	
		0	Enable and initialize cache
		1	Do not initialize or enable cache
4 (R/W)	NOMEMINIT	No Memory Initialization. The `RCU_BCODE.NOMEMINIT` bit configures the RCU to not perform a memory initialization.	
		0	Perform memory initialization
		1	Do not perform memory initialization
3 (R/W)	HBTOVW	Execute Wakeup. The `RCU_BCODE.HBTOVW` bit configures the RCU to execute a wakeup.	
		0	Do not wakeup
		1	Execute wakeup
2 (R/W)	HALT	Halt. The `RCU_BCODE.HALT` bit configures the RCU to execute the no boot routine.	
		0	Do not execute routine
		1	Execute routine
1 (R/W)	NOVECTINIT	No Vector Initialize. The `RCU_BCODE.NOVECTINIT` bit configures the RCU to not vector to the application.	
		0	Vector
		1	Do not vector
0 (R/W)	NOKERNEL	No Boot Kernel. The `RCU_BCODE.NOKERNEL` bit configures the RCU to not execute the boot kernel.	
		0	Execute boot kernel
		1	Do not execute boot kernel

Core Reset Outputs Control Register

The RCU core reset control n registers (`RCU_CRCTL`) include a lock bit (`RCU_CRCTL.LOCK`) and a core reset bit (`RCU_CRCTL.CR[n]`) for each core reset signal on the product.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 1 1 0

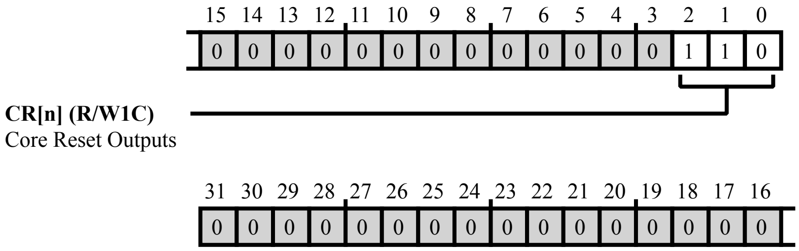
Table 6-7: RCU_CRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (`SPU_CTL.GLCK` bit =1) and the `RCU_CRCTL.LOCK` bit is set, the `RCU_CRCTL` register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	CR[n]	Core Reset Outputs. The `RCU_CRCTL.CR[n]` bits control CRES[1:0] core reset signals. The RCU_CRES[n] signals can be individually controlled. They are reset to their default value by a hard reset or a system reset. For each RCU_CRES[n], the selected RCU0_CRMSKi[n] bit is cleared.	
		0	RCU_CRES[2:0] Deasserted
		7	RCU_CRES[2:0] Asserted

Core Reset Outputs Status Register

The RCU core reset status register (RCU_CRSTAT) contains status bits, indicating which core reset signals have been asserted.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

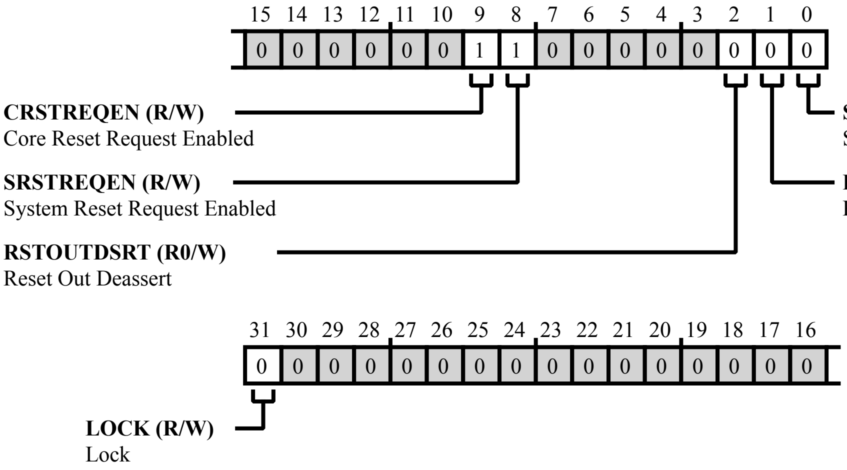
Figure 6-3: RCU_CRSTAT Register Diagram

Table 6-8: RCU_CRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/W1C)	CR[n]	Core Reset Outputs. The `RCU_CRSTAT.CR[n]` bits indicate which cores have been reset since the last time the bit was cleared. Bits masked by CORE_DISABLE_MASK[15:0] are permanently disabled and the corresponding CR bits set. CR bits are sticky, they need to be cleared by software.	
		0	RCU_CRES[1:0] deasserted. CR[n] corresponds to RCU_CRES[n].
		7	RCU_CRES[2:0] were asserted since the last time bits were cleared. CR[n] corresponds to RCU_CRES[n].

Control Register

The RCU control register (`RCU_CTL`) provides a register lock, enables for the core and system reset requests inputs and control for the Reset Output pin.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

LOCK (R/W)
Lock

Figure 6-4: RCU_CTL Register Diagram

Table 6-9: RCU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (`SPU_CTL.GLCK` bit =1) and the `RCU_CTL.LOCK` bit is set, the `RCU_CTL` register is read only (locked). This bit is cleared by a hard reset or any system reset event.	
		0	Unlock
		1	Lock
9 (R/W)	CRSTREQEN	Core Reset Request Enabled. The `RCU_CTL.CRSTREQEN` bit controls whether the SYSCLK domain source(s) of reset is/are enabled to reset the core(s) when asserted. This bit is cleared by hard reset or any system reset event.	
		0	Disabled
		1	Enabled
8 (R/W)	SRSTREQEN	System Reset Request Enabled. The `RCU_CTL.SRSTREQEN` bit controls whether the SYSCLK domain sources of reset are enabled to do a system reset when asserted. This bit is cleared by a hard reset.	
		0	Disabled
		1	Enabled

Table 6-9: RCU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R0/W)	RSTOUTDSRT	Reset Out Deassert. The `RCU_CTL.RSTOUTDSRT` bit controls the deassertion of the system reset pin.	
		0	No Action
		1	Deassert RSTOUT
1 (R0/W)	RSTOUTASRT	Reset Out Assert. The `RCU_CTL.RSTOUTASRT` bit controls assertion of the system reset pin.	
		0	No Action
		1	Assert RSTOUT
0 (R0/W)	SYSRST	System Reset. The `RCU_CTL.SYSRST` bit provides reset for all system units.	
		0	No Action
		1	System Reset

Message Register

The `RCU_MSG` is a general-purpose register. It is intended to provide flexibility for Boot ROM code and to pass predefined variables to the debugger. Please see the Booting chapter for product-specific details.

Table 6-10: RCU_MSG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CALLERR	Call Error Flag. The `RCU_MSG.CALLERR` bit indicates that a flag has been set by the boot code prior to an error call.	
		0	Flag not set
		1	Flag set

Table 6-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	CALLBACK	Callback Call Flag. The `RCU_MSG.CALLBACK` bit indicates that a flag has been set by the boot code prior to a callback call.	
		0	Flag not set
		1	Flag set
29 (R/W)	CALLINIT	Call Initcode Flag. The `RCU_MSG.CALLINIT` bit indicates that a flag has been set by the boot code prior to an initcode call.	
		0	Flag not set
		1	Flag set
28 (R/W)	CALLAPP	Call Application Flag. The `RCU_MSG.CALLAPP` bit indicates that a flag has been set by the boot code prior to an application call.	
		0	Flag not set
		1	Flag set
27 (R/W)	HALTONERR	Halt on Error Call. The `RCU_MSG.HALTONERR` bit generates an emulation exception prior to an error call.	
		0	Do not generate exception
		1	Generate exception
26 (R/W)	HALTONCALL	Halt on Callback Call. The `RCU_MSG.HALTONCALL` bit generates an emulation exception prior to a callback call.	
		0	Do not generate exception
		1	Generate exception
25 (R/W)	HALTONINIT	Halt on Initcode Call. The `RCU_MSG.HALTONINIT` bit generates an emulation exception prior to an initcode call.	
		0	Do not generate exception
		1	Generate exception

Table 6-10: RCU_MSG Register Fields (Continued)

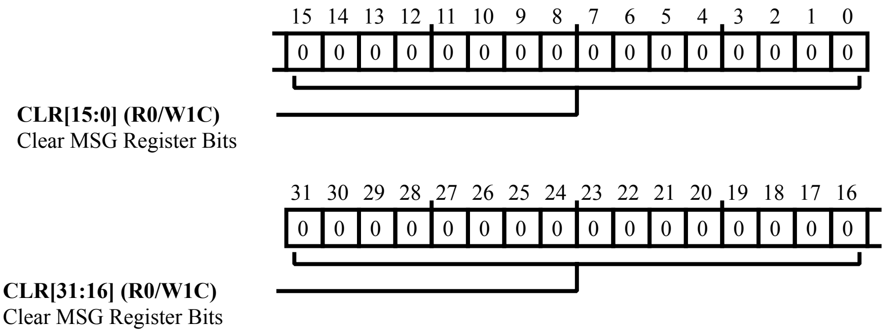
Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	HALTONAPP	Halt on Application Call. The `RCU_MSG.HALTONAPP` bit generates an emulation exception prior to an application call.	
		0	Do not generate exception
		1	Generate exception
22 (R/W)	L2INIT	L2 Initialized. The `RCU_MSG.L2INIT` bit indicates that the L2 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
21 (R/W)	SECINIT	SEC Initialized. The `RCU_MSG.SECINIT` bit is used by tools for initialization of the SEC.	
20 (R/W)	C2ACTIVATE	Core 2 Activated. The `RCU_MSG.C2ACTIVATE` bit is used by tools for activation of Core 2.	
19 (R/W)	C1ACTIVATE	Core 1 Activated. The `RCU_MSG.C1ACTIVATE` bit is used by tools for activation of Core 1.	
18 (R/W)	C2L1INIT	Core 2 L1 Initialized. The `RCU_MSG.C2L1INIT` bit indicates that the core 2 L1 resource is initialized.	
17 (R/W)	C1L1INIT	Core 1 L1 Initialized. The `RCU_MSG.C1L1INIT` bit indicates that the core 1 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
16 (R/W)	C0L1INIT	Core 0 L1 Initialized. The `RCU_MSG.C0L1INIT` bit indicates that the core 0 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
10 (R/W)	C2IDLE	Core 2 Idle. The `RCU_MSG.C2IDLE` bit indicates that core 2 is in a safe idle state in ROM.	
9 (R/W)	C1IDLE	Core 1 Idle. The `RCU_MSG.C1IDLE` bit indicates that core 1 is in a safe idle state in ROM.	
8 (R/W)	C0IDLE	Core 0 Idle. The `RCU_MSG.C0IDLE` bit indicates that core 0 is in a safe idle state in ROM.	

Table 6-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	ERRCODE	ROM Error Code. The `RCU_MSG.ERRCODE` bit indicates the error code of the ROM. It is valid only when in the error handler.

Message Clear Bits Register

The `RCU_MSG_CLR` register is used to clear bits in `RCU_MSG` register. Reading this register returns 0x00000000.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

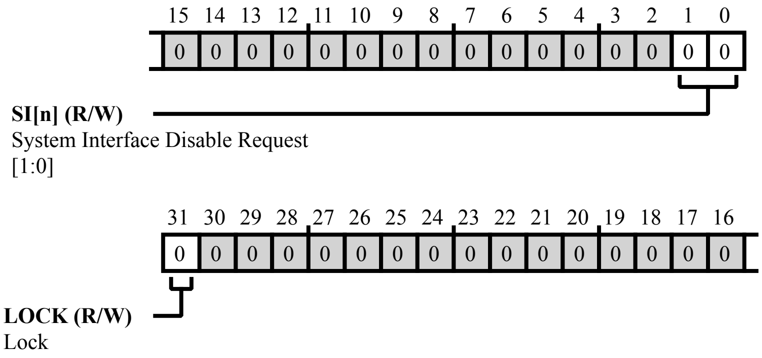
Table 6-12: RCU_MSG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1S)	SET	Set Message Bits. The `RCU_MSG_SET.SET` bit sets MSG bit n.

System Interface Disable Register

The RCU system interface disable register (`RCU_SIDIS`) lets the RCU assert a system interface disable request to functional units in the processor. This register is set to its default values by a hard reset or any system reset event. For information on mapping between `RCU_SIDIS` bits and functional units, see the RCU functional description.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

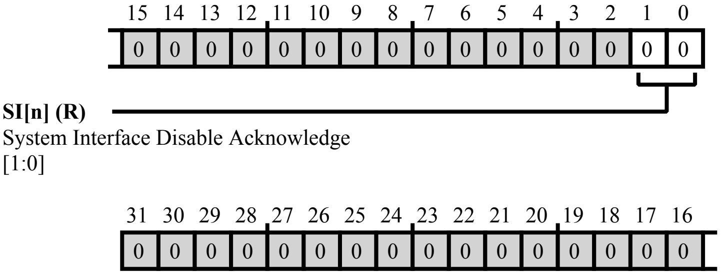
31 (R/W)	LOCK	Lock. If the global lock bit is set (`SPU_CTL.GLCK` bit =1) and the `RCU_SIDIS.LOCK` bit is set, the `RCU_SIDIS` register is read only (locked).	
		0	Unlock
		1	Lock
1:0 (R/W)	SI[n]	System Interface Disable Request [1:0]. Each `RCU_SIDIS.SI[n]` bit corresponds to a functional unit in the processor that supports the system interface disable request-acknowledge protocol.	
		0	RCU_SI_DISABLE_REQ[1:0] deasserted
		3	RCU_SI_DISABLE_REQ[1:0] asserted

System Interface Status Register

The RCU system interface status register (`RCU_SISTAT`) indicates whether a functional unit has or has not acknowledged an RCU unit disable request.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

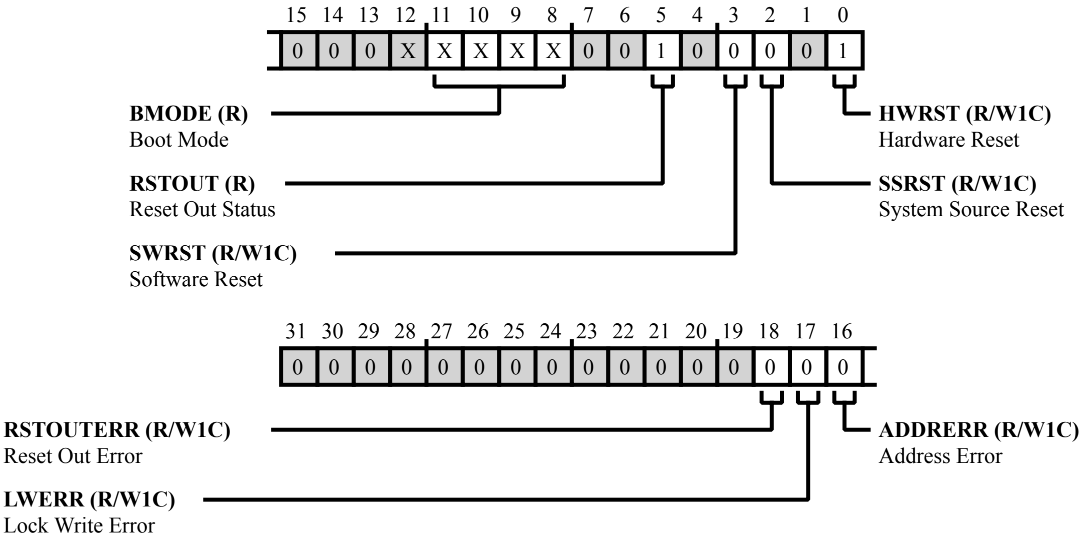
1:0 (R/NW)	SI[n]	System Interface Disable Acknowledge [1:0]. The `RCU_SISTAT.SI[n]` bit indicates whether a functional unit has or has not acknowledged an RCU unit disable request.	
		0	No Acknowledge
		3	SI_DISABLE_ACK[1:0] asserted

Status Register

The RCU status register (`RCU_STAT`) contains status bits for all RCU reset sources, reset status, and boot mode inputs. Status bits for reset sources are sticky and can cleared by software. Error status bits are cleared by any reset event.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

ADDRERR (R/W1C)
Address Error

Figure 6-10: RCU_STAT Register Diagram

Table 6-15: RCU_STAT Register Fields

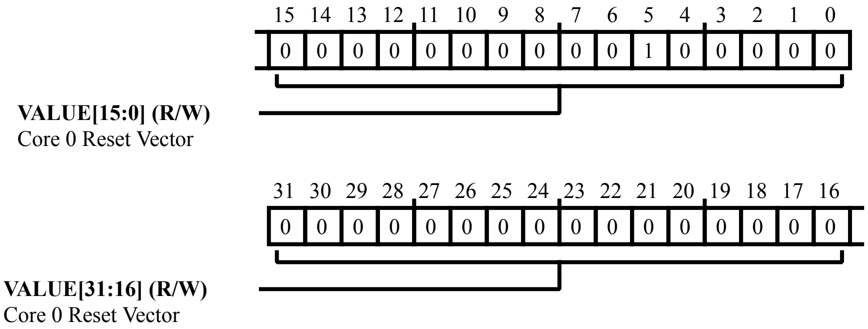
Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W1C)	RSTOUTERR	Reset Out Error. The `RCU_STAT.RSTOUTERR` bit indicates (if set) that a write attempted to set the `RCU_CTL.RSTOUTASRT` and `RCU_CTL.RSTOUTDSRT` simultaneously. This condition triggers a bus error.	
		0	No Error
		1	Error Occurred
17 (R/W1C)	LWERR	Lock Write Error. The `RCU_STAT.LWERR` bit indicates (when set) there was an attempted write to an RCU register while the `RCU_CTL.LOCK` bit was set and the global lock bit is enabled (`SPU_CTL.GLCK` bit =1). This status bit is sticky; write-1-to-clear	
		0	No Error
		1	Error Occurred

Table 6-15: RCU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ADDRERR	Address Error. The `RCU_STAT.ADDRERR` bit indicates that the RCU generated an address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
11:8 (R/NW)	BMODE	Boot Mode. The `RCU_STAT.BMODE` bits indicate the input on the boot mode pins.	
5 (R/NW)	RSTOUT	Reset Out Status. The `RCU_STAT.RSTOUT` bit indicates the assertion status of the system reset pin.	
		0	RSTOUT Deasserted
		1	RSTOUT Asserted
3 (R/W1C)	SWRST	Software Reset. The `RCU_STAT.SWRST` bit indicates that a system reset (which was triggered by software) has occurred since the last time a hardware reset occurred or since the `RCU_STAT.SWRST` bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
2 (R/W1C)	SSRST	System Source Reset. The `RCU_STAT.SSRST` bit indicates that a system reset triggered by hardware in the system clock domain, clock A domain, or clock B domain has occurred since the last time a hardware reset occurred or since the `RCU_STAT.SSRST` bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
0 (R/W1C)	HWRST	Hardware Reset. The `RCU_STAT.HWRST` bit indicates that a hardware reset has occurred.	
		0	Inactive
		1	Reset Occurred

Software Vector Register 0

The `RCU_SVECT0` register contains the default location of the first instruction to execute after a reset.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

31:0 (R/W)	VALUE	Reset Vector.

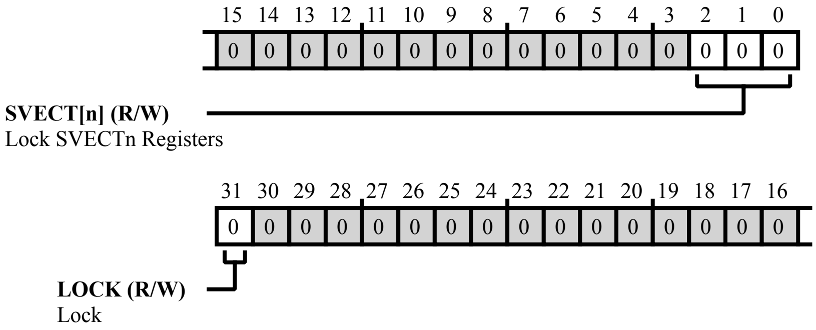
SVECT Lock Register

The RCU software vector lock register (RCU_SVECT_LCK) provides a register lock and software vector n enable bits for each processor core on the product. This register is set to its default values by a hard reset or any system reset event.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SVECT[n] (R/W)
Lock SVECTn Registers

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LOCK (R/W)
Lock

Figure 6-14: RCU_SVECT_LCK Register Diagram

Table 6-19: RCU_SVECT_LCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (`SPU_CTL.GLCK` bit =1) and the `RCU_SVECT_LCK.LOCK` bit is set, the `RCU_SVECT_LCK` register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	SVECT[n]	Lock SVECTn Registers. If the global lock bit is set (`SPU_CTL.GLCK` bit =1) and the `RCU_SVECT_LCK.SVECT[n]` bit is set, the `RCU_SVECT0` and `RCU_SVECT1` registers are read only (locked).	

7 System Event Controller (SEC) and Generic Interrupt Controller (GIC)

There are two interrupt controllers—a generic interrupt controller (GIC) for the ARM core and the system event controller (SEC) for the SHARC cores.

System event management is the responsibility of the system event controller (SEC). The SEC manages the configuration of all system event sources. The SEC also manages the propagation of system events to all connected cores and the system fault interface.

All of the peripheral interrupts are routed using a single SEC interrupt to the desired core. The SEC allows programmability of the peripheral interrupt's priority, supporting up to 256 priority levels that are arbitrated within the SEC itself. The SEC also allows these interrupts to be grouped and masked by priority level and provides the flexibility to choose which core(s) the interrupt is routed to.

The SEC also supports self-nesting of interrupts, which is required when sharing a single interrupt request to an individual core, as this allows for a higher-priority peripheral interrupt to be passed to the core while it is currently servicing a lower-priority peripheral interrupt. For more details please refer to "Self-Nesting Mode for System Event Controller Interrupt (SECI)" in the *SHARC+ Core Programming Reference*.

For more information about the ARM GIC, visit the ARM Information Center.

SEC Features

The following list describes the system event controller features.

- Comprehensive system event source management including interrupt enable, fault enable, priority, core mapping, and source grouping.
- Fault management including fault action configuration, timeout, external indication, and system reset.
- Determinism where all system events have the same propagation delay and provide unique identification of a specific system event source.
- Distributed programming model where each system event source control and all status fields are independent of all others.

- Slave control port which provides access to all SEC registers for configuration, status, and interrupt or fault service model.
- Global locking supports a register level protection model to prevent writes to “locked” registers.

SEC Functional Description

The following sections provide a functional description of the SEC.

The *SEC/GIC Interrupt Signal Flow* figure shows an overview of the interrupt systems.

ADSP-SC58x SEC Register List

The System Event Controller (SEC) manages the system fault sources, including control features such as enable/ disable, priority, and active/pending source status. For more information on SEC functionality, see the SEC register descriptions.

Table 7-1: ADSP-SC58x SEC Register List

Name	Description
`SEC_CACT[n]`	SCI Active Register n

Combined SEC and GIC Interrupt List

The *Combined SEC and GIC Interrupt List* table provides a complete list of the processor and Cortex interrupts. Note that the DAI has its own system interrupt controllers. For more information see the DAI System Interrupt Controller (SIC). Note in the table below many interrupts are supported by all cores. In the cases were an interrupt is not supported its ID number (GIC_ID for ARM Cortex-A5 or SEC_ID for SHARC+) is reserved.

Table 7-3: ADSP-SC58x *Combined SEC and GIC Interrupt List*

Module	Event/Interrupt	SEC ID	GIC ID	SEC/GIC Interrupt Name
GIC	SW Interrupt 0, core reset, core ID = 0	N/A	0	GIC_SOFT00
GIC	SW Interrupt 1, undefined instruction, core ID = 0	N/A	1	GIC_SOFT01

Table 7-3: ADSP-SC58x *Combined SEC and GIC Interrupt List* (Continued)

SEC Definitions

The event controller uses the following definitions.

System Events

System source indications including interrupts and faults.

System Source

Point of origin of system event.

SID (Identification, unique)

Source numeric identifier for each system source connected to the SEC.

SSI

SEC source interface, system event source control, and status subblock of the SEC.

SCI

SEC core interface, core interface subblock of the SEC

SPR

SEC prioritizer determines the highest priority pending interrupt and the highest priority active interrupt. The SPR provides these interrupts in the appropriate registers of the SCI for the priority and nesting model of the SCI.

SFI

SEC Fault Interface, fault management subblock of the SEC.

SEC Block Diagram

The ***SEC Block Diagram*** shows the event management architecture.

System sources connect to the SEC through the SSI. Each core has a dedicated SCI. The SFI provides fault action connections to the rest of the system.

SEC Fault Interface (SFI)

The SFI manages fault events and associated actions. The fault management support provided in the SEC helps satisfy the safety requirements of various applications. The SSI provides the highest priority pending source that is enabled as a fault. The SFI captures this value and enables a countdown, and once the countdown expires, takes the prescribed action.

Fault actions which can be configured, as shown in ***SFI Block Diagram***, include

- Trigger Output
- System Reset
- Fault Output
    - Computer Operating Properly (COP) mode
    - Fault Mode

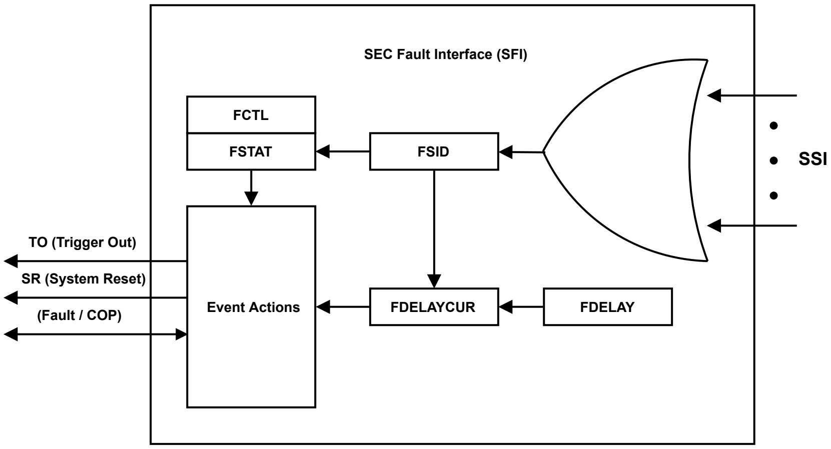

Figure 7-3: SFI Block Diagram

Fault Management

System sources can be enabled as fault sources in the `SEC_SCTL[n]` register. When a source enabled as a fault moves to pending, it is forwarded to the SFI as a fault indication. The pending bit (`SEC_FSTAT.PND`) indicates a source has signaled a fault assertion but it has not yet triggered the event actions (if delay is enabled). The SEC fault interface sets the `SEC_FSTAT.PND` bit when the fault source ID register (`SEC_FSID`) is updated on assertion of a fault source input. The system source pending triggers a fault pending and after a programmable delay the fault moves to active. Event actions then execute if appropriate action is not taken by the core. The `SEC_FSTAT.ACT` bit indicates that the SEC has received a fault source input, the delay has expired, and the fault actions are enabled.

The `SEC_FSTAT.NPND` bit indicates if one or more sources have signaled a fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the `SEC_FSTAT.NPND` bit when the fault interface detects assertion of any enabled fault source input, while either the `SEC_FSTAT.PND` or `SEC_FSTAT.ACT` bits are set. The SEC clears the `SEC_FSTAT.NPND` bit when there are no fault sources waiting.

A fault indication from an external device can also be detected on sampling the fault signals. When a fault is detected the `SEC_FSTAT.ACT` and `SEC_FSID.FEXT` bits are set. The assertion of either signal results in a fault input detection.

The `SEC_FEND` register receives a fault end indication from the core. The core writes the SID of the fault to the `SEC_FEND` register. If the SID matches the value in the `SEC_FSID` register, the `SEC_FSTAT.PND` and `SEC_FSTAT.ACT` bits are cleared.

More information can be found in the Fault Management Interface Programming Model section.

SEC Core Interface (SCI)

The SCI manages communication between the corresponding core and the SEC. The SEC prioritizer (SPR) of the SCI receives pending, active, and priority information from the SSI for each system event source assigned to this SCI. The SPR determines the highest-priority pending system event and the SCI determines whether it propagates to the core. The SCI maintains the coherency for the system event service model implemented on the connected core.

SEC Architectural Concepts

The following sections describe SEC architectural features.

System Interrupt Acknowledge

A system interrupt acknowledge occurs when the core provides an indication that it has acquired the SID of the interrupt last issued by the SEC. The SEC core interface option allows generation by:

- A slave port write to the `SEC_CSID[n]` register.
- The assertion of an input acknowledge signal (the connected core generates the signal).

System Interrupt Groups

System sources can be assigned to groups using the `SEC_SCTL[n].GRP` bit field. Source groups allow fast context switching for system interrupts at each SCI. The `SEC_CGMSK[n]` register allows quick masking of interrupt groups of unlimited size with a single write operation.

System Interrupt Flow

An enabled and asserted system interrupt source is latched at the SSI and routed to the appropriate SCI based on the core target select (`SEC_SCTL[n].CTG`) bit field setting. The SEC priority ordering determines the highest priority pending system interrupt and the SCI updates the `SEC_CPND[n].SID` and `SEC_CACT[n].PRIO` bit field values. The SCI compares the `SEC_CPND[n]` register value against the highest priority active source in the `SEC_CACT[n]` register).

The priority level register (`SEC_CPLVL[n]`) determines how many of the MSBs the SEC uses in the comparison. The priority mask register (`SEC_CPMSK[n]`) and the group mask register (`SEC_CGMSK[n]`) determines which pending interrupt sources participate. If the `SEC_CPND[n]` register value is a higher priority (lower value) than the priority of the `SEC_CACT[n]` register from the comparison based on the `SEC_CPLVL[n]` register, the system interrupt output is asserted. The source ID register (`SEC_CSID[n]`) is updated with the `SEC_CPND[n].SID` bit field value and forwarded to the connected core.

After the core provides an interrupt acknowledgment, the interrupt source is active, until the SEC completes interrupt service with a write to the `SEC_END.SID` bit field with the same value. Note the following:

- Interrupt acknowledgement occurs with an MMR write of the `SEC_CSID[n]` register or the core version of the `SEC_CSID[n]` register.
- Interrupt active status indication is `SEC_SSTAT[n].ACT`==1.

The following sequence shows the example flow for a single interrupt.

1. The SEC compares the `SEC_CPND[n]` register value to the `SEC_CACT[n]` register value. If the interrupt in the `SEC_CPND[n]` register is higher priority, continue.
2. The SEC copies the `SEC_CPND[n]` register value to the `SEC_CSID[n]` register and asserts the interrupt signal.
3. The core reads the `SEC_CSID[n]` register (or core version).
4. The core writes to the `SEC_CSID[n]` register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the interrupt signal and clears the `SEC_SSTAT[n].PND` bit and sets the `SEC_SSTAT[n].ACT` bit of the source going active.
6. The core writes the `SEC_CSID[n]` of the active interrupt to the `SEC_END` register.
7. The SEC clears the`SEC_SSTAT[n].ACT` bit of the source being ended.

The following sequence shows the example flow for interrupt nesting where interrupt A is a lower priority and occurs earlier than interrupt B.

1. The SEC compares the `SEC_CPND[n]` (A) register value to the `SEC_CACT[n]` register and if the interrupt in the `SEC_CPND[n]` register is a higher priority, continue.
2. The SEC copies `SEC_CPND[n]` (A) register to the `SEC_CSID[n]` register and asserts the interrupt signal.
3. The core reads the `SEC_CSID[n]` (A) register (or core version).
4. The core writes to the `SEC_CSID[n]` register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the `INT` signal and clears the `SEC_SSTAT[n].PND` bit and sets the `SEC_SSTAT[n].ACT` bit of the source (A) going active.
6. The SEC compares the `SEC_CPND[n]` (B) register value to the `SEC_CACT[n]` (A) register value. If the `SEC_CACT[n]` (A) register value is a higher priority, continue.
7. The SEC copies the `SEC_CPND[n]` (B) register value to `SEC_CSID[n]` register and asserts the interrupt signal.
8. The core reads the `SEC_CSID[n]` (B) register (or core version).
9. The core writes to the `SEC_CSID[n]` register (or core version, asserts the acknowledge signal).
10. The SEC deasserts the `INT` signal and clears the `SEC_SSTAT[n].PND` bit and sets the `SEC_SSTAT[n].ACT` bit of the source (B) going active.
11. The core writes the `SEC_CSID[n]` of the active interrupt (B) to the `SEC_END` register.
12. The SEC clears the `SEC_SSTAT[n].ACT` bit of the source (B) being ended.
13. The core writes the `SEC_CSID[n]` of the active interrupt (A) to the `SEC_END` register.
14. The SEC clears the `SEC_SSTAT[n].ACT` bit of the source (A) being ended.

System Interrupt Priorities

Each system interrupt source has its own programmable priority level which is configured using the `SEC_SCTL[n].PRIO` bit field. The SCI evaluates the priority of all pending sources to determine the source of the highest-priority pending system interrupt for forwarding to the attached core. If more than one source of the pending system interrupt has the same priority setting, the SCI chooses the one with the lowest SID. For example, if SID 0, SID 1, and SID 2 are all pending and have the same priority setting, the SCI chooses SID 0 as the highest-priority source.

SEC Error

The processor includes an SEC error (`SEC_GSTAT.ERR`) as a source input to the SEC to allow for handling the error as an interrupt or fault.

SEC Programming Model

Implementing a system interrupt service model using the SEC requires, at a minimum:

- Proper configuration of a system interrupt source (for example a peripheral or DMA)
- A core interrupt or event service model

The core must be configured for response to system interrupts from the SEC. The SEC must be configured to enable and map the system interrupt source to the correct SCI and to forward interrupts to the connected core.

The system interrupt source must be configured to generate interrupt assertions. Alternatively, the processor can use software triggering for interrupt assertion. Software driven interrupts are generated by writing the source ID of the interrupt to be triggered to the `SEC_RAISE` register.

Programming Concepts

The following list provides the basic programming concepts necessary for configuring the SEC.

- Configuring an SSI as a system interrupt for a specific core.
- Configuring an SCI to provide system interrupts to the connected core. (See Configuring a System Source to Interrupt a Core.)
- Configuring an SSI as a system fault. (See Configuring a System Source as a Fault.)
- Configuring the SFI to manage system faults.

Programming Examples

This section provides example programming tasks that are typical for SEC usage.

Fault Management Interface Programming Model

The SFI interface can be programmed to manage fault events from system sources and associated actions such as issuing a system reset when watchdog expiration event occurs.

1. Set the `SEC_GCTL.EN` bit to enable the SEC.
2. Write to the `SEC_FCTL` register to configure specific fault actions.
    - Trigger Output. Set the `SEC_FCTL.TOEN` bit for the SEC to produce trigger outputs when a fault becomes active. The `SEC_FCTL.TES` bit can be programmed to select the event that directs the SEC to assert trigger output when a fault is pending or active. Configure slaves for SEC fault trigger master output.

      NOTE: If the `SEC_FCTL.TOEN` and or the `SEC_FCTL.TES` bits =1 (Trigger Output Enabled and Trigger on Fault Pending), an external fault (if enabled by the `SEC_FCTL.FIEN` bit) will not issue a trigger since Fault Pending is bypassed for external faults.

    - System Reset. The Reset Control Unit (RCU) controls how the functional units enter and exit reset. Configure the `RCU_CTL.SRSTREQEN` bit. This bit controls whether the sources of reset are enabled to perform a system reset. To issue a system reset request when a fault becomes active, set the `SEC_FCTL.SREN` bit. The SEC fault system reset delay register (`SEC_FSRDLY`) can be programmed for the delay, if required, from a fault becoming active to system reset request assertion.

- Fault Output. This configuration alows the SEC to indicate the fault status based on the `SEC_FCTL.CMS` bit configuration.
    - Computer Operating Normally (COP) mode. To configure fault output for COP mode, set the `SEC_FCTL.FOEN` bit to enable fault output. Set the `SEC_FCTL.CMS` bit to select COP mode to toggle the fault pin when no fault is active. Program the `SEC_FCOPP` period register with a desired width value for the COP toggled output pin.
    - Fault mode. Set the `SEC_FCTL.FOEN` bit to enable fault output. The `SEC_FCTL.CMS` bit should be set to Fault mode to toggle the fault pin when a fault is active.

3. If required, program the Fault Input to sample fault inputs from external devices on fault pins. Configure the `SEC_FCTL.FIEN` bit to enable the SEC to sample a fault input from an external device.

   ADDITIONAL INFORMATION: The `SEC_FCTL.FIEN` bit should be set only while the `SEC_FCTL.EN` bit is low. If the `SEC_FCTL.EN` bit is already high and the `SEC_FCTL.FIEN` bit needs to be set, the `SEC_FCTL.EN` bit should be cleared first. Fault input can only be enabled when Fault mode is selected by the `SEC_FCTL.CMS` bit.

4. Program the required fault delay to the `SEC_FDLY.COUNT` bit field if a delay between fault source assertion and the fault response is required.
5. Configure the `SEC_FCTL` register to enable the SEC.

   ADDITIONAL INFORMATION: The `SEC_FCTL.EN` bit should be set only while the `SEC_FSTAT.ACT` bit is low.

6. Write to the control register of a specific source register using the `SEC_SCTL[n]` register to enable the source as a fault.

Configuring a System Source to Interrupt a Core

To configure a system source to interrupt a core, the SEC itself must be enabled with the source interface (SSI) and core interface (SCI) properly initialized. Specifically, the SCI must be set up to accept interrupt signaling from the SEC and pass them to the specified core, and the SSI must properly enable each of the peripheral interrupt sources to generate interrupt signals and optionally define a priority scheme that overrides the default priority settings. In summary:

1. Write to the `SEC_GCTL` register to enable the SEC.
2. Write to the appropriate SCI `SEC_CCTL[n]` register to enable SEC interrupts to be sent to that core.
3. Write to the appropriate SSI `SEC_SCTL[n]` register to enable that peripheral as an interrupt source and to set the core target field to map the source to the desired SCI.
4. (Optional) By default, all the SEC interrupts are grouped as a single priority level, so passing of peripheral interrupt requests from the SEC is based solely on the default enumerated source ID. By programming the `SEC_CPLVL[n].PLVL` register, interrupt sources can be grouped into priority levels within the SEC such that arbitration is first performed by source ID within a grouped priority level before proceeding to the next

priority level, thus providing the flexibility to have lower-priority interrupt sources considered before higher-priority sources.

ADDITIONAL INFORMATION: The `SEC_CPMSK[n]` and `SEC_CGMSK[n]` registers must also can be programmed to mask the interrupts based on the customized levels and grouping.

Core/SEC Handshaking Requirements to Ensure Proper Interrupt Handling

Interrupt handling within an individual core requires specific handshaking with the SEC to ensure that nested interrupts are properly tracked and that new peripheral interrupts being raised within the SEC are either passed immediately to the core or held off and queued within the SEC for later servicing. Inside the SEC ISR, the following steps are required:

Use this procedure to write a custom dispatcher inside the Interrupt Service Routine. Note that the core needs to read the `SEC_CSID[n]` register and acknowledge it by writing the same value. It should also write to the `SEC_END` register after the ISR execution completes.

1. Read the `SEC_CSID[n]` register to obtain the source ID of the peripheral interrupt request.
2. Write the read value back to the `SEC_CSID[n]` register to send the acknowledge signal to the SEC that the core has accepted and begun processing for the interrupt request.
3. Execute the actual ISR (typically a call to a specific handler function from a look-up table based on the peripheral source ID). Write to the `SEC_GCTL` register to enable the SEC.
4. Write the `SEC_CSID[n]` of the active interrupt (read in step 1 above) to the `SEC_END` register to signal to the SEC that the interrupt has now been serviced.
5. Return from interrupt.

With this implementation in place, a higher-priority interrupt being raised by the SEC can be serviced by the core after step 2. The SEC knows what it passed to the core by virtue of its write to the `SEC_CSID[n]` register. After the core acknowledges that write, the SEC knows whether or not newly raised peripheral interrupts are higher priority than the highest-priority interrupt being processed by the core. If the new interrupt is higher priority, it pushes the current `SEC_CSID[n]` to an internal stack, writes the new `SEC_CSID[n]` value, and asserts a new SEC interrupt request. If it is lower priority, the SEC queues the interrupt until the core writes to the `SEC_END` register with the source ID of the higher-priority interrupt, thus confirming that it was fully processed, at which point that `SEC_CSID[n]` value is popped from the internal stack and any pending peripheral interrupt requests are arbitrated among before the SEC writes the new `SEC_CSID[n]` value and asserts a new interrupt request. Meanwhile, the core self-nests the latched SEC interrupt requests, as needed, when a higher-priority interrupt is presented to it, and the write to the `SEC_END` register in the SEC handler epilog code guarantees that each nested level has the required handshaking to signal to the SEC block that each individual source ID interrupt request is fully serviced. Please refer to the *SHARC+ Core Programming Reference* for more details regarding SEC handler code.

Configuring a System Source as a Fault

1. Write to the `SEC_GCTL` register to enable the SEC.

2. Write to the `SEC_FCTL` register to configure specific fault actions.
3. Write to the `SEC_FDLY` bit field to specify fault delay.
4. Write to the control register of a specific source to enable the source as a fault.

Configuring the WDOG Expiry Event to Issue a System Reset

Use the following procedure to configure the WDOG timer to issue a system reset.

1. Configure the `SEC_GCTL` register to enable the SEC.

   ADDITIONAL INFORMATION:

   ```
   *pREG_SEC0_GCTL = BITM_SEC_GCTL_EN;
   ```

2. Configure the `SEC_FCTL` register to choose the Fault response mode. In the following code example, the system reset is issued.

   ADDITIONAL INFORMATION:

   ```
   *pREG_RCU0_CTL  |= BITM_RCU_CTL_SRSTREQEN;
   *pREG_SEC0_FCTL |= BITM_SEC_FCTL_SREN;
   ```

   ADDITIONAL INFORMATION: Similarly, the program can also choose to signal the fault pin or choose to issue a trigger via the TRU as a response to the fault source (WDOG expiry is the fault source in this example) by programming the relevant bit fields in the `SEC_FCTL` register.

3. Configure the `SEC_SCTL[n].SEN` and `SEC_SCTL[n].FEN` bits in the Source Control 3 (n=3) register registers to determine how the fault source is handled. To configure the WDOG as the fault source, program the register. The program can configure any interrupt as the fault source by programming the corresponding register.

   ADDITIONAL INFORMATION:

   ```
    *pREG_SEC0_SCTL3 = BITM_SEC_SCTL_FEN|BITM_SEC_SCTL_SEN;
   ```

   ADDITIONAL INFORMATION: The SEC ID corresponding to WDOG0 is 3, as indicated in Table 7-3 ADSP-SC58x *Combined SEC and GIC Interrupt List*.

4. Write to the enable bit.

   ADDITIONAL INFORMATION:

   ```
   *pREG_SEC0_FCTL |= BITM_SEC_FCTL_EN;
   ```

SEC Programming Restrictions

Setting the `SEC_FCTL.EN` bit while the `SEC_FSTAT.ACT` bit is high can result in unpredictable behavior. To avoid this issue, set the `SEC_FCTL.EN` bit while the `SEC_FSTAT.ACT` bit is low. The `SEC_FSTAT.ACT` bit is only set when the `SEC_FCTL.EN` bit is high. Therefore, the problem can only occur if the `SEC_FCTL.EN` bit transitions from 1 to 0 and then to 1 again.

Writing to `SEC_FEND` to end a fault with both the `SEC_FCTL.FOEN` bit and the `SEC_FCTL.FIEN` bit set can result in erroneous external fault detection. If this operation (ending a fault) and configuration (fault input and fault output enabled) are required by the application, clear the `SEC_FCTL.FOEN` bit prior to writing to `SEC_FEND`. The recommended sequence for ending a fault with the `SEC_FCTL.FIEN` or `SEC_FCTL.FOEN`==1 is as follows:

1. Clear the `SEC_FCTL.FOEN` bit.
2. Write to the `SEC_FEND` register.
3. Set the `SEC_FCTL.FOEN` bit.

ADSP-SC58x SEC Register Descriptions

System Event Controller (SEC) contains the following registers.

Table 7-4: ADSP-SC58x SEC Register List

Name	Description
`SEC_CACT[n]`	SCI Active Register n
`SEC_CCTL[n]`	SCI Control Register n
`SEC_CGMSK[n]`	SCI Group Mask Register n
`SEC_CPLVL[n]`	SCI Priority Level Register n

Figure 7-7: SEC_CCTL[n] Register Diagram

Table 7-6: SEC_CCTL[n] Register Fields

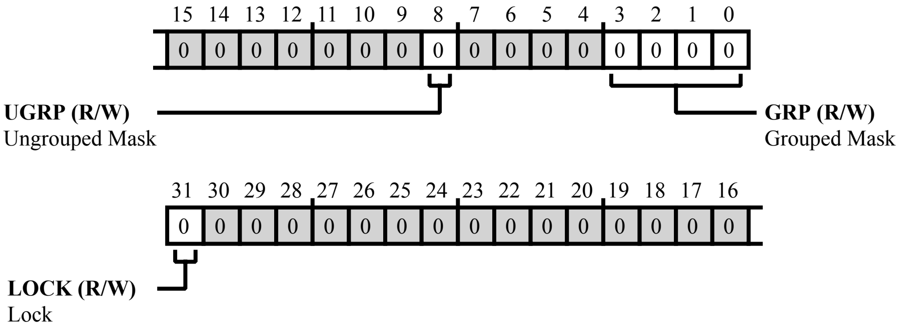
Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `SEC_CCTL[n].LOCK` bit is enabled, the `SEC_CCTL[n]` register is read only.	
		0	Unlock
		1	Lock
16 (R/W)	NMIEN	NMI Enable. The `SEC_CCTL[n].NMIEN` bit controls NMI propagation to the core. When the `SEC_CCTL[n].NMIEN` bit is enabled, the SCI allows NMIs to propagate to the core for servicing.	
		0	Disable
		1	Enable
12 (R0/W)	WFI	Wait For Idle. When set, the `SEC_CCTL[n].WFI` bit forces the SCI to wait for indication of core idle before the SCI resumes activity.	
		0	No Action
		1	Wait for Idle

Table 7-6: SEC_CCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R0/W)	RESET	Reset. When set, the `SEC_CCTL[n].RESET` bit resets all SCI registers to their default values.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The `SEC_CCTL[n].EN` bit controls operation of the SCI. Clearing the `SEC_CCTL[n].EN` bit halts the execution of the SCI without resetting status registers. (The INT signal to a core is not affected.) Setting the `SEC_CCTL[n].EN` bit enables the SCI to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

SCI Group Mask Register n

The SEC SCI group mask register (`SEC_CGMSK[n]`) contains selections for a group mask, an ungroup mask, and a register lock. This register contains the system interrupt group masks for the connected core. The core uses the `SEC_CGMSK[n].UGRP` and `SEC_CGMSK[n].GRP` fields to mask (disable) interrupts from the specified groups.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

SCI Priority Level Register n

The SEC SCI priority level register (`SEC_CPLVL[n]`) contains selections for priority levels and a register lock. This register is used to divide the total number of priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same level.

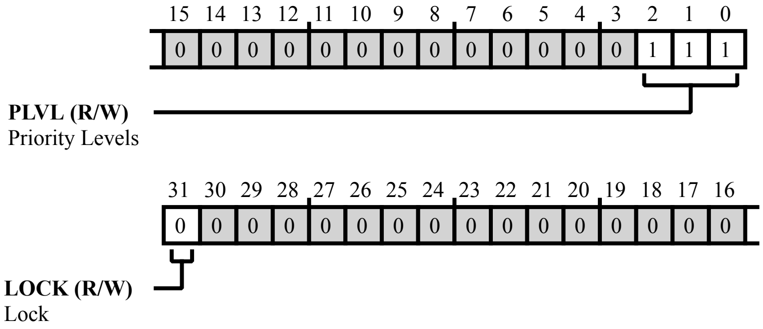

Figure 7-9: SEC_CPLVL[n] Register Diagram

Table 7-8: SEC_CPLVL[n] Register Fields

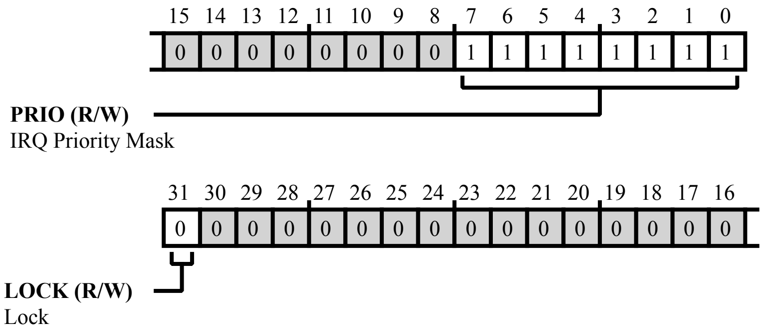
Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `SEC_CPLVL[n].LOCK` bit is enabled, the `SEC_CPLVL[n]` register is read only.	
		0	Unlock
		1	Lock
2:0 (R/W)	PLVL	Priority Levels. The `SEC_CPLVL[n].PLVL` field serves to divide the total number of interrupt priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same interrupt level. The sub-level priority value specifies the number of MSBs (minus 1) designated to interrupt levels, while the remaining LSBs are designated for sub-level specification. For example, if the `SEC_CPLVL[n].PLVL` field is set to two, the result is four priority levels are specified, because only the two MSBs are used for preemption evaluation. The remaining bits of the priority setting are used for sub-level prioritization.	
		0	1 MSBs (2 priority levels)
		1	2 MSBs (4 priority levels)
		2	3 MSBs (8 priority levels)
		3	4 MSBs (16 priority levels)
		4	5 MSBs (32 priority levels)
		5	6 MSBs (64 priority levels)

Table 7-8: SEC_CPLVL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	7 MSBs (128 priority levels)
		7	8 MSBs (256 priority levels)

SCI Priority Mask Register n

The SEC SCI priority mask register (`SEC_CPMSK[n]`) contains the SCI priority mask for core n and includes a register lock.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

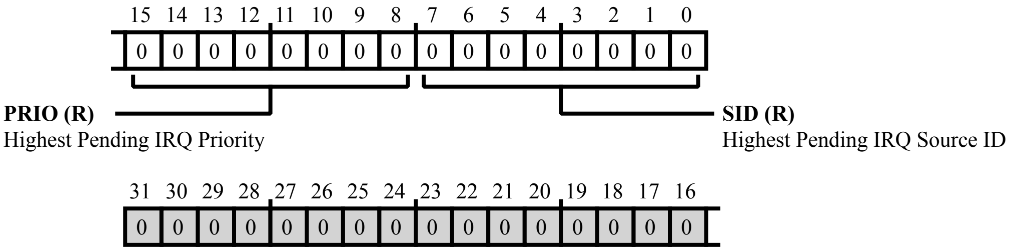
31 (R/W)	LOCK	Lock. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `SEC_CPMSK[n].LOCK` bit is enabled, the `SEC_CPMSK[n]` register is read only.	
		0	Unlock
		1	Lock
7:0 (R/W)	PRIO	IRQ Priority Mask. The `SEC_CPMSK[n].PRIO` contains the system interrupt priority mask for core n. The core uses the `SEC_CPMSK[n].PRIO` field to mask (block) interrupts below the specified level.	
		0	Priority level 0 (highest)
		1-254	
		255	Priority level 255 (lowest)

Core Pending Register n

The SCI pending interrupt register (`SEC_CPND[n]`) contains the source ID and priority of the highest priority pending interrupt detected by the SEC prioritizer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PRIO (R)

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

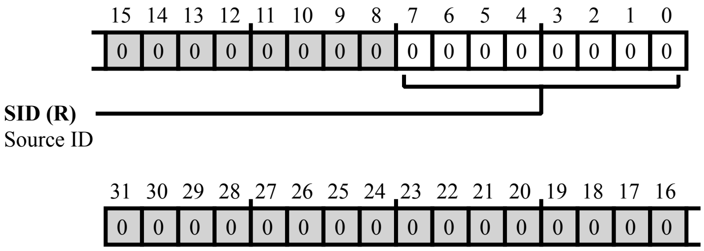
Figure 7-11: SEC_CPND[n] Register Diagram

Table 7-10: SEC_CPND[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Pending IRQ Priority. The `SEC_CPND[n].PRIO` indicates the priority value of the highest priority pending interrupt for core n.
7:0 (R/NW)	SID	Highest Pending IRQ Source ID. The `SEC_CPND[n].SID` identifies the source ID value of the highest priority pending interrupt for core n.

SCI Source ID Register n

The SCI source ID register (`SEC_CSID[n]`) contains the source ID of the interrupt last issued to core n. The `SEC_CSID[n]` register value is loaded by the SCI when a system interrupt indication is sent to core n. The SCI does not change the `SEC_CSID[n]` until after the interface receives an interrupt acknowledge from core n. Writing to the `SEC_CSID[n]` register generates an interrupt acknowledge, but does not update the value in the register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
NMI (R/W1C)
Non-Maskable Interrupt

Figure 7-13: SEC_CSTAT[n] Register Diagram

Table 7-12: SEC_CSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	NMI	Non-Maskable Interrupt. The `SEC_CSTAT[n].NMI` bit indicates whether an NMI has occurred since the bit was last cleared.	
		0	No NMI Occurred
		1	NMI Occurred
12 (R/W1C)	WFI	Wait For Idle. The `SEC_CSTAT[n].WFI` bit indicates (if set) that the SCI is temporarily disabled, pending a core idle indication. This bit is set when `SEC_CCTL[n].WFI` is set.	
		0	Not Waiting
		1	Waiting
10 (R/NW)	SIDV	SID Valid. The `SEC_CSTAT[n].SIDV` bit indicates (if set) that the current value in the `SEC_CSID[n]` register is valid. The SCI sets the `SEC_CSTAT[n].SIDV` bit when the updating the `SEC_CSID[n]` register with a new value. The `SEC_CSTAT[n].SIDV` bit is cleared when the `SEC_CSID[n]` register is written. This status indication may be used to extract all pending interrupts in a single interrupt service routine.	
		0	Invalid
		1	Valid

Table 7-12: SEC_CSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	ACTV	ACT Valid. The `SEC_CSTAT[n].ACTV` bit indicates (if set) that the current value in the `SEC_CACT[n]` register is valid. The SCI sets the `SEC_CSTAT[n].ACTV` bit when updating the `SEC_CACT[n]` registers with a new value. The `SEC_CSTAT[n].ACTV` bit is cleared when the `SEC_CSID[n]` register is written.	
		0	Invalid
		1	Valid
8 (R/NW)	PNDV	PND Valid. The `SEC_CSTAT[n].PNDV` bit indicates (if set) that the current value in the `SEC_CPND[n]` register is valid. The SCI sets the `SEC_CSTAT[n].PNDV` bit when updating the `SEC_CPND[n]` register with a new value. The `SEC_CSTAT[n].PNDV` bit is cleared when the `SEC_CSID[n]` register is written.	
		0	Invalid
		1	Valid
5:4 (R/NW)	ERRC	Error Cause. The `SEC_CSTAT[n].ERRC` bits are updated on assertion of the `SEC_CSTAT[n].ERR` bit to indicate the SCI error type. `SEC_CSTAT[n].ERRC` is only updated on the assertion of `SEC_CSTAT[n].ERR`. Subsequent errors while `SEC_CSTAT[n].ERR` is asserted do not update `SEC_CSTAT[n].ERRC`.	
		0	Reserved
		1	Acknowledge Error. SCI has received an acknowledge without a pending, unacknowledged interrupt present.
		2	Reserved
		3	Reserved
1 (R/W1C)	ERR	Error. The `SEC_CSTAT[n].ERR` bit indicates that an error has occurred in the SCI. When `SEC_CSTAT[n].ERR` is set, the SCI updates the `SEC_CSTAT[n].ERRC` field to the value of the corresponding error cause.	
		0	No Error
		1	Error Occurred

Global End Register

The SEC global end register (SEC_END) contains a source ID interrupt service end field (SEC_END.SID). When a core has finished servicing an interrupt, the core writes the SEC_END.SID field in the SEC_END register. This write causes the SEC to clear the SEC_SSTAT[n].ACT bit in the SEC_SSTAT[n] register of the corresponding interrupt.

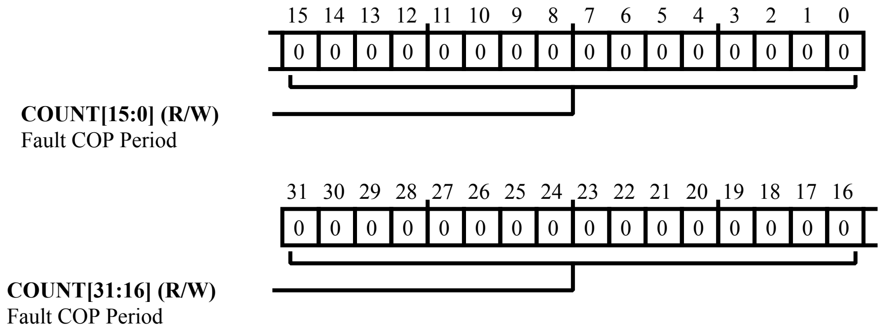
Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID IRQ to End. The SEC_END.SID bit field contains the source ID interrupt service end value.

Fault COP Period Register

The SEC fault COP period register (`SEC_FCOPP`) contains the width value (count in (SEC) clock cycles) for the high and low phase of the computer operating properly (COP) toggled output on the COP pin. Note that the actual high/low phase value is the `SEC_FCOPP.COUNT` programmed value plus 1.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Fault COP Period

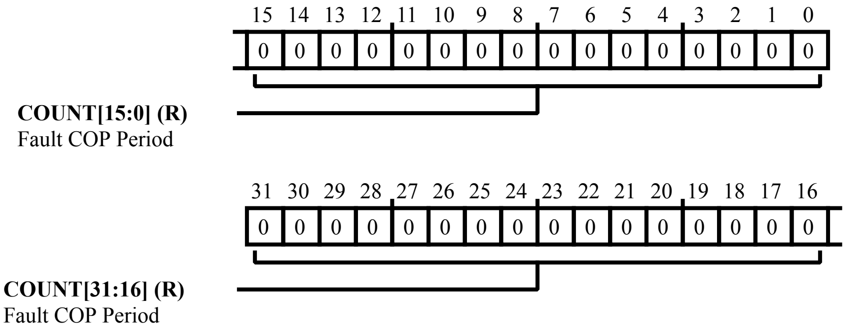
Figure 7-15: SEC_FCOPP Register Diagram

Table 7-14: SEC_FCOPP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault COP Period. The `SEC_FCOPP.COUNT` bit field is the width value for the high and low phase of the computer operating properly (COP) toggled output on the COP pin.

Fault COP Period Current Register

The SEC fault COP period current register (SEC_FCOPP_CUR) contains the active count (in (SEC) clock periods) for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin. The SEC loads the SEC_FCOPP_CUR register from the SEC_FCOPP register when the SEC_FCOPP_CUR.COUNT field is cleared and the SEC is in COP mode (SEC_FCTL.CMS bit =1). The SEC decrements the SEC_FCOPP_CUR count each (SEC) clock cycle while SEC_FCTL.CMS is set and the SEC_FSTAT.ACT bit is not set.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
COUNT[31:16] (R)
Fault COP Period

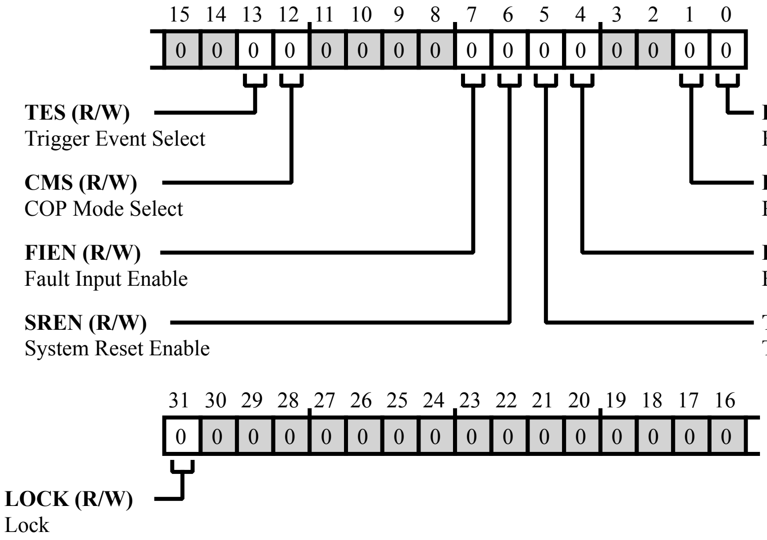
Figure 7-16: SEC_FCOPP_CUR Register Diagram

Table 7-15: SEC_FCOPP_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault COP Period. The SEC_FCOPP_CUR.COUNT bit field is the active count for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin.

Fault Control Register

The SEC fault control register (SEC_FCTL) contains fault control bits for all SEC channels. This register controls the operation of the System Fault Management Interface (SFI).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LOCK (R/W)
Lock

Figure 7-17: SEC_FCTL Register Diagram

Table 7-16: SEC_FCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `SEC_FCTL.LOCK` bit is enabled, the `SEC_FCTL` register is read only.	
		0	UnLock
		1	Lock
13 (R/W)	TES	Trigger Event Select. The `SEC_FCTL.TES` bit selects the event that directs the SEC to assert trigger output. In fault pending mode, the SEC asserts trigger output when a fault is pending. In fault active mode, the SEC asserts trigger output when a fault is active.	
		0	Fault Active Mode
		1	Fault Pending Mode

Table 7-16: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	CMS	COP Mode Select. The `SEC_FCTL.CMS` selects the SEC mode for handling fault input. In COP mode, the SEC toggles the COP pin to indicate that no fault is active and ceases toggling the pin to indicate that a fault is active. In fault mode, the SEC deasserts the fault pin (=0) and fault_b pin (=1) when no fault is active and asserts the fault pin (=1) and fault_b pin (=0) when a fault is active. Not all processors feature both the fault and fault_b pins. Refer to the product data sheet for details.	
		0	Fault Mode
		1	COP Mode
7 (R/W)	FIEN	Fault Input Enable. The `SEC_FCTL.FIEN` bit enables the SEC to sample fault input. If `SEC_FCTL.FIEN` is set (=1), a fault indication from an external device sets the `SEC_FSTAT.ACT` bit and `SEC_FSID.FEXT` bit.	
		0	Disable
		1	Enable
6 (R/W)	SREN	System Reset Enable. The `SEC_FCTL.SREN` bit enables the SEC to issue a system reset request when a fault becomes active.	
		0	Disable
		1	Enable
5 (R/W)	TOEN	Trigger Output Enable. The `SEC_FCTL.TOEN` bit enables the SEC to produce trigger output when a fault becomes active.	
		0	Disable
		1	Enable
4 (R/W)	FOEN	Fault Output Enable. The `SEC_FCTL.FOEN` bit enables the SEC to indicate fault status, according to the `SEC_FCTL.CMS` bit configuration.	
		0	Disable
		1	Enable
1 (R0/W)	RESET	Reset. Setting the `SEC_FCTL.RESET` bit resets ALL SEC registers to their default values.	
		0	No Action
		1	Reset

COUNT[31:16] (R/W)
Fault Delay

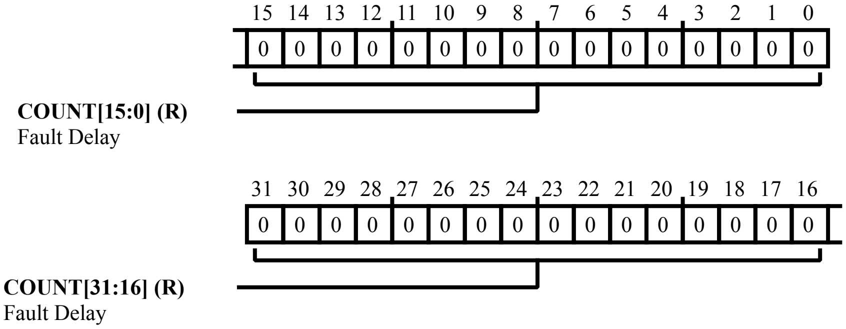
Figure 7-18: SEC_FDLY Register Diagram

Table 7-17: SEC_FDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault Delay. The `SEC_FDLY.COUNT` bit field is the number of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

Fault Delay Current Register

The SEC fault delay current register (`SEC_FDLY_CUR`) contains the active count (`SEC_FDLY_CUR.COUNT` field) in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled. The count is loaded from the `SEC_FDLY` register when a fault becomes pending (`SEC_FSTAT.PND` bit is set). The SEC decrements the value in `SEC_FDLY_CUR` each (SEC) clock cycle while the `SEC_FSTAT.PND` bit is set.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

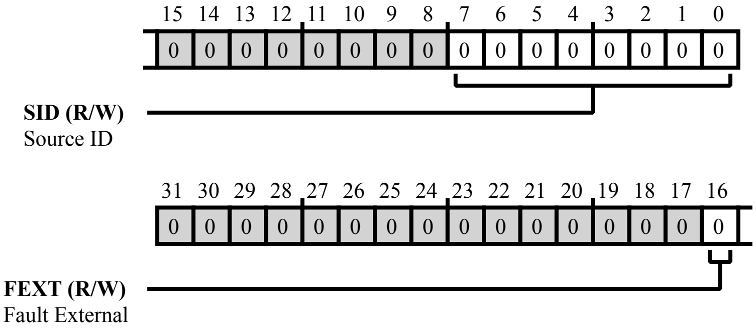
31:0 (R/NW)	COUNT	Fault Delay. The `SEC_FDLY_CUR.COUNT` bit field is the active count in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled.

Fault End Register

The SEC fault end register (`SEC_FEND`) contains fault source ID and internal/external fields. This register receives fault end indication from a core.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SID (R/W)
Source ID
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
FEXT (R/W)
Fault External

Figure 7-20: SEC_FEND Register Diagram

Table 7-19: SEC_FEND Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	FEXT	Fault External. Setting the `SEC_FEND.FEXT` bit, when the `SEC_FEND.SID` field is cleared, clears an active fault from an external source.	
		0	Fault Internal
		1	Fault External
7:0 (R/W)	SID	Source ID. The `SEC_FEND.SID` identifies a fault to be ended as indicated to the SEC by the core. The core loads the `SEC_FEND.SID` field value. If the `SEC_FEND.SID` value matches the `SEC_FSID.SID` value, the `SEC_FSTAT.PND` bit and `SEC_FSTAT.ACT` bit are cleared.	

Fault Source ID Register

The SEC fault source ID register (`SEC_FSID`) contains a fault source ID and internal/external fields.

NOTE:These bits are not reset by system reset so that a fault that automatically triggers a system reset to avoid a fault may be analyzed after the reset occurs.

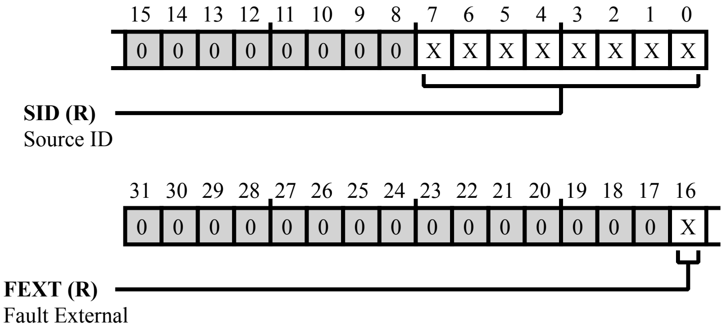


Figure 7-21: SEC_FSID Register Diagram

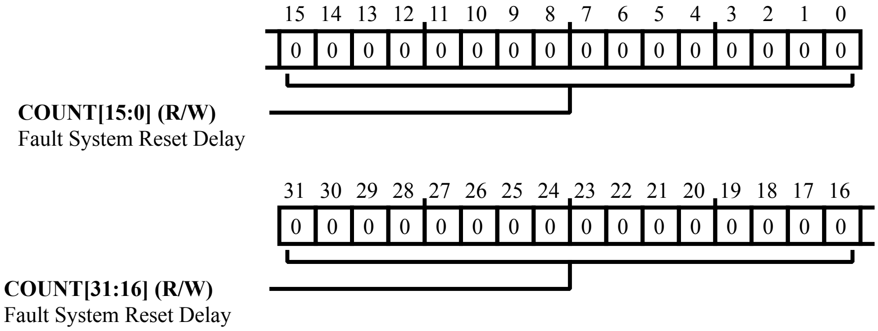
Table 7-20: SEC_FSID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	FEXT	Fault External. The `SEC_FSID.FEXT` bit indicates that the last active fault was asserted by an external device. The SEC sets the `SEC_FSID.FEXT` bit when the `SEC_FSTAT.ACT` bit is set by the fault input pins. The `SEC_FSID.FEXT` bit is cleared when the `SEC_FSTAT.ACT` bit is set by an internal fault or when the external fault is ended. When the `SEC_FSID.FEXT` bit is set, the `SEC_FSID.SID` is cleared.	
		0	Fault Internal
		1	Fault External
7:0 (R/NW)	SID	Source ID. The `SEC_FSID.SID` identifies the fault assertion detected by the SEC fault interface. The SEC loads the `SEC_FSID.SID` field value when a system fault indication is asserted. The SEC fault interface does not change the `SEC_FSID.SID` value until the fault is no longer pending or active, as indicated by the `SEC_FSTAT.PND` bit and `SEC_FSTAT.ACT` bit being cleared in the `SEC_FSTAT` register.	

Fault System Reset Delay Register

The SEC fault system reset delay register (`SEC_FSRDLY`) contains the number (`SEC_FSRDLY.COUNT` field) of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion, if enabled.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Fault System Reset Delay

Figure 7-22: SEC_FSRDLY Register Diagram

Table 7-21: SEC_FSRDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault System Reset Delay. The `SEC_FSRDLY.COUNT` bit field is the number of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion.

Fault System Reset Delay Current Register

The SEC fault system reset delay current register (`SEC_FSRDLY_CUR`) contains the active count (`SEC_FSRDLY_CUR.COUNT` field) in (SEC) clock periods for the delay from fault active to system reset assertion, if enabled. The count is loaded from the `SEC_FSRDLY` register when a fault becomes active (`SEC_FSTAT.ACT` bit is set). The SEC decrements the value in `SEC_FSRDLY_CUR` each (SEC) clock cycle while the `SEC_FSTAT.ACT` bit is set.

Figure 7-24: SEC_FSTAT Register Diagram

Table 7-23: SEC_FSTAT Register Fields

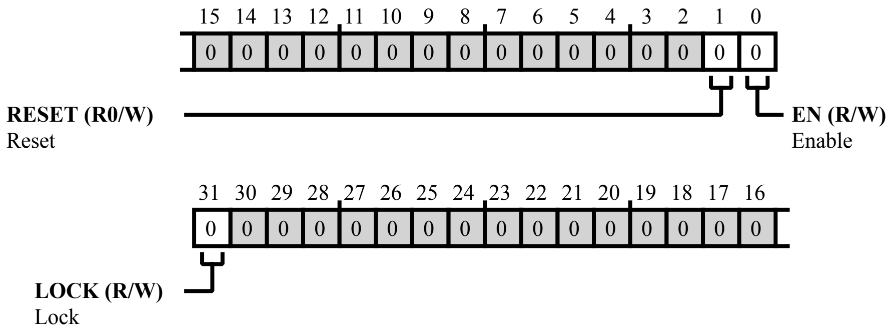
Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/NW)	NPND	Next Pending Fault. The SEC_FSTAT.NPND bit indicates that one or more sources have signaled fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.	
		0	Not Pending
		1	Pending
9 (R/NW)	ACT	Fault Active. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the current fault delay count (in the SEC_FDLY_CUR register) has expired, and the fault actions are enabled. The SEC also sets the SEC_FSTAT.ACT bit on fault input detection if the SEC_FCTL.FIEN bit is set. The SEC_FSTAT.ACT bit is cleared by writing the ID value of the asserted fault from SEC_FSID register to the SEC_FEND register.	
		0	No Fault
		1	Active Fault

Table 7-23: SEC_FSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	PND	Pending Fault. The `SEC_FSTAT.PND` bit indicates a fault source has signaled a fault assertion to the SEC, but the SEC has not yet triggered the event actions due to the delay selected with the `SEC_FDLY` register. The SEC fault interface sets the `SEC_FSTAT.PND` bit when the `SEC_FSID` is updated on assertion of a fault source input. The `SEC_FSTAT.PND` bit is only set when the `SEC_FSTAT.ACT` bit is cleared. The SEC updates the `SEC_FSID` register with the SID value when the `SEC_FSTAT.PND` bit is set. The `SEC_FSTAT.PND` bit is cleared *either* by the SEC fault interface when the current delay count in the `SEC_FDLY_CUR` register expires *or* by writing the `SEC_FSID.SID` field value (which indicates the ID of the asserted fault) to the `SEC_FEND` register.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the `SEC_FSTAT.ERR` bit is asserted, the SEC updates `SEC_FSTAT.ERRC` field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the `SEC_FSTAT.ACT` bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The `SEC_FSTAT.ERR` bit indicates an SEC fault interface error. When `SEC_FSTAT.ERR` is set, the SEC updates the `SEC_FSTAT.ERRC` field to indicate the corresponding error cause. When multiple errors occur, the `SEC_FSTAT` register captures the status for the first error and does not capture subsequent errors until the status is cleared.	
		0	No Error
		1	Error Occurred

Global Control Register

The SEC global control register (`SEC_GCTL`) provides register locking, reset, and enable for the SEC module.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RESET (R0/W)
Reset
EN (R/W)
Enable

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LOCK (R/W)
Lock

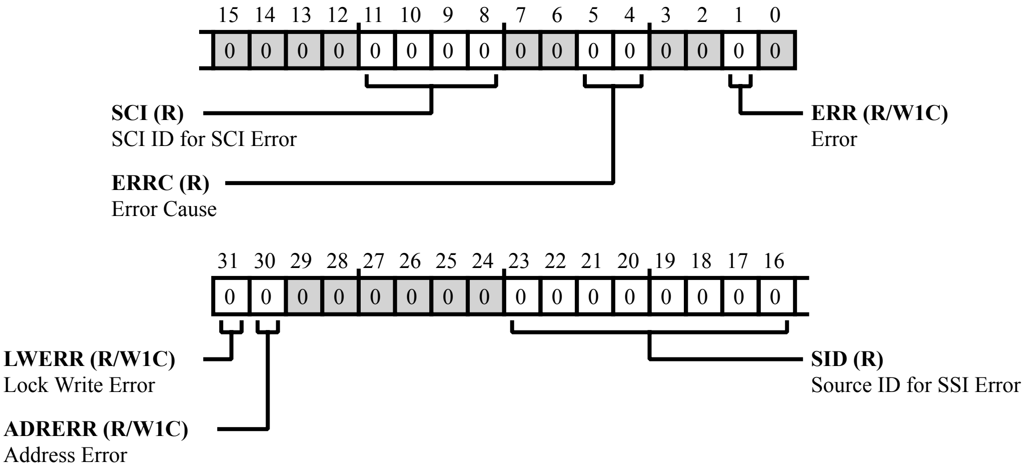
Figure 7-25: SEC_GCTL Register Diagram

Table 7-24: SEC_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `SEC_GCTL.LOCK` bit is enabled, the `SEC_GCTL` register is read only.	
		0	Unlock
		1	Lock
1 (R0/W)	RESET	Reset. The `SEC_GCTL.RESET` bit is write-1-action and triggers a soft reset to all SEC registers.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The `SEC_GCTL.EN` bit is read/write and must be set for the SEC to begin/resume SEC operation with the current configuration and status. Clearing the `SEC_GCTL.EN` bit halts the execution of the SFI and all SCIs. All SSIs remain active, along with all error detection, without resetting status registers.	
		0	Disable
		1	Enable

Global Status Register

The SEC global status register (`SEC_GSTAT`) contains global status bits for the SEC.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SCI (R)
SCI ID for SCI Error

Error Cause
ERR (R/W1C)
Error
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LWERR (R/W1C)
Lock Write Error
ADRERR (R/W1C)
Address Error
SID (R)
Source ID for SSI Error

Figure 7-26: SEC_GSTAT Register Diagram

Table 7-25: SEC_GSTAT Register Fields

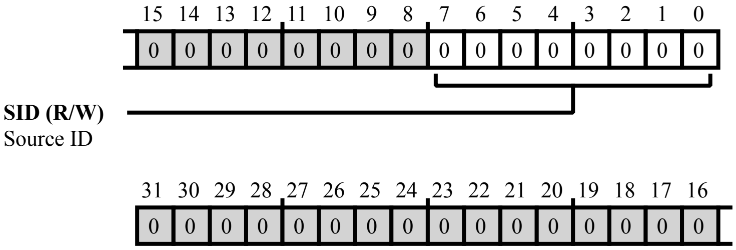
Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Lock Write Error. The `SEC_GSTAT.LWERR` bit indicates (when set) there was an attempted write to an SEC register while the `SEC_GCTL.LOCK` bit was set and while the global lock bit was enabled (`SPU_CTL.GLCK` bit =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
30 (R/W1C)	ADRERR	Address Error. The `SEC_GSTAT.ADRERR` bit indicates that the SEC generated and address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
23:16 (R/NW)	SID	Source ID for SSI Error. The `SEC_GSTAT.SID` bits indicate the source ID that generated the last SSI error conveyed in the `SEC_GSTAT.ERRC` field.	
11:8 (R/NW)	SCI	SCI ID for SCI Error. The `SEC_GSTAT.SCI` bits indicate the number for the specific SCI that generated the last SCI error conveyed in the `SEC_GSTAT.ERRC` field.	

Table 7-25: SEC_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	ERRC	Error Cause. When the SEC updates the `SEC_GSTAT.ERR` bit, the SEC updates the `SEC_GSTAT.ERRC` bits to indicate the error type. Note that for SCI errors, the error status represents an OR of all the errors from each SCI. Note that for SSI errors, the error status indicates an error is active for any SSI input. This error is an OR of all the interrupt source errors.	
		0	SFI Error
		1	SCI Error
		2	SSI Error
		3	Reserved
1 (R/W1C)	ERR	Error. The `SEC_GSTAT.ERR` bit indicates an error has occurred in the SEC. When the SEC asserts this bit (=1), the SEC updates the `SEC_GSTAT.ERRC` field to indicate the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of this bit. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred

Global Raise Register

The SEC global raise register (`SEC_RAISE`) contains a source ID event set-to-pending field (`SEC_RAISE.SID`). When a source ID value is written to this field, the SEC raises the source's event status to pending.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

LOCK (R/W)
Lock
CTG (R/W)
Core Target Select
GRP (R/W)
Group Select

Figure 7-28: SEC_SCTL[n] Register Diagram

Table 7-27: SEC_SCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `SEC_SCTL[n].LOCK` bit is enabled, the `SEC_SCTL[n]` register is read only.	
		0	Unlock
		1	Lock
27:24 (R/W)	CTG	Core Target Select. The `SEC_SCTL[n].CTG` bits selects the specific SEC core interface to which the interrupt is mapped. Each system interrupt is mapped uniquely to one specific SEC core interface and (as a result) to a specific core.	

Table 7-27: SEC_SCTL[n] Register Fields (Continued)

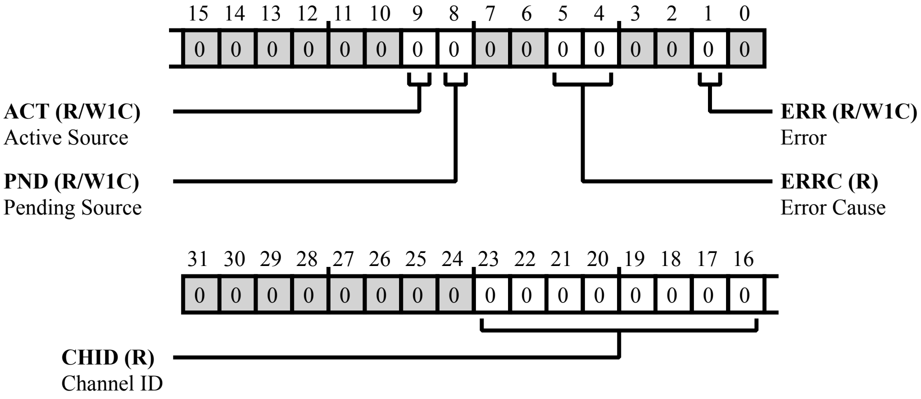
Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	GRP	Group Select. The `SEC_SCTL[n].GRP` bits each select a specific group for the interrupt. Each system interrupt can be assigned to any combination of groups supported by the `SEC_SCTL[n].GRP` field. For example, consider the situation where `SEC_SCTL[n].GRP`0 represents interrupt group 0, `SEC_SCTL[n].GRP`1 represents interrupt group 1, and so on. One group might be used for all enabled interrupts (for example, group 0) and an additional group might be used for all wakeup interrupts (for example, group 1). This approach supports a model of all interrupts and just the wakeup subset. Before going to idle or sleep, all non-wakeup interrupts can be masked off to allow only wakeup interrupts to be enabled for service. Selecting no group (all `SEC_SCTL[n].GRP` bits = 0) places the interrupt source in the category of "ungrouped".	
15:8 (R/W)	PRIO	Priority Level Select. The `SEC_SCTL[n].PRIO` bits sets the relative priority for an interrupt request. A pending interrupt request forwards its `SEC_SCTL[n].PRIO` value to the SEC core interface.	
4 (R/W)	ERREN	Error Enable. The `SEC_SCTL[n].ERREN` bit permits the `SEC_SSTAT[n].ERR` status bit to be set on error detection. If `SEC_SCTL[n].ERREN` is cleared, no errors are detected.	
		0	Disable
		1	Enable
3 (R/W)	ES	Edge Select. The `SEC_SCTL[n].ES` bit selects the operational and sensitivity mode of the SEC source interface input.	
		0	Level Sensitive
		1	Edge Sensitive
2 (R/W)	SEN	Source (signal) Enable. The `SEC_SCTL[n].SEN` bit controls whether the system event source input signal may affect the pending status of the source. Clearing the `SEC_SCTL[n].SEN` bit disables the source input signal from affecting the pending status. Setting `SEC_SCTL[n].SEN` enables the source input signal to affect the pending status.	
		0	Disable
		1	Enable

Table 7-27: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FEN	Fault Enable. The `SEC_SCTL[n].FEN` bit controls whether the SEC may forward an interrupt request to the SEC fault interface as a fault source. This bit does not affect the ability of an interrupt source to set an interrupt as pending. The `SEC_SCTL[n].FEN` bit only affects whether the pending request may be forwarded to the SEC fault interface.	
		0	Disable
		1	Enable
0 (R/W)	IEN	Interrupt Enable. The `SEC_SCTL[n].IEN` bit controls whether the SEC may forward an interrupt request to a core for servicing. This bit does not affect the ability of an interrupt source to set an interrupt as pending.	
		0	Disable
		1	Enable

Source Status Register n

The SEC event source status register (`SEC_SSTAT[n]`) contains bits indicating the status of the corresponding event source n. An event source may be: pending, active, active and pending, or neither pending nor active.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CHID (R)
Channel ID

Figure 7-29: SEC_SSTAT[n] Register Diagram

Table 7-28: SEC_SSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/NW)	CHID	Channel ID. The `SEC_SSTAT[n].CHID` bits indicate the ID of the specific source (from a set of sources sharing one SEC source interface input) that asserted the SEC source interface input. An SEC source interface input may support multiple system sources, in which case the assertion must be qualified by an identifier to determine the channel that generated the assertion. The `SEC_SSTAT[n].CHID` field provides this value in the form of a numeric reference that is mapped to a specific interrupt source. The prioritization for simultaneously asserted sources is according to ID, with 0 being the highest priority. The `SEC_SSTAT[n].CHID` is captured when the SEC source interface input is acknowledged.	
9 (R/W1C)	ACT	Active Source. The `SEC_SSTAT[n].ACT` bit indicates the source has been accepted by a core for servicing, but the service is not yet complete. An `SEC_SSTAT[n].ACT` bit is set by the SEC when the specific system interrupt is acknowledged by the core through the SEC core interface. An `SEC_SSTAT[n].ACT` bit is cleared by the SEC when the core provides interrupt service end indication for the specific system interrupt through the SEC core interface.	
		0	Not Active
		1	Active

Table 7-28: SEC_SSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	PND	Pending Source. The `SEC_SSTAT[n].PND` bit indicates the source has signaled an event request, but the event request has not been (or is not currently being) serviced. A `SEC_SSTAT[n].PND` bit is set by the SEC on detection of an assertion of the corresponding system source input. A `SEC_SSTAT[n].PND` bit is cleared by the SEC when the specific system event is acknowledged by the core through the SEC core interface or by a W1C operation.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the `SEC_SSTAT[n].ERR` bit is asserted, the SEC updates `SEC_SSTAT[n].ERRC` field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the `SEC_SSTAT[n].ACT` bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The `SEC_SSTAT[n].ERR` bit indicates an error for a specific system interrupt source. When the `SEC_SSTAT[n].ERR` bit is set, the SEC updates the `SEC_SSTAT[n].ERRC` field to the value of the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of the `SEC_SSTAT[n].ERR` bit.	
		0	No Error
		1	Error Occurred

GIC Overview

The generic interrupt controller (GIC) provides an interface to the uniprocessor Cortex A5 core in the processor and collects up to 270 interrupt requests from all processor system sources. In addition, the GIC also supports eight software generated interrupts that are internal to the Cortex A5 core and not connected to the SECs. All GIC interrupts are also connected to the SEC in the same order.

Each interrupt can be configured as a normal or a secure interrupt. Software force registers and software priority masking are also supported. The "Register Descriptions" section in this chapter provide brief descriptions of these ARM-based registers. For complete information refer to the *ARM® Generic Interrupt Controller Architecture version 1.0 Architecture Specification*.

GIC Functional Description

The GIC splits logically into a GICPORT0 (distributor block) and one GICPORT1 (CPU interface blocks).

General Interrupt Controller Port0 (GIC Distributer)

The distributor block provides a programming interface to perform the following tasks.

- Globally enable the forwarding of interrupts to the CPU interfaces
- Enable or disable each interrupt
- Set the priority level of each interrupt
- Set the target processor list of each interrupt
- Set each peripheral interrupt to be level-sensitive or edge-triggered
- Set each interrupt as either Group 0 or Group 1
- Forward an SGI to one or more target processors

In addition, the Distributor provides:

- Visibility of the state of each interrupt
- A mechanism for software to set or clear the pending state of a peripheral interrupt.

General Interrupt Controller Port1 (GIC CPU)

GICPORT1 (CPU interface) block performs priority masking and preemption handling for a connected processor in the system. GICPORT1 supports 8 SGIs (software generated interrupts) and 262 SPIs (shared peripheral interrupts).

Each CPU interface provides a programming interface to perform the following tasks.

- Enable signaling of interrupt requests to the processor
- Acknowledge interrupts
- Indicate that interrupt processing is complete
- Set interrupt priority masks for the processor
- Define the preemption policy for the processor
- Determine the highest priority pending interrupt for the processor

GIC Block Diagram

The *GIC Block Diagram* shows the event management architecture.

GICDST_SPI_SECURITY[n]	Shared Peripheral Interrupt Security Register
GICDST_SPI_TRGT[n]	Shared Peripheral Interrupt Processor Targets Register

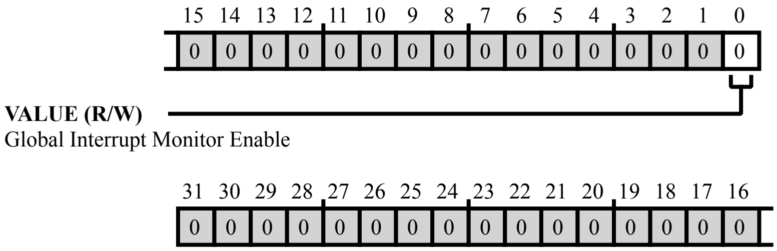
GIC Port 0 Enable

The `GICDST_EN` register enables global monitoring of the peripheral interrupt signals and forwarding pending interrupts to the CPU interfaces.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R/W)
Global Interrupt Monitor Enable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 7-31: GICDST_EN Register Diagram

Table 7-32: GICDST_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	Global Interrupt Monitor Enable. The `GICDST_EN.VALUE` bit field enables global monitoring of the peripheral interrupt signals and forwarding pending interrupts to the CPU interfaces.

Software Generated Interrupt Priority Register

The `GICDST_SGI_PRIO[n]` register provides the 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

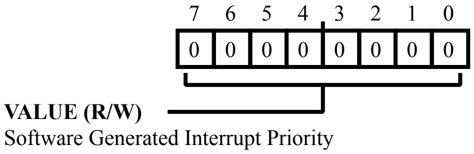


Figure 7-32: GICDST_SGI_PRIO[n] Register Diagram

Table 7-33: GICDST_SGI_PRIO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Software Generated Interrupt Priority. The `GICDST_SGI_PRIO[n].VALUE` bit field contains the 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

Shared Peripheral Interrupt Priority Register

The `GICDST_SPI_PRIO[n]` registers provide an 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

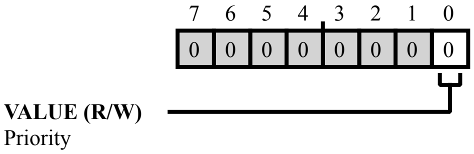

Figure 7-33: GICDST_SPI_PRIO[n] Register Diagram

Table 7-34: GICDST_SPI_PRIO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	Priority. The `GICDST_SPI_PRIO[n].VALUE` bit field stores the priority of the corresponding interrupt (byte offset 3 to Byte offset 0).

Software Generated Interrupt Active Register

The `GICDST_SGI_ACTIVE` registers provide a Set-active bit for each interrupt that the GIC supports. Writing to a Set-active bit Activates the corresponding interrupt. These registers are used when preserving and restoring GIC state.

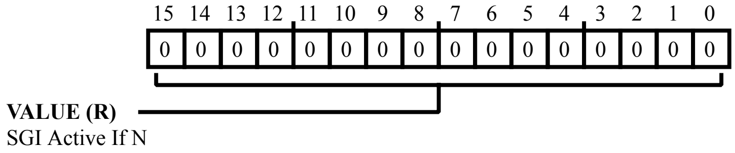

Figure 7-34: GICDST_SGI_ACTIVE Register Diagram

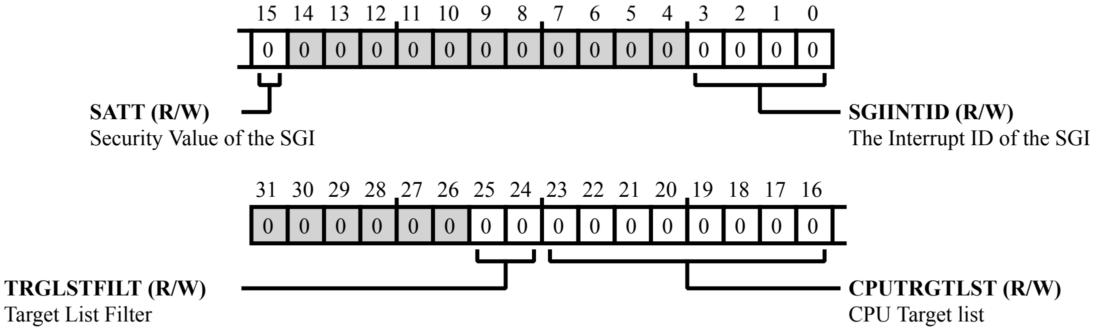
Table 7-35: GICDST_SGI_ACTIVE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	SGI Active If N. The `GICDST_SGI_ACTIVE.VALUE` bit field provides a Set-active bit for each interrupt that the GIC supports.

Software Generated Interrupt Control Register

The `GICDST_SGI_CTL` register controls the generation of SGIs.It is implementation defined whether this register has any effect when the forwarding of interrupts by Distributor is disabled by the GICD_CTLR settings.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SATT (R/W)
Security Value of the SGI
SGIINTID (R/W)

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TRGLSTFILT (R/W)
Target List Filter
CPUTRGTLST (R/W)
CPU Target list

Figure 7-35: GICDST_SGI_CTL Register Diagram

Table 7-36: GICDST_SGI_CTL Register Fields

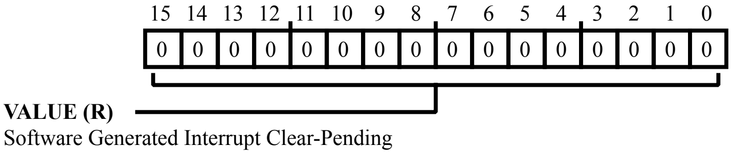
Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRGLSTFILT	Target List Filter. The `GICDST_SGI_CTL.TRGLSTFILT` bit field determines how the distributor must process the requested SGI.	
		0	Forward the interrupt to the CPU interfaces specified in the CPUTargetList field
		1	Forward the interrupt to all CPU interfaces except that of the processor that requested the interrupt
		2	Forward the interrupt only to the CPU interface of the processor that requested the interrupt
		3	Reserved
23:16 (R/W)	CPUTRGTLST	CPU Target list. When the `GICDST_SGI_CTL.CPUTRGTLST` bit field TargetList Filter = 0b00, defines the CPU interfaces to which the Distributor must forward the interrupt. Each bit of the `GICDST_SGI_CTL.CPUTRGTLST` bit field refers to the corresponding CPU interface, for example CPUTargetList[0] corresponds to CPU interface 0. Setting a bit to 1 indicates that the interrupt must be forwarded to the corresponding interface. If this field is 0x00 when TargetListFilter is 0b00, the Distributor does not forward the interrupt to any CPU interface.	

Table 7-36: GICDST_SGI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SATT	Security Value of the SGI. The `GICDST_SGI_CTL.SATT` bit is implemented only if the GIC includes the Security Extensions. This field is writable only by a Secure access. Any Non-secure write to the GICD_SGIR generates an SGI only if the specified SGI is programmed as Group 1, regardless of the value of bit[15] of the write.	
		0	Forward the SGI specified in the SGIINTID field to a specified CPU interface only if the SGI is configured as Group 0 on that interface.
		1	Forward the SGI specified in the SGIINTID field to a specified CPU interfaces only if the SGI is configured as Group 1 on that interface.
3:0 (R/W)	SGIINTID	The Interrupt ID of the SGI.	

Software Generated Interrupt Clear-Pending Register

The `GICDST_SGI_PND_CLR` register provides a clear pending bit for each interrupt supported by the GIC. Writing 1 to a clear-pending bit clears the pending status of the corresponding peripheral interrupt. Reading a bit identifies whether the interrupt is pending.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R)
Software Generated Interrupt Clear-Pending

Figure 7-36: GICDST_SGI_PND_CLR Register Diagram

Table 7-37: GICDST_SGI_PND_CLR Register Fields

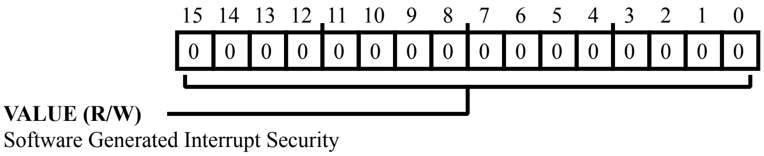
Table 7-38: GICDST_SGI_PND_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Software Generated Interrupt Set-Pending. Writing 1 to a Set-pending bit in the `GICDST_SGI_PND_SET.VALUE` bit field sets the status of the corresponding peripheral interrupt to pending. Reading a bit identifies whether the interrupt is pending.

Software Generated Interrupt Security Register

The `GICDST_SGI_SECURITY` registers provide a status bit for each interrupt supported by the GIC. Each bit controls whether the corresponding interrupt is in Group 0 or Group 1. Typically, when used with a processor that implements the ARM Security Extensions, Group 0 interrupts are Secure interrupts, and Group 1 interrupts are Non-secure interrupts,



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

STAT[31:16] (R)
Shared Peripheral Interrupt Status

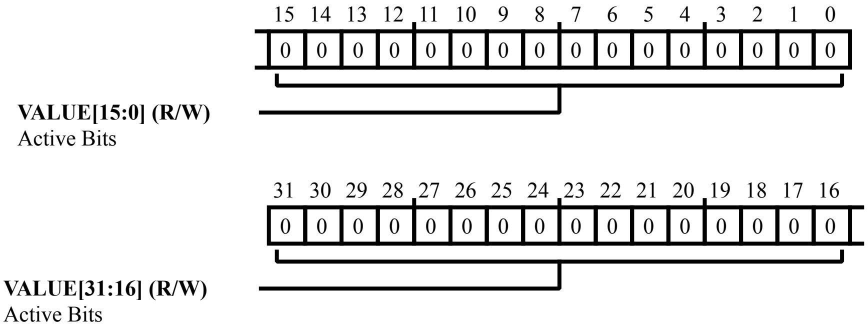
Figure 7-39: GICDST_SPI[n] Register Diagram

Table 7-40: GICDST_SPI[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	STAT	Shared Peripheral Interrupt Status. The `GICDST_SPI[n].STAT` bit field returns the status of the SPI[987:0] inputs on the distributor where bit [x] = 0 SPI[x] is low and bit [x] = 1 SPI[x] is high.

Shared Peripheral Interrupt Active Register

The `GICDST_SPI_ACTIVE[n]` register provides an active bit for each interrupt supported by the GIC.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

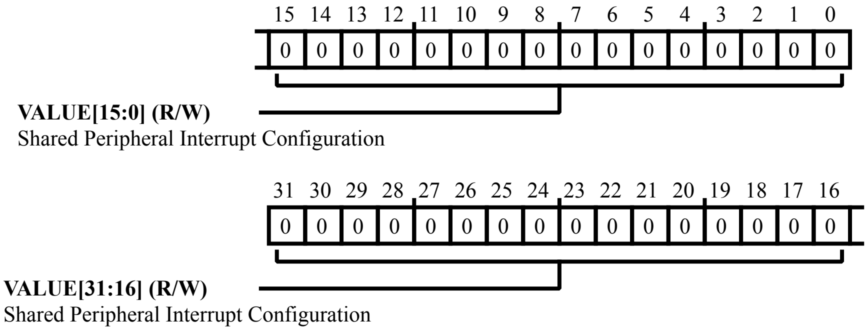
Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Active Bits. The `GICDST_SPI_ACTIVE[n].VALUE` bit field contains an Active bit for each interrupt supported by the GIC. Reading an active bit identifies whether the corresponding interrupt is active (=1) or not active (=0).

Shared Peripheral Interrupt Configuration Register

The `GICDST_SPI_CFG[n]` register provides a 2-bit Int_config field for each interrupt supported by the GIC.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Security Interrupt Security. The `GICDST_SPI_SECURITY[n].VALUE` bits control the security status of the corresponding interrupt.

Shared Peripheral Interrupt Processor Targets Register

The `GICDST_SPI_TRGT[n]` register provides an 8-bit CPU targets field for each interrupt supported by the GIC.

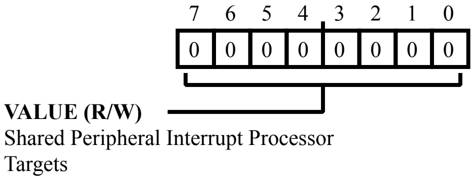

Figure 7-47: GICDST_SPI_TRGT[n] Register Diagram

Table 7-48: GICDST_SPI_TRGT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Shared Peripheral Interrupt Processor Targets. The `GICDST_SPI_TRGT[n].VALUE` bit field stores the list of processors that the interrupt is sent to if it is asserted.

ADSP-SC58x GICCPU Register Descriptions

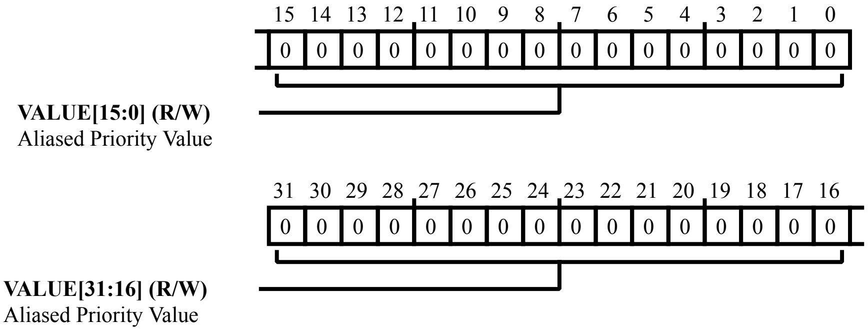
GIC CPU Port (GICCPU) contains the following registers.

Table 7-49: ADSP-SC58x GICCPU Register List

Name	Description
`GICCPU_BIN_PT_ALIAS`	Aliased Binary Point Register (ICCABPR)
`GICCPU_BIN_PT`	Binary Point Register (ICCBPR)
`GICCPU_CTL`	CPU Interface Control Register (ICCICR)
`GICCPU_EOI`	End of Interrupt Register (ICCEOIR)
`GICCPU_PND_HI`	Highest Pending Interrupt Register (ICCHPIR)
`GICCPU_INT_ACK`	Interrupt Acknowledge Register (ICCIAR)
`GICCPU_PRIO_MSK`	Priority Mask Register (ICCIPMR)
`GICCPU_RUN_PRIO`	Running Priority Register (ICCRPR)

Aliased Binary Point Register (ICCABPR)

The `GICCPU_BIN_PT_ALIAS` register Provides an alias for the non secure `GICCPU_BIN_PT` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Aliased Priority Value

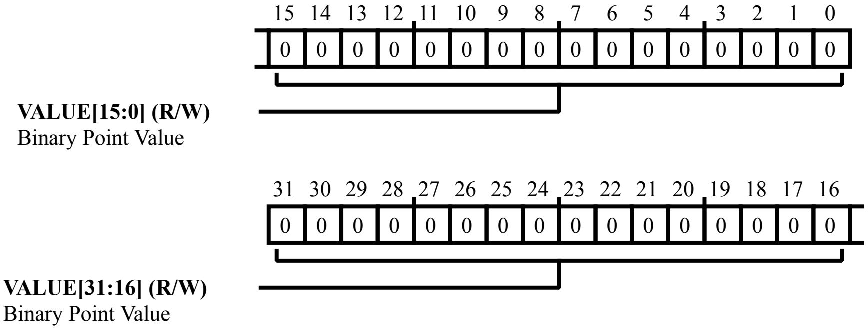
Figure 7-48: GICCPU_BIN_PT_ALIAS Register Diagram

Table 7-50: GICCPU_BIN_PT_ALIAS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Aliased Priority Value.

Binary Point Register (ICCBPR)

The `GICCPU_BIN_PT` register defines the point at which the priority value fields split into two parts, the group priority field and the sub-priority field. The group priority field is used to determine interrupt preemption.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

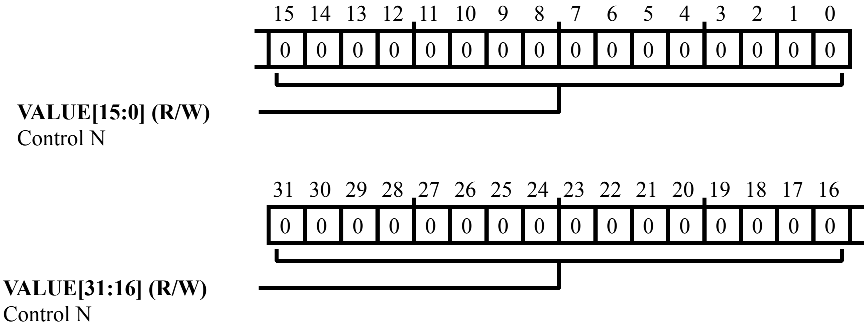
Table 7-51: GICCPU_BIN_PT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Binary Point Value. The `GICCPU_BIN_PT.VALUE` bit field defines the point at which the priority value fields split into two parts.

CPU Interface Control Register (ICCICR)

The `GICCPU_CTL` register enables the signaling of interrupts to the target processors. In a GIC that implements the Security Extensions, provides additional global controls for handling Secure interrupts.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

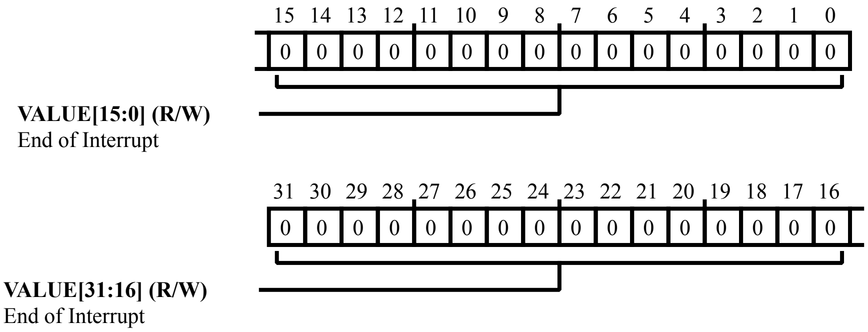
Table 7-52: GICCPU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Control N.

End of Interrupt Register (ICCEOIR)

A processor writes to the `GICCPU_EOI` register to inform the CPU interface that it has completed its interrupt service routine for the specified interrupt.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
End of Interrupt
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
End of Interrupt

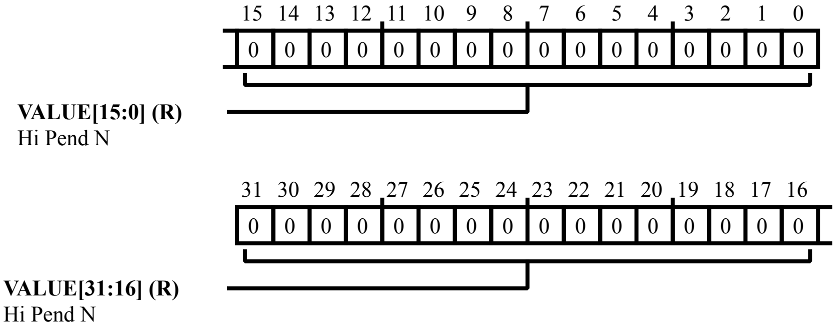
Figure 7-51: GICCPU_EOI Register Diagram

Table 7-53: GICCPU_EOI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	End of Interrupt. The `GICCPU_EOI.VALUE` bit field indicates to the CPU interface that it has completed its interrupt service routine for the specified interrupt.

Highest Pending Interrupt Register (ICCHPIR)

The `GICCPU_PND_HI` register indicates the Interrupt ID, and processor ID if appropriate, of the pending interrupt with the highest priority on the CPU interface.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

VALUE[15:0] (R)
Hi Pend N
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R)
Hi Pend N

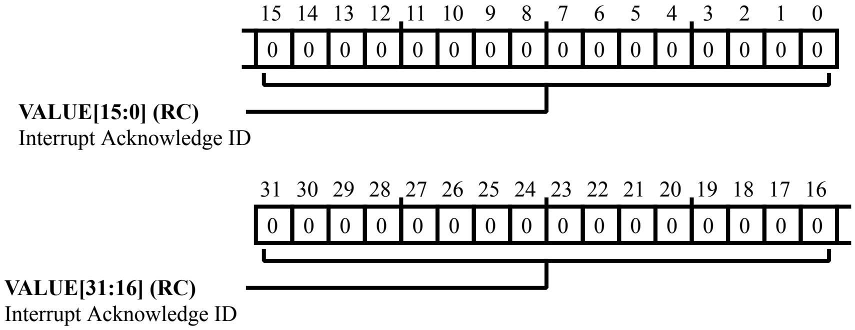
Figure 7-52: GICCPU_PND_HI Register Diagram

Table 7-54: GICCPU_PND_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Hi Pend N. Highest Pending Interrupt Register (ICCHPIR)

Interrupt Acknowledge Register (ICCIAR)

The processor reads the `GICCPU_INT_ACK` register to obtain the interrupt ID of the signaled interrupt. This read acts as an acknowledge for the interrupt.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (RC)
Interrupt Acknowledge ID
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (RC)
Interrupt Acknowledge ID

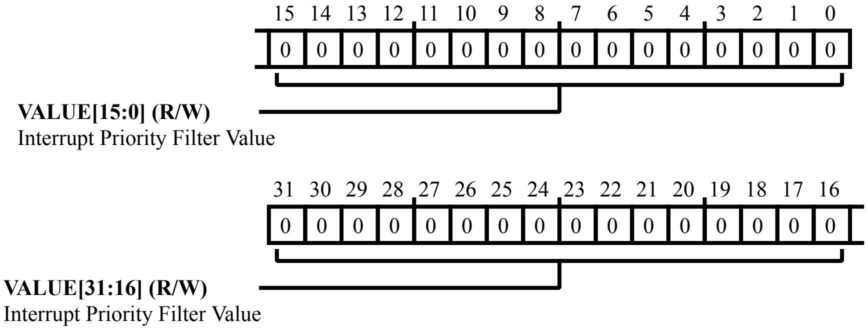
Figure 7-53: GICCPU_INT_ACK Register Diagram

Table 7-55: GICCPU_INT_ACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RC/NW)	VALUE	Interrupt Acknowledge ID. The `GICCPU_INT_ACK.VALUE` bit field contains the interrupt ID of the signaled interrupt.

Priority Mask Register (ICCIPMR)

The GICCPU_PRIO_MSK register provides an interrupt priority filter. Only interrupts with higher priority than the value in this register can be signaled to the processor.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Interrupt Priority Filter Value
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Interrupt Priority Filter Value

Figure 7-54: GICCPU_PRIO_MSK Register Diagram

Table 7-56: GICCPU_PRIO_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Interrupt Priority Filter Value. The `GICCPU_PRIO_MSK.VALUE` bit field contains the interrupt priority filter value.

Running Priority Register (ICCRPR)

The GICCPU_RUN_PRIO register indicates the priority of the highest priority interrupt that is active on the CPU interface.

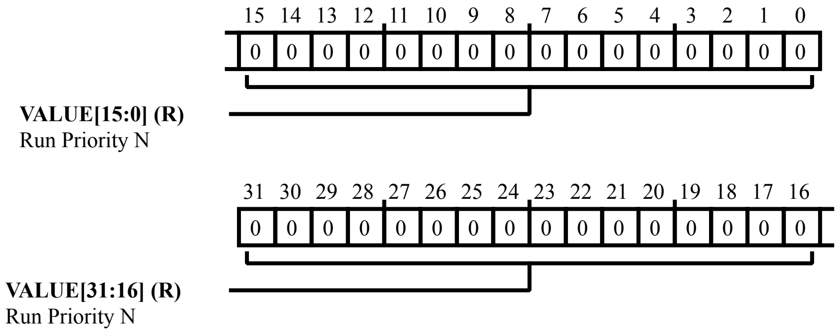


Figure 7-55: GICCPU_RUN_PRIO Register Diagram

Table 7-57: GICCPU_RUN_PRIO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Run Priority N. The `GICCPU_RUN_PRIO.VALUE` bit field contains the priority value of the highest priority interrupt that is active on the CPU interface. If there is no active interrupt on the CPU interface, and the GIC implements 8-bit priority fields, a read of this register returns the value 0xFF, corresponding to the lowest possible interrupt priority. If the GIC implements priority fields of less than 8 bits, the read might return the register reset value of 0xFF, or might return a value corresponding to the lowest possible interrupt priority. Software cannot determine the number of implemented priority bits from a read of this register.

ADSP-SC58x GICDST Register Descriptions

GIC Distributor Port (GICDST) contains the following registers.

Table 7-58: ADSP-SC58x GICDST Register List

Name	Description
GICDST_EN	GIC Port 0 Enable
GICDST_SGI_PRIO[n]	Software Generated Interrupt Priority Register
GICDST_SPI_PRIO[n]	Shared Peripheral Interrupt Priority Register
GICDST_SGI_ACTIVE	Software Generated Interrupt Active Register
GICDST_SGI_CTL	Software Generated Interrupt Control Register
GICDST_SGI_PND_CLR	Software Generated Interrupt Clear-Pending Register

Table 7-58: ADSP-SC58x GICDST Register List (Continued)

Name	Description
GICDST_SGI_PND_SET	Software Generated Interrupt Pending Set Register

Table 7-59: GICDST_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	Global Interrupt Monitor Enable. The `GICDST_EN.VALUE` bit field enables global monitoring of the peripheral interrupt signals and forwarding pending interrupts to the CPU interfaces.

Software Generated Interrupt Priority Register

The `GICDST_SGI_PRIO[n]` register provides the 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

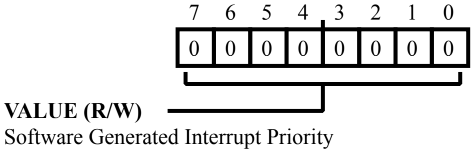

Figure 7-57: GICDST_SGI_PRIO[n] Register Diagram

Table 7-60: GICDST_SGI_PRIO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Software Generated Interrupt Priority. The `GICDST_SGI_PRIO[n].VALUE` bit field contains the 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

Shared Peripheral Interrupt Priority Register

The `GICDST_SPI_PRIO[n]` registers provide an 8-bit priority field for each interrupt supported by the GIC. This field stores the priority of the corresponding interrupt.

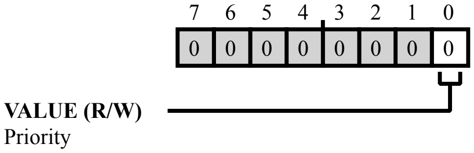

Figure 7-58: GICDST_SPI_PRIO[n] Register Diagram

Table 7-61: GICDST_SPI_PRIO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	Priority. The `GICDST_SPI_PRIO[n].VALUE` bit field stores the priority of the corresponding interrupt (byte offset 3 to Byte offset 0).

Software Generated Interrupt Active Register

The `GICDST_SGI_ACTIVE` registers provide a Set-active bit for each interrupt that the GIC supports. Writing to a Set-active bit Activates the corresponding interrupt. These registers are used when preserving and restoring GIC state.

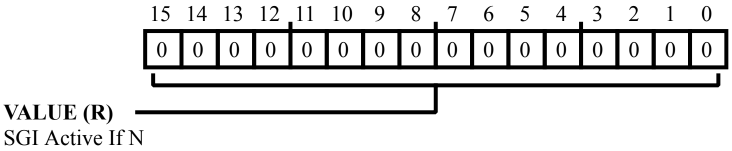

Figure 7-59: GICDST_SGI_ACTIVE Register Diagram

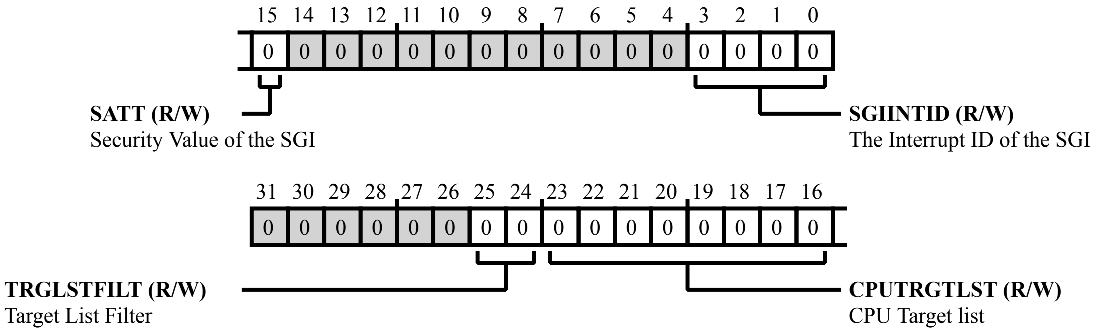
Table 7-62: GICDST_SGI_ACTIVE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	SGI Active If N. The `GICDST_SGI_ACTIVE.VALUE` bit field provides a Set-active bit for each interrupt that the GIC supports.

Software Generated Interrupt Control Register

The `GICDST_SGI_CTL` register controls the generation of SGIs.It is implementation defined whether this register has any effect when the forwarding of interrupts by Distributor is disabled by the GICD_CTLR settings.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SATT (R/W)
Security Value of the SGI
SGIINTID (R/W)
The Interrupt ID of the SGI
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TRGLSTFILT (R/W)
Target List Filter
CPUTRGTLST (R/W)
CPU Target list

Figure 7-60: GICDST_SGI_CTL Register Diagram

Table 7-63: GICDST_SGI_CTL Register Fields

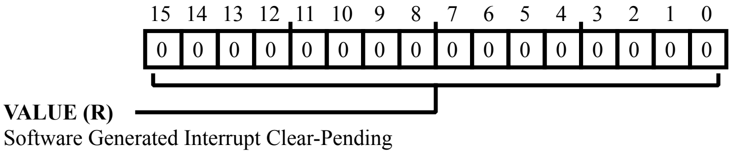
Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRGLSTFILT	Target List Filter. The `GICDST_SGI_CTL.TRGLSTFILT` bit field determines how the distributor must process the requested SGI.	
		0	Forward the interrupt to the CPU interfaces specified in the CPUTargetList field
		1	Forward the interrupt to all CPU interfaces except that of the processor that requested the interrupt
		2	Forward the interrupt only to the CPU interface of the processor that requested the interrupt
		3	Reserved
23:16 (R/W)	CPUTRGTLST	CPU Target list. When the `GICDST_SGI_CTL.CPUTRGTLST` bit field TargetList Filter = 0b00, defines the CPU interfaces to which the Distributor must forward the interrupt. Each bit of the `GICDST_SGI_CTL.CPUTRGTLST` bit field refers to the corresponding CPU interface, for example CPUTargetList[0] corresponds to CPU interface 0. Setting a bit to 1 indicates that the interrupt must be forwarded to the corresponding interface. If this field is 0x00 when TargetListFilter is 0b00, the Distributor does not forward the interrupt to any CPU interface.	

Table 7-63: GICDST_SGI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SATT	Security Value of the SGI. The `GICDST_SGI_CTL.SATT` bit is implemented only if the GIC includes the Security Extensions. This field is writable only by a Secure access. Any Non-secure write to the GICD_SGIR generates an SGI only if the specified SGI is programmed as Group 1, regardless of the value of bit[15] of the write.	
		0	Forward the SGI specified in the SGIINTID field to a specified CPU interface only if the SGI is configured as Group 0 on that interface.
		1	Forward the SGI specified in the SGIINTID field to a specified CPU interfaces only if the SGI is configured as Group 1 on that interface.
3:0 (R/W)	SGIINTID	The Interrupt ID of the SGI.	

Software Generated Interrupt Clear-Pending Register

The `GICDST_SGI_PND_CLR` register provides a clear pending bit for each interrupt supported by the GIC. Writing 1 to a clear-pending bit clears the pending status of the corresponding peripheral interrupt. Reading a bit identifies whether the interrupt is pending.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R)
Software Generated Interrupt Clear-Pending

Bit No. (Access)	Bit Name	Description/Enumeration
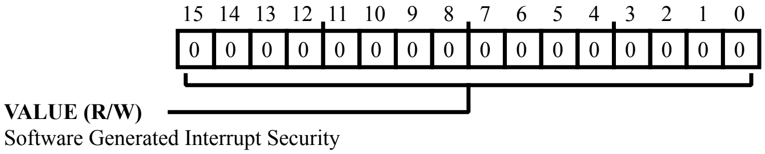
15:0 (R/NW)	VALUE	Software Generated Interrupt Set-Pending. Writing 1 to a Set-pending bit in the `GICDST_SGI_PND_SET.VALUE` bit field sets the status of the corresponding peripheral interrupt to pending. Reading a bit identifies whether the interrupt is pending.

Software Generated Interrupt Security Register

The `GICDST_SGI_SECURITY` registers provide a status bit for each interrupt supported by the GIC. Each bit controls whether the corresponding interrupt is in Group 0 or Group 1. Typically, when used with a processor that implements the ARM Security Extensions, Group 0 interrupts are Secure interrupts, and Group 1 interrupts are Non-secure interrupts,



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
STAT[31:16] (R)
Shared Peripheral Interrupt Status

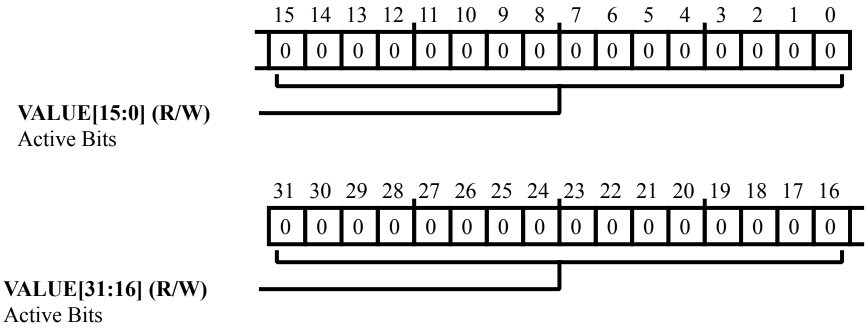
Figure 7-64: GICDST_SPI[n] Register Diagram

Table 7-67: GICDST_SPI[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	STAT	Shared Peripheral Interrupt Status. The `GICDST_SPI[n].STAT` bit field returns the status of the SPI[987:0] inputs on the distributor where bit [x] = 0 SPI[x] is low and bit [x] = 1 SPI[x] is high.

Shared Peripheral Interrupt Active Register

The `GICDST_SPI_ACTIVE[n]` register provides an active bit for each interrupt supported by the GIC.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

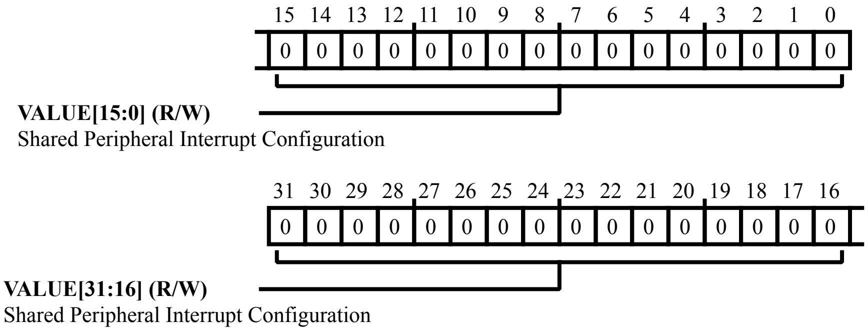
Table 7-68: GICDST_SPI_ACTIVE[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Active Bits. The `GICDST_SPI_ACTIVE[n].VALUE` bit field contains an Active bit for each interrupt supported by the GIC. Reading an active bit identifies whether the corresponding interrupt is active (=1) or not active (=0).

Shared Peripheral Interrupt Configuration Register

The `GICDST_SPI_CFG[n]` register provides a 2-bit Int_config field for each interrupt supported by the GIC.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Shared Peripheral Interrupt Configuration

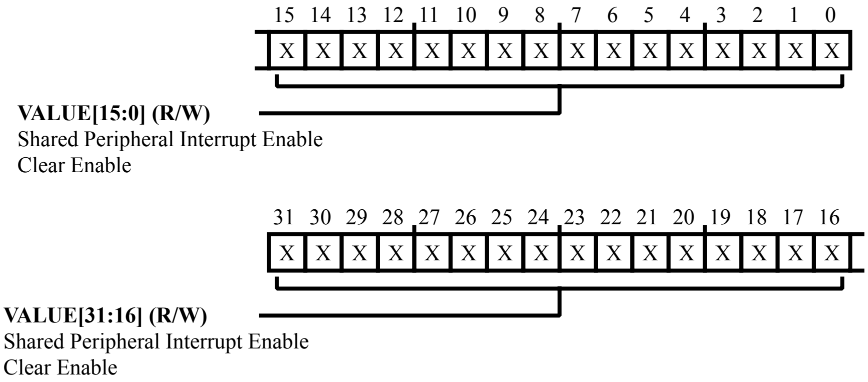
Figure 7-66: GICDST_SPI_CFG[n] Register Diagram

Table 7-69: GICDST_SPI_CFG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Shared Peripheral Interrupt Configuration. The `GICDST_SPI_CFG[n].VALUE` bit field identifies whether the corresponding interrupt is: edge-triggered or level-sensitive handled using the 1-N model or using the N-N model

Shared Peripheral Interrupt Enable Clear Register

The `GICDST_SPI_EN_CLR[n]` register provides a clear-enable bit for each interrupt supported by the GIC.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
X X X X X X X X X X X X X X X X

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Shared Peripheral Interrupt Processor Targets. The `GICDST_SPI_TRGT[n].VALUE` bit field stores the list of processors that the interrupt is sent to if it is asserted.

8 Trigger Routing Unit (TRU)

The TRU provides system-level sequence control without core intervention. The TRU maps trigger masters (generators of triggers) to trigger slaves (receivers of triggers). Slave endpoints can be configured to respond to triggers in various ways. Multiple TRUs may be provided in a multiprocessor system to create a trigger network. Common applications enabled by the TRU include:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes
- Software triggering
- Synchronization of concurrent activities

TRU Features

The TRU supports the following features:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes. Once a DMA channel completes data transfer, it can act as a Trigger Master and signal an internal trigger pulse to the programmed Trigger Slave which can also be another DMA channel. The Slave Trigger connected to the DMA channel kicks off the DMA transfer automatically. None of this requires core intervention once the initialization is done.
- Software triggers. The best use of triggers is to minimize core intervention. It is also possible to initiate a trigger pulse to a Trigger Slave, in the software.
- Synchronization of concurrent activities. A single Trigger Master can initiate a trigger pulse to multiple Trigger Slaves so that several system level activities can be synchronized on an internally or externally generated event.
- Configuration protection through register-level lock bits and global lock indication

TRU Functional Description

The following sections provide a description of the TRU.

ADSP-SC58x TRU Register List

The Trigger Routing Unit (TRU) provides simple sequence control of distributed modules without the penalties associated with core intervention (for example, interrupt overhead). The TRU receives trigger inputs from all master trigger inputs (MTI) and the TRU master trigger register (`TRU_MTR`). Based on these inputs, the TRU logic generates trigger outputs that initiate slave operations in the processor core and peripherals. A set of registers governs TRU operations. For more information on TRU functionality, see the TRU register descriptions.

Table 8-1: ADSP-SC58x TRU Register List

Name	Description
`TRU_ERRADDR`	Error Address Register
`TRU_GCTL`	Global Control Register
`TRU_MTR`	Master Trigger Register
`TRU_SSR[n]`	Slave Select Register
`TRU_STAT`	Status Information Register

TRU Definitions

The following definitions are helpful when using the TRU module.

Trigger Master

A trigger master is any system module that provides trigger event indication to the TRU. Trigger master modules define trigger events and conditions for assertion.

Trigger Master ID

Trigger masters are assigned a unique numeric ID according to their physical connection to the TRU. Trigger master ID 0 is reserved and defined as null.

Trigger Slave

A trigger slave is any system module that receives a trigger event indication from the TRU. Trigger slave modules define a trigger event response.

TRU Block Diagram

Trigger masters and the Master Trigger Register (MTR) generate trigger assertions. Each trigger slave has a dedicated Slave Select Register (SSR) that specifies the unique trigger master from which it receives the trigger indication.

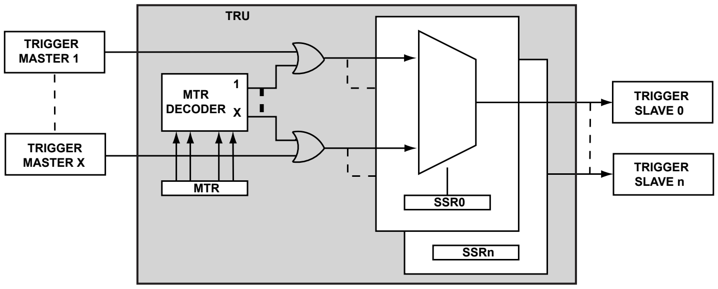

Figure 8-1: TRU Block Diagram

TRU Architectural Concepts

The TRU supports a simple trigger-in/trigger-out model for modules that comply with the triggering functional model. The TRU is the controller of the trigger system. Trigger outputs from trigger masters are mapped to trigger inputs of trigger slaves through a set of programmable registers (`TRU_SSR[n]`).

System modules are trigger master only, trigger slave only, or trigger master and trigger slave.

All of the trigger input and output signals are connected to a trigger routing unit (TRU) which manages the connections of triggers between modules.

In multi-processor systems, multiple TRU units are provided. These TRUs are networked together. Generic Trigger Ports (GTPs) are provided to forward trigger events from one TRU unit to another, forming a pathway from trigger masters to trigger slaves wherever they might lie in the system.

TRU Programming Model

Implementing sequence control using the TRU requires, at a minimum, proper configuration of a trigger slave, a trigger master, and the TRU module itself. The only requirement for the configuration procedure is that the trigger master is configured and enabled as the last step.

Complete the following other steps:

- Configure the trigger slave for response to triggers.
- Configure the TRU to map the trigger master to the trigger slave through the `TRU_SSR[n]` registers.
- Configure the trigger master to generate trigger assertions.
- Alternatively, use software triggering for trigger assertion. Writing the trigger master ID to the MTR register generates software triggers.

Programming Concepts

The following concepts aid in programming the TRU.

- *Trigger Sequence Configuration.* A simple sequence consists of one trigger master and one trigger slave. More complex trigger sequences consist of several trigger slaves functioning as trigger slave and trigger master. Additionally, trigger sequences can loopback to the original master forming a perpetual sequence.
- *Software Triggering.* Writing a trigger master ID to the MTR generates a trigger within the TRU from the trigger master ID specified.
- *Synchronization.* The TRU can be used to coarsely synchronize events by mapping multiple trigger slaves to the same trigger master or by generating multiple trigger master assertions simultaneously through the MTR.
- *Configuration Protection.* The `TRU_SSR[n].LOCK` bit and the `TRU_GCTL.LOCK` bit enable register level write-protection when the global lock is asserted in the SPU.

Programming Examples

The following examples shows the steps to create a single trigger and a Timer period expiry event automatically toggling a GPIO.

Configuring a Simple Trigger Sequence

The following example shows the steps to create a simple trigger.

1. Write to the `TRU_GCTL` register to enable the TRU.
2. Write to the `TRU_SSR[n]` register of a specific trigger slave to assign it to a specific trigger master.
3. Enable the trigger slave to wait for and accept a trigger.
4. Enable the trigger master to generate a trigger.

Toggle a GPIO on Timer Expiry Event

This example shows a case where a Timer period expiry event automatically toggles a GPIO. This is achieved by programming the Slave trigger register for GPIO with the Timer as Master.

1. Enable a specific pin in the PORT F to toggle up on trigger ( )
2. Enable timer to generate trigger up (`TIMER_TRG_MSK` register)
3. Program the Slave trigger 23 (`TRU_SSR[n]` register) (this toggles the PORTs) with the Timer as the Master.
4. Enable the TRU (`TRU_GCTL.EN` bit).

```
*pREG_PORTF_TRIG_TGL = 0x00000010;
*pREG_TIMER1_TRG_MSK &= ~BITM_TIMER_TRG_MSK_TMR03;
*pREG_TRU1_SSR23 = TRGM_TIMER1_TMR3_MST;
*pREG_TRU1_GCTL = 0x1;
```

TRU Event Control

The TRU is a major part of event control solutions. It is the center of the trigger functional model and can extend to support the interrupt and fault management models as well.

TRU Status and Error Signals

The TRU does not have dedicated status and error output signals other than the MMR interface. Slave errors are reported to the master over the standard peripheral bus protocol.

ADSP-SC58x TRU Register Descriptions

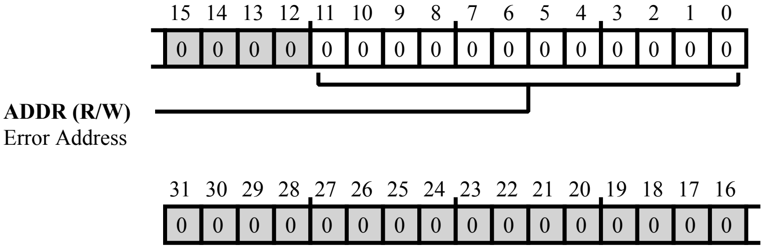
Trigger Routing Unit (TRU) contains the following registers.

Table 8-5: ADSP-SC58x TRU Register List

Name	Description
`TRU_ERRADDR`	Error Address Register
`TRU_GCTL`	Global Control Register
`TRU_MTR`	Master Trigger Register
`TRU_SSR[n]`	Slave Select Register
`TRU_STAT`	Status Information Register

Error Address Register

The TRU error address register (TRU_ERRADDR) holds the address from the memory-mapped register access generating an access error of TRU registers.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDR (R/W)
Error Address
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

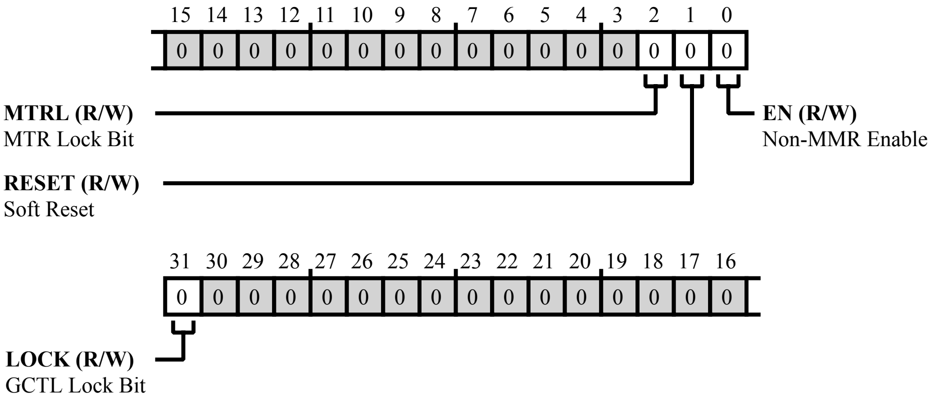
Figure 8-2: TRU_ERRADDR Register Diagram

Table 8-6: TRU_ERRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	ADDR	Error Address. The TRU_ERRADDR.ADDR holds the address from the memory-mapped register access generating an access error of TRU registers. These errors occur on access to the TRU_SSR[n] or TRU_MTR registers when these registers are locked or on access to an invalid address. See the TRU_SSR[n] and TRU_MTR register descriptions for more information about locking. The TRU_ERRADDR register holds the address of the first error to occur. In the event of multiple errors occurring, the TRU_ERRADDR register contains the address of the first error. To re-enable the TRU_ERRADDR register for update, both status bits (TRU_STAT.LWERR and TRU_STAT.ADDRERR) in the TRU_STAT register must be cleared.

Global Control Register

The TRU global control register (`TRU_GCTL`) provides register locking, TRU reset, and TRU enable.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
MTRL (R/W)
MTR Lock Bit
EN (R/W)
Non-MMR Enable
RESET (R/W)
Soft Reset
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LOCK (R/W)
GCTL Lock Bit

Figure 8-3: TRU_GCTL Register Diagram

Table 8-7: TRU_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	GCTL Lock Bit. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `TRU_GCTL.LOCK` bit is enabled, the `TRU_GCTL` register is read only.	
		0	Read write
		1	Read only
2 (R/W)	MTRL	MTR Lock Bit. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `TRU_GCTL.MTRL` bit is enabled, the `TRU_MTR` register is read only.	
		0	Read write
		1	Read only
1 (R/W)	RESET	Soft Reset. The `TRU_GCTL.RESET` bit is write-1-action and triggers a soft reset to all TRU registers.	
		0	No action
		1	Soft reset

Table 8-7: TRU_GCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Non-MMR Enable. The `TRU_GCTL.EN` bit is read/write and must be set for the TRU to propagate trigger events. All TRU register read/write operations continue to operate independent of the `TRU_GCTL.EN` bit.	
		0	No trigger events
		1	Propagate trigger events

Master Trigger Register

The TRU master trigger register (`TRU_MTR`) permits trigger generation through software by writing a trigger master ID value to one of the four fields in the `TRU_MTR` register. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `TRU_GCTL.LOCK` bit is set, the `TRU_MTR` register is read only. Note this register is primarily used for debug to trigger a TRU output

Figure 8-5: TRU_SSR[n] Register Diagram

Table 8-9: TRU_SSR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	SSRn Lock. If the global lock is enabled (`SPU_CTL.GLCK` bit =1) and the `TRU_SSR[n].LOCK` bit is enabled, the `TRU_SSR[n]` register is read only.	
		0	Unlock register
		1	Lock register
7:0 (R/W)	SSR	SSRn Slave Select. The `TRU_SSR[n]` register selects the trigger master ID to which the trigger slave responds. For example, when a `TRU_SSR[n]` register is set to respond to trigger master ID n, a trigger that is generated by trigger master ID n results in a trigger out to the slave.	
		0	No master specified
		1-139	Range of valid masters

Status Information Register

The TRU status register (TRU_STAT) contains the status of TRU_MTR and TRU_SSR[n] register writes and status of bus read/write errors.

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 8-6: TRU_STAT Register Diagram

Table 8-10: TRU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	ADDRERR	Address Error Status. The `TRU_STAT.ADDRERR` bit is set when an invalid address is provided for an MMR access while the TRU is selected. Writing a one to this bit clears the error indication. The TRU_ERRADDR register also is updated when an address error occurs during an MMR access while the TRU is selected.	
		0	No error
		1	Error occurred
0 (R/W1C)	LWERR	Lock Write Error Status. If `TRU_STAT.LWERR` is set, a lock write error has occurred. Writing a one to this bit clears the error indication.	
		0	No error
		1	Error occurred

9 L2 System Memory

L2 system memories have significant bandwidth for core accesses, but it is important to note that L2 responds slower to core accesses than L1 memories. L2 SRAM is the ideal storage for multiple processor cores to share data and instruction resources, such as semaphores, shared buffers, and code libraries. Due to sophisticated data integrity protection and write protection, L2 SRAM is also ideal for data and instructions critical for safe operation of the application.

L2 System Memory Features

The L2 system memory features include:

- Operation at SYSCLK_0 frequency
- ECC protection of SRAM area
- ECC memory refresh

Three instances of L2 system memory: SRAM and 2x ROM.

- L2CTL0 contains 256K bytes of RAM grouped into eight banks, 32K bytes each and 32K bytes of boot ROM (ARM core).
- L2CTL1 contains 256K bytes of application ROM grouped into eight banks, 32K bytes each and 32K bytes of boot ROM (SHARC core).
- L2CTL2 contains 256K bytes of application ROM grouped into eight banks, 32K bytes each and 32K bytes of boot ROM (any of the cores).
- All instances supports exclusive access through SMPU.
- SHARC core data ports can access L2 memory through direct path as well as through ARM L2 cache.

L2 System Memory Functional Description

The L2 system memory manages all of the L2 SRAM and ROM memory banks. The system memory interface arbitrates competing accesses, write protection, and ensures SRAM data integrity. The L2 system memory domain is a unified instruction and data memory. It can hold any mixture of code and data required by the system design.

The following sections provide a functional description of the L2 system memory.

ADSP-SC58x L2CTL Interrupt List

Table 9-1: ADSP-SC58x L2CTL Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
8	L2CTL0_ECC_ERR	L2CTL0 ECC Error	Level	

ADSP-SC58x L2CTL Register List

The L2 memory controller (L2CTL) includes the controls to manage each L2 memory bank independently. A set of registers governs L2CTL operations. For more information on L2CTL functionality, see the L2CTL register descriptions.

Table 9-2: ADSP-SC58x L2CTL Register List

Name	Description
`L2CTL_CTL`	Control Register

L2 System Memory Architectural Concepts

The following sections describe architecture features of the L2 system memory.

- Read/Write Latency and Throughput
- Arbitration and Priority

Access Characteristics

The L2 system memory interface converts all 8-bit, 16-bit, and 32-bit accesses to 64-bit accesses. Additionally, it converts 8-bit, 16-bit, and 32-bit bursts to an equivalent internal 64-bit access. For example, the L2 system memory interface converts a 64-bit address-aligned burst of 8-bit accesses of burst length 8 to a single 64-bit access.

Read/Write Latency and Throughput

The L2 memory design is optimized for burst accesses at the crossbar interface. The L2 system memory buffers and converts write data of 8/16/32-bit to an equivalent 64-bit access. This conversion creates modulo-32-bit writes if the starting addresses are 32-bit aligned. A single 8-bit or 16-bit access, or a non-32-bit address-aligned 8-bit or 16-bit burst access to an ECC-enabled bank creates an extra latency of two SYSCLK_0 cycles. No extra latency is seen if the ECC is disabled.

NOTE: Continuous 8/16-bit core access to an ECC-enabled L2 bank is not recommended from a throughput perspective.

L2 Memory Controller Block Diagram (Instance)

As shown in the following figure, the L2 controller has two ports that interface to system crossbars. Port 0 is a 64-bit interface that is dedicated to core traffic, and port 1 is a 32-bit interface that connects through DMA access. For L2 SRAM both ports (0/1) have a read channel and a write channel, for L2 ROM both ports (0/1) have read channels only. The SRAM/ROM are organized in multiple banks, and each bank has 32K Bytes of data. For ADSP-SC58x parts, the L2CTL0 has an additional bank for the boot ROM; for ADSP-2158x parts, the L2CTL1 has an additional bank for the boot ROM.

Within each bank, data is organized into 4096 words, with each word comprising 64 bits of data and 14 bits of ECC checksum. ROM memory is not protected by the ECC scheme. When the L2 controller accesses RAM and ROM cells, it always reads and writes whole 64-bit words. Despite this, the L2 controller supports 8-, 16-, and 32-bit reads and writes from cores and system by applying respective data masks.

Figure 9-2: L2 System Memory Block Diagram

Arbitration and Priority

Each bank of L2 RAM or ROM has an arbiter which receives requests from the two crossbar ports.

Each arbiter follows a fixed priority scheme for giving grants when more than one channel requests the same bank. The arbiter also supports priority elevation through urgent priority requests.

NOTE: Attempting a write access to both L2 ROM spaces returns an error.

The *Fixed Priority* table shows the priority for fixed priority mode (with urgent priority disabled) for each SCB channel.

If two cores (or the 64-bit Max BW DMA) simultaneously try to access L2 for the same instance (both read or both write), even to different banks, software allows only one master access at a time. One access port can support one read and write at the same time. However, if one core issues a write and the other issues a read, then access can proceed simultaneously. There is no extra latency inside L2, as long as the accesses are to different banks (assuming pending DMA traffic is also to a non-conflicting bank).

When a core and DMA both access the same bank via the same port (both read or both writes), the best access rate that DMA can achieve is one 64-bit access in every three SYSCLK_0 cycles during the conflict period. This access rate is achieved by programming the read priority count register (`L2CTL_RPCR.RPC0`) bit and the write priority count register (`L2CTL_WPCR.WPC0`) bit to 0, while programming the `L2CTL_RPCR.RPC1` and the `L2CTL_WPCR.WPC1` bits to 1.

Table 9-3: Fixed Priority

Channel	Priority Level
L2 Refresh Request	5 (highest)
Port 0 Read Channel	4
Port 0 Write Channel	3
Port 1 Read Channel	2
Port 1 Write Channel	1 (lowest)

The arbiters also support priority elevation for a particular channel that has been starved of grants for many SYSCLK_0 cycles. If a channel does not get a grant for *N* cycles after its request, then that channel can elevate the priority of its request by issuing an urgent priority request. This request causes that particular channel to become the highest priority master for the next grant cycle (pipelined arbitration for urgent priority). The number of cycles *N*, after which the priority is elevated, can be programmed for each channel separately using the `L2CTL_RPCR` and `L2CTL_WPCR` registers.

Programming the bits in the `L2CTL_RPCR` and `L2CTL_WPCR` registers appropriately achieves the best grant rate for DMA. This grant rate of one in three SYSCLK_0 cycles during the conflict period is achievable under the following conflict conditions:

- An access conflict between the core and DMA to the same memory bank in the fixed priority arbitration scheme with core activity always prioritized over DMA activity
- An access conflict within the pipelined implementation of urgent priority

To disable urgent priority requests, set the `L2CTL_CTL.DISURP` bit. This bit disables the urgent priority requests for all port channels. Each channel can also be prevented from raising the urgent priority request through the priority count register for the specific channel. However, there is no support for disabling urgent priority for a specific memory bank arbiter.

The *Fixed Priority With Priority Elevation* table provides the various priority levels for the L2 system memory.

Table 9-4: Fixed Priority With Priority Elevation

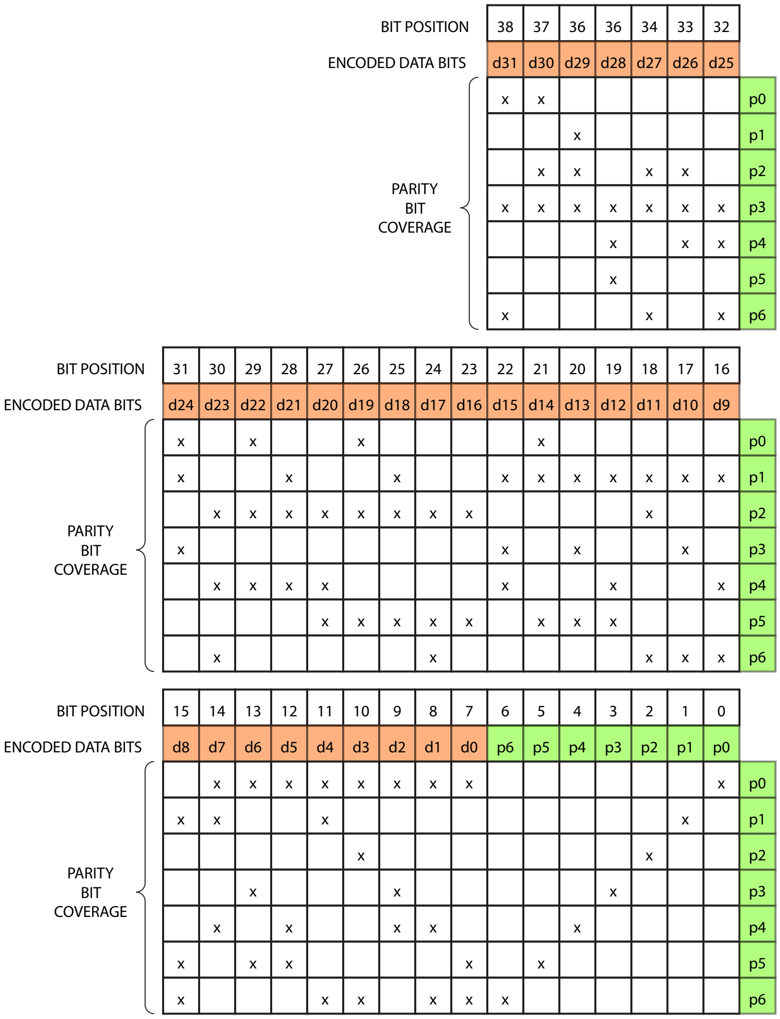
Channel	Priority Level
L2 Refresh Request	9 (highest)
Port 0 Read Channel Urgent Request	8
Port 0 Write Channel Urgent Request	7
Port 1 Read Channel Urgent Request	6
Port 1 Write Channel Urgent Request	5
Port 0 Read Channel Normal Request	4
Port 0 Write Channel Normal Request	3
Port 1 Read Channel Normal Request	2
Port 1 Write Channel Normal Request	1 (lowest)

Data Integrity

The following sections provide information on how the L2 system memory ensures data integrity.

ECC Algorithm

Hsaio encoding calculates the ECC syndrome. A 7-bit syndrome is generated during write operation and stored as a 7-bit parity field along with the 32 data bits. Each data bit contributes to three parity bits according. Each parity bit represents the XOR value of 13 or 14 data bits according to the following mapping:



BIT POSITION	38	37	36	36	34	33	32	
ENCODED DATA BITS	d31	d30	d29	d28	d27	d26	d25	
PARITY BIT COVERAGE	x	x						p0
			x					p1
		x	x		x	x		p2
	x	x	x	x	x	x	x	p3
				x		x	x	p4
				x				p5
	x				x		x	p6

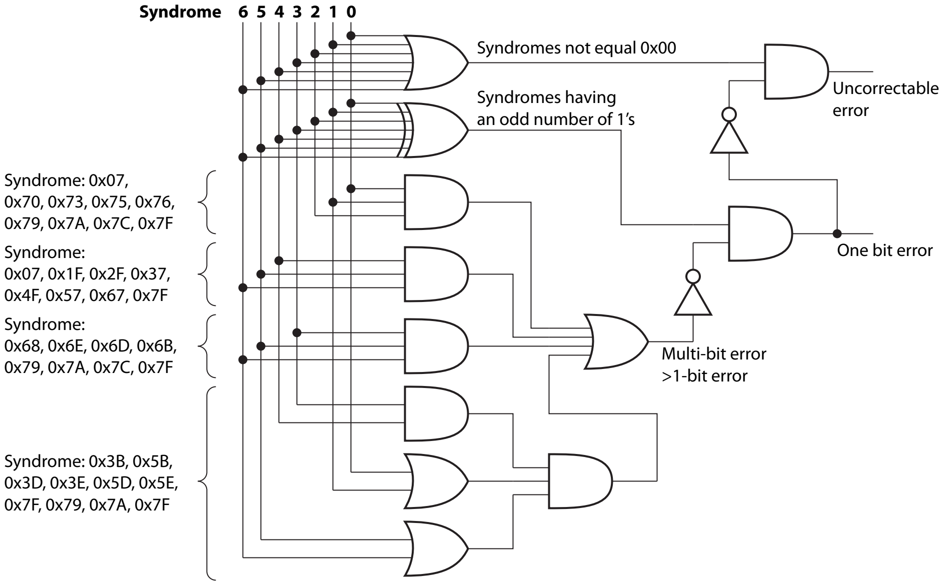
BIT POSITION	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
ENCODED DATA BITS	d24	d23	d22	d21	d20	d19	d18	d17	d16	d15	d14	d13	d12	d11	d10	d9	
PARITY BIT COVERAGE	x		x			x					x						p0
	x			x			x			x	x	x	x	x	x	x	p1
		x	x	x	x	x	x	x	x					x			p2
	x									x		x			x		p3
		x	x	x	x					x			x			x	p4
					x	x	x	x	x		x	x	x				p5
		x						x						x	x	x	p6

BIT POSITION	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
ENCODED DATA BITS	d8	d7	d6	d5	d4	d3	d2	d1	d0	p6	p5	p4	p3	p2	p1	p0	
PARITY BIT COVERAGE		x	x	x	x	x	x	x	x							x	p0
	x	x			x										x		p1
						x								x			p2
			x				x						x				p3
		x		x			x	x				x					p4
	x		x	x					x		x						p5
	x				x	x		x	x	x							p6

Figure 9-3: Hsaio Parity Bit Mapping

During read operation, the parity bits become part of the syndrome equation. The new syndrome bits are now the XOR values of the 13 or 14 data bits plus the respective stored parity bit. If any of the seven syndrome bits is set, an error situation is detected. An OR gate cross of the 7 bits reports the error, without specifying the type of the error.

If a single parity bit failed, the new 7-bit syndrome has 1 bit that is set. If a single data bit failed, the new syndrome has 3 bits that are set, because all three related parity bits fail. So, an XOR gate cross of all seven syndrome bits detects a single-bit error, indicating that an odd number of syndrome bits is set.



Syndrome 6 5 4 3 2 1 0
Syndromes not equal 0x00
Syndromes having an odd number of 1's
Uncorrectable error
One bit error
Multi-bit error >1-bit error
Syndrome: 0x07, 0x70, 0x73, 0x75, 0x76, 0x79, 0x7A, 0x7C, 0x7F
Syndrome: 0x07, 0x1F, 0x2F, 0x37, 0x4F, 0x57, 0x67, 0x7F
Syndrome: 0x68, 0x6E, 0x6D, 0x6B, 0x79, 0x7A, 0x7C, 0x7F
Syndrome: 0x3B, 0x5B, 0x3D, 0x3E, 0x5D, 0x5E, 0x7F, 0x79, 0x7A, 0x7F

Figure 9-4: Hsiao Error Reports

The XOR gate detects single-bit errors and does not flag any dual-bit error. But, the gate does flag 50% of the other multi-bit errors undesirably. Extra logic is implemented to increase the detection rate of multi-bit errors to 68.7% as shown in the figure.

If a single-bit error is detected, the failing bit can be localized and corrected. If all three syndrome bits corresponding to a specific data bit are 1, a data error is assumed. The respective data bit is toggled on its way to the system bus.

ECC Hardware Control

After reset, ECC protection is enabled. The boot code initializes all L2 SRAM data and checksum cells. ECC protection adds some cycle penalty when 8-bit and 16-bit values write L2 memory. Disable ECC protection for individual SRAM banks by setting the `L2CTL_CTL.BK0EDIS` through `L2CTL_CTL.BK7EDIS` disable bits. Due to caching mechanisms of the processor cores and data bursting of the DMA channels, 8-bit and 16-bit write accesses are rather uncommon. Typically, only two-dimensional DMA operations or uncached 8-bit and 16-bit store instruction can trigger these writes.

For system integrity testing, the L2 system memory also provides a method for accessing the ECC checksum area directly. The `L2CTL_CTL.ECCMAP0` through `L2CTL_CTL.ECCMAP7` bits map the ECC checksum values into the address space of the data bits. This feature can be activated per SRAM bank. In this mode, only 32-bit accesses are allowed. 32-bit reads return the checksum value in the lower 7 bits while the upper bits read zero. Any 32-bit write overwrites the checksum. The upper bits are ignored.

Using this checksum mapping feature, safety critical applications can verify the ECC hardware during boot up sequence or even at run time. It is not required to set the `L2CTL_CTL.BK0EDIS` through `L2CTL_CTL.BK7EDIS` disable bits explicitly. To test the ECC hardware, use the following steps:

1. Write data values to L2 SRAM destination (preferable an even number of 32-bit words).
2. If data cache enabled, make sure that it flushes out data.

3. Execute SYNC instruction.
4. Set `L2CTL_CTL.ECCMAP7-L2CTL_CTL.ECCMAP0` bits of interest.
5. Execute SYNC instruction.
6. Write checksum values using 32-bit store instructions.
7. If data cache enabled, make sure that it flushes out checksum values.
8. Execute SYNC instruction.
9. Clear `L2CTL_CTL.ECCMAP7-L2CTL_CTL.ECCMAP0` bits.
10. Execute SYNC instruction.
11. Read data values back.

ECC Error Management

The L2 system memory flags 2-bit and multi-bit errors to the system by:

- Raising the ECC_ERR interrupt
- Reporting a read error to the system bus
- Setting the sticky `L2CTL_STAT.ECCERR7-L2CTL_STAT.ECCERR0` status flag
- Latching the address of the failing operation into the respective `L2CTL_ERRADDR7-L2CTL_ERRADDR0` register.

There is one error status bit and one error address register per L2 SRAM bank.

Typically, ECC_ERR events are declared as system faults in the system event controller (SEC). Whether these faults are reported, the interrupt service routine can consult the `L2CTL_STAT` register and the `L2CTL_ERRADDR0` through `L2CTL_ERRADDR7` registers to determine whether:

- The data at the failing L2 address was critical enough to require an immediate reboot of the system
- The data at the failing L2 address was less critical or can be restored

The `L2CTL_STAT.ECCERR0` through `L2CTL_STAT.ECCERR7` flags are cleared with a W1C operation.

Memory Refresh

If data in L2 SRAM contains single-bit errors, the data is corrected on its way to the system buses. The corrected value is not written back to the SRAM location. To prevent any risk of accumulation of single-bit errors over time and to minimize likelihood of multi-bit errors, the L2 system memory provides a special memory refresh mechanism.

Software can initiate a memory refresh cycle of a 64-bit SRAM entity by writing the address of interest into the refresh address register, `L2CTL_RFA`. The write triggers an atomic operation. In this operation, the L2 system memory:

- Reads a 64-bit entity from the targeted memory

- Applies an ECC algorithm to the two 32-bit words
- Writes the corrected data back to memory

While the atomic refresh operation is ongoing, other accesses to the same SRAM bank are locked-out. The `L2CTL_STAT.RFRS` status bit signals an ongoing refresh operation. Hardware clears the bit after the operation has finished. The content of the `L2CTL_RFA` register must not change while the refresh operation is ongoing.

In safety-critical applications, software can refresh all L2 SRAM by periodically writing to the `L2CTL_RFA` register with values. It increments with a value of eight until all SRAM locations are refreshed.

Memory refresh operation is meaningless when the `L2CTL_CTL.BK0EDIS` through `L2CTL_CTL.BK7EDIS` disable bits are set.

L2 System Memory Event Control

The following sections describe event control features of the L2 system memory, such as error response.

ECC Error Interrupt

A bus error is signaled under any of the following conditions.

- A write access to ROM address space
- A read/write access to reserved address space
- An ECC multi-bit error in an ECC-enabled bank. A non-modulo, 32-bit write to an ECC-enabled bank can also potentially create a bus error response due to an ECC multi-bit error. This response is because the L2 system memory implements a 32-bit ECC, and therefore a non-modulo, 32-bit write results in a read. This read can create multi-bit errors even if the memory was initialized.

Bus error notifications are stored in the `L2CTL_STAT` register, and the addresses that generated the error on a given port are stored in the `L2CTL_EADDR0`/`L2CTL_EADDR1` register of that port. The details of the error are stored in the `L2CTL_ET0`/`L2CTL_ET1` register of the port.

ADSP-SC58x L2CTL Register Descriptions

L2 Memory Controller (L2CTL) contains the following registers.

Table 9-5: ADSP-SC58x L2CTL Register List

Name	Description
`L2CTL_CTL`	Control Register
`L2CTL_EADDR0`	Error Type 0 Address Register
`L2CTL_EADDR1`	Error Type 1 Address Register
`L2CTL_ERRADDR0`	ECC Error Address 0 Register

Table 9-5: ADSP-SC58x L2CTL Register List (Continued)

Name	Description
`L2CTL_ERRADDR1`	ECC Error Address 1 Register
`L2CTL_ERRADDR2`	ECC Error Address 2 Register
`L2CTL_ERRADDR3`	ECC Error Address 3 Register

Error Type 0 Address Register

The `L2CTL_EADDR0` register holds the address that created an access error on the L2 port 0 bus interface (cores). This register is be updated only if the corresponding error status bit (`L2CTL_STAT.ERR0`) is cleared. After the status bit is set for an error, further errors do not update the `L2CTL_EADDR0` register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

Error Type 1 Address Register

The `L2CTL_EADDR1` register holds the address that created an access error on the L2 port 1 bus interface (DMA). This register is be updated only if the corresponding error status bit (`L2CTL_STAT.ERR1`) is cleared. After the status bit is set for an error, further errors do not update the `L2CTL_EADDR1` register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

Error Type 0 Register

The `L2CTL_ET0` register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 0 (cores). This register is updated only if the corresponding error status bit `L2CTL_STAT.ERR0` is cleared. After the status bit is set for an error, further errors do not update the `L2CTL_ET0` register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the `L2CTL_ET0` captures the write access error, keeping in sync with the error address register (`L2CTL_EADDR0`).

4 (R/NW)	RDWR	Read/Write Error. The `L2CTL_ET1.RDWR` bit indicates whether a read or write access caused an error.	
		0	Read access created error
		1	Write access created error
3 (R/NW)	ECCERR	ECC Error. If the `L2CTL_ET1.ECCERR` bit =1, the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. If the `L2CTL_ET1.ACCERR` bit =1, the access went to a restricted bank.	
0 (R/NW)	ROMERR	ROM Error. If the `L2CTL_ET1.ROMERR` bit =1, a write access went to a ROM area.	

Refresh Address Register

The `L2CTL_RFA` register stores the refresh address value. When this register is written, L2 initiates an atomic read-write operation to the address value written into the register. This is a read/write register, but a new value in the corresponding field has to be written only when there are no outstanding refresh request pending (`L2CTL_STAT.RFRS` =0). If a write occurs while a request is pending, the L2CTL generates a bus error, and the write does not take effect.

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	ADDRHI	Address High. The `L2CTL_RFA.ADDRHI` bits hold the high 16-bits of the L2 refresh address. Note that the upper 14 bits are hard-coded to the upper bits of the L2 address map.
15:0 (R/W)	ADDRLO	Address Low. The `L2CTL_RFA.ADDRLO` bits hold the low 16-bits of the L2 refresh address. Note that the lowest three bits are do-not-care.

Read Priority Count Register

The `L2CTL_RPCR` register stores the count value to be used for priority elevation for bus read channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SYSCLK_0 cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

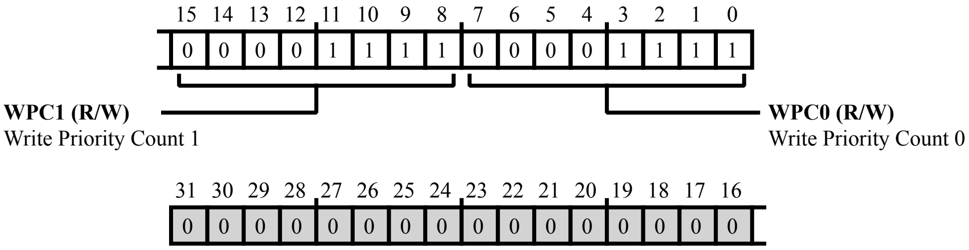
1 (R/W1C)	ERR1	Error Port 1. The `L2CTL_STAT.ERR1` indicates whether the L2CTL has detected a bus access error on L2s bus port 1.	
		0	No Error
		1	Bus Access Error
0 (R/W1C)	ERR0	Error Port 0. The `L2CTL_STAT.ERR0` indicates whether the L2CTL has detected a bus access error on L2s bus port 0.	
		0	No Error
		1	Bus Access Error

Write Priority Count Register

The `L2CTL_WPCR` register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SYSCLK_0 cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 9-22: L2CTL_WPCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	WPC1	Write Priority Count 1. The `L2CTL_WPCR.WPC1` bits hold the priority count for L2 bus write channel 0.
7:0 (R/W)	WPC0	Write Priority Count 0. The `L2CTL_WPCR.WPC0` bits hold the priority count for L2 bus write channel 1.

10 Dynamic Memory Controller (DMC)

The dynamic memory controller (DMC) provides a glueless interface between DDR3/DDR2/LPDDR SDRAMs and the system crossbar interface (SCB). The DMC enables execution of instructions from, as well as transfer of data to and from, DDR3, DDR2 SDRAM or LPDDR SDRAM respectively.

NOTE: The terms DDR2, DDR3, and LPDDR SDRAM are referred to generically as DDR SDRAM in the rest of this chapter unless otherwise noted.

NOTE: According to JEDEC STD specification (JESD79-3-1A.01) DDR3L marked devices (1.35V) can also be connected to ADSP-SC589 processors as these devices also meet 1.5V voltage level specifications of DDR3 marked devices.

The DMC is partitioned in a manner that allows reconfiguration and maintainability. The memory access protocol state machine along with JEDEC standard specific logic is embedded in the *protocol controller*. An access and operation reordering mechanism is incorporated as an *efficiency controller*. An SCB slave interface is provided to interface with the on-chip interconnect. This interface results in an efficient slave implementation owing to its out-of-order transaction capabilities. The control and status registers present in the DMC can be accessed using the MMR access bus.

The DMC supports access to the external memory by core and DMA accesses.

DMC Features

The DMC includes a protocol controller that supports:

- JESD79-3E compatible double data rate DDR3 SDRAM devices
- JESD79-2E compatible DDR2 SDRAM devices
- JESD209A low-power DDR (LPDDR) SDRAM devices

The features of the dynamic memory controller are:

- Provides 16-bit data only interface to SDRAM devices
- Supports a single external rank (one chip select)
- Supports various burst lengths

- Provides page hit detection that supports multiple column accesses to the same row
- User-specified active, precharge, and refresh commands.
- Programmable SDRAM access timing parameters
- Enables automatic refresh generation with programmable refresh intervals
- Self-refresh mode to reduce system power consumption
- Efficient transaction processing to improve throughput and bandwidth using:
    - Software programmable SCB IDs to allow SCB ID-based priority
    - The ability to postpone up to eight auto-refresh commands
    - Software selectable closed page scheme on a per bank basis
    - Simple transaction scheduling mechanism to reduce read write turnaround frequency on the memory bus
    - Accesses with the same SCB ID are scheduled back-to-back to take advantage of same page access in SDRAM
    - Caching of SDRAM read data burst for specific masters to reduce the latency for same burst accesses.

The DDR2 features are:

- 256M bit to 4G-bit device sizes
- Burst length BL = 4 or 8
- Support for additive latency
- Support for programmable ODT and drive impedance from memory end
- Support for programmable (and ZQ calibration) ODT and drive impedance from the processor end

The DDR 3 features are:

- 512 Mb to 8 Gb device sizes
- Burst length BL = 8
- Support for additive latency
- Support for programmable (and ZQ calibration) ODT and drive impedance
- Support for programmable (and ZQ calibration) ODT and drive impedance from the processor end

The LPDDR features are:

- 64M bit to 2G-bit device sizes
- Burst length BL = 4 or 8
- Support for deep power-down mode

Feature Exclusions

The DMC exclusions are as follows:

For DDR2:

- 4-bit and 8-bit wide DDR2 DRAM memories are not supported
- OCD is not supported
- Burst interleaved accesses are not supported
- Single-ended signaling mode not supported

For DDR3:

- 4-bit and 8-bit wide DDR2 DRAM memories are not supported
- Burst interleaved accesses are not supported
- Both burst chop-BC4 and BC4-on-the-fly are not supported
- Auto refresh pull-in is not supported
- Write leveling is not supported
- DLL off mode is not supported

For LPDDR:

- 32-bit wide LPDDR memory devices are not supported
- Status register read (SRR) is not supported
- Sampling the optional temperature output (TQ) signal is not supported
- Clock stop mode is not supported
- Bursts of 2 and 16 words are not supported
- No support for BURST_TERMINATE command
- Dual-die, two CS# and two CKE packages are not supported

DMC Functional Description

The dynamic memory controller consists of master and slave interfaces, a protocol controller, and an efficiency controller. The following sections describe the function of these interfaces and controllers.

ADSP-SC58x DMC Register List

The Dynamic Memory Controller module (DMC) provides an interface to external double-data-rate SDRAM. This interface supports various DDR standards (see chapter descriptions). A set of registers governs DMC controller operations. For more information on DMC controller functionality, see the DMC Controller Register Descriptions.

Table 10-1: ADSP-SC58x DMC Register List

Name	Description
DMC_CFG	Configuration Register
DMC_CPHY_CTL	Controller to PHY Interface Register
DMC_CTL	Control Register
DMC_DLLCTL	DLL Control Register
DMC_DT_CALIB_ADDR	Data Calibration Address Register
DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0 Register
DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1 Register
DMC_EFFCTL	Efficiency Control Register
DMC_EMR1	Shadow EMR1 DDR2 Register
DMC_EMR2	Shadow EMR2 Register (DDR2)/Shadow EMR Register (LPDDR)
DMC_MR	Shadow MR Register (DDR2/LPDDR), Shadow MR0 Register (DDR3)
DMC_MR1	Shadow MR1 Register (DDR3)
DMC_MR2	Shadow MR2 Register (DDR3)
DMC_MSK	Mask (Mode Register Shadow) Register
DMC_PRIO	Priority ID Register 1
DMC_PRIO2	Priority ID Register 2
DMC_PRIOMSK	Priority ID Mask Register 1
DMC_PRIOMSK2	Priority ID Mask Register 2
DMC_RDDATABUFID1	DMC Read Data Buffer ID Register 1
DMC_RDDATABUFID2	DMC Read Data Buffer ID Register 2
DMC_RDDATABUFMSK1	DMC Read Data Buffer Mask Register 1
DMC_RDDATABUFMSK2	DMC Read Data Buffer Mask Register 2
DMC_STAT	Status Register
DMC_TR0	Timing 0 Register
DMC_TR1	Timing 1 Register
DMC_TR2	Timing 2 Register

ADSP-SC58x DMC Register List

A set of registers governs DMCPHY operations. For more information on functionality, see the register descriptions.

Table 10-2: ADSP-SC58x DMC Register List

Name	Description
DMC_CAL_PADCTL0	Calibration PAD Control 0 Register
DMC_CAL_PADCTL2	Calibration PAD Control 2 Register
DMC_PHY_CTL0	PHY Control 0 Register
DMC_PHY_CTL1	PHY Control 1 Register
DMC_PHY_CTL2	PHY Control 2 Register
DMC_PHY_CTL3	PHY Control 3 Register
DMC_PHY_CTL4	PHY Control 4 Register

Protocol Controller

The DDR SDRAM protocol controller translates memory access requests from the SCB (system crossbar) interface to JEDEC protocol-specific transactions used by DDR SDRAM devices.

The protocol controller ensures that the various timing parameters are met before reading and writing the SDRAM. The controller also performs the SDRAM initialization sequence as mandated by the standard. The protocol controller can:

- Issue reads and writes
- Precharge a row in a bank
- Activate a row in a bank
- Put the SDRAM devices in self-refresh and power-down modes

The protocol controller takes mode register writes from the MMR interface and translates them into mode register writes to SDRAM. Writing into the mode register is restricted through a mask register.

Efficiency Controller

The efficiency controller controls the ordering of transfers buffered in the read and write command buffers. It attempts to order transfers to optimize the available memory bandwidth. The DMC uses a number of schemes, described in the following sections, to increase the throughput.

Page-Based Scheduling

The DMC parses each write and read transaction that it buffered and gets the information of the row (page) and bank address. The protocol controller maintains the information about the pages that are opened in each bank. The efficiency controller uses the information about the opened pages while scheduling the buffered transactions. The transactions to the opened pages are given higher priority than the other outstanding transactions.

Same Master Transaction Scheduling

The DMC also stores the ID of each transaction that it buffered. In most of the cases, the transactions related to a master result in page hits from the locality of reference rule. The efficiency controller uses the ID information of the transactions while scheduling. When the page-based scheduling of the buffered transactions is complete, same master transaction scheduling is triggered. If multiple transactions from a master are received, the efficiency controller schedules the transactions back-to-back.

DMC Read Data Buffer

The DMC read data buffer contains a data buffer and an address buffer. The depth of the data buffer is equal to the burst length that is programmed in SDRAM. The address buffer holds the corresponding SDRAM burst address. When an SDRAM write address from any master matches an address in the DMC read data buffer, the DMC invalidates the related data in the read buffer. When the `DMC_RDDATABUFMSK1` or `DMC_RDDATABUFMSK2` register is programmed with a value other than zero, the DMC read data buffer operation is enabled. The set of masters whose data is buffered and retrieved are programmed in the `DMC_RDDATABUFID1` or `DMC_RDDATABUFID2` registers. The DMC can use the `DMC_RDDATABUFMSK1` and `DMC_RDDATABUFMSK2` ID registers to select a set of masters similar to the programming of the `DMC_PRIOMSK` and `DMC_PRIOMSK2` registers.

See the SCB ID-Based Priority section for details.

Closed Page Per Bank

The `DMC_EFFCTL` register provides per-bank granularity for closing pages. The software can determine that most accesses to a given bank in memory always result in a missed page. In this case, set the `PREC_BANK` bit corresponding to the required bank to close the row after every transfer. This proactive step can result in reduced thrashing and increases memory throughput.

SCB ID-Based Priority

The primary goal of the dynamic memory controller is to improve sustainable memory system bandwidth so that the service time for the average request can be reduced. However, to service critical requests from any master in the system, the DMC provides a mechanism to elevate priority of a given access. The DMC priority ID registers (`DMC_PRIO` and `DMC_PRIO2`) can be programmed with up to two SCB IDs with elevated priority.

After every access in a snapshot, the command buffers are searched to determine whether a commands ID matches with the ID programmed in the `DMC_PRIO` and `DMC_PRIO2` registers. The priority SCB ID access is sent before the subsequent access in the snapshot if:

- A match occurs, and
- The direction of the access (for example write) is the same as the direction of the snapshot (write)

There is an alternative to providing priority to a specific SCB ID. If a number of IDs from the same master require priority, program the DMC priority mask ID registers (`DMC_PRIOMSK` and `DMC_PRIOMSK2`) so that the corresponding bits are 0. The DMC uses a combination of the `DMC_PRIO` and `DMC_PRIO2` registers and the `DMC_PRIOMSK`/`DMC_PRIOMSK2` registers to elevate the priority of a select few or all IDs that belong to a master. By default, none of the IDs are prioritized. The following are a few possibilities.

- The `DMC_PRIOMSK` field is set to 0x00000000. If a single ID (7234) needs priority, set the `DMC_PRIOMSK` field to 0xFFFFFFFF and set the `DMC_PRIO` field to 7234.
- If the `DMC_PRIOMSK` field is set to 0xFFFFFFFE, the SCB IDs 7234 and 7235 are given priority.

- If the `DMC_PRIOMSK` field is set to 0xFFFFFFFC, the SCB IDs 7234, 7235, 7236 and 7237 are given priority.
- If two transactions with priority, one read and the other a write, are outstanding, the priority transaction that does not change the direction of the DMC access gets priority.
- The other priority transaction is handled at the beginning of the next snapshot. For example, if a write snapshot is in progress, the write priority transaction is sent. The read priority transaction is sent at the beginning of the next read snapshot.

NOTE: Use SCB-ID-based priority judiciously because it can significantly reduce the throughput of the DMC.

Delaying up to Eight Auto-Refresh Commands

The DMC uses this method to ensure that auto-refresh does not interfere with any critical data transfers. Up to eight auto-refresh commands can accumulate in the DMC. The exact number of auto-refresh commands can be programmed using the `DMC_EFFCTL.NUMREF` bit.

After the first refresh command is accumulated, the DMC constantly looks for an opportunity to schedule a refresh command. When the SCB read and write command buffers become empty for the programmed number of clock cycles (`DMC_EFFCTL.IDLECYC` bit field), the accumulated number of refresh commands are sent back-to-back to the DRAM. (The empty state of the SCB command buffers implies that no access is outstanding.)

After every refresh, the SCB command buffers are checked to ensure that they stay empty. If the SCB command buffers are always full, once the programmed number of refresh commands accumulates, the refresh operation is elevated to urgent priority. One refresh command is sent immediately. After this process, the DMC continues to wait for an opportunity to send out refresh commands. If self-refresh mode is enabled, all pending refresh commands are given out only after that DMC enters into self-refresh mode.

Page and Bank Interleaving

Page and bank interleaving allow consecutive row accesses to fall into the same bank (bank interleaving) or into a different bank (page interleaving). The DMC uses bank interleaving by default (`DMC_CTL.ADDRMODE` bit =0). If the `DMC_CTL.ADDRMODE` bit =1, the DMC uses page interleaving. Page misses in one addressing mode result in hits in the other addressing mode.

System Crossbar Slave Interface

The DMC uses the system crossbar slave interface to move all data. The system crossbar interface accepts interleaved write transactions and sends out-of-order responses. The read and write interfaces consist of buffers for address, data, and control information transferred to or from the system crossbar bus.

The system crossbar interface transactions are sent to the SDRAM only after the SDRAM has been initialized. However, if transactions arrive before or during initialization, they accumulate in the system crossbar interface and are sent out to the protocol controller once the initialization completes.

To increase throughput, the system crossbar write-response is sent out as soon as the final DDR burst is scheduled for transfer into the SDRAM. However, if an auto-refresh is needed, the scheduled write data is sent only after the auto-refresh. A delay can occur. The delay is a maximum of 64 clock cycles from the moment the write response is sent on the SCB to the write operation of the data into SDRAM.

The system crossbar interface performs the following operations:

- Buffers read and write command requests from the system crossbar bus
- Processes the requests by converting them to protocol controller user-interface transfers
- Sends and receives data to or from the protocol controller
- Creates a suitable read/write response and sends read data back to the system crossbar bus

The system crossbar slave interface supports the following:

- All burst lengths (1–16)
- Incremental and wrap bursts
- Data transfer sizes of 8-bit, 16-bit, or 32-bit
- Arrival of write data before write address
- Generation of error responses which include:
  - Any access to an unimplemented region of the external memory space
  - Any access when the SDRAM is in self-refresh, power-down, or deep power-down mode (in case of LPDDR)
  - Any access when the direct command interface is in operation

Read/Write Command and Data Buffers

The system crossbar interface consists of a four-deep read command buffer and a four-deep write command buffer. Up to four write commands and four read commands can be waiting for access to the SDRAM. The system crossbar write buffer is 32 deep. It can support write data interleaving of two. The system crossbar read buffer is 32 deep.

Peripheral Bus Slave Interface

The peripheral bus slave interface connects the dynamic memory controller to the peripheral bus and provides a host controller with access to the registers. The peripheral bus slave interface supports the following features:

- Read and write word accesses
- 32-bit data bus

Architectural Concepts

The following sections provide information on the architecture of the interface.

Controller On Die Termination (ODT)

The controller ODT is enabled with the granularity of a byte lane. The description of this feature can be obtained in the description of the corresponding PHY registers. Controller ODT involves extra overhead in terms of power consumption during reads.

The DMC implements dynamic on die termination at processor pads. When controller ODT is enabled, the termination resistors in the pads are turned on when the controller reads data from the DRAM. These resistors are turned off when the controller writes to the DRAM.

Mode Register Set and Extended Mode Register Set Command

The load mode register command initializes the SDRAM operation parameters. The DMC supports the mode register set and extended mode register set commands. The controller automatically issues the mode register set command during power-on initialization and also when the `DMC_MR` register is written with the `DMC_MSK.MR` bit. The mode register set command is sent after the ongoing data transfer completes.

The DMC automatically issues the mode register set command when the shadow EMR1/EMR2/EMR3 registers are written. The corresponding `DMC_MSK.EMR3DMC_MSK.EMR2`/`DMC_MSK.EMR1` bits must be enabled.

DDR3 Reset Functionality

DDR3 contains an additional pin corresponding to reset functionality. Reset is part of the initialization sequence but it can be performed asynchronously when needed. The reset procedure is similar to the steps involved in the initialization except the initial part of power-up.

To perform reset on the DDR3 module:

1. Check to ensure the module is in the idle state by polling the `DMC_STAT.IDLE` bit (0x0008).
2. Set the `DMC_CTL.RESET` bit (0x0004).
3. Monitor the `DMC_STAT.RESETDONE` bit for the completion of the reset function.

Do not perform any transactions during a module reset. Wait for the `DMC_STAT.RESETDONE` signal.

DDR3 SDRAM Organization

The DMC supports DDR3 SDRAM memory modules ranging from 512 Mb to 8 Gb. The following tables list the address translation mechanism from the user interface to DDR3 memory interface. The controller also supports two types of addressing modes: bank interleaving (`DMC_CTL.ADDRMODE` =1) and page interleaving (`DMC_CTL.ADDRMODE` =0).

Bank Interleaving

The ***DDR3 Bank Interleaving*** table shows DDR3 bank interleaving.

Table 10-3: DDR3 Bank Interleaving

SDRAM size	Bank address bits	Row address bits	Column address bits
512 Mb	25:24	23:11	10:1

Table 10-3: DDR3 Bank Interleaving (Continued)

SDRAM size	Bank address bits	Row address bits	Column address bits
1 Gb	26:24	23:11	10:1
2 Gb	27:25	24:11	10:1
4 Gb	28:26	25:11	10:1
8 Gb	29:27	26:11	10:1

Page Interleaving

The ***DDR3 Page Interleaving*** table shows DDR3 page interleaving.

2 Gb	27:14	13:11	10:1
4 Gb	28:14	13:11	10.1
8 Gb	29:14	13:11	10.1

DDR2 SDRAM Organization

The DMC supports DDR2 SDRAM memory modules ranging from 256M bit to 4G bit. The following tables list the address translation mechanism from the user interface to DDR2 memory interface. The controller also supports two types of addressing modes: bank interleaving (`DMC_CTL.ADDRMODE` =1) and page interleaving (`DMC_CTL.ADDRMODE` =0).

Bank Interleaving

The ***DDR2 Bank Interleaving*** table shows DDR2 bank interleaving.

Table 10-5: DDR2 Bank Interleaving

SDRAM size	Bank address bits	Row address bits	Column address bits
256 Mb	24:23	22:10	9:1
512 Mb	25:24	23:11	10:1
1 Gb	26:24	23:11	10:1
2 Gb	27:25	24:11	10:1
4 Gb	28:26	25:11	10:1

Page Interleaving

512 Mb	25:13	12:11	10:1
1 Gb	26:14	13:11	10:1
2 Gb	27:14	13:11	10:1
4 Gb	28:14	13:11	10.1

LPDDR SDRAM Organization

The DMC supports LPDDR SDRAM memory modules ranging from 64M bit to 2G bit. The following tables list the address translation mechanism from the user interface to LPDDR memory interface.

The controller also supports two types of addressing modes: bank interleaving (`DMC_CTL.ADDRMODE`=1) and page interleaving (`DMC_CTL.ADDRMODE`=0).

Bank Interleaving

The ***LPDDR Bank Interleaving*** table shows LPDDR bank interleaving.

Table 10-7: LPDDR Bank Interleaving

1 Gb	26:14	13:11	10:1

Table 10-8: LPDDR Page Interleaving (Continued)

SDRAM size	Row address bits	Bank address bits	Column address bits
2 Gb	27:14	13:11	10.1

DMC Clocking

The DMC uses a divided-down version of the *PLLCLK* (PLL clock) to generate an internal clock for clocking the DMC block and interface. The specific value of the *DCLK* frequency is programmed in the `CGU_DIV` register. The section Initializing the DMC (ADSP-SC58x) describes the procedure.

For information on the maximum clock frequency supported for specific modes, refer to the processor data sheet.

NOTE: For the processor variants that have two DMC blocks, both blocks run on the same DCLK frequency.

NOTE: In some cases, it might be required to generate a DCLK frequency asynchronous to CCLK (for example, CCLK=450 MHz and DCLK=400 MHz). For these cases, one CGU can be used to generate CCLK and another can be used to generate DCLK. For more details, refer to the CGU chapter.

DMC DMA

The DMC supports DMA-based transfers to and from external DDR SDRAM memory and internal memory.

The DMC DMA controller, part of the distributed DMA engines (DDE) that are dispersed through the infrastructure, connects to the system crossbar fabric.

The DMC uses two DDEs for memory-to-memory DMA (MDMA). One channel is the source channel, and the second, the destination channel.

DMA transfers on the processor are descriptor-based or register-based. Register-based DMA allows the processor to program DMA control registers directly to initiate a DMA transfer. On completion, the control registers can be automatically updated with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. This transfer allows the chaining together of multiple DMA sequences. In descriptor-based DMA operations, a DMA channel can be programmed to set up and start another DMA transfer automatically after the current sequence completes.

Refer to the DMA chapter for further details.

Enhanced DMA operations (such as delay line DMA, scatter or gather DMA) are also supported to or from the DMC module. For more details, refer to the Extended Memory DMA (EMDMA) chapter.

DMC Operating Modes

By default, the DMC is in DDR2 mode. To enable DDR3 or LPDDR mode, the corresponding bits in the `DMC_CTL` and `DMC_PHY_CTL4` register must be configured.

DDR2 Mode

This mode is the default mode of the DMC module and supports JESD79-2E compatible DDR2 SDRAM. In this mode, the `DMC_CTL.DDR3EN` bit =0, the `DMC_CTL.LPDDR` bit =0, and the `DMC_PHY_CTL4.DDRMODE` bit field is 0b'01.

DDR3 Mode

The DMC module supports JESD79-3E compatible double data rate DDR3 SDRAM. To configure this mode of operation, first set (=1) the `DMC_CTL.DDR3EN` bit and set the `DMC_PHY_CTL4.DDRMODE` bit field to 0b'00.

LPDDR Mode

The DMC module supports JESD209A low-power DDR (LPDDR) SDRAM. To configure this mode of operation, set (=1) the `DMC_CTL.LPDDR` bit and set the `DMC_PHY_CTL4.DDRMODE` bit field to 0b'11.

Deep Power-Down Mode

The DMC module supports JESD209A low-power DDR (LPDDR) SDRAM. To configure this mode of operation, set (=1) the `DMC_CTL.LPDDR` bit and set the `DMC_PHY_CTL4.DDRMODE` bit field to 0b'11.

When the processor does not require the data stored in SDRAM (assume reset state of SDRAM), the DMC can put the SDRAM in deep power-down mode. When the DMC is in deep power-down, any data accesses cause the DMC to generate a bus error. To configure this mode, set (=1) the `DMC_CTL.DPDREQ` bit when low-power DMC operation is enabled (`DMC_CTL.LPDDR` =1).

The `DMC_STAT.IDLE` bit indicates the activity in the DMC. If this bit is set, there is no activity all through the DMC. Deep power can be entered by setting the `DMC_CTL.DPDREQ` bit. The `DMC_STAT.DPDACK` bit is asserted when the SDRAM enters deep power-down mode. The DMC stays in deep power-down mode as long as the `DMC_CTL.DPDREQ` bit is asserted.

Clearing (=0) the `DMC_CTL.DPDREQ` bit causes the DMC to exit deep power-down mode. Also, when exiting deep power-down mode, the controller clears the `DMC_STAT.DPDACK` bit. The user must re-initialize the DMC after it comes out of deep power-down mode.

Self-Refresh Mode

For low-power consumption, the SDRAM can be put in self-refresh mode. When no data activity occurs, the DMC can put the SDRAM in self refresh to save power. The `DMC_STAT.IDLE` bit indicates the activity on the DMC. If this bit is set, there is no activity in the DMC.

Enable self-refresh mode by writing the `DMC_CTL.SRREQ` bit. The DMC stays in a self-refresh state as long as this bit is asserted. The `DMC_STAT.SRACK` bit indicates when the SDRAM enters self-refresh mode.

When the DMC is in self-refresh mode, the DMC generates an SCB error when any data accesses (read or write requests) is requested.

The DMC can be brought out of self-refresh mode by clearing the `DMC_CTL.SRREQ` bit again. The controller clears the `DMC_STAT.SRACK` bit after the self-refresh operation completes.

DMC Event Control

The DMC has no related interrupt or trigger event information.

DMC Programming Model

The dynamic memory controller contains five groups of memory-mapped registers. The DMC uses the MMR access bus to connect to these registers.

- Control and status registers. These registers control the various operation modes of the dynamic memory controller and provide status.
- Timing parameter registers. The value programmed in these registers depends on the speed grade of the SDRAM device used.
- Mode register mirror registers. These shadow registers are copies of the mode registers residing in the SDRAM device.
- PHY control and status registers. The DMC uses these registers to control the operation of the PHY.
- PAD control registers. The DMC uses these registers to control the various aspects of the I/O pads.

The DMC control registers contain sensitive timing parameters and settings for the DDR SDRAM. These registers are programmed with values that are in the operating range of the DDR used.

Writing to reserved fields or writing any reserved values in register bits can cause the dynamic memory controller to function erroneously.

Programming Considerations for DDR2, DDR3, and LPDDR Memory

The ***DDR2, DDR3, and LPDDR Programming*** table shows important programming considerations and differences across DDR2, DDR3, and LPDDR memory technologies. The table serves as a quick reference when configuring the DMC and PHY registers.

Table 10-9: DDR2, DDR3, and LPDDR Programming

PHY/Controller	Description	Registers and Bit Fields Involved	DDR3	DDR2	LPDDR
PHY	Enabling DDR3/DDR2/LPDDR modes	`DMC_PHY_CTL4`	Select DDR3 mode by setting the `DMC_PHY_CTL4.DDRMODE` bit field to 00.	Select DDR2 mode by setting the`DMC_PHY_CTL4.DDRMODE` bit field to 01.	Select LPDDR mode by setting the `DMC_PHY_CTL4.DDRMODE` bit field to 11.

Table 10-9: DDR2, DDR3, and LPDDR Programming (Continued)

PHY/Controller	Description	Registers and Bit Fields Involved	DDR3	DDR2	LPDDR
PHY	ODT and drive impedance calibration	DMC_CAL_PADCTL0, DMC_CAL_PADCTL2	The DMC supports ODT and drive impedance calibration. Configure the DMC_CAL_PADCTL0 and DMC_CAL_PADCTL2 registers accordingly. For details, refer PAD Calibration for Driver Impedance and On Die Termination (ODT) section. Programming driver impedance is required. Programming ODT is optional. To disable ODT, set the DMC_PHY_CTL1.BYPODTEN bit.	The DMC supports OCD calibration. Configure the DMC_CAL_PADCTL0 register accordingly.	The DMC does not support ODT and drive impedance calibration. No need to program the DMC_CAL_PADCTL0 and DMC_CAL_PADCTL2 registers. Must make sure that the DMC_PHY_CTL1.BYPODTEN bit is set to bypass the processor ODT settings.
Controller	Enabling DDR3/DDR2/LPDDR modes	DMC_CTL.DDR3EN, DMC_CTL.LPDDR	Select DDR3 mode by setting the DMC_CTL.DDR3EN bit. Make sure that the bit DMC_CTL.LPDDR is cleared.	Default is DDR2 mode. Make sure that both the bits DMC_CTL.LPDDR and DMC_CTL.DDR3EN are cleared.	Select LPDDR mode by setting the DMC_CTL.LPDDR bit. Make sure that the bit DMC_CTL.DDR3EN is cleared.
Controller	Configuring DMC_CTL.RDTOWR bit field	DMC_CTL.RDTOWR	Make sure that the DMC_CTL.RDTOWR bit field is always set to 010 (=2 in decimal).		
Controller	Configuring DMC_CFG register fields	DMC_CFG	Make sure that the DMC_CFG.IFWID and DMC_CFG.SDRWID bit fields are always set to 0010 (=2 in decimal) as the DMC only supports 16-bit wide interface and SDRAM widths. Make sure that the bit field DMC_CFG.EXTBANK is always set to 0000 as the DMC only supports one external bank. Select the DMC_CFG.SDRSIZE as per the SDRAM size. Supported sizes are 64 Mb to 2 Gb for LPDDR, 256 Mb to 4 Gb for DDR2, and 512 Mb to 8 Gb for DDR3.		
Controller	Configuring controller timing parameter registers	DMC_TR0, DMC_TR1, DMC_TR2	Configure the parameters t_{RCD}, t_{WTR}, t_{RP}, t_{RAS}, t_{MRD}, t_{REF}, t_{RFC}, t_{RRD}, t_{WR}, t_{XP}, t_{CKE} (DDR3/DDR2/LPDDR), and t_{FAW}, t_{RTP} (DDR3/DDR2) in terms of DCLK cycles.		

Table 10-9: DDR2, DDR3, and LPDDR Programming (Continued)

PHY/Controller	Description	Registers and Bit Fields Involved	DDR3	DDR2	LPDDR
Controller	Configuring burst length	`DMC_MR.BLEN` (for DDR2 and LPDDR), DMC_MR0.BLEN for DDR3	The DMC only supports burst length of 8. Configure the DMC_MR0.BLEN field to 00 only.	The DMC supports both burst length of 4 and 8. Configure `DMC_MR.BLEN` field to 10 for burst length of 4 and to 11 for burst length of 8 words.	The DMC supports both burst length of 4 and 8. Configure `DMC_MR.BLEN` field to 10 for burst length of 4 and to 11 for burst length of 8 words.
Controller	Configuring CAS latency	`DMC_MR.CL` (for DDR2 and LPDDR), DMC_MR0.CL0, and DMC_MR0.CL (for DDR3)	The DMC supports CAS latencies of 5 to14. Refer to the `DMC_MR.CL` register description for more details.	The DMC supports CAS latencies of 3 to 6. Refer to the `DMC_MR` register description for more details.	The DMC supports CAS latency of 3. Refer to the `DMC_MR` register description for more details.
Controller	Configuring the `DMC_MR.DLLRST` bit (DDR2/LPDDR) or DMC_MR0(DDR3)	`DMC_MR.DLLRST`/ DMC_MR0.DLLRST	Set this bit while performing the initialization	Setting of this bit is optional for DDR2.	Reserved
Controller	Write recovery timing	`DMC_MR.WRRECOV` and DMC_MR0.WRRECOV	The DMC supports WR values of 5 to 16. Refer to the DMC_MR0 register description for more details.	The DMC supports WR values of 2 to 8. Refer to the `DMC_MR` register description for more details.	Reserved
Controller	Configuring DMC_MR1(DDR3) or `DMC_EMR1` (DDR2) register	DMC_MR1(DDR3) or `DMC_EMR1` (DDR2)	The DMC can use this register to configure memory drive impedance, ODT, and additive latency parameters. Refer to the corresponding register descriptions for more details.		This register is not used for LPDDR programming.
Controller	Configuring DMC_MR2(DDR3) or `DMC_EMR2` (DDR2) or DMC_EMR (LPDDR) register	DMC_MR2(DDR3) or `DMC_EMR2`(DDR2) or DMC_EMR (LPDDR)	Configure the write latency field (CWL) to the required value. The DMC can also use this register to enable Auto Self-Refresh (ASR) and to select Self-Refresh Temperature (SRT) functionalities in the memory device. For more details on these functionalities, refer to the	The DMC can use this register to configure the Partial Array Self-Refresh (PASR) and High Temperature Self-Refresh Rate Enable (SRF) functionalities of DDR2 memory device. For more details on these functionalities, refer to the DDR2 memory device data sheet.	The DMC can use this register to configure the Partial Array Self-Refresh (PASR), Temperature compensated self-refresh (TCSR), and drive strength (DS) functionalities of the memory device. For more details on these functionalities, refer to the LPDDR memory device data sheet.

Table 10-9: DDR2, DDR3, and LPDDR Programming (Continued)

PHY/Controller	Description	Registers and Bit Fields Involved	DDR3	DDR2	LPDDR
			DDR3 memory device data sheets.		
Controller	Configuring the `DMC_DLLCTL` register	`DMC_DLLCTL`	Always configure the `DMC_DLLCTL.DLLCALRDCNT` field to 0x48 and `DMC_DLLCTL.DATACYC` field to 0x9.		

PHY DLL Calibration

The PHY DLL calibration is performed as part of the SDRAM power-up initialization. It calibrates data against the DQS and CLK signal. However, running DLL calibration after self-refresh or at an arbitrary time is required in certain cases.

The DMC allows PHY DLL calibration to start by setting the `DMC_CTL.DLLCAL` bit. The `DMC_STAT.DLLCALDONE` bit can be used to monitor the progress of the calibration. Once calibration is over, this bit is set. Once the calibration procedure is started by writing to the `DMC_CAL_PADCTL0.CALSTRT` bit, the full calibration takes 300 DCLK cycles to complete.

NOTE: DLL calibration can be initiated only when the DMC is idle (`DMC_STAT.IDLE`= 1).

DDR2 OCD Calibration

OCD calibration is not supported by the ADSP-SC58x processors.

DDR3 ZQ Calibration Short CMD

The ZQ calibration short command is generally used to correct small variations in ZQ (approximately 0.5%). To perform ZQ calibration, the controller is first checked for its idle state. Once the idle bit is obtained, a ZQCS command can be issued by setting the `DMC_STAT.ZQCSDONE` bit (0x0004). The `DMC_STAT.ZQCSDONE` bit (0x0008) can be used to monitor the calibration sequence. When this bit is “0”, it indicates that the calibration is ongoing. When it is “1”, it indicates that the calibration is done. As an example, a GP timer can be used to periodically trigger a ZQCS command to address tiny variations.

NOTE: The ZQ calibration function is essential for normal operation of DDR3. With the reference of the external resistance (240Ω ± 1%) connected to the DMC_RZQ pin, DDR3 calibrates the Ron and Rtt values of the ZQ pin against temperature and voltage variations.

DDR3 ZQ Calibration Long CMD

Several DDR3 impedance calibrations are implemented for optimal signal integrity. The long ZQ calibration is used after power-up and the short ZQ calibration is used periodically during normal operation to compensate for voltage and temperature drift. These calibration sequences improve connectivity between the SDRAM pads and the PCB trace. The DMC_RZQ pin on the SDRAM is connected to an external precision resistor that adjusts the output driver impedance Rtt and ODT values to match the trace impedance. The connection reduces impedance discontinuity and minimizes signal reflections.

The command has two variants named as ZQ calibration long (ZQCL) and ZQ calibration short (ZQCS). The ZQCL command is issued during initialization and after self-refresh exit command. It can be issued later depending on the system environment.

The DMC pads can be autocalibrated to the required driver impedance Rtt using an external resistance RZQ and the On Die Termination (ODT) value using the corresponding bits (`DMC_CAL_PADCTL2`). The autocalibration logic translates these values into a corresponding drive strength control inside the PHY and then routed to the PADS. Autocalibration starts as soon as the `DMC_CAL_PADCTL0.CALSTRT` bit is programmed (set the DCLK at the required frequency before setting this bit). Autocalibration expects the program to select two different member sets of pads (address/command pads versus CLK/Data/DQS/DM pads).

On Die Termination (DDR2/DDR3)

The DMC supports dynamic On Die Termination (ODT) at the pads. When the controller ODT is set, the termination resistors in the pads are turned on when the controller reads data from the DRAM. These resistors are turned off when the controller is writing to the DRAM. Controller ODT is enabled with the granularity of a byte lane. The description of this feature can be obtained in the description of the corresponding PHY registers.

ODT resistance Rtt is selectable in the same way as DDR2 SDRAM ([A9, A6, A2] in MR1, [A10, A9] in MR2)

DDR3 SDRAM inherits the ODT function provided for DDR2 SDRAM, and provides extended ODT mode.

Synchronous ODT: ODT timing is the same as that of DDR2 SDRAM

Asynchronous ODT: ODT timing in the slow exit power-down mode

Dynamic ODT: Function that can dynamically switch the ODT resistance during a write operation without an MRS command. It improves signal quality during a write operation.

Output Driver Impedance

Output driver impedance (Rtt) of DQ, DQS, /DQS/DM is selectable in the same way as DDR2 SDRAM ([A5, A1] in MR1). Rtt can fluctuate with the process, voltage, and temperature (PVT). DDR2 SDRAM can calibrate Rtt fluctuation due to PVT using the optional OCD (off-chip driver calibration) function. DDR3 SDRAM uses the ZQ calibration function instead of the OCD function.

In addition to the driver impedance, the bidirectional pads (Data and DQS) also require the initialization sequence to program the termination impedance by writing to the field `DMC_CAL_PADCTL2.IMPRTT`. The DMC pads use parallel termination, one branch goes from the pad to the I/O supply. The other branch goes to the I/O ground. The value programmed to this 8-bit field is the value to be used for each branch. There is a correction factor involved while programming this register. The value of this correction factor is 0.8. For example, suppose that a termination of 50 Ω is required on the data pads to match with the board trace. The value is programmed to 100 × 0.8 = 80, as the two parallel paths lead to an effective impedance of 50 ohms.

Initializing the DMC (ADSP-SC58x)

To initialize the DMC, use the following steps. If it is not the first time that the DMC initializes, check to first ensure that the DMC is idle and not in the midst of any activity.

If DMC initialization occurs for the first time after power-up, PHY and PAD initialization is a requirement. The initialization occurs with the following steps:

For LPDDR mode, set the `DMC_PHY_CTL4.DDRMODE` bits to 0b'11 (3 in decimal) and set the `DMC_PHY_CTL1.BYPODTEN` bit.

For DDR2/DDR3 modes, follow these steps to perform pad impedance calibration:

1. Set the device mode in the `DMC_PHY_CTL4.DDRMODE` to DDR2 or DD3.
2. Configure the required values in the `DMC_CAL_PADCTL0` and `DMC_CAL_PADCTL2` registers without setting the `DMC_CAL_PADCTL0.CALSTRT` bit.
3. Set the `DMC_CAL_PADCTL0.CALSTRT` bit.
4. Wait for 300 DCLK cycles for the PAD calibration to complete.

   Bits 0, 1, 2, 3 of the `DMC_PHY_CTL0` register and the bits 31 through 26 of the `DMC_PHY_CTL2` register are timing trim bits. Always set these bits for DDR2 and DDR3 modes. For example, set these bits during first-time DMC initialization. Then, software does not need to touch or clear these bits.

   Bits 0, 1, 2, 3 of the `DMC_PHY_CTL0` register and bits 26, 27, 28, 29, 30, and 31 of the `DMC_PHY_CTL2` register are timing trim bits. Always set these bits for DDR2 and DDR3 modes. For example, set these bits during first-time DMC initialization. Then, software does not need to touch or clear these bits.

   Use the following C code to set these bits for the first time DMC initialization:

```
*pREG_DMC0_PHY_CTL0 |= 0x0000000F;
*pREG_DMC0_PHY_CTL2 |= 0xFC000000;
```

NOTE: Bits 6, 7, 25 and 27 of the `DMC_PHY_CTL3` register should always be set for all the DDR modes (DDR3/DDR2/LPDDR). The program can set these bits during first-time DMC initialization. Then, software need not touch or clear these bits. Use the following C code to set these bits for the first time DMC initialization:

```
*pREG_DMC0_PHY_CTL3=0xA0000C0;
```

NOTE: For DDR3 mode, set bit 1 and configure bits [5:2] of the `DMC_CPHY_CTL` register with WL = CWL + AL in DCLK cycles. For example, in case of DMC0, if CWL =6 and AL =0, program the `DMC_CPHY_CTL` register with the value 0x0000001A.

Use the following steps for first-time DMC initialization and reinitialization:

1. Perform first-time DMC initialization, as needed.

   ADDITIONAL INFORMATION: Perform this step only for the first time DMC initialization after power-up or reset. Skip this step if reinitializing the DMC.

   a. Set the `DMC_PHY_CTL0.RESETDLL` bit of the `DMC_PHY_CTL0` register.

   b. Initialize the CGU to change the DCLK frequency.

   a. Clear the `DMC_PHY_CTL0.RESETDLL` bit of the `DMC_PHY_CTL0` register.

2. Reinitialize the DMC with a DCLK change

   a. Place the DMC in self-refresh mode.

   b. Set the `DMC_PHY_CTL0.RESETDLL` bit of the `DMC_PHY_CTL0` register.

   c. Initialize the CGU to change the DCLK frequency.

   d. Clear the `DMC_PHY_CTL0.RESETDLL` bit of the `DMC_PHY_CTL0` register.

   e. Bring the DMC out of self-refresh mode.

3. If not already done, wait 9000 DCLK cycles to ensure that the DLL locked.

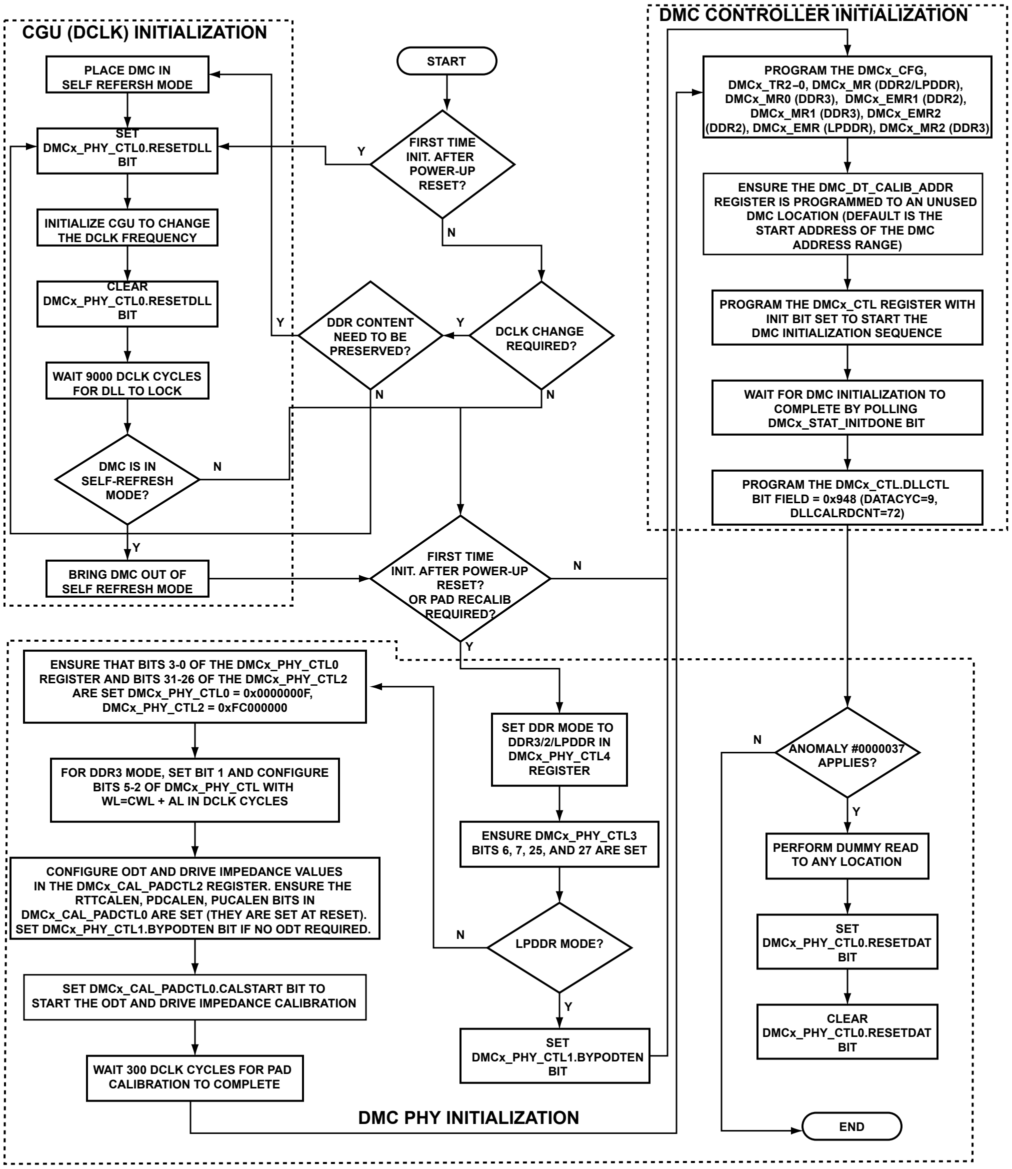
4. Program the `DMC_CFG`, `DMC_CTL`, `DMC_TR0`, `DMC_TR1`, and `DMC_TR2` registers to the appropriate values to set proper SDRAM cycle timing options.

   ADDITIONAL INFORMATION: For example, t_{RAS}, t_{RC}, t_{RP}, t_{RCD}, t_{WR}, t_{FAW} are some of the parameters.

5. Program the shadow registers `DMC_MR` (DDR2/DDR3/LPDDR), `DMC_EMR1` (DDR2)/`DMC_EMR1`(DDR3), `DMC_EMR1` (DDR2)/`DMC_EMR1` (LPDDR) `DMC_EMR1` (DDR3), with the needed burst length, CAS latency, additive latency, and other parameters.

6. Finally, after programming these registers, write the `DMC_CTL.INIT` bit to the DMC control register to begin the power-up initialization sequence.

7. Wait for the SDRAM initialization sequence to complete by making sure that the `DMC_STAT.INITDONE` bit is set.



CGU (DCLK) INITIALIZATION

Figure 10-1: DMC Initialization Flow

The DMC accumulates system crossbar transactions that occur during or before initialization and sends them to SDRAM once the SDRAM initialization or DLL calibration is complete.

NOTE: During the DMC PHY DLL calibration, a particular set of locations in the DRAM is written followed immediately by a series of reads. The DMC PHY needs information about the data to be read during the PHY DLL calibration prior to the operation. The controller performs one burst write operation to the address programmed in the `DMC_DT_CALIB_ADDR` register. The exact address chosen does not matter during memory initialization.

If calibration of the PHY is performed when the DRAM contains valid data, ensure that this address points to an unused address. Otherwise, this operation modifies application data stored at the address selected. The DLL calibration modifies all 16 bytes corresponding to the 16-byte aligned address, even if the address programmed is not 16-byte aligned. For example, it updates all the locations 0x80000000 to 0x8000000F regardless of whether the address is programmed as 0x80000000 or 0x80000004.

The program performs second-time initialization for cases where the DMC has already been initialized. The initialization can be through a preload during a debug session, or through code executed during the booting process.

ADSP-SC58x DMC Register Descriptions

Dynamic Memory Controller (DMC) contains the following registers.

Table 10-10: ADSP-SC58x DMC Register List

Name	Description
DMC_CFG	Configuration Register
DMC_CPHY_CTL	Controller to PHY Interface Register
DMC_CTL	Control Register
DMC_DLLCTL	DLL Control Register

ZQCL (R0/W)
ZQ Calibration Long
ZQCS (R0/W)
ZQ Calibration Short

Figure 10-4: DMC_CTL Register Diagram

Table 10-13: DMC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R0/W)	ZQCL	ZQ Calibration Long. The `DMC_CTL.ZQCL` bit starts the ZQ calibration long sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration long sequence
24 (R0/W)	ZQCS	ZQ Calibration Short. The `DMC_CTL.ZQCS` bit starts the ZQ calibration short sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration short sequence

Table 10-13: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R0/W)	DLLCAL	DLL Calibration Start. The `DMC_CTL.DLLCAL` bit starts the PHY DLL calibration sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Start PHY DLL calibration
12 (R/W)	PPREF	Postpone Refresh. The `DMC_CTL.PPREF` bit enables postponing the DMCs sending of auto-refresh commands. When enabled, the DMC accumulates refresh commands. The `DMC_EFFCTL.NUMREF` field selects the number of refresh commands that the DMC can accumulate. When disabled, the `DMC_TR1.TREF` field selects the interval for auto-refresh command distribution. A maximum of eight auto-refresh commands can be accumulated in DDR2 and DDR3 mode and a maximum of four auto-refresh commands in low power DDR mode.	
		0	Disable Postpone Refresh
		1	Enable Postpone Refresh
11:9 (R/W)	RDTOWR	Read-to-Write Cycle. The `DMC_CTL.RDTOWR` bits select the number of cycles that the DMC adds when a write operation follows a read operation. For proper operation, it should be programmed with the value of 010.	
		0	1 Cycle Added from JEDEC Spec Value
		1	2 Cycles Added from JEDEC Spec Value
		2	3 Cycles Added from JEDEC Spec Value
		3	4 Cycles Added from JEDEC Spec Value
		4	5 Cycles Added from JEDEC Spec Value
		5	6 Cycles Added from JEDEC Spec Value
		6	7 Cycles Added from JEDEC Spec Value
		7	8 Cycles Added from JEDEC Spec Value

Table 10-13: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	ADDRMODE	Addressing (Page/Bank) Mode. The `DMC_CTL.ADDRMODE` bit selects whether the DMC uses page or bank interleaving for addressing. When using page interleaving, the bank address bits follow the most significant column address bits. When using bank interleaving, the bank address bits follow the most significant row address bits.	
		0	Bank Interleaving
		1	Page Interleaving
7 (R/W)	RESET	Reset SDRAM. The `DMC_CTL.RESET` bit starts the reset sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Starts reset sequence
6 (R/W)	PREC	Precharge. The `DMC_CTL.PREC` bit enables precharge, which closes DRAM rows immediately after access. When disabled, all accesses result in the respective DRAM rows remaining open, until the DMC needs to close them.	
		0	No Effect
		1	Enable Precharge
5 (R/W)	DPDREQ	Deep Power-Down Request. The `DMC_CTL.DPDREQ` bit enables deep power-down mode if low power DMC operation is enabled (`DMC_CTL.LPDDR` =1). When the processor does not require the data stored in SDRAM (assume reset state of SDRAM), the DMC may put the SDRAM in deep power-down mode. When the DMC is in deep power-down mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in deep power-down mode as along as this bit is 1.	
		0	Disable Deep Power-Down
		1	Enable Deep Power-Down
4 (R/W)	PDREQ	Power Down Request. The `DMC_CTL.PDREQ` bit enables power-down mode. When the DMC is in power-down mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in power-down mode as along as this bit is 1.	
		0	Disable Power-Down
		1	Enable Power-Down

Table 10-13: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	SRREQ	Self-Refresh Request. The `DMC_CTL.SRREQ` bit enables self-refresh mode. When the DMC is in self-refresh mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in self-refresh mode as along as this bit is 1.	
		0	Disable Self-Refresh
		1	Enable Self-Refresh
2 (R0/W)	INIT	Initialize DRAM Start. The `DMC_CTL.INIT` bit starts the power up DRAM initialization sequence and DLL calibration sequence. Note that this bit always reads as 0.	
		0	No Effect
		1	Start DRAM Initialization
1 (R/W)	LPDDR	Low Power DDR Mode. The `DMC_CTL.LPDDR` bit selects whether the DMC operates in low power DDR mode or DDR2 mode.	
		0	DDR2 mode
		1	LPDDR mode
0 (R/W)	DDR3EN	DDR3 Mode. The `DMC_CTL.DDR3EN` bit selects whether the DMC operates in DDR3 mode or DDR2 mode.	
		0	Enable DDR2 mode
		1	Enable DDR3 mode

DLL Control Register

The `DMC_DLLCTL` register holds the programmable parameters associated with the DLLs within the DMC PHY.

Figure 10-5: DMC_DLLCTL Register Diagram

Table 10-14: DMC_DLLCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:8 (R/W)	DATACYC	Data Cycles. The `DMC_DLLCTL.DATACYC` bits select the latency after which the DMC reads data from the PHY. This field must be written with the value (9). All other values are reserved. Taking round trip delay into account, the DLL indicates whether a latency of 2 cycles is supported by means of status bits.
7:0 (R/W)	DLLCALRDCNT	DLL Calibration RD Count. The `DMC_DLLCTL.DLLCALRDCNT` field selects the number of read operations that the PHY uses for DLL calibration.

Data Calibration Address Register

The DMC_DT_CALIB_ADDR register provides the address used for the data calibration for read and write. During the DMC PHY DLL calibration, a particular set of locations in the DRAM is written and a series of reads are performed back to back to calibrate the PHY. The DMC PHY needs prior information about the data that would be read during the PHY DLL calibration. The controller performs one burst write operation to the address programmed in DMC_DT_CALIB_ADDR (0x0090).

Note: While the exact address chosen does not matter much during memory initialization, if calibration of the PHY is performed when the DRAM contains valid data, care needs to be taken to ensure that this address points to an unused address. Else, this operation will modify application data stored at the address selected.

Figure 10-9: DMC_EFFCTL Register Diagram

Table 10-18: DMC_EFFCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:20 (R/W)	IDLECYC	Idle Cycle. The `DMC_EFFCTL.IDLECYC` bits select the number of cycles after which the DMC issues any accumulated auto-refresh commands if postpone refresh is enabled (`DMC_CTL.PPREF` =1). When `DMC_EFFCTL.IDLECYC` is set to 0, the DMC ignores the `DMC_CTL.PPREF` selection and does not accumulate/postpone periodic auto-refresh commands. Note 1: By default, accumulated auto-refresh commands are issued after counting four idle cycles. Note 2: This value is ignored if `DMC_CTL.PPREF` is not set. Note 3: Setting this value to 0000 overrides the "postpone refresh" feature and does not accumulate/postpone periodic auto refreshes.	
		0-15	0 to 15 Idle Cycles to Postpone Refresh Commands

Table 10-18: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	NUMREF	Number of Refresh Commands. The `DMC_EFFCTL.NUMREF` bits select the number of auto-refresh commands that the DMC can accumulate if postpone refresh is enabled (`DMC_CTL.PPREF` =1). The number of auto-refresh commands that can accumulate depends on whether the DMC is in DDR2 or LPDDR mode as selected by the `DMC_CTL.LPDDR` bit. In LPDDR mode, the DMC can accumulate up to four auto-refresh commands. In DDR2 mode, the DMC may accumulate up to eight auto-refresh commands. Note 1: By default, accumulated auto-refresh commands are issued after counting four idle cycles. Note 2: This value is ignored if `DMC_CTL.PPREF` is not set.	
		0	No Refresh Commands Accumulate
		1	1 Refresh Command May Accumulate
		2	2 Refresh Commands May Accumulate
		3	3 Refresh Commands May Accumulate
		4	4 Refresh Commands May Accumulate
		5	5 Refresh Commands May Accumulate
		6	6 Refresh Commands May Accumulate
		7	7 Refresh Commands May Accumulate
		8	8 Refresh Commands May Accumulate
15 (R/W)	PRECBANK7	Precharge Bank 7. The `DMC_EFFCTL.PRECBANK7` bit enables precharge (closes the page) of bank 7 after each transfer if the DMC precharge feature is enabled (`DMC_CTL.PREC` =1). Note: The (`DMC_CTL.PREC`) takes precedence over value in this register. If (`DMC_CTL.PREC` =1) then all banks are precharged.	
		0	Disable Precharge Bank 7
		1	Enable Precharge Bank 7
14 (R/W)	PRECBANK6	Precharge Bank 6. The `DMC_EFFCTL.PRECBANK6` bit enables precharge (closes the page) of bank 6 after each transfer if the DMC precharge feature is enabled (`DMC_CTL.PREC` =1). Note: The (`DMC_CTL.PREC`) takes precedence over value in this register. If (`DMC_CTL.PREC` =1) then all banks are precharged.	
		0	Disable Precharge Bank 6
		1	Enable Precharge Bank 6

Table 10-18: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	PRECBANK5	Precharge Bank 5. The `DMC_EFFCTL.PRECBANK5` bit enables precharge (closes the page) of bank 5 after each transfer if the DMC precharge feature is enabled (`DMC_CTL.PREC` =1). Note: The (`DMC_CTL.PREC`) takes precedence over value in this register. If (`DMC_CTL.PREC` =1) then all banks are precharged.	
		0	Disable Precharge Bank 5
		1	Enable Precharge Bank 5
12 (R/W)	PRECBANK4	Precharge Bank 4. The `DMC_EFFCTL.PRECBANK4` bit enables precharge (closes the page) of bank 4 after each transfer if the DMC precharge feature is enabled (`DMC_CTL.PREC` =1). Note: The (`DMC_CTL.PREC`) takes precedence over value in this register. If (`DMC_CTL.PREC` =1) then all banks are precharged.	
		0	Disable Precharge Bank 4
		1	Enable Precharge Bank 4
11 (R/W)	PRECBANK3	Precharge Bank 3. The `DMC_EFFCTL.PRECBANK3` bit enables precharge (closes the page) of bank 3 after each transfer if the DMC precharge feature is enabled (`DMC_CTL.PREC` =1). Note: The (`DMC_CTL.PREC`) takes precedence over value in this register. If (`DMC_CTL.PREC` =1) then all banks are precharged.	
		0	Disable Precharge Bank 3
		1	Enable Precharge Bank 3
10 (R/W)	PRECBANK2	Precharge Bank 2. The `DMC_EFFCTL.PRECBANK2` bit enables precharge (closes the page) of bank 2 after each transfer if the DMC precharge feature is enabled (`DMC_CTL.PREC` =1). Note: The (`DMC_CTL.PREC`) takes precedence over value in this register. If (`DMC_CTL.PREC` =1) then all banks are precharged.	
		0	Disable Precharge Bank 2
		1	Enable Precharge Bank 2
9 (R/W)	PRECBANK1	Precharge Bank 1. The `DMC_EFFCTL.PRECBANK1` bit enables precharge (closes the page) of bank 1 after each transfer if the DMC precharge feature is enabled (`DMC_CTL.PREC` =1). Note: The (`DMC_CTL.PREC`) takes precedence over value in this register. If (`DMC_CTL.PREC` =1) then all banks are precharged.	
		0	Disable Precharge Bank 1
		1	Enable Precharge Bank 1

Table 10-18: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PRECBANK0	Precharge Bank 0. The `DMC_EFFCTL.PRECBANK0` bit enables precharge (closes the page) of bank 0 after each transfer if the DMC precharge feature is enabled (`DMC_CTL.PREC` =1). Note: The (`DMC_CTL.PREC`) takes precedence over value in this register. If (`DMC_CTL.PREC` =1) then all banks are precharged.	
		0	Disable Precharge Bank 0
		1	Enable Precharge Bank 0

Shadow EMR1 DDR2 Register

The `DMC_EMR1` register in the DMC shadows the EMR1 register in the SDRAM when the DMC is in DDR2 mode (`DMC_CTL.LPDDR` =0). This register is used only when the DMC is operating in DDR2 mode.

If unmasked by the corresponding bit in the shadow mask register (`DMC_MSK.EMR1` =1), a write to `DMC_EMR1` triggers an extended "mode register set" command on the memory interface. If masked, a write to `DMC_EMR1` only updates the register in the DMC, not the register in the SDRAM.

Figure 10-10: DMC_EMR1 Register Diagram

Table 10-19: DMC_EMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	QOFF	Output Buffer Enable. The `DMC_EMR1.QOFF` bit enables the SDRAM output pins. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Enable
		1	Disable
10 (R/W)	DQS	LDQS/UDQS Enable. The `DMC_EMR1.DQS` bit enables the single ended operation of the `DMC_LDQS`/`DMC_LDQS` or `DMC_UDQS`/`DMC_UDQS` pin. For more information about this operation, see the data sheet for the SDRAM being used in your system. The DDR Controller enables differential signaling mode (EMR1) by default. Because the controller supports differential signaling mode only, setting this bit is not allowed.	
6 (R/W)	RTT1	RTT Termination Resistance 1. The `DMC_EMR1.RTT1` bit combines with the `DMC_EMR1.RTT0` bit to set the termination resistance. See the `DMC_EMR1.RTT0` bit description for more information.	

Table 10-19: DMC_EMR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:3 (R/W)	AL	Additive Latency. The `DMC_EMR1.AL` bits select a number of added latency time for CAS operations in terms of clock cycles (t_{CK}). For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	0 Clock Cycles Added
		1	1 Clock Cycle Added
		2	2 Clock Cycles Added
		3	3 Clock Cycles Added
		4	4 Clock Cycles Added
		5	5 Clock Cycles Added
2 (R/W)	RTT0	Termination Resistance 0. The `DMC_EMR1.RTT0` bit and the `DMC_EMR1.RTT1` bits select the SDRAM termination resistance. RTT1=0, RTT0=0: No ODT at memory device RTT1=0, RTT0=1: 75 Ohm ODT at memory device RTT1=1, RTT0=0: 150 Ohm ODT at memory device RTT1=1, RTT0=1: 50 Ohm ODT at memory device For more information about this operation, see the data sheet for the SDRAM being used in your system.	
1 (R/W)	DIC	Output Driver Impedance Control. The `DMC_EMR1.DIC` bit selects the drive strength mode for the SDRAM. For more information about this operation, see the data sheet for the SDRAM being used in your system. It must be kept at 0 if the SDRAM does not support this bit.	
		0	Full Strength
		1	Reduced Strength
0 (R/W)	DLLEN	DLL Enable. The `DMC_EMR1.DLLEN` bit enables the DLL in the SDRAM. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Enable DLL (Normal Operation)
		1	Disable DLL (Test/Debug Operation)

Shadow EMR2 Register (DDR2)/Shadow EMR Register (LPDDR)

The `DMC_EMR2` register in the DMC shadows the EMR2 register in the SDRAM when the DMC is in DDR2 mode (`DMC_CTL.LPDDR` =0) and shadows the EMR register in the SDRAM when the DMC is in LPDDR mode (`DMC_CTL.LPDDR` =1). If unmasked by the corresponding bit in the shadow mask register (`DMC_MSK.EMR2` =1), a write to `DMC_EMR2` triggers an extended "mode register set" command on the memory interface. If masked, a write to `DMC_EMR2` only updates the register in the DMC, not the register in the SDRAM.

Table 10-20: DMC_EMR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SRF	High Temperature Self-Refresh. The `DMC_EMR2.SRF` bit enables the SDRAM's high temperature self-refresh rate feature when the DMC is in DDR2 mode. (This bit is reserved in LPDDR mode.) For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Disable
		1	Enable
6:5 (R/W)	DS	Drive Strength. The `DMC_EMR2.DS` bits select the drive strength value when the DMC is in LPDDR mode. (These bits are reserved when the DMC is in DDR2 mode.) Note that all values other than those shown are reserved. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		4	Octant Drive strength
		0	Full Drive Strength
		1	1/2 Drive Strength
		2	3/4 Drive Strength
		3	1/4 Drive Strength

Table 10-20: DMC_EMR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/W)	TCSR	Temperature Compensated Self-Refresh. The `DMC_EMR2.TCSR` bits select the temperature for applying temperature compensated self-refresh when the DMC is in LPDDR mode. (These bits are reserved when the DMC is in DDR2 mode.) For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	70 degree C (in LPDDR Mode)
		1	45 degree C
		2	15 degree C
		3	85 degree C
2:0 (R/W)	PASR	Partial Array Self-Refresh. The `DMC_EMR2.PASR` bits select the amount of memory to be refreshed during self-refresh. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Full Array for DDR2 , DDR3, and LPDDR Modes. Applies to both 4 and 8 bank devices.
		1	1/2 Array for DDR2 , DDR3, and LPDDR Modes. For 4 bank devices, BA[1:0] =00 and 01. For 8 bank devices, BA[2:0] = 000, 001, 010, 011
		2	1/4 Array for DDR2 , DDR3, and LPDDR Modes. For 4 bank devices, BA[1:0] = 00. For 8 bank devices, BA[2:0] = 000 and 001.
		3	1/8 Array for 8 DDR2 or DDR3 Banks Only. Reserved for LPDDR. For 4 bank devices, not defined. For 8 bank devices, BA[2:0] = 000.
		4	3/4 Array for DDR2 or DDR3. Reserved for LPDDR. For 4 bank devices, BA[1:0]=01, 10 and 11. For 8 bank devices, BA[2:0] = 010, 011, 100, 101, 110, and 111.
		5	1/2 Array for DDR2 or DDR3. 1/8 Array for LPDDR. For 4 bank devices, BA[1:0]=10 and 11. For 8 bank devices, BA[2:0] = 100, 101, 110, and 111.
		6	1/4 Array for DDR2 or DDR3. 1/16 Array for LPDDR. For 4 bank devices, BA[1:0]=11. For 8 bank devices, BA[2:0] =110 and 111.
		7	1/8 array (for DDR2 or DDR3 Banks only); Reserved (LPDDR)

Shadow MR Register (DDR2/LPDDR), Shadow MR0 Register (DDR3)

The `DMC_MR` register in the DMC shadows the MR register in the SDRAM when the DMC is in DDR2 mode or LPDDR mode (`DMC_CTL.LPDDR` =0 or =1 and `DMC_CTL.DDR3EN` =0) or DDR3 mode (`DMC_CTL.DDR3EN` =0 or =1 and `DMC_CTL.LPDDR` =0). If unmasked by the corresponding bit in the shadow mask register (`DMC_MSK.MR` =1), a write to `DMC_MR` triggers a "mode register set" command on the memory interface. If masked, a write to `DMC_MR` only updates the register in the DMC, not the register in the SDRAM.

Figure 10-12: DMC_MR Register Diagram

Table 10-21: DMC_MR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	PD	Active Power Down Mode. The `DMC_MR.PD` bit selects the active power-down mode. Note that this parameter applies only for DDR2/DDR3 mode and is reserved for LPDDR mode. For more information about this mode, see the data sheet for the SDRAM being used in your system.	
		0	Fast Exit (normal)
		1	Slow Exit (low power)
11:9 (R/W)	WRRECOV	Write Recovery. The `DMC_MR.WRRECOV` bit selects the write recovery time in terms of clock cycles (t_{CK}). Note that this parameter applies only for DDR2/DDR3 mode and is reserved for LPDDR mode. For more information about this mode, see the data sheet for the SDRAM being used in your system.	
		0	16 clock cycles for DDR3 only
		1	2 Clock Cycles for DDR2 and 5 clock cycles for DDR3
		2	3 Clock Cycles for DDR2 and 6 clock cycles for DDR3
		3	4 Clock Cycles for DDR2 and 7 clock cycles for DDR3
		4	5 Clock Cycles for DDR2 and 8 clock cycles for DDR3

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	6 Clock Cycles for DDR2 and 10 clock cycles for DDR3
		6	7 Clock Cycles for DDR2 and 12 clock cycles for DDR3
		7	8 Clock Cycles for DDR2 and 14 clock cycles for DDR3
8 (R/W)	DLLRST	DLL Reset. The `DMC_MR.DLLRST` bit initiates a DLL reset on the SDRAM. Note that this parameter applies only for DDR2/DDR3 mode and is reserved for LPDDR mode. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Normal Operation
		1	Reset DLL

Table 10-21: DMC_MR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:4 (R/W)	CL	CAS Latency. The `DMC_MR.CL` bit field selects latency from the assertion of a read/write signal to the SDRAM until the first valid data on the output from the SDRAM in terms of clock cycles. For more information about this operation, see the data sheet for the SDRAM being used in your system. The valid numbers for DDR2 and LPDDR are: 010 = Reserved 011 = 3 100 = 4 (DDR2 only) 101 = 5 (DDR2 only) 110 = 6 (DDR2 only) For DDR3 only bit [2] `DMC_MR.CL0` should be used along with bits [6:4]: 0010 = 5 0100 = 6 0110 = 7 1000 = 8 1010 = 9 1100 = 10 1110 = 11 0001 = 12 0011 = 13 0101 = 14 All other combinations are reserved.
2 (R/W)	CL0	CAS Latency 0. The `DMC_MR.CL0` bit is applicable for DDR3 only and is used in conjunction with the `DMC_MR.CL` bits.
1:0 (R/W)	BLEN	Burst Length. The `DMC_MR.BLEN` bits select burst length for transfers. For more information about this operation, see the data sheet for the SDRAM being used in your system. Note that values other than those shown are not supported. 0 | 8-Bit Burst Length - DDR3 only 2 | 4-Bit Burst Length -LPDDR/DDR2 only 3 | 8-Bit Burst Length - LPDDR/DDR2 only

Shadow MR1 Register (DDR3)

The DMC_MR1 register is a mirror of the DDR3 SDRAM Mode register 1. This register is used only when the DMC is operating in DDR3 mode. A write to this register triggers an extended "mode register 1 set" command on the memory interface provided the corresponding mask bit is set in the mask register. Else, only the mirror register is updated.

		7	4 banks: not defined, 8 banks: 1/8th array (BA[2:0] = 111)

Mask (Mode Register Shadow) Register

The `DMC_MSK` register permits masking (disabling) writes to the MR and EMRn registers in the SDRAM. When masked, writes to these registers go instead to shadow copies of these registers (`DMC_MR`, `DMC_EMR1`, `DMC_EMR2`), which are maintained within the DMC. When a shadow register's corresponding bit is unmasked (enabled), the DMC generates the MRS or EMRS command to transfer the contents of the shadow register (in the DMC) to the actual register (in the SDRAM).

Figure 10-15: DMC_MSK Register Diagram

Table 10-24: DMC_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	EMR3	Shadow EMR3 Unmask. The `DMC_MSK.EMR3` bit masks or unmasks writes to the EMR3 register (in DDR2) in the SDRAM. When masked, writes to this register instead go to the EMR3 register. When unmasked, the DMC writes the EMR3 value to the EMR3 register (in DDR2) in the SDRAM. After completing the write, the DMC clears this bit. Note that this bit must not be enabled when in LPDDR mode (`DMC_CTL.LPDDR` =1).	
		0	Mask (Disable) Write to EMR3
		1	Unmask (Enable) Write to EMR3
10 (R/W)	EMR2	Shadow EMR2 Unmask. The `DMC_MSK.EMR2` bit masks or unmasks writes to the EMR2 register (in DDR2) or the EMR register (in LPDDR) in the SDRAM. When masked, writes to this register instead go to the `DMC_EMR2` register. When unmasked, the DMC writes the `DMC_EMR2` value to the EMR2 register (in DDR2) or the EMR register (in LPDDR) in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to EMR2
		1	Unmask (Enable) Write to EMR2

Table 10-24: DMC_MSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	EMR1	Shadow EMR1 Unmask. The `DMC_MSK.EMR1` bit masks or unmasks writes to the EMR1 register in the SDRAM. When masked, writes to this register instead go to the `DMC_EMR1` register. When unmasked, the DMC writes the `DMC_EMR1` value to the EMR1 register in the SDRAM. After completing the write, the DMC clears this bit. Note that this bit must not be enabled when in LPDDR mode (`DMC_CTL.LPDDR` =1).
		0 Mask (Disable) Write to EMR1
		1 Unmask (Enable) Write to EMR1
8 (R/W)	MR	Shadow MR Unmask. The `DMC_MSK.MR` bit masks or unmasks writes to the MR register in the SDRAM. When masked, writes to this register instead go to the `DMC_MR` register. When unmasked, the DMC writes the `DMC_MR` value to the MR register in the SDRAM. After completing the write, the DMC clears this bit.
		0 Mask (Disable) Write to MR
		1 Unmask (Enable) Write to MR

Priority ID Register 1

The `DMC_PRIO` register allows transactions from selected masters that generate specific SCB IDs to obtain higher priority than the transactions proceeding in the usual fashion. The contents of the register are masked with the contents of the `DMC_PRIOMSK` register to obtain a single SCB ID or a range of IDs that get elevated priority.

Table 10-33: DMC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/NW)	ZQCLDONE	ZQ Calibration Long Done. The DMC_STAT.ZQCLDONE bit checks if the ZQ calibration long sub routine is done.	
		0	ZQ Calibration long is ongoing
		1	ZQ Calibration long is done
24 (R/NW)	ZQCSDONE	ZQ Calibration Short Done. The DMC_STAT.ZQCSDONE bit checks if the ZQ calibration short sub routine is done.	
		0	ZQ Calibration short is ongoing
		1	ZQ Calibration Short is done
23:20 (R/NW)	PHYRDPHASE	PHY Read Phase. The DMC_STAT.PHYRDPHASE bits indicate the latency after which the DMC may read from the PHY. Taking round trip delay into account, the DLL indicates the exact number of clock cycles after which the controller needs to read data. Values other than those shown are reserved.	

Table 10-33: DMC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	2 Clock Cycles Latency
		3	3 Clock Cycles Latency
		4	4 Clock Cycles Latency
		5	5 Clock Cycles Latency
		6	6 Clock Cycles Latency
		7	7Clock Cycles Latency
19:16 (R/NW)	PENDREF	Pending Refresh. The `DMC_STAT.PENDREF` bits indicate the number of pending auto-refresh commands whose value can be from "0000" to "0111". When the DMC is in low power DDR mode (`DMC_CTL.LPDDR` =1), the maximum value for `DMC_STAT.PENDREF` is 3.	
13 (R/NW)	DLLCALDONE	DLL Calibration Done. The `DMC_STAT.DLLCALDONE` indicates that the PHY DLL calibration sequence is complete.	
		0	No Status
		1	Completed PHY DLL Calibration
7 (R/NW)	RESETDONE	Reset Done. The `DMC_STAT.RESETDONE` bit indicates that the reset sequence is complete.	
		0	SDRAM Reset is ongoing
		1	SDRAM Reset is done
5 (R/NW)	DPDACK	Deep Power-Down Acknowledge. The `DMC_STAT.DPDACK` bit indicates that deep power-down mode is active. Note that this status is available in low power DDR mode (`DMC_CTL.LPDDR` =1) only.	
		0	Not in Deep Power-Down Mode
		1	Deep Power-Down Mode Active
4 (R/NW)	PDACK	Power-Down Acknowledge. The `DMC_STAT.PDACK` bit indicates that power-down mode is active.	
		0	Not in Power-Down Mode
		1	Power-Down Mode Active
3 (R/NW)	SRACK	Self-Refresh Acknowledge. The `DMC_STAT.SRACK` bit indicates that self-refresh mode is active.	
		0	Not in Self-Refresh Mode
		1	Self-Refresh Mode Active

Table 10-33: DMC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	INITDONE	Initialization Done. The `DMC_STAT.INITDONE` bit indicates that the initialization sequence is complete.	
		0	No Status
		1	Initialize Done
0 (R/NW)	IDLE	Idle State. The `DMC_STAT.IDLE` bit indicates whether the DMC is idle or busy.	
		0	Busy
		1	Idle

Timing 0 Register

The `DMC_TR0` register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in `DMC_TR0` are in increments of clock cycle time (t_{CK}).

Table 10-34: DMC_TR0 Register Fields

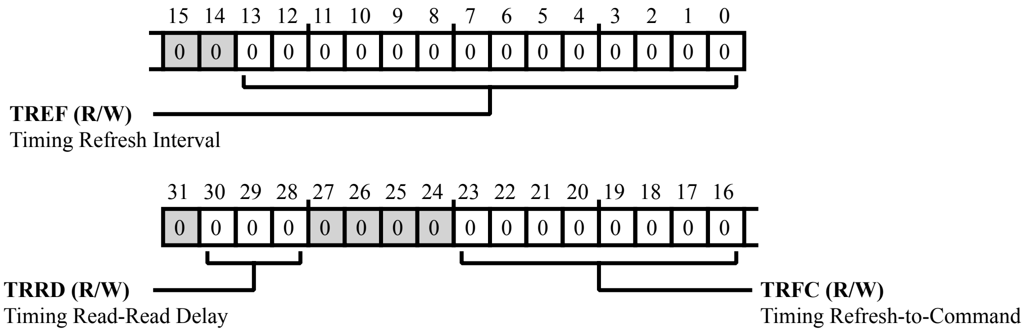
Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	TMRD	Timing Mode Register Delay. The `DMC_TR0.TMRD` field selects the set-to-active timing parameter (t_{MRD}), which is the number of clock cycles that occur after the mode registers in the SDRAM are set and before the next command is issued.
25:20 (R/W)	TRC	Timing Row Cycle. The `DMC_TR0.TRC` field selects the active-to-active time (t_{RC}), which is the minimum number of clock cycles that occur from an active command to the next active command in the same bank.
16:12 (R/W)	TRAS	Timing Row Active Time. The `DMC_TR0.TRAS` field selects the active-to-precharge time (t_{RAS}), which is the number of clock cycles that occur from an active command until a precharge command is allowed.
11:8 (R/W)	TRP	Timing RAS Precharge. The `DMC_TR0.TRP` field selects the precharge-to-active time (t_{RP}), which is the number of clock cycles that occur while the SDRAM recovers from a precharge command and becomes ready to accept the next active command.

Table 10-34: DMC_TR0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/W)	TWTR	Timing Write to Read. The `DMC_TR0.TWTR` field selects the write-to-read delay time (t_{WTR}), which is the number of clock cycles that occur from the last write data to the next read command.
3:0 (R/W)	TRCD	Timing RAS to CAS Delay. The `DMC_TR0.TRCD` field selects the RAS to CAS delay time (t_{RCD}), which is the number of clock cycles that occur from an active command to a read/write assertion.

Timing 1 Register

The DMC_TR1 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC_TR1 are in increments of clock cycle time (t_{CK}).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TREF (R/W)
Timing Refresh Interval
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TRRD (R/W)
Timing Read-Read Delay
TRFC (R/W)
Timing Refresh-to-Command

Table 10-35: DMC_TR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:28 (R/W)	TRRD	Timing Read-Read Delay. The `DMC_TR1.TRRD` field selects the active-to-active time (t_{RRD}), which is the minimum number of clock cycles occurring from a bank x active command to a bank y active command.
23:16 (R/W)	TRFC	Timing Refresh-to-Command. The `DMC_TR1.TRFC` field selects the refresh-to-active command delay (t_{RFC}), which is the number of clock cycles required for the SDRAM to recover from a refresh signal to be ready to take the next command. It is also the number of clock cycles needed for the SDRAM to recover from executing one active command and ready to accept the next active command.
13:0 (R/W)	TREF	Timing Refresh Interval. The `DMC_TR1.TREF` field selects the refresh interval time (t_{REF}), which is the number of clock cycles occurring from one refresh command to the next refresh command. The actual timing of issuing a precharge command may be delayed by if the SDRAM is processing a normal access. However, the delay is not accumulative so there is no need to shorten the refresh interval to account for the memory access time. The non-accumulative refresh delay typically increases memory bandwidth by a few percentage points.

Timing 2 Register

The `DMC_TR2` register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and before initializing the SDRAM.

Note that all values for bit fields in `DMC_TR2` are in increments of clock cycle time (t_{CK}).

Table 10-36: DMC_TR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:20 (R/W)	TCKE	Timing Clock Enable. The `DMC_TR2.TCKE` field selects the CKE minimum pulsewidth (t_{CKE}).
19:16 (R/W)	TXP	Timing Exit Power Down. The `DMC_TR2.TXP` field selects the exit power down to next valid command time (t_{XP}).
15:12 (R/W)	TWR	Timing Write Recovery. The `DMC_TR2.TWR` field selects the write recovery time (t_{WR}). Note that this parameter applies to LPDDR only.
11:8 (R/W)	TRTP	Timing Read-to-Precharge. The `DMC_TR2.TRTP` bit field selects the internal read to precharge time (t_{RTP}) for DDR2/DDR3 modes. If the resulting value in DDR2/DDR3 mode is less than 2, program the bit field to 2. This value (2) is the minimum t_{RTP} time for DDR2/DDR3 mode. For LPDDR mode program this bit field to zero.
4:0 (R/W)	TFAW	Timing Four-Activated-Window. The `DMC_TR2.TFAW` field selects the four-banks-activated window time (t_{FAW}). No more than four SDRAM banks should be activated within this window.

ADSP-SC58x DMC Register Descriptions

DMCPHY (DMC) contains the following registers.

Table 10-37: ADSP-SC58x DMC Register List

Name	Description
`DMC_CAL_PADCTL0`	Calibration PAD Control 0 Register
`DMC_CAL_PADCTL2`	Calibration PAD Control 2 Register
`DMC_PHY_CTL0`	PHY Control 0 Register
`DMC_PHY_CTL1`	PHY Control 1 Register
`DMC_PHY_CTL2`	PHY Control 2 Register

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	RTTCALEN	RTT Calibration Enable. The `DMC_CAL_PADCTL0.RTTCALEN` bit is set to 1 at reset. Programming this bit to 0 is not allowed.
30 (R/W)	PDCALEN	PULLDOWN Calibration Enable. The `DMC_CAL_PADCTL0.PDCALEN` bit is set to 1 at reset. Programming this bit to 0 is not allowed.
29 (R/W)	PUCALEN	PULLUP Calibration Enable. The `DMC_CAL_PADCTL0.PUCALEN` bit is set to 1 at reset. Programming this bit to 0 is not allowed.
28 (R/W)	CALSTRT	Start New Calibration (Hardware Cleared).

Calibration PAD Control 2 Register

The `DMC_CAL_PADCTL2` register sets the pad calibration controls. The DMC pads can be auto-calibrated to the required driver impedance and the On Die Termination (ODT) value using the corresponding bits in this register. These values are translated by the auto calibration logic into a corresponding drive strength control inside the PHY and then routed to the PADS. Auto-calibration starts as soon as the `DMC_CAL_PADCTL0.CALSTRT` bit is programmed. The DCLK needs to be set at the required frequency before setting the `DMC_CAL_PADCTL0.CALSTRT` bit.

11 Static Memory Controller (SMC)

The static memory controller is a protocol converter and data transfer interface between the internal processor bus and the external L3 memory. It provides a glueless interface to various external memories and peripheral devices, including:

- SRAM
- ROM
- EPROM
- NOR flash memory
- FPGA/ASIC devices

The SMC acts as an SCB slave. The processor SCB interconnect fabric arbitrates accesses to the SMC. On the chip boundary, the SMC connects to an address bus, a data bus, and signal pins for memory control (such as read, write, output enable, and memory select lines).

SMC Features

SMC features include:

- 16-bit I/O width
- Provides flexible timing control through extended timing parameters
- Supports asynchronous access extension (`SMC_ARDY` pin)
- Supports 8-bit data masking writes

SMC Definitions

The timing registers contain bits to program the setup time, hold time, and access time for read and write access to each bank separately. The SMC allows for different setup, hold, or access times for reads and writes. The `SMC_B0TIM` – `SMC_B3TIM` registers control the timing characteristics of the asynchronous memory interface using the following parameter definitions. Each of these parameters can be programmed in terms of SCLK0_0 clock cycles.

Read setup time

The time between the beginning of a memory cycle (`SMC_AMS0` signal low) and the read-enable assertion (`SMC_ARE` signal low).

Read hold time

The time between read-enable deassertion (`SMC_ARE` signal high) and the end of the memory cycle (`SMC_AMS0` signal high).

Read access

The time between read-enable assertion (`SMC_ARE` signal low) and deassertion (`SMC_ARE` signal high).

Write setup time

The time between the beginning of a memory cycle (`SMC_AMS0` signal low) and the write-enable assertion (`SMC_AWE` signal low).

Write hold time

The time between write-enable deassertion (`SMC_AWE` signal high) and the end of the memory cycle (`SMC_AMS0` signal high).

Write access

The time between write-enable assertion (`SMC_AWE` signal low) and deassertion (`SMC_AWE` signal high).

The SMC provides another register for defining more timing characteristics of control signals by programming the extended `SMC_B0TIM` – `SMC_B3TIM` timing registers. These registers contain bits to program following timing characteristics.

Pre-setup time

The number of cycles the `SMC_AMS0` signal is asserted before the `SMC_AOE` signal is asserted.

Pre-access time

The number of cycles inserted after the `SMC_AOE` signal is deasserted and before the `SMC_ARE` signal is asserted for the next access.

Memory idle time

The number of bus idle cycles between the `SMC_AMS0` deasserting edge and next asserting edge.

Memory transition time

The number of bus idle cycles extending the idle time cycles. These idle cycles occur in the case where a subsequent access has a different data direction or the access is to a different bank.

Bus contention

State of the bus in which more than one device on the bus attempts to place values on the bus at the same time. For more information, see Avoiding Bus Contention.

ARDY signal

The SMC uses the `SMC_ARDY` signal to insert wait states for slower asynchronous memories. There is no upper limit to how many wait states the `SMC_ARDY` signal can enter. As long as it is held, the processor waits for the access to the asynchronous memory. Once asserted, the processor accesses the memory according to the timing diagrams. For more information, see ARDY Input Control.

SMC Functional Description

The SMC contains memory-mapped registers that control the access characteristics for each asynchronous memory bank. Different banks can be programmed in various modes and independently-controlled using the functional and cycle time bit settings for each bank.

Independent bank control

The SMC provides separate sets of registers, `SMC_B0CTL` through `SMC_B3CTL` (control), `SMC_B0TIM` through `SMC_B3TIM` (timing) and `SMC_B0ETIM` through `SMC_B3ETIM` (extended timing) to control the mode and timing characteristic of each bank independently. The control registers contain bits for enabling the bank and bits for selecting mode of operation.

Bank select control signal control

The control registers also contain bits to control the type of bank select control signal. External FIFO devices often do not have a separate chip select pin. As a result, for a read, the FIFOs output enable (`SMC_AOE`) pin must be connected to the OR of the `SMC_AMS0` and the `SMC_ARE`. Similarly, the write case requires an OR between `SMC_AMS0` and `SMC_AWE`. The SMC provides this function so that an external OR gate is not required. The appropriate AMS function can be selected for each memory bank region using the `SMC_B0CTL.SELCTRL` bits.

ADSP-SC58x SMC Register List

The Static Memory Controller SMC is a protocol converter and data transfer interface between the internal processor bus and the external L3 memory. The SMC acts as a bus slave, and accesses to SMC are arbitrated by the module's system crossbar. On the chip boundary, the SMC is connected to an external memory address bus, a 16-bit data bus and memory control signal pins (read, write, select). This memory interface can support a sizable external memory connected to one or more banks, each bank being controlled by a chip select signal. A set of registers governs SMC operations. For more information on SMC functionality, see the SMC register descriptions. For the memory map, see the product data sheet.

Table 11-1: ADSP-SC58x SMC Register List

Name	Description
SMC_B0CTL	Bank 0 Control Register
SMC_B0ETIM	Bank 0 Extended Timing Register
SMC_B0TIM	Bank 0 Timing Register
SMC_B1CTL	Bank 1 Control Register
SMC_B1ETIM	Bank 1 Extended Timing Register
SMC_B1TIM	Bank 1 Timing Register
SMC_B2CTL	Bank 2 Control Register
SMC_B2ETIM	Bank 2 Extended Timing Register
SMC_B2TIM	Bank 2 Timing Register
SMC_B3CTL	Bank 3 Control Register
SMC_B3ETIM	Bank 3 Extended Timing Register
SMC_B3TIM	Bank 3 Timing Register

SMC Architectural Concepts

The SMC can support connection to multiple different external banks, with each bank controlled by the SMC_AMS[n] chip select signal. Check the processor data sheet for details on the bank address ranges and configurations.

NOTE: The processor data sheet shows the address range allocated to each bank. It is not necessary to populate all of an enabled memory bank.

The processor does not directly support 8-bit accesses to the external memories. So, the SMC address lines start from SMC_A01; there is no SMC_A0 pin.

The SMC does indirectly support 8-bit accesses through the additional byte enable signals SMC_ABE0 and SMC_ABE1. Some 16-bit memory systems allow the processor to perform 8-bit reads and writes, which are selected through the SMC_ABE0 and SMC_ABE1 signals.

The byte enable pins are both three-stated during all asynchronous reads and are driven low during 16-bit asynchronous writes. When an asynchronous write is made to the upper byte of a 16-bit memory, `SMC_ABE1` =0 and `SMC_ABE0` =1. When an asynchronous write is made to the lower byte of a 16-bit memory, `SMC_ABE1` =1 and `SMC_ABE0` =0.

NOTE: Some SRAM devices expect byte-enable signals to be driven low during read accesses rather than being three-stated, which can be achieved using external pull-down resistors. For applications requiring alternate functions on the byte-enable pins during run time where pull-down resistors are not an option, the same functionality can be achieved using the external logic shown as follows:

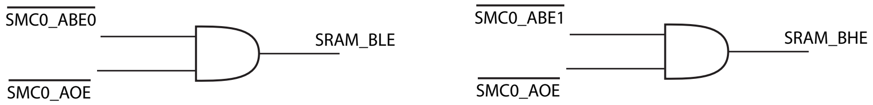

Figure 11-1: External Logic

Avoiding Bus Contention

Bus contention occurs when one device is getting off the bus and another is getting on. If the first device is slow to three-state and the second device is quick to drive, the devices contend. Bus contention causes excessive power dissipation and can lead to device failure.

There are two cases where contention can occur.

- When a read followed by a write to the same memory space occurs, there is a potential for bus contention. The data bus drivers used for the write can potentially contend with the drivers used by the memory device being read.
- When there are back-to-back reads from two different memory spaces, the two memory devices addressed by the two reads can contend at the transition between the two read operations.

To avoid contention, program the turnaround time appropriately in the extended time registers (`SMC_B0ETIM` – `SMC_B3ETIM`). The programming is done by setting the number of clock cycles between these types of accesses on a bank-by-bank basis.

The idle time bit (`SMC_B0ETIM.IT`) applies to similar back-to-back access types on the same bank. The transition time bit (`SMC_B0ETIM.TT`) applies to the `SMC_B0ETIM.IT` bit. For actual turnaround situations, idle time and transition time function in an accumulated fashion. The sequence of access types and times are:

- A write followed by write to same bank – `SMC_B0ETIM.IT`
- A read followed by read to same bank – `SMC_B0ETIM.IT`
- A write followed by read to same bank – `SMC_B0ETIM.IT` + `SMC_B0ETIM.TT`
- A read followed by write to same bank – `SMC_B0ETIM.IT` + `SMC_B0ETIM.TT`
- Any access to a given bank followed by any access to a different bank – `SMC_B0ETIM.IT` + `SMC_B0ETIM.TT`

The reset value of turnaround transition time is two cycles. Program the SMC_B0ETIM.TT bit to a value either greater than or equal to two cycles, depending on memory AC-timing specifications. It is important to be aware that the SMC_B0ETIM.TT bit is programmed to 0 *only* when:

- There are *either* only read accesses *or* only write accesses possible to external memory devices for the current device configuration or processor operation situation.

ARDY Input Control

Each bank can be programmed to sample the SMC_ARDY input after the read or write access timer has counted down. It can also be programmed to ignore this input signal. If enabled and disabled at the sample window, the SMC module uses SMC_ARDY to extend the access time, as required.

The processor treats SMC_ARDY as an asynchronous input. The input must reach the desired value (either asserted or deasserted) more than two SCLK0_0 cycles before the completion of access time (scheduled rising edge of SMC_AWE or SMC_ARE). This timing determines whether the SMC extends the access with the assertion of SMC_ARDY. After the processor samples SMC_ARDY high, the total delay between SMC_ARDY going high at the pads and SMC_ARE being deasserted at the pads is a maximum of five SCLK0_0 cycles. (The memory device asserts SMC_ARDY.)

Asynchronous SRAM writes are also possible with the SMC_ARDY signal enabled. In asynchronous SRAM writes, the write access is extended beyond the programmed write access cycles depending on the SMC_ARDY signal state. Once SMC_ARDY is sampled asserted, the SMC_AWE signal is deasserted after two *CLKOUT* cycles and the write access ends.

The polarity of SMC_ARDY is programmable on a per-bank basis. Since SMC_ARDY is not sampled until an access is in-progress to a bank in which the SMC_ARDY enable is asserted, it is not driven by default. When using flash memory, connect the WAIT input to SMC_ARDY.

To avoid stalls in the case of erroneous SMC_ARDY behavior, set the SMC_B0CTL.RDYABTEN bit to enable the SMC_ARDY abort counter. When the abort counter is enabled, it starts counting down as soon as the programmed read/write access cycles expire. If the SMC interface does not sample the SMC_ARDY signal as asserted within 64 cycles, a counter-timeout occurs. This timeout ensures that the processor does not hang if SMC_ARDY is not sampled correctly.

SMC Operating Modes

The SMC supports the following operating modes:

- Asynchronous Flash Mode
- Asynchronous Page Mode

Asynchronous Flash Mode

When the access selected mode is asynchronous flash (`SMC_B0CTL.MODE` =01), external bank accesses operate the same as in standard asynchronous mode, except for the pin configuration. Use this mode when accessing burst devices in non-read array modes.

Asynchronous Page Mode

When asynchronous page mode access is selected (`SMC_B0CTL.MODE` =10), asynchronous page reads are enabled. The SMC module supports page sizes of 4, 8 and 16 words. When performing a page mode read, the first access in the page proceeds according to the read access time configured in `SMC_B0TIM` register. This access opens the page and the subsequent reads in that page have a period equal to the page wait states programmed in the `SMC_B0ETIM` register. Besides the start of the setup phase, the read address is incremented at the start of every page cycle.

The SMC module supports page mode access only for back-to-back accesses, such as cache line fills (16 words), 64-bit instruction reads (4 words), and DMA reads. It treats write accesses in asynchronous page mode as simple asynchronous flash write accesses.

SMC Event Control

SMC event control consists of recording the status of SMC errors. Accesses to reserved locations and writes to read-only registers result in bus errors. The SMC translates bus errors into internal SCB crossbar errors which get translated into interrupts. To report errors occurring in the slave memory devices (for both this memory interface and the MMR interface), the core combines the SCB crossbar response signals. This combination generates a combined error signal indication which is routed to the fault management unit.

SMC Programmable Timing Characteristics

This section describes the programmable timing characteristics for the SMC. Timing relationships depend on the programming of the SMC bank registers, whether initiation is from the core or from DMA. The relationships also depend on the sequence of transactions (read followed by read, read followed by write, and others).

NOTE: All memory control, address, and data signals are driven out of the chip based on the falling edge of the *CLKOUT* signal. The *CLKOUT* signal is SCLK0_0 on the chip pins (pad delayed).

Asynchronous SRAM Reads and Writes

The ***Basic Asynchronous SRAM Write Followed by Read*** figure shows a basic single write and read operation to an external device with the SMC programmed in asynchronous SRAM mode.

Figure 11-2: Basic Asynchronous SRAM Write Followed by Read

For the current bank, the programmed time cycles are:

- Write setup time = 2 cycles
- Write access time = 4 cycles
- Write hold time is = 2 cycles
- Read setup time = 3 cycles
- Read access time = 5 cycles
- Read hold time = 1 cycle
- Turnaround transition time = 2 cycles
- Idle transition time = 0 cycles

The asynchronous SRAM bus cycles proceed as follows.

1. At the start of the write setup period, the chip select signal (`SMC_AMS[n]`) for the target bank is asserted. The write data (`WD0`), address (`AW0`), and byte enables become valid.
2. At the end of the setup phase and at the start of the write access period, the write enable (`SMC_AWE`) is asserted.
3. At the end of the programmed write access, the `SMC_AWE` signal is deasserted. The target device is assumed to have captured the write data before `SMC_AWE` is deasserted.
4. At the end of the write hold period, the `SMC_AWE` signal is deasserted because the pending access is a read access, and the turnaround transition time cycles start. The write data and byte enables become invalid within 1 cycle of the `SMC_AMS0` signal deasserting.
5. At the end of turnaround transition time, the read setup period starts with the assertion of the `SMC_AMS0` and `SMC_AOE` signals and a new read address (`AR0`) is presented on the address bus.

6. At the start of the read access period, the read enable signal, `SMC_ARE` is asserted.
7. At the end of the read access period, the `SMC_ARE` signal is deasserted and the read hold period starts. Read data is latched along with `SMC_ARE` deasserting.
8. At the end of the read hold period, the SMC pulls the `SMC_AMS[n]` signal high and appends turnaround transition cycles unless there is a pending read request to the same bank.

Asynchronous SRAM Reads with IDLE Transition Cycles Inserted

The *Asynchronous SRAM Read with IDLE Transition* figure shows two consecutive asynchronous SRAM modes reads to the same bank separated by programmed IDLE transition time cycles.

Figure 11-3: Asynchronous SRAM Read with IDLE Transition

Programmed cycle times are:

- `SMC_B0TIM.RST` = 2 cycles
- `SMC_B0TIM.RAT` = 4 cycles
- `SMC_B0TIM.RHT` = 1 cycle
- IDLE transition time = 2 cycles

At the start of the IDLE transition cycle, the SMC deasserts the `SMC_AMS[n]` and `SMC_AOE` signals. The setup period of the second read starts at the end of the IDLE transition cycle with the assertion of the `SMC_AMS[n]` and `SMC_AOE` signals and a new address on the address bus.

High-Speed Asynchronous SRAM Read Burst

The *Fast Asynchronous SRAM Reads, Burst of Four Word* figure shows a high-speed asynchronous SRAM read bus cycle. This read bus cycle is typical for SRAM devices with small access times connecting through SCB read bursts, especially for boot purposes.

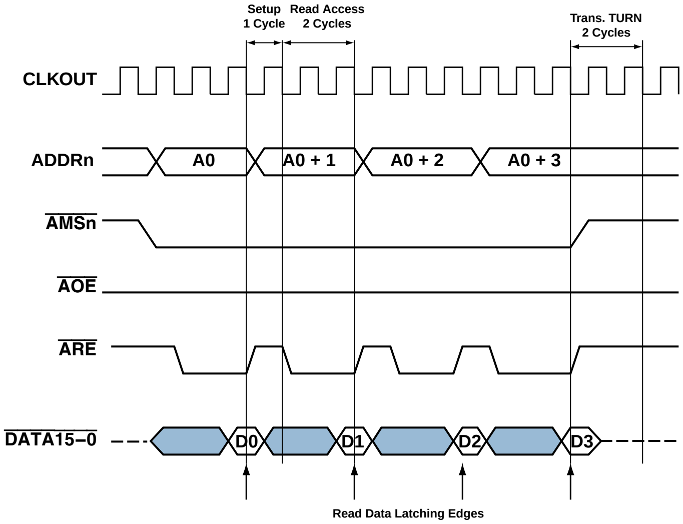

Figure 11-4: Fast Asynchronous SRAM Reads, Burst of Four Word

In this case, the target SMC bank has been programmed with:

- read setup time = 1 cycle
- read access time = 2 cycles
- read hold time = 0
- `SMC_B0ETIM.PREAT` = 0
- `SMC_B0ETIM.PREST` = 0
- IDLE transition time = 0

The `SMC_AMS[n]` signal is asserted at the start of the setup cycle of the first read out of the burst. Since the hold time and the idle transition time have been programmed to 0, the `SMC_AMS[n]` signal does not deassert until the entire set of reads concludes. Only the `SMC_ARE` signal deasserts periodically for 1 cycle for the setup period. The read address changes to the next address at the start of each individual setup cycle. Read data words are latched at the end of each individual read access period.

High-Speed Asynchronous SRAM Writes

High-speed asynchronous SRAM writes are similar to the high-speed read accesses. The ***Fast Asynchronous SRAM Writes*** figure shows the bus protocol for a write burst of 4 words. Here, the write setup time is 1 cycle and the write access time has been programmed to 2 cycles. Write hold time, pre-access time, pre-setup time, and idle transition time are programmed to 0.

The chip select signal `SMC_AMS[n]` asserts at the start of the entire write burst and deasserts only at the end of the last individual write access period. Write address, byte enables and write data for each individual write access are presented onto the bus at the start of each individual write setup cycle. The `SMC_AWE` signal asserts for the write access period and deasserts during the setup period for each individual data write.

Figure 11-6: Asynchronous SRAM Read with ARDY

NOTE: SCLK in the *Asynchronous SRAM Read with ARDY* figure is SCLK0_0.

The programmed SMC bank control parameters are:

- Pre-setup time = 1 cycle
- Read setup time = 3 cycles
- Read access time = 6 cycles
- Read hold time = 2 cycles
- `SMC_B0CTL.RDYPOL` =1 (memory is ready when `SMC_ARDY` =1)

The bus cycles proceed as follows:

- At the start of the pre-setup phase, `SMC_AMS[n]` asserts, and read address `SMC_A01` is presented on the address bus.
- At the start of the setup period, `SMC_AOE` is asserted.
- At the start of the read access, `SMC_ARE` is asserted.
- The CLKOUT signal is SCLK0_0 which is driven out of the pads. The CLKOUT signal falling edge can be delayed from the internal SCLK0_0 falling edge. See the data sheet for the specification related to this delay. All output signals out of the pads, for example `SMC_ARE` and `SMC_AOE`, are driven with regard to the falling edge of CLKOUT.
- The SMC starts sampling the `SMC_ARDY` signal on every rising edge of internal SCLK0_0 two cycles before the programmed number of read access cycles expires. The read access is extended (`SMC_ARE` is kept asserted) until the SMC samples `SMC_ARDY` high.
- Once the SMC samples the `SMC_ARDY` signal (asserted by memory device) high in SCLK0_0, the read signal is pulled off internally in the SCLK0_0 domain. The total delay between the `SMC_ARDY` signal going high at the pads and the deassertion of the `SMC_ARE` signal at the pads can be a maximum of five SCLK0_0 cycles.
- Read data is latched at the falling edge of CLKOUT on the same edge where the SMC deasserts `SMC_ARE`.
- Hold bus cycles start after the SMC deasserts the `SMC_ARE` signal.
- At the end of the hold period, the `SMC_AMS[n]` and `SMC_AOE` signals deassert and the SMC goes into the transition state.

Asynchronous Flash Reads

The ***Asynchronous Flash Read with Pre-Setup and Pre-Access Cycles*** figure illustrates a single asynchronous flash mode read bus cycle.

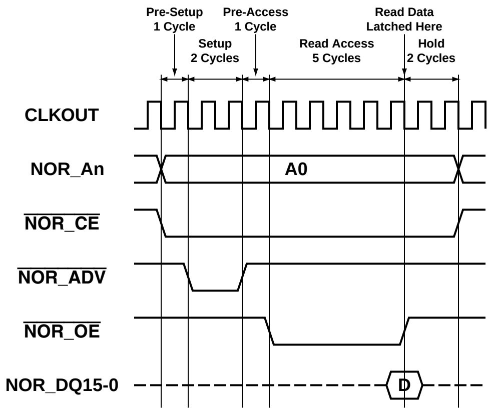

Figure 11-7: Asynchronous Flash Read with Pre-Setup and Pre-Access Cycles

In this case, the target SMC bank has been programmed with:

- Pre-setup time = 1 cycle
- Read setup time = 2 cycles
- Pre-access time = 1 cycle
- Read access time = 5 cycles
- Read hold time = 2 cycles

The read bus cycle is almost identical to the asynchronous SRAM read bus cycle. The only difference is the behavior of the `SMC_AOE` signal which the SMC uses as the flash address valid `SMC_NORDV` signal. The flash address valid `SMC_NORDV` signal asserts at the start of the setup cycle and deasserts at the end of the setup cycle.

The pre-access cycle inserts a one-cycle gap between the deassertion of the flash address valid `SMC_NORDV` signal and the assertion of the flash read strobe `NOR_OE` at the start of read access. The SMC also uses asynchronous flash reads with `SMC_ARDY` enabled for flash devices which use `SMC_NORWT` in asynchronous mode. In this case, the read bus cycle operation is identical to the asynchronous SRAM with `SMC_ARDY` enabled except for the `SMC_AOE`/`SMC_NORDV` signal behavior.

The ***32-bit Asynchronous Flash Read*** figure shows a 32-bit read access to a flash device in asynchronous mode which is split into two 16-bit external memory accesses. For this bank, read setup and read hold are programmed as two cycles whereas the read access time is five cycles. The flash device chip select signal (`NOR_CE`) remains asserted for the entire duration of both read accesses. `NOR_CE` is deasserted at the end of the hold period of the second read access. The SMC asserts the `SMC_NORDV` signal during the setup phase of both read accesses. Read data is latched at the end of the read access period.

Figure 11-9: Asynchronous Flash Write Operation

For this example, the SMC has been programmed with:

- Pre-setup time = 1 cycle
- Write setup time = 2 cycles
- Write access time = 6 cycles
- Write hold time = 2 cycles
- Pre-access time = 0

The asynchronous flash write bus cycle is again almost identical to the asynchronous SRAM write. The `SMC_AWE` pin is connected to flash write enable signal (NOR_WE). However, in asynchronous flash writes the SMC uses the

`SMC_AOE` signal as the address valid signal (`SMC_NORDV`). The `SMC_AOE` signal asserts during the setup period, unlike in asynchronous SRAM writes where the `SMC_AOE` signal never asserts.

Asynchronous Flash Page Mode Reads

The ***Asynchronous Page Mode Read Bus Cycle*** figure shows an asynchronous page mode bus read cycle for a burst of five reads. The reads are split into four reads followed by a single read.

Page Access 2 Cycles
Page Access 2 Cycles
Read Hold 2 Cycles
Read Setup 2 Cycles
Read Access 6 Cycles
Read Hold 2 Cycles

Figure 11-10: Asynchronous Page Mode Read Bus Cycle

The programmed bank parameters are:

- Read setup time = 2 cycles
- Read access time = 6 cycles
- Page wait = 2 cycles
- Hold time =2 cycles

The maximum number of read bursts in a total page access depends on the bank `SMC_B0CTL.PGSZ` bits (00 =4 words, 01 =8 words, 1x =16 words). The first read access is extended for three more page-read cycles whose period is equal to the page wait states. Besides the start of the setup phase, the read address is incremented at the start of every page cycle. Read data is latched with the falling edge of CLKOUT the end of the read access period, and also at the end of the page cycles.

Asynchronous FIFO Reads and Writes

The ***Asynchronous FIFO Read Bus Cycles*** figure shows the read bus cycles for an asynchronous FIFO device. The SMC bank is programmed in asynchronous SRAM mode, with `SMC_B0CTL.SELCTRL` =01 (`SMC_AMS[n]` is OR'ed with `SMC_ARE`).

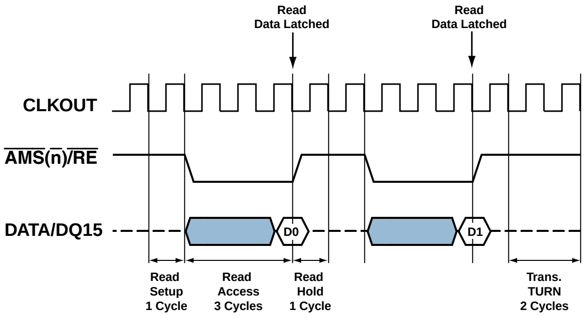

Figure 11-11: Asynchronous FIFO Read Bus Cycles

Other settings are:

- Read setup time = 1 cycle
- Read access time = 3 cycles
- Read hold time = 1 cycle
- Idle transition time = 0 cycles
- Turnaround transition time = 2 cycles

The `SMC_AMS[n]` signal connects to the read enable (`RE`) of the FIFO device, and the data bus connects to the output data bus (`DQ`) of the FIFO. The `SMC_AMS[n]` signal or the FIFO read strobe assert only during the read access. Read data is latched at the falling edge of CLKOUT at the end of the read access, when the SMC deasserts `SMC_AMS[n]`.

The ***Asynchronous FIFO Write Bus Cycles*** figure illustrates the write bus cycles for an asynchronous FIFO device. The SMC bank is programmed in asynchronous SRAM mode, with `SMC_B0CTL.SELCTRL` =10 (`SMC_AMS[n]` is OR'ed with `SMC_AWE`). Other settings are:

- Write setup time = 1 cycle
- Write access time = 3 cycles
- Write hold time = 1 cycle
- Idle transition time = 0
- Turnaround transition time = 2 cycles

The `SMC_AMS[n]` signal connects to the write enable (WE) of the FIFO device. The data bus connects to the input data bus (DIN) of the FIFO. The `SMC_AMS[n]` signal or the FIFO write strobe asserts only during the write access. However, the SMC asserts write data at the start of the setup cycle and removes it at the end of the hold period for each individual write access.

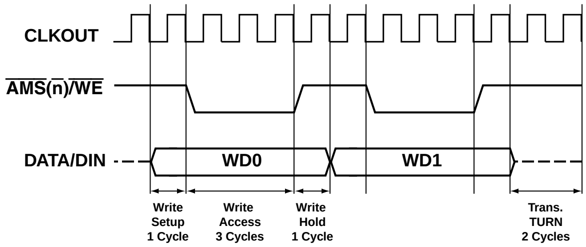

Figure 11-12: Asynchronous FIFO Write Bus Cycles

SMC Programming Model

The following general guidelines are used for configuring and enabling the SMC interface. Failure to follow these guidelines can lead to erroneous behavior.

- In asynchronous page mode, always program `SMC_B0CTL.RDYEN` to 0.
- Enable the ARDY abort counter (the `SMC_B0CTL.RDYABTEN` bit =1) whenever the `SMC_ARDY` signal is enabled (the `SMC_B0CTL.RDYEN` is set to 1). This step ensures that the interface does not hang due to erroneous `SMC_ARDY` signal behavior or erroneous sampling of the `SMC_ARDY` signal.
- Do not program read access time (`SMC_B0TIM.RAT`), write access time (`SMC_B0TIM.WAT`), read setup time (`SMC_B0TIM.RST`), and write setup time (`SMC_B0TIM.WST`) to 0.
- Never program page mode wait-states (`SMC_B0ETIM.PGWS`) to 0 or 1.
- Program the page size bits (`SMC_B0CTL.PGSZ`) to match the configurations of the flash device connected to the SMC interface.
- Select the `SMC_B0CTL.RDYPOL` bit to be the complement of the `WAIT` polarity that is configured in the flash device.
- In asynchronous SRAM and asynchronous flash modes with `SMC_ARDY` enabled, and where `SMC_B0TIM.RHT`, `SMC_B0TIM.WHT`, `SMC_B0TIM.RAT`, and `SMC_B0TIM.WAT` are the read and write hold and access times and `SMC_B0ETIM.IT` and `SMC_B0ETIM.TT` are the idle and transition times, ensure that the following conditions are true:
  - `SMC_B0TIM.RHT` + `SMC_B0ETIM.IT` + `SMC_B0ETIM.TT`≥ 2
  - `SMC_B0TIM.WHT` + `SMC_B0ETIM.IT` + `SMC_B0ETIM.TT`≥ 2
  - `SMC_B0TIM.RAT`≥ 5
  - `SMC_B0TIM.WAT`≥ 5

ADSP-SC58x SMC Register Descriptions

Static Memory Controller (SMC) contains the following registers.

Table 11-2: ADSP-SC58x SMC Register List

Figure 11-13: SMC_B0CTL Register Diagram

Table 11-3: SMC_B0CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	PGSZ	Flash Page Size. The `SMC_B0CTL.PGSZ` bits select the flash page size, if page flash or sync burst flash protocol has been enabled (`SMC_B0CTL.MODE` > 1). Note that the `SMC_B0CTL.PGSZ` bits must be set to match the flash protocol of the external flash memory device in the system. The typical `SMC_B0CTL.PGSZ` selection for external devices supporting async flash or async flash page protocols is 4 or 8 words. The typical `SMC_B0CTL.PGSZ` selection for external devices supporting sync burst flash protocol is 16 words.	
		0	4 words
		1	8 words
		2	16 words
		3	16 words

Table 11-3: SMC_B0CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	RDYABTEN	ARDY Abort Enable. The `SMC_B0CTL.RDYABTEN` bit enables the abort counter for the `SMC_ARDY` pin, if enabled (`SMC_B0CTL.RDYEN` =1). After `SMC_B0TIM.RAT` or `SMC_B0TIM.WAT` cycles, the SMC starts sampling the `SMC_ARDY` pin and starts the abort down counter (if enabled). The abort count is 64 cycles of SCLK0_0. If the SMC detects that `SMC_ARDY` remains de-asserted when the counter expires, the SMC aborts the access and returns an error response back on the system bus.	
		0	Disable abort counter
		1	Enable abort counter
13 (R/W)	RDYPOL	ARDY Polarity. The `SMC_B0CTL.RDYPOL` bit selects the polarity (active high or low) for the `SMC_ARDY` pin, if enabled (`SMC_B0CTL.RDYEN` =1). When the SMC samples the `SMC_ARDY` pin in the selective active state, the transaction completes.	
		0	Low active ARDY
		1	High active ARDY
12 (R/W)	RDYEN	ARDY Enable. The `SMC_B0CTL.RDYEN` bit enables `SMC_ARDY` pin operation for bank 0 accesses. When enabled, the SMC uses `SMC_ARDY` (after the access time countdown) to determine completion of access to this memory bank. When disabled, the SMC ignores `SMC_ARDY` for accesses to this memory bank.	
		0	Disable ARDY
		1	Enable ARDY
9:8 (R/W)	SELCTRL	Select Control. The `SMC_B0CTL.SELCTRL` bits select the handling of the `SMC_AMS[n]`, `SMC_ARE`, `SMC_AOE`, and `SMC_AWE` pins for memory access control.	
		0	AMS0 only
		1	AMS0 ORed with ARE
		2	AMS0 ORed with AOE
		3	AMS0 ORed with AWE

Table 11-4: SMC_B0ETIM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	PGWS	Page Wait States. The `SMC_B0ETIM.PGWS` bits select a page access extension time (in SCLK0_0 cycles) that the SMC waits during read accesses when configured for flash page protocol (`SMC_B0CTL.MODE` =2). The wait time is from 2 to 15 SCLK0_0 cycles.	
		0	Not supported
		1	Not supported
		2-15	2-15 SCLK0_0 clock cycles
14:12 (R/W)	IT	Idle Time. The `SMC_B0ETIM.IT` bits select a bus idle time (in SCLK0_0 cycles) that the SMC waits between de-asserting the `SMC_AMS[n]` pin and asserting the `SMC_AMS[n]` pin for the next access. Note that the `SMC_B0ETIM.IT` period may be extended using the `SMC_B0ETIM.TT` selection. The idle time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		7	7 SCLK0_0 clock cycles

Table 11-4: SMC_B0ETIM Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10:8 (R/W)	TT	Transition Time. The `SMC_B0ETIM.TT` bits select a bus idle time (in SCLK0_0 cycles) that the SMC extends the `SMC_B0ETIM.IT` to allow for the subsequent access either using a different transfer direction or accessing a different bank. The transition time is from 1 to 7 SCLK0_0 cycles.	
		0	No bank transition
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
5:4 (R/W)	PREAT	Pre Access Time. The `SMC_B0ETIM.PREAT` bits select the pre-access time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_AOE`/ADV pin before asserting the `SMC_ARE`/`SMC_AWE` pin for the current access. The pre-access time is from 0 to 3 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		3	3 SCLK0_0 clock cycles
1:0 (R/W)	PREST	Pre Setup Time. The `SMC_B0ETIM.PREST` bits select the pre-setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AMS[n]` pin before asserting the `SMC_AOE`/ADV pin for an access. The pre-setup time is from 0 to 3 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		3	3 SCLK0_0 clock cycles

Bank 0 Timing Register

The `SMC_B0TIM` register configures bank 0 read and write access, setup, and hold timing for this bank. Note that read and write timing configurations are independent and may differ.

18:16 (R/W)	RST	Read Setup Time. The `SMC_B0TIM.RST` bits select the setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AOE` pin before asserting the `SMC_ARE` pin for an access. The setup time is from 1 to 8 SCLK0_0 cycles.	
		0	8 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
13:8 (R/W)	WAT	Write Access Time. The `SMC_B0TIM.WAT` bits select the access time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AWE` pin for a write access. The access time is from 1 to 63 SCLK0_0 cycles.	
		0	Not supported
		1	1 SCLK0_0 clock cycle
		63	63 SCLK0_0 clock cycles
6:4 (R/W)	WHT	Write Hold Time. The `SMC_B0TIM.WHT` bits select the hold time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_AWE` pin before de-asserting the `SMC_AOE` pin for the current access. The hold time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
2:0 (R/W)	WST	Write Setup Time. The `SMC_B0TIM.WST` bits select the setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AOE` pin before asserting the `SMC_AWE` pin for a write access. The setup time is from 1 to 8 SCLK0_0 cycles.	
		0	8 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles

Bank 1 Control Register

The SMC_B1CTL register enables bank 1 accesses and configures the memory access features for this bank.

Figure 11-16: SMC_B1CTL Register Diagram

Table 11-6: SMC_B1CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	PGSZ	Flash Page Size. The SMC_B1CTL.PGSZ bits select the flash page size, if page flash or sync burst flash protocol has been enabled (SMC_B1CTL.MODE > 1). Note that the SMC_B1CTL.PGSZ bits must be set to match the flash protocol of the external flash memory device in the system. The typical SMC_B1CTL.PGSZ selection for external devices supporting async flash or async flash page protocols is 4 or 8 words. The typical SMC_B1CTL.PGSZ selection for external devices supporting sync burst flash protocol is 16 words.	
		0	4 words
		1	8 words
		2	16 words
		3	16 words

Table 11-6: SMC_B1CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	RDYABTEN	ARDY Abort Enable. The `SMC_B1CTL.RDYABTEN` bit enables the abort counter for the `SMC_ARDY` pin, if enabled (`SMC_B1CTL.RDYEN` =1). After `SMC_B1TIM.RAT` or `SMC_B1TIM.WAT` cycles, the SMC starts sampling the `SMC_ARDY` pin and starts the abort down counter (if enabled). The abort count is 64 cycles of SCLK0_0. If the SMC detects that `SMC_ARDY` remains de-asserted when the counter expires, the SMC aborts the access and returns an error response back on the system bus. 0 Disable abort counter 1 Enable abort counter
13 (R/W)	RDYPOL	ARDY Polarity. The `SMC_B1CTL.RDYPOL` bit selects the polarity (active high or low) for the `SMC_ARDY` pin, if enabled (`SMC_B1CTL.RDYEN` =1). When the SMC samples the `SMC_ARDY` pin in the selective active state, the transaction completes. 0 Low active ARDY 1 High active ARDY
12 (R/W)	RDYEN	ARDY Enable. The `SMC_B1CTL.RDYEN` bit enables `SMC_ARDY` pin operation for bank 1 accesses. When enabled, the SMC uses `SMC_ARDY` (after the access time countdown) to determine completion of access to this memory bank. When disabled, the SMC ignores `SMC_ARDY` for accesses to this memory bank. 0 Disable ARDY 1 Enable ARDY
9:8 (R/W)	SELCTRL	Select Control. The `SMC_B1CTL.SELCTRL` bits select the handling of the `SMC_AMS[n]`, `SMC_ARE`, `SMC_AOE`, and `SMC_AWE` pins for memory access control. 0 AMS1 only 1 AMS1 ORed with ARE 2 AMS1 ORed with AOE 3 AMS1 ORed with AWE

Table 11-6: SMC_B1CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/W)	MODE	Memory Access Mode. The `SMC_B1CTL.MODE` bits select the protocol the SMC uses for static memory read/write access. Note that the write protocol for async flash, async flash page, and sync burst flash are all similar; only the read protocols differ for these modes.	
		0	Async SRAM protocol
		1	Async flash protocol
		2	Async flash page protocol
		3	Reserved
0 (R/W)	EN	Bank 1 Enable. The `SMC_B1CTL.EN` bit enables accesses to the memory in bank 1. When this bit is disabled, accesses to bank 1 return an error response.	
		0	Disable access
		1	Enable access

Bank 1 Extended Timing Register

The `SMC_B1ETIM` register configures extensions to access times and idle times, augmenting the setup, hold, and access times configured with the `SMC_B1TIM` register.

Page Wait States

Figure 11-17: SMC_B1ETIM Register Diagram

Table 11-7: SMC_B1ETIM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	PGWS	Page Wait States. The `SMC_B1ETIM.PGWS` bits select a page access extension time (in SCLK0_0 cycles) that the SMC waits during read accesses when configured for flash page protocol (`SMC_B1CTL.MODE` =2). The wait time is from 2 to 15 SCLK0_0 cycles.	
		0	Not supported
		1	Not supported
		2-15	2-15 SCLK0_0 clock cycles
14:12 (R/W)	IT	Idle Time. The `SMC_B1ETIM.IT` bits select a bus idle time (in SCLK0_0 cycles) that the SMC waits between de-asserting the `SMC_AMS[n]` pin and asserting the `SMC_AMS[n]` pin for the next access. Note that the `SMC_B1ETIM.IT` period may be extended using the `SMC_B1ETIM.TT` selection. The idle time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		7	7 SCLK0_0 clock cycles

Table 11-7: SMC_B1ETIM Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10:8 (R/W)	TT	Transition Time. The `SMC_B1ETIM.TT` bits select a bus idle time (in SCLK0_0 cycles) that the SMC extends the `SMC_B1ETIM.IT` to allow for the subsequent access either using a different transfer direction or accessing a different bank. The transition time is from 1 to 7 SCLK0_0 cycles.	
		0	No bank transition
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
5:4 (R/W)	PREAT	Pre Access Time. The `SMC_B1ETIM.PREAT` bits select the pre-access time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_AOE`/ADV pin before asserting the `SMC_ARE`/`SMC_AWE` pin for the current access. The pre-access time is from 0 to 3 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		3	3 SCLK0_0 clock cycles
1:0 (R/W)	PREST	Pre Setup Time. The `SMC_B1ETIM.PREST` bits select the pre-setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AMS[n]` pin before asserting the `SMC_AOE`/ADV pin for an access. The pre-setup time is from 0 to 3 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		3	3 SCLK0_0 clock cycles

Bank 1 Timing Register

The `SMC_B1TIM` register configures bank 1 read and write access, setup, and hold timing for this bank. Note that read and write timing configurations are independent and may differ.

Table 11-8: SMC_B1TIM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:24 (R/W)	RAT	Read Access Time. The `SMC_B1TIM.RAT` bits select the access time (in SCLK0_0 cycles) that the SMC asserts the `SMC_ARE` pin for a read access. The access time is from 1 to 63 SCLK0_0 cycles.	
		0	Not supported
		1	1 SCLK0_0 clock cycle
		63	63 SCLK0_0 clock cycles
22:20 (R/W)	RHT	Read Hold Time. The `SMC_B1TIM.RHT` bits select the hold time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_ARE` pin before asserting the `SMC_AOE` pin for the next access. The hold time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles

Table 11-8: SMC_B1TIM Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	RST	Read Setup Time. The `SMC_B1TIM.RST` bits select the setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AOE` pin before asserting the `SMC_ARE` pin for an access. The setup time is from 1 to 8 SCLK0_0 cycles.	
		0	8 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
13:8 (R/W)	WAT	Write Access Time. The `SMC_B1TIM.WAT` bits select the access time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AWE` pin for a write access. The access time is from 1 to 63 SCLK0_0 cycles.	
		0	Not supported
		1	1 SCLK0_0 clock cycle
		63	63 SCLK0_0 clock cycles
6:4 (R/W)	WHT	Write Hold Time. The `SMC_B1TIM.WHT` bits select the hold time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_AWE` pin before de-asserting the `SMC_AOE` pin for the current access. The hold time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
2:0 (R/W)	WST	Write Setup Time. The `SMC_B1TIM.WST` bits select the setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AOE` pin before asserting the `SMC_AWE` pin for a write access. The setup time is from 1 to 8 SCLK0_0 cycles.	
		0	8 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles

Bank 2 Control Register

The `SMC_B2CTL` register enables bank 2 accesses and configures the memory access features for this bank.

Figure 11-19: SMC_B2CTL Register Diagram

Table 11-9: SMC_B2CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	PGSZ	Flash Page Size. The `SMC_B2CTL.PGSZ` bits select the flash page size, if page flash or sync burst flash protocol has been enabled (`SMC_B2CTL.MODE` > 1). Note that the `SMC_B2CTL.PGSZ` bits must be set to match the flash protocol of the external flash memory device in the system. The typical `SMC_B2CTL.PGSZ` selection for external devices supporting async flash or async flash page protocols is 4 or 8 words. The typical `SMC_B2CTL.PGSZ` selection for external devices supporting sync burst flash protocol is 16 words.	
		0	4 words
		1	8 words
		2	16 words
		3	16 words

Table 11-9: SMC_B2CTL Register Fields (Continued)

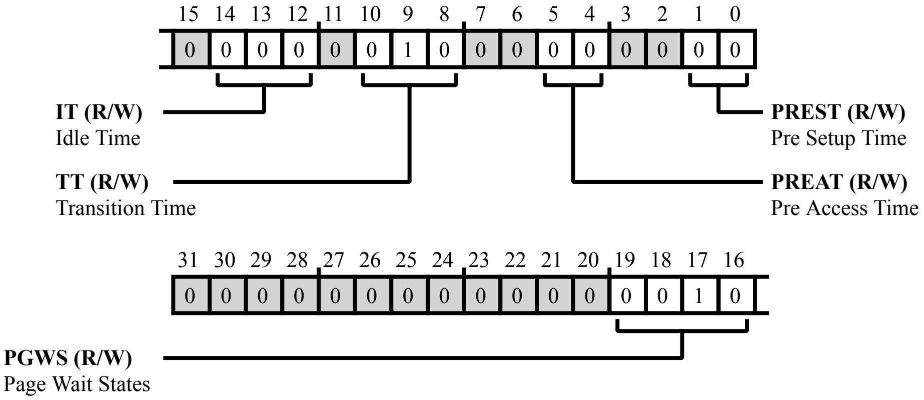
Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	RDYABTEN	ARDY Abort Enable. The `SMC_B2CTL.RDYABTEN` bit enables the abort counter for the `SMC_ARDY` pin, if enabled (`SMC_B2CTL.RDYEN` =1). After `SMC_B2TIM.RAT` or `SMC_B2TIM.WAT` cycles, the SMC starts sampling the `SMC_ARDY` pin and starts the abort down counter (if enabled). The abort count is 64 cycles of SCLK0_0. If the SMC detects that `SMC_ARDY` remains de-asserted when the counter expires, the SMC aborts the access and returns an error response back on the system bus.	
		0	Disable abort counter
		1	Enable abort counter
13 (R/W)	RDYPOL	ARDY Polarity. The `SMC_B2CTL.RDYPOL` bit selects the polarity (active high or low) for the `SMC_ARDY` pin, if enabled (`SMC_B2CTL.RDYEN` =1). When the SMC samples the `SMC_ARDY` pin in the selective active state, the transaction completes.	
		0	Low active ARDY
		1	High active ARDY
12 (R/W)	RDYEN	ARDY Enable. The `SMC_B2CTL.RDYEN` bit enables `SMC_ARDY` pin operation for bank 2 accesses. When enabled, the SMC uses `SMC_ARDY` (after the access time countdown) to determine completion of access to this memory bank. When disabled, the SMC ignores `SMC_ARDY` for accesses to this memory bank.	
		0	Disable ARDY
		1	Enable ARDY
9:8 (R/W)	SELCTRL	Select Control. The `SMC_B2CTL.SELCTRL` bits select the handling of the `SMC_AMS[n]`, `SMC_ARE`, `SMC_AOE`, and `SMC_AWE` pins for memory access control.	
		0	AMS2 only
		1	AMS2 ORed with ARE
		2	AMS2 ORed with AOE
		3	AMS2 ORed with AWE

Table 11-9: SMC_B2CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/W)	MODE	Memory Access Mode. The `SMC_B2CTL.MODE` bits select the protocol the SMC uses for static memory read/write access. Note that the write protocol for async flash, async flash page, and sync burst flash are all similar; only the read protocols differ for these modes.	
		0	Async SRAM protocol
		1	Async flash protocol
		2	Async flash page protocol
		3	Reserved
0 (R/W)	EN	Bank 2 Enable. The `SMC_B2CTL.EN` bit enables accesses to the memory in bank 2. When this bit is disabled, accesses to bank 2 return an error response.	
		0	Disable access
		1	Enable access

Bank 2 Extended Timing Register

The `SMC_B2ETIM` register configures extensions to access times and idle times, augmenting the setup, hold, and access times configured with the `SMC_B2TIM` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 11-10: SMC_B2ETIM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	PGWS	Page Wait States. The `SMC_B2ETIM.PGWS` bits select a page access extension time (in SCLK0_0 cycles) that the SMC waits during read accesses when configured for flash page protocol (`SMC_B2CTL.MODE` =2). The wait time is from 2 to 15 SCLK0_0 cycles.	
		0	Not supported
		1	Not supported
		2-15	2-15 SCLK0_0 clock cycles
14:12 (R/W)	IT	Idle Time. The `SMC_B2ETIM.IT` bits select a bus idle time (in SCLK0_0 cycles) that the SMC waits between de-asserting the `SMC_AMS[n]` pin and asserting the `SMC_AMS[n]` pin for the next access. Note that the `SMC_B2ETIM.IT` period may be extended using the `SMC_B2ETIM.TT` selection. The idle time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		7	7 SCLK0_0 clock cycles

Table 11-10: SMC_B2ETIM Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10:8 (R/W)	TT	Transition Time. The `SMC_B2ETIM.TT` bits select a bus idle time (in SCLK0_0 cycles) that the SMC extends the `SMC_B2ETIM.IT` to allow for the subsequent access either using a different transfer direction or accessing a different bank. The transition time is from 1 to 7 SCLK0_0 cycles.	
		0	No bank transition
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
5:4 (R/W)	PREAT	Pre Access Time. The `SMC_B2ETIM.PREAT` bits select the pre-access time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_AOE`/ADV pin before asserting the `SMC_ARE`/`SMC_AWE` pin for the current access. The pre-access time is from 0 to 3 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		3	3 SCLK0_0 clock cycles
1:0 (R/W)	PREST	Pre Setup Time. The `SMC_B2ETIM.PREST` bits select the pre-setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AMS[n]` pin before asserting the `SMC_AOE`/ADV pin for an access. The pre-setup time is from 0 to 3 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		3	3 SCLK0_0 clock cycles

Bank 2 Timing Register

The `SMC_B2TIM` register configures bank 2 read and write access, setup, and hold timing for this bank. Note that read and write timing configurations are independent and may differ.

Table 11-11: SMC_B2TIM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:24 (R/W)	RAT	Read Access Time. The `SMC_B2TIM.RAT` bits select the access time (in SCLK0_0 cycles) that the SMC asserts the `SMC_ARE` pin for a read access. The access time is from 1 to 63 SCLK0_0 cycles.	
		0	Not supported
		1	1 SCLK0_0 clock cycle
		63	63 SCLK0_0 clock cycles
22:20 (R/W)	RHT	Read Hold Time. The `SMC_B2TIM.RHT` bits select the hold time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_ARE` pin before asserting the `SMC_AOE` pin for the next access. The hold time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles

Table 11-11: SMC_B2TIM Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	RST	Read Setup Time. The `SMC_B2TIM.RST` bits select the setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AOE` pin before asserting the `SMC_ARE` pin for an access. The setup time is from 1 to 8 SCLK0_0 cycles.	
		0	8 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
13:8 (R/W)	WAT	Write Access Time. The `SMC_B2TIM.WAT` bits select the access time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AWE` pin for a write access. The access time is from 1 to 63 SCLK0_0 cycles.	
		0	Not supported
		1	1 SCLK0_0 clock cycle
		63	63 SCLK0_0 clock cycles
6:4 (R/W)	WHT	Write Hold Time. The `SMC_B2TIM.WHT` bits select the hold time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_AWE` pin before de-asserting the `SMC_AOE` pin for the current access. The hold time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
2:0 (R/W)	WST	Write Setup Time. The `SMC_B2TIM.WST` bits select the setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AOE` pin before asserting the `SMC_AWE` pin for a write access. The setup time is from 1 to 8 SCLK0_0 cycles.	
		0	8 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles

Bank 3 Control Register

The `SMC_B3CTL` register enables bank 3 accesses and configures the memory access features for this bank.

Table 11-12: SMC_B3CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	PGSZ	Flash Page Size. The `SMC_B3CTL.PGSZ` bits select the flash page size, if page flash or sync burst flash protocol has been enabled (`SMC_B3CTL.MODE` > 1). Note that the `SMC_B3CTL.PGSZ` bits must be set to match the flash protocol of the external flash memory device in the system. The typical `SMC_B3CTL.PGSZ` selection for external devices supporting async flash or async flash page protocols is 4 or 8 words. The typical `SMC_B3CTL.PGSZ` selection for external devices supporting sync burst flash protocol is 16 words.	
		0	4 words
		1	8 words
		2	16 words
		3	16 words

Table 11-12: SMC_B3CTL Register Fields (Continued)

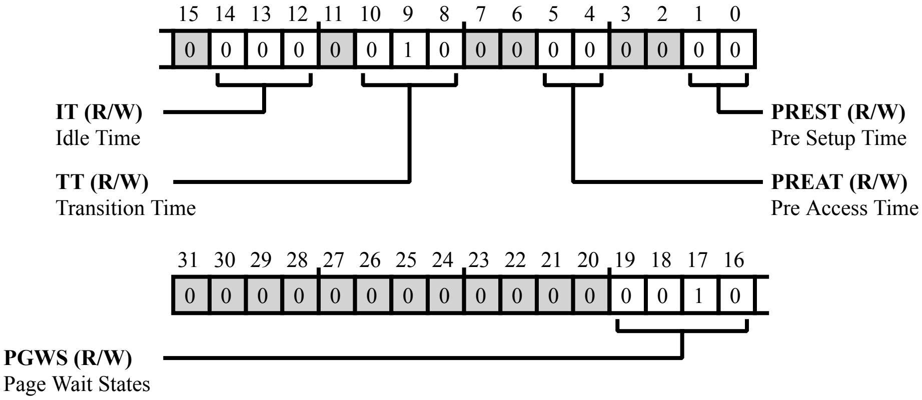
Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	RDYABTEN	ARDY Abort Enable. The `SMC_B3CTL.RDYABTEN` bit enables the abort counter for the `SMC_ARDY` pin, if enabled (`SMC_B3CTL.RDYEN` =1). After `SMC_B3TIM.RAT` or `SMC_B3TIM.WAT` cycles, the SMC starts sampling the `SMC_ARDY` pin and starts the abort down counter (if enabled). The abort count is 64 cycles of SCLK0_0. If the SMC detects that `SMC_ARDY` remains de-asserted when the counter expires, the SMC aborts the access and returns an error response back on the system bus.	
		0	Disable abort counter
		1	Enable abort counter
13 (R/W)	RDYPOL	ARDY Polarity. The `SMC_B3CTL.RDYPOL` bit selects the polarity (active high or low) for the `SMC_ARDY` pin, if enabled (`SMC_B3CTL.RDYEN` =1). When the SMC samples the `SMC_ARDY` pin in the selective active state, the transaction completes.	
		0	Low active ARDY
		1	High active ARDY
12 (R/W)	RDYEN	ARDY Enable. The `SMC_B3CTL.RDYEN` bit enables `SMC_ARDY` pin operation for bank 3 accesses. When enabled, the SMC uses `SMC_ARDY` (after the access time countdown) to determine completion of access to this memory bank. When disabled, the SMC ignores `SMC_ARDY` for accesses to this memory bank.	
		0	Disable ARDY
		1	Enable ARDY
9:8 (R/W)	SELCTRL	Select Control. The `SMC_B3CTL.SELCTRL` bits select the handling of the `SMC_AMS[n]`, `SMC_ARE`, `SMC_AOE`, and `SMC_AWE` pins for memory access control.	
		0	AMS3 only
		1	AMS3 ORed with ARE
		2	AMS3 ORed with AOE
		3	AMS3 ORed with AWE

Table 11-12: SMC_B3CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/W)	MODE	Memory Access Mode. The `SMC_B3CTL.MODE` bits select the protocol the SMC uses for static memory read/write access. Note that the write protocol for async flash, async flash page, and sync burst flash are all similar; only the read protocols differ for these modes.	
		0	Async SRAM protocol
		1	Async flash protocol
		2	Async flash page protocol
		3	Reserved
0 (R/W)	EN	Bank 3 Enable. The `SMC_B3CTL.EN` bit enables accesses to the memory in bank 3. When this bit is disabled, accesses to bank 3 return an error response.	
		0	Disable access
		1	Enable access

Bank 3 Extended Timing Register

The `SMC_B3ETIM` register configures extensions to access times and idle times, augmenting the setup, hold, and access times configured with the `SMC_B3TIM` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Page Wait States

Figure 11-23: SMC_B3ETIM Register Diagram

Table 11-13: SMC_B3ETIM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	PGWS	Page Wait States. The `SMC_B3ETIM.PGWS` bits select a page access extension time (in SCLK0_0 cycles) that the SMC waits during read accesses when configured for flash page protocol (`SMC_B3CTL.MODE` =2). The wait time is from 2 to 15 SCLK0_0 cycles.	
		0	Not supported
		1	Not supported
		2-15	2-15 SCLK0_0 clock cycles
14:12 (R/W)	IT	Idle Time. The `SMC_B3ETIM.IT` bits select a bus idle time (in SCLK0_0 cycles) that the SMC waits between de-asserting the `SMC_AMS[n]` pin and asserting the `SMC_AMS[n]` pin for the next access. Note that the `SMC_B3ETIM.IT` period may be extended using the `SMC_B3ETIM.TT` selection. The idle time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		7	7 SCLK0_0 clock cycles

Table 11-13: SMC_B3ETIM Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10:8 (R/W)	TT	Transition Time. The `SMC_B3ETIM.TT` bits select a bus idle time (in SCLK0_0 cycles) that the SMC extends the `SMC_B3ETIM.IT` to allow for the subsequent access either using a different transfer direction or accessing a different bank. The transition time is from 1 to 7 SCLK0_0 cycles.	
		0	No bank transition
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
5:4 (R/W)	PREAT	Pre Access Time. The `SMC_B3ETIM.PREAT` bits select the pre-access time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_AOE`/ADV pin before asserting the `SMC_ARE`/`SMC_AWE` pin for the current access. The pre-access time is from 0 to 3 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		3	3 SCLK0_0 clock cycles
1:0 (R/W)	PREST	Pre Setup Time. The `SMC_B3ETIM.PREST` bits select the pre-setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AMS[n]` pin before asserting the `SMC_AOE`/ADV pin for an access. The pre-setup time is from 0 to 3 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		3	3 SCLK0_0 clock cycles

Bank 3 Timing Register

The `SMC_B3TIM` register configures bank 3 read and write access, setup, and hold timing for this bank. Note that read and write timing configurations are independent and may differ.

Figure 11-24: SMC_B3TIM Register Diagram

Table 11-14: SMC_B3TIM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:24 (R/W)	RAT	Read Access Time. The `SMC_B3TIM.RAT` bits select the access time (in SCLK0_0 cycles) that the SMC asserts the `SMC_ARE` pin for a read access. The access time is from 1 to 63 SCLK0_0 cycles.	
		0	Not supported
		1	1 SCLK0_0 clock cycle
		63	63 SCLK0_0 clock cycles
22:20 (R/W)	RHT	Read Hold Time. The `SMC_B3TIM.RHT` bits select the hold time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_ARE` pin before asserting the `SMC_AOE` pin for the next access. The hold time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles

Table 11-14: SMC_B3TIM Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	RST	Read Setup Time. The `SMC_B3TIM.RST` bits select the setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AOE` pin before asserting the `SMC_ARE` pin for an access. The setup time is from 1 to 8 SCLK0_0 cycles.	
		0	8 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
13:8 (R/W)	WAT	Write Access Time. The `SMC_B3TIM.WAT` bits select the access time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AWE` pin for a write access. The access time is from 1 to 63 SCLK0_0 cycles.	
		0	Not supported
		1	1 SCLK0_0 clock cycle
		63	63 SCLK0_0 clock cycles
6:4 (R/W)	WHT	Write Hold Time. The `SMC_B3TIM.WHT` bits select the hold time (in SCLK0_0 cycles) that the SMC waits after de-asserting the `SMC_AWE` pin before de-asserting the `SMC_AOE` pin for the current access. The hold time is from 0 to 7 SCLK0_0 cycles.	
		0	0 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles
2:0 (R/W)	WST	Write Setup Time. The `SMC_B3TIM.WST` bits select the setup time (in SCLK0_0 cycles) that the SMC asserts the `SMC_AOE` pin before asserting the `SMC_AWE` pin for a write access. The setup time is from 1 to 8 SCLK0_0 cycles.	
		0	8 SCLK0_0 clock cycles
		1	1 SCLK0_0 clock cycle
		7	7 SCLK0_0 clock cycles

12 One-Time Programmable Memory Controller (OTPC)

This chapter describes the operation of the OTP controller. The OTP module is a complete system integrating an OTP memory core with a programming controller, charge pump, and voltage regulator. A built-in Hamming Code Error Correction (ECC), and a fully implemented double-redundant program or read scheme protect the OTP data.

OTP memory access is through the OTP API Overview provided by the ROM.

CAUTION: OTP memory does not support burst transfers, which are required to support cache line fills. As such, OTP memory should not be made cacheable. If it is, the OTP controller returns an error when a read access is attempted.

OTPC Features

The OTP memory and controller have the following features:

- Built-in redundant read mode
- Built-in integrated power supply
- Built-in Hamming Code Error Correction (ECC)
- Full word serial (single bit at a time) programming with internal VPP

Error Correction

The OTP memory features a Hamming error correction implementation. Signal bit errors are automatically corrected, and dual-bit errors are detected. Refer to OTPC Interrupt Signals.

ECC is always enabled. ECC applies to each 16-bit segment. Because of this functionality, each 16-bit location can only be written to once. Writing to a 16-bit location a second time results in unexpected behavior.

OTP Layout

This section details the memory layout of the OTP memory.

OTP Layout

Table 12-1: ADSP-SCxx OTP Layout

Name	Byte Address	Size (bits)	Description
Customer OTP Area - 896 bytes			
huk	0x0 + 0 - 0x1c	256	Hardware unique key
pvt_128key0	0x168 + 0 - 0x174	128	Customer private key 0 128bits
pvt_128key1	0x178 + 0 - 0x184	128	Customer private key 1 128bits
pvt_128key2	0x188 + 0 - 0x194	128	Customer private key 2 128bits
pvt_128key3	0x198 + 0 - 0x1a4	128	Customer private key 3 128bits
ek	0x1a8 + 0 - 0x1c4	256	Endorsement key
secure_emu_key	0x1c8 + 0 - 0x1d4	128	Secure emulation key
Reserved	0x1d8 + 0 - 0x1fc	320	Reserved
public_key0	0x200 + 0 - 0x23c	512	Customer public key 0
public_key1	0x240 + 0 - 0x27c	512	Customer public key 1
boot_info	0x280 + 0 - 0x2bc	512	Customer programmable boot information
antiroll_nv_cntr	0x2c0 + 0 - 0x2fc	512	AntiRollback NV counter
gp1	0x300 + 0 - 0x33c	512	General purpose 1
Reserved	0x340 + 0 - 0x340	24	Reserved
bootModeDisable	0x343 + 24 - 0x343	8	Boot mode disable bits
preboot_ddr_cfg	0x344 + 0 - 0x370	384	User preboot DDR configuration
stageID	0x374 + 0 - 0x376	48	Stage ID
Reserved	0x37a + 16 - 0x37a	16	Reserved
Reserved	0x37c + 0 - 0x37c	32	Reserved
Overlaid Fields in Customer OTP Area			
otpTiming	0x2be + 16 - 0x2be	16	OTP read timing override
Overlaid Fields in ADI BOOT			
Customer BOOT - 116 Bytes			
lock	0x48c + 0 - 0x48c	1	Lockbit
Reserved	0x48c + 1 - 0x4fc	927	Reserved

OTPC Event Control

The following sections provide information on OTP events and error management.

OTPC Interrupt Signals

When making 32-bit accesses to OTP memory, a double-bit error in any 16-bit segment triggers the OTPC_INT interrupt. The OTPC also has the OTPC dual bit error (OTPC0_ERR) with the SEC ID of 5 and the GIC ID of 37. See the System Event Controller (SEC) and Generic Interrupt Controller (GIC) chapter for more information.

OTPC Status and Error Signals

The OTP controller does not produce error signals.

OTP API Overview

The ROM provides a set of functions to facilitate OTP field access. The OTP memory is broken up into a set of specialized fields that are described in this section. The API removes the requirement of understanding the details of the layout or OTP access procedures.

All OTP accesses are made through the provided API.

OTP Programming

The OTP programming API provides a simple access, abstracting particulars of the OTP controller.

Any fields that contain zero or null pointers are skipped.

All addresses are assumed to be byte addresses unless otherwise noted.

A list of APIs follows:

`bool adi_rom_otp_pgm(otp_data* data);`	OTP Program
`bool adi_rom_lock();`	Lock API

OTP Program

Program OTP memory using a struct containing the following predefined data fields.

Name	OTP Program	-
PP Define	`FUNC_ROM_OTPPGM`	
Prototype	`bool adi_rom_otp_pgm(otp_data* data);`	-
Argument	data	struct containing data to program OTP with
Return Value	bool	true for programming success
Stack Requirements	valid stack	-

```
bool res = adi_rom_otp_pgm(data);
```

The following type of struct is available for programming. Refer to the ROM header file for the exact definition

```
typedef struct {
    uint32_t  (*huk)[8];
    uint32_t  (*pvt_128key1)[4];
    uint32_t  (*pvt_128key2)[4];
    uint32_t  (*pvt_128key3)[4];
    uint32_t  (*pvt_128key4)[4];
    uint32_t  (*pvt_192key1)[6];
    uint32_t  (*pvt_192key2)[6];
    uint32_t  (*public_key0)[16];
    uint32_t  (*public_key1)[16];
    uint32_t  (*ek)[8];
    uint32_t  (*secure_emu_key)[4];
    uint8_t   bootModeDisable;
    uint32_t  (*boot_info)[16];
    uint32_t  (*gp0)[16];
    uint32_t antiroll_nv_cntr;
    uint8_t   stageID;
    uint32_t  (*preboot_ddr_cfg)[11];
} otp_data;
```

NOTE: Make OTP memory a non-cacheable region if the core needs access to it.

OTP Reading

This API provides a unified source for retrieving OTP data fields.

All addresses are assumed to be byte addresses, unless otherwise noted.

A list of APIs follow:

`bool adi_rom_otp_get( OTPCMD cmd, uint32_t* data);`	OTP Get Field

OTP Get Field

Retrieves indicated data from OTP memory.

Name	OTP Get Field	
Prototype	`bool adi_rom_otp_get( OTPCMD cmd, uint32_t* data);`	
Argument	cmd	Indicates what data to fetch, based on the`OTPCMD` enum.
Argument	data	memory location to write the data to
Return Value	bool	true for a successful read
Stack Requirements	valid stack	

```
bool res = adi_rom_otp_get(otpcmd_info,data);
```

The data specified by the `OTPCMD` enum parameter is fetched from OTP memory and placed in the location specified by data. The `OTPCMD` enum contains entries for each field defined in OTP memory, for the most current list please refer to the OTP header file.

An example of the enum style follows:

```
                /*  Field Name               Description                  No of 
Bits */
                typedef enum {
                  /* add msi bits */
                  otpcmd_reserved0 = 0,
                  otpcmd_pvt_128key1,      /* Private 128-bit Key 1 
[128] */
                  otpcmd_pvt_128key2,      /* Private 128-bit Key 2 
[128] */
                  otpcmd_pvt_128key3,      /* Private 128-bit Key 3 
[128] */
                  otpcmd_pvt_128key4,      /* Private 128-bit Key 4 
[128] */
                  otpcmd_pvt_192key1,      /* Private 192-bit Key 1 
[192] */
                  otpcmd_pvt_192key2,      /* Private 192-bit Key 2 
[192] */
                  otpcmd_huk,              /* Hardware Unique Key 
[256] */
                  otpcmd_ek,               /* Endorsement Key (EK) 
[256] */
                  otpcmd_secure_emu_key,   /* Secure Emulation Key 
[128] */
                  otpcmd_public_key1,      /* Customer Public Key 1 
[512] */
                  otpcmd_public_key2,      /* Customer Public Key 2 
[512] */
                  otpcmd_antiroll_nv_cntr, /* Anti-Rollback NV Counter 
[32] */
                  otpcmd_nonvolatile_cntr, /* NV Counter 
[32] */
                  otpcmd_bootModeDisable,  /* Boot Mode disable 
field              [8] */
                  otpcmd_stageID,          /* Stage 
ID                            [8] */
                  otpcmd_gp0,              /* General Purpose 
[512] */
                  otpcmd_boot_info,        /* Customer Programmable Boot info 
[384] */
                  otpcmd_preboot_ddr_cfg,  /* User Preboot DDR configuration 
[352] */
                  otpcmd_reserved1        /* invalid */
                } OTPCMD;
```

OTP Counters

The OTPC module implements a counter API to allow easy reading or writing of the counter without dealing with the complexities of rewriting OTP memory sections that are ECC protected.

The OTPC module provides two functional APIs for counters. These APIs are not extra; the module uses the same `get` and `pgm` APIs. The APIs are functionally unique in the way that they set and retrieve data as counters in OTP memory.

The API uses a different method to count bits because each bit in OTP memory can only be set =1 once, and the ECC protects each 16-bit unit. This functionality essentially means that each 16-bit unit can only be written to once. Therefore, a counter that can count 0–31 requires 32 × 16 bits of memory.

The API receives and returns the value of the counter as a `uint8_t` binary number. Writing a value less than the current value of the counter or greater than the maximum value results in an error.

To implement this functionality, the driver counts by shifting 1's from the left, treating each block as 1 bit. A three-bit counter is encoded as follows.

bit 2	bit 1	bit 0	Value
0000	0000	0000	0
0001	0000	0000	1
0001	0001	0000	2
0001	0001	0001	3

Lock API

This API locks the device.

Name	Lock API	-
PP Define	`FUNC_ROM_LOCK`	-
Prototype	`bool adi_rom_lock();`	-
Return Value	bool	true for success
Stack Requirements	valid stack	-

```
bool res = adi_rom_lock();
```

Calling this function locks the device, making it a secure. Once locked, the `OTPC_SECU_STATE` register indicates that the part is locked, and access is limited. For more information, refer to the security documentation regarding a locked device.

NOTE: Locked Status. The `OTPC_SECU_STATE` register is updated only after the part is rebooted. After calling the lock function, the register still indicates that the part is open.

ADSP-SC58x OTPC Interrupt List

Table 12-2: ADSP-SC58x OTPC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
5	OTPC0_ERR	OTPC0 Dual-bit error	Level	

ADSP-SC58x OTPC Register Descriptions

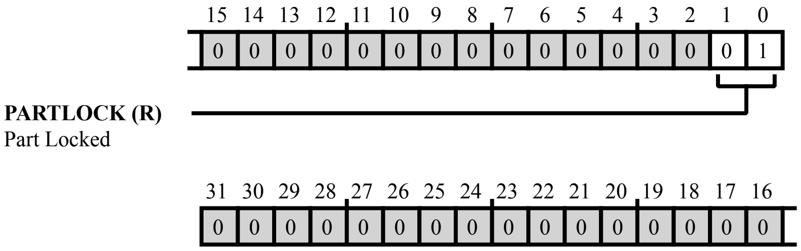
OTP Memory Controller (OTPC) contains the following registers.

Table 12-3: ADSP-SC58x OTPC Register List

Name	Description
`OTPC_SECU_STATE`	OTP Security State Register
`OTPC_STAT`	OTP Status Register

OTP Security State Register

The `OTPC_SECU_STATE` register provides lock status information.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1
PARTLOCK (R)
Part Locked
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

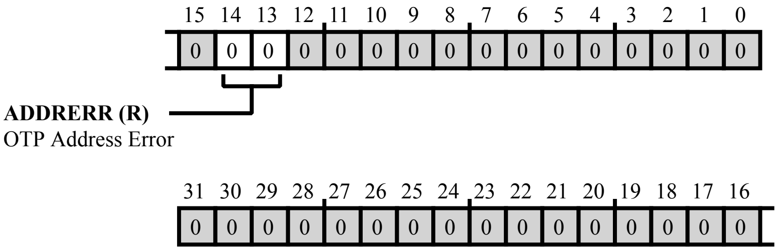
Figure 12-1: OTPC_SECU_STATE Register Diagram

Table 12-4: OTPC_SECU_STATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PARTLOCK	Part Locked. The `OTPC_SECU_STATE.PARTLOCK` bit indicates a locked part.	
		0	OPEN part
		1	Locked part
		2	Unlocked part

OTP Status Register

The `OTPC_STAT` register bits indicate errors and flag status and control the protection bits.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDRERR (R)
OTP Address Error
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 12-2: OTPC_STAT Register Diagram

Table 12-5: OTPC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:13 (R/NW)	ADDRERR	OTP Address Error. The `OTPC_STAT.ADDRERR` bit field indicates errors which occur when the OTP programming address is out of range or tries to access protected space.	
		0	No error - proper OTP address
		1	OTP address out of range
		2	8-bit OTP address
		3	Protected OTP address

13 System Memory Protection Unit (SMPU)

The SMPU provides a flexible way of protecting memory regions against read or write access from any or all masters in the system. In addition, it can guard against memory access depending on security privileges of the system master.

SMPU Features

The system memory protection unit has the following features.

- After reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces by any master.
- Each SMPU instance can be configured to monitor multiple regions. Each can be individually enabled.
- Each region can be configured with its own protection settings.
- Provides general read or write protection.
- Read and write transactions are restricted or allowed depending on the transaction ID.

On the ADSP-SC58x, ten SMPU instances are available to protect the L2, external memory (DMC/SMC), and memory mapped I/O (PCIe) interfaces. Six instances are allotted to protect the L2 memory, two instances for DMC0 and DMC1, one instance for SMC and one instance for PCIe as shown below:

Table 13-1: SMPU Instances

Module	SMPU Instance
SMC	0
Core_L2_RAM_Boot_ROM0	2
DMA_L2_RAM_Boot_ROM0	3
Core_L2_ROM1_Boot_ROM1	4
DMA_L2_ROM1_Boot_ROM1	5
Core_L2_ROM2_Boot_ROM2	6
DMA_L2_ROM2_Boot_ROM2	7
PCIe	8

Table 13-1: SMPU Instances (Continued)

Module	SMPU Instance
DMC0	9
DMC1	10

All the SMPU instances can be configured up to eight regions.

- Up to eight outstanding read or write transactions supported on SMPU instances for Core_L2_RAM_Boot_ROM0, DMC0 and DMC1.
- Up to four outstanding read or write transactions supported on the SMPU instances for DMA_L2_RAM_Boot_ROM0, Core_L2_ROM1_Boot_ROM1, DMA_L2_ROM1_Boot_ROM1, Core_L2_ROM2_Boot_ROM2, DMA_L2_ROM2_Boot_ROM2, SMC, and PCIe.
- Exclusive access enabled by hardware for the SMPU instances of Core_L2_RAM_Boot_ROM0, DMC 0, DMC1, and SMC. Up to four exclusive-access-capable masters can be supported.

SMPU Functional Description

The following sections provide details on the function of the SMPU module. If the region security settings allow transactions to go through, the ID in the ID-based region protection settings can still filter the transactions.

For the memory that an SMPU protects, programs can configure region-based settings with the `SMPU_RCTL[n]` registers. (There can be multiple SMPUs in a system.) The `SMPU_RCTL[n]` registers define the ID-based protection for memory regions.

If the target address does not reside in any configured memory region, the transaction permission resorts back to the global configuration setting.

Protection Units

Each SMPU provides two protection units, A and B for ID-based matching in the region-based memory protection. This feature provides a degree of flexibility for the user to match against multiple IDs.

Instruction Fetches

When the core executes instructions from memory, this operation is also considered a memory transaction. If the SMPU is configured to protect a memory region from read accesses that contain instructions, the core cannot fetch and execute these instructions.

Using Cache

When the processor uses both cache and the SMPU, there are a few issues to be aware of. If the SMPU is configured to protect a memory region from write accesses, instruction fetches from a core are still possible since instructions are not updated and replaced during run time.

NOTE: The debugger typically replaces an instruction with a breakpoint instruction for software breakpoints. If a memory region is protected against write accesses, software breakpoints are not possible unless the SMPU is configured with the appropriate system master ID of the debugger. The configuration allows it to perform a write-access.

In the case where memory is used for data, a read access or cache fill is not possible if the memory is blocked from read accesses. If read accesses are allowed but write accesses are disallowed, then there is an issue with coherency. The cache is filled but when the cache is updated and must be written back to the SMPU protected memory, the write-access is blocked.

In general, practice caution when using both the SMPU and cache.

Speculative Reads

If speculative reads are enabled (`SMPU_CTL.RSDIS` =0), the SMPU forwards the read transaction directly to the memory before checking the protection setting corresponding to the addressed memory region. This functionality saves one clock cycle in the clock domain of the SMPU. The SMPU checks the protection setting while the read transaction occurs with the memory. If the protection setting dictates that the target memory address is blocked, the SMPU blocks the read to the master.

If speculative reads are disabled (`SMPU_CTL.RSDIS` =1), the SMPU checks the protection settings first and forwards the transaction to memory only if it passes the configured protection settings. This functionality incurs a one-cycle latency per read.

NOTE: Reads affect certain memory operations such as automatic clearing of the memory (that is, FIFOs). When the SMPU protects this type of memory, disable read speculation since the blocking can occur without the read transaction reaching the target memory.

ADSP-SC58x SMPU Register List

The System Memory Protection Unit (SMPU) provides selective protection of the processor's memory resources. The SMPU includes a set of processor events that can be monitored during program execution. A set of registers governs SMPU operations. For more information on SMPU functionality, see the SMPU register descriptions.

Table 13-2: ADSP-SC58x SMPU Register List

Name	Description
`SMPU_BADDR`	Bus Error Address Register
`SMPU_BDTLS`	Bus Error Details Register
`SMPU_CTL`	SMPU Control Register
`SMPU_EXACADD[n]`	Exclusive Access IDn Address
`SMPU_EXACSTAT[n]`	Exclusive Access Status
`SMPU_IADDR`	Interrupt Address Register

Table 13-2: ADSP-SC58x SMPU Register List (Continued)

Name	Description
`SMPU_IDTLS`	Interrupt Details Register
`SMPU_RADDR[n]`	Region n Address Register
`SMPU_RCTL[n]`	Region n Control Register
`SMPU_REVID`	SMPU Revision ID Register
`SMPU_RIDA[n]`	Region n ID A Register
`SMPU_RIDB[n]`	Region n ID B Register
`SMPU_RIDMSKA[n]`	Region n ID Mask A Register
`SMPU_RIDMSKB[n]`	Region n ID Mask B Register
`SMPU_SECURECTL`	SMPU Control Secure Accesses Register
`SMPU_SECURERCTL[n]`	Region n Control Secure Accesses Register
`SMPU_STAT`	SMPU Status Register

ADSP-SC58x SMPU Interrupts

The SMPU has one interrupt with the SEC ID = 242. See the System Event Controller (SEC) and Generic Interrupt Controller (GIC) chapter for complete information on interrupt generation and use.

Memory Writes

A write transaction to address n is prevented when the following is true.

Address n is in memory region m and memory region m is write-protected (`SMPU_RCTL[n].WPROTEN` =1) and ID is not a match. (See ID Comparison). The block occurs because the memory region is configured for write-protection and the ID comparison does not result in a match. If an ID comparison results in a match, the write transaction is allowed through.

Memory Reads

A read transaction from address n is prevented when the following is true:

- Address n is in memory region and memory region m is read-protected (`SMPU_RCTL[n].RPROTEN` =1) and
- ID is not a match

The block occurs because the memory region is configured for read-protection and the ID comparison does not result in a match. If the ID comparison results in a match, the read transaction is permitted. (See ID Comparison).

ID Comparison

ID comparison automatically occurs during region-based memory protection. ID matches allow the transaction to bypass the configured memory protection for that region. The following sections describe the calculation of a write ID match and read ID match.

Write Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming write transaction:

- The `SMPU_RCTL[n].WIDCINV` bit
- The `SMPU_RIDA[n].ID` and `SMPU_RIDB[n].ID` bit fields
- The `SMPU_RIDMSKA[n].MSK` and `SMPU_RIDMSKB[n].MSK` bit fields

Write IDA match = ((ID of incoming write transaction AND `SMPU_RIDMSKA[n].MSK`) == (`SMPU_RIDA[n].ID` AND `SMPU_RIDMSKA[n].MSK`))

Write IDB match = ((ID of incoming write transaction AND `SMPU_RIDMSKB[n].MSK`) == (`SMPU_RIDB[n].ID` AND `SMPU_RIDMSKB[n].MSK`))

Write ID match = (Write IDA match OR Write IDB match) XOR `SMPU_RCTL[n].WIDCINV` bit

Read Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming read transaction:

- The `SMPU_RCTL[n].RIDCINV` bit
- The `SMPU_RIDA[n].ID` and `SMPU_RIDB[n].ID` bit fields
- The `SMPU_RIDMSKA[n].MSK` and `SMPU_RIDMSKB[n].MSK` bit fields

Read IDA match = ((ID of incoming read transaction AND `SMPU_RIDMSKA[n].MSK`) == (`SMPU_RIDA[n].ID` AND `SMPU_RIDMSKA[n].MSK`))

Read IDB match = ((ID of incoming read transaction AND `SMPU_RIDMSKB[n].MSK`) == (`SMPU_RIDB[n].ID` AND `SMPU_RIDMSKB[n].MSK`))

Read ID match = (Read IDA match OR Read IDB match) XOR `SMPU_RCTL[n].RIDCINV`

In the two cases described above, the incoming transaction (either write or read) ID is AND'ed with the configured mask value in protection unit A. It is then compared to the value of the configured ID value which is also AND'ed with the configured mask value in protection unit A. The mask provides a method to allow a group of IDs to match. This process is also performed for protection unit B. The two outcomes (from A and B) are then OR'ed together.

Depending on the setting of the `SMPU_RCTL[n].RIDCINV` or the `SMPU_RCTL[n].WIDCINV` bits, the ID match comparison is inverted or not. The final result after applying the inversion, `SMPU_RCTL[n].RIDCINV`, or `SMPU_RCTL[n].WIDCINV`, determines whether the transaction bypasses the protection.

Usage

The masks, `SMPU_RIDMSKA[n]` and `SMPU_RIDMSKB[n]`, are AND'ed with both the incoming transaction ID and the configured ID in `SMPU_RIDA[n].ID` and `SMPU_RIDB[n].ID`, respectively. By default the masks are zero. If ID-based region protection is enabled by setting the `SMPU_RCTL[n].WPROTEN` or `SMPU_RCTL[n].RPROTEN` bit fields and the masks are not set, the ID comparison essentially compares zeros. The comparison allows all transactions to bypass (if the region-based security setting is also configured in a way to allow transactions to go through for the region). To have the ID-based region protection to function, the mask registers and ID registers must also be set.

System IDs

The ***System Master IDs*** table provides the IDs for the system masters. An x means that the bit can be a 0 or a 1. There are multiple IDs associated with that particular system master.

Table 13-3: System Master IDs

Master Name	SCB Input Switch	Master ID SCB Input	ID

Memory Region

Memory regions can start at address 0x00000000 or at any address that is a multiple of its size. The ***Supported Memory Region Size and Alignment*** table shows the memory region sizes that the processor supports and the alignment of the memory region. (X values are do-not-care).

SMPU0 and SMPU2 support a maximum of four regions. SMPU1 supports a maximum of eight regions.

Table 13-4: Supported Memory Region Size and Alignment

Size	SMPU_RCTLn.SIZE	Address	Possible Values for N
	0b00000	0xXXXXX000	-

Table 13-4: Supported Memory Region Size and Alignment (Continued)

Size	SMPU_RCTLn.SIZE	Address	Possible Values for N
4KB			
8KB	0b00001	0xXXXXN000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
16KB	0b00010	0xXXXXN000	0x0, 0x4, 0x8, 0xC
32KB	0b00011	0xXXXXN000	0x0, 0x8
64KB	0b00100	0xXXXX0000	-
128KB	0b00101	0xXXXN0000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
256KB	0b00110	0xXXXN0000	0x0, 0x4, 0x8, 0xC
512KB	0b00111	0xXXXN0000	0x0, 0x8
1MB	0b01000	0xXXX00000	-
2MB	0b01001	0xXXN00000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
4MB	0b01010	0xXXN00000	0x0, 0x4, 0x8, 0xC
8MB	0b01011	0xXXN00000	0x0, 0x8
16MB	0b01100	0xXX000000	-
32MB	0b01101	0xXN000000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
64MB	0b01110	0xXN000000	0x0, 0x4, 0x8, 0xC
128MB	0b01111	0xXN000000	0x0, 0x8
256MB	0b10000	0xX0000000	-
512MB	0b10001	0xN0000000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
1GB	0b10010	0xN0000000	0x0, 0x4, 0x8, 0xC
2GB	0b10011	0xN0000000	0x0, 0x8
4GB	0b10100	0x00000000	-

For the case where the region size is selected as 4 GB, the region address must be at address 0x00000000.

NOTE: If a memory region address is not aligned to its size, the memory region start address protected by the SMPU is the configured address with the corresponding least significant bits masked. For example, if the size is configured for 16 KB (`SMPU_RCTL[n].SIZE` =0b00010), and the base address is configured for `SMPU_RADDR[n].BADDR`=0x00005018, the actual base address used by the SMPU is 0x00004000. When `SMPU_RADDR[n].BADDR` is read back, the program reads 0x00005000. This functionality is because only bits [11:0] are reserved as 0's. Programs must use care when setting the base address as it is not always the true base address.

SMPU Definitions

To make the best use of the SMPU, it is useful to understand the terms in this section.

Global Protection

Guarding of the entire memory space for the particular SMPU instantiation.

Region-Based Protection

Guarding individual segments of memory inside the memory space for the particular SMPU instantiation.

ID Match

A successful comparison of the ID associated with the incoming transaction and the ID and MASK configured in the SMPU.

SMPU Block Diagram

The ***SMPU Top-Level Block Diagram*** shows the SMPU block.

As seen in the diagram, the SMPU sits between the memory port (SCB master port) and the SCB fabric (SCB slave port). It acts as a gateway analyzing the transaction requests. It either rejects the transaction request or allows access based on the user-programmed configuration of the SMPU.

SMPU Architectural Concepts

The following sections provide brief descriptions of the architecture of the SMPU module.

Default Setting

At reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces.

Latency

The SMPU adds latency to all the transactions to the memory except reads when read speculation is enabled (`SMPU_CTL.RSDIS` =0). In this case, read accesses are always forwarded to the memory and read responses are generated according to the SMPU settings. If read speculation is disabled (`SMPU_CTL.RSDIS` =1), reads are blocked if they cause a security or protection violation. The SMPU generates the SCB read response that corresponds to a blocked transaction.

If read speculation is enabled, the SMPU adds 1 clock cycle latency to the read transaction. If read speculation is disabled, the SMPU adds 2 clock cycles latency to the read transaction.

SMPU Operating Modes

The SMPU does not have any strict modes of operation. However, it can be configured for region-based protection where a master with a particular ID can be blocked or allowed based on settings in the `SMPU_RCTL[n]` register.

Region-based protection is programmed with registers:

- `SMPU_RCTL[n]`
- `SMPU_RADDR[n]`
- `SMPU_RIDA[n]`
- `SMPU_RIDMSKA[n]`
- `SMPU_RIDB[n]`
- `SMPU_RIDMSKB[n]`

Exclusive Accesses. On the ADSP-SC5xx processors, the hardware supports the exclusive accesses. The exclusive accesses are supported for the SMPU instances that correspond to SMC, DMC 0, DMC 1 and Core_L2_0. The exclusive accesses are automatically enabled when one of the cores (ARM Core 0, SHARC+ Core 1, and SHARC+ Core 2) executes the exclusive access instruction. Refer to the Programming Reference manual for more details on how the exclusive access works.

SMPU Interrupt Signals

There is one interrupt signal associated with the SMPU. If interrupts are enabled, the `SMPU_STAT.IRQ` bit is set. The SMPU_IRQ signal is asserted when the SMPU detects a memory access violation. The target address triggering the interrupt is found in the `SMPU_IADDR` register. The `SMPU_IDTLS` register provides further details about the cause of the interrupt.

Write errors are prioritized over read errors.

Protection violations (an ID-based violation) can trigger the SMPU interrupt, and can be enabled independently. The protection violation interrupt is enabled by setting the `SMPU_CTL.PINTEN` bit.

The SMPU interrupt is asserted for any of the following conditions:

If a second memory access violation occurs while the `SMPU_STAT.IRQ` bit is set, the `SMPU_STAT.IOVR` (interrupt overrun) bit is set. The `SMPU_IADDR` and the `SMPU_IDTLS` registers are not updated until the `SMPU_STAT.IRQ` bit is cleared. Any information on the subsequent interrupt is lost. Once the `SMPU_STAT.IRQ` bit and the `SMPU_STAT.IOVR` bit are cleared, any new memory access violations can trigger an interrupt and its details can be captured.

NOTE: When a blocked access occurs, the SMPU triggers an interrupt when interrupt generation is enabled. The SMPU can also be configured to generate a bus error that propagates back to the system master. The system master can also trigger an interrupt due to this bus error.

NOTE: On the processor, each SMPU instance has an interrupt. All of the SMPU interrupts are OR'ed and mapped to a single SMPU interrupt on the SEC/GIC. While servicing the SMPU interrupt, check all of the `SMPU_STAT` registers to determine which triggered the interrupt. The interrupt service routine clears the `SMPU_STAT.IRQ` bit of the all of the `SMPU_STAT` registers for which the interrupt is triggered.

SMPU Status and Error Signals

If bus errors are enabled (`SMPU_CTL.PBEDIS` =0), the SMPU generates and returns a bus error to the master initiating the blocked access. This bit also sets the `SMPU_STAT.BERR` bit. The `SMPU_BADDR` and `SMPU_BDTLS` registers can be read to get the address and details of the transaction that caused the SMPU to generate the error.

Write errors are prioritized over read errors.

A bus error status is returned to the system master if:

- an ID-based violation happened and the `SMPU_CTL.PBEDIS` bit =0

If a second memory access violation occurs while the `SMPU_STAT.BERR` bit is set, the `SMPU_STAT.BEOVR` bit (bus error overrun) is set. The `SMPU_BADDR` and the `SMPU_BDTLS` registers are not updated until the `SMPU_STAT.IRQ` bit is cleared. The information about the transaction that caused the `SMPU_STAT.BEOVR` bit to be set is lost.

NOTE: If both the protection violation interrupt is not enabled (`SMPU_CTL.PINTEN` =0) and the protection bus error is disabled (`SMPU_CTL.PBEDIS` =1), the SMPU blocks invalid transactions. However, it does not provide any status or interrupt information indicating that a transaction is blocked.

SMPU Programming Example

The following example corresponds to using SMPU1 to protect M4 SRAM from MDMA write accesses. In the example the region configured for protection is 4KB at the start of M4 SRAM Bank A.

1. Enable SMPU1 interrupts by writing to the `SMPU_CTL` register.
2. Define the memory region to be protected by writing to the `SMPU_RADDR[n]` register.

```
*pREG_SMPU_RADDR0 = 0x20000000;
```

3. Program the `SMPU_RIDA[n]` and `SMPU_RIDB[n]` registers with the ID which is to be an exception to the rule.

```
*pREG_SMPU_RIDA0 = 0x0081; //corresponds to MDMA_WR
*pREG_SMPU_RIDB0 = 0x0081;
```

4. Program the `SMPU_RIDMSKA[n]` and`SMPU_RIDMSKB[n]` registers with the mask to be applied to the ID values programmed in the `SMPU_RIDA[n]` and `SMPU_RIDB[n]` registers respectively.

```
*pREG_SMPU_RIDMSKA0 = 0xFFFF;
*pREG_SMPU_RIDMSKB0 = 0xFFFF;
```

5. Program the Region Control register (`SMPU_RCTL[n]` register) with the required fields. Control fields like ID invert, write protection enable, read protection enable and memory region size can be configured in this register.

```
*pREG_SMPU_RCTL0 = ENUM_SMPU_RCTL_WPROTEN|ENUM_SMPU_RCTL_RPROTDIS|
BITM_SMPU_RCTL_WIDCINV|BITM_SMPU_RCTL_RIDCINV| ((0<<BITP_SMPU_RCTL_SIZE) &
BITM_SMPU_RCTL_SIZE)
```

6. Set the `SMPU_RCTL[n].EN` bit.

```
*pREG_SMPU_RCTL0  |= BITM_SMPU_RCTL_EN;
```

Any accesses violation to the protection enabled by this procedure will be blocked. If the corresponding interrupt is enabled, an interrupt is generated on protection violations.

ADSP-SC58x SMPU Register Descriptions

The System Memory Protection Unit (SMPU) contains the following registers.

Table 13-5: ADSP-SC58x SMPU Register List

Name	Description
`SMPU_BADDR`	Bus Error Address Register
`SMPU_BDTLS`	Bus Error Details Register
`SMPU_CTL`	SMPU Control Register
`SMPU_EXACADD[n]`	Exclusive Access IDn Address
`SMPU_EXACSTAT[n]`	Exclusive Access Status
`SMPU_IADDR`	Interrupt Address Register
`SMPU_IDTLS`	Interrupt Details Register
`SMPU_RADDR[n]`	Region n Address Register

Table 13-5: ADSP-SC58x SMPU Register List (Continued)

Name	Description
`SMPU_RCTL[n]`	Region n Control Register
`SMPU_REVID`	SMPU Revision ID Register
`SMPU_RIDA[n]`	Region n ID A Register
`SMPU_RIDB[n]`	Region n ID B Register
`SMPU_RIDMSKA[n]`	Region n ID Mask A Register
`SMPU_RIDMSKB[n]`	Region n ID Mask B Register
`SMPU_SECURECTL`	SMPU Control Secure Accesses Register
`SMPU_SECURERCTL[n]`	Region n Control Secure Accesses Register
`SMPU_STAT`	SMPU Status Register

Bus Error Address Register

Programs read the `SMPU_BADDR` and the `SMPU_BDTLS` registers to determine the cause of a bus error. Write errors are prioritized over read errors.

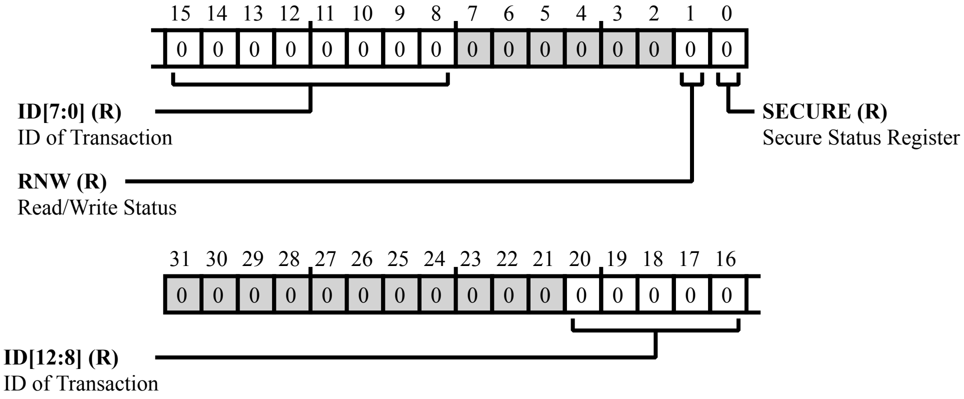
Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Bus Error Address. The `SMPU_BADDR.VALUE` bit field contains the address of the bus error.

Bus Error Details Register

The SMPU_BDTLS register indicates the ID of the bus error transaction, whether the transaction that caused the last bus error was a read, a write, secure or non-secure.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

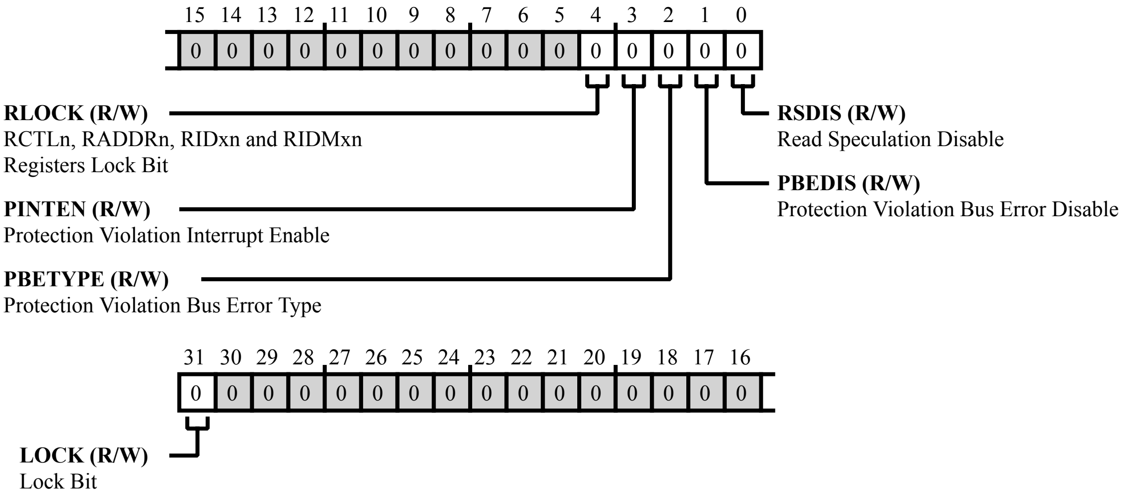
Table 13-7: SMPU_BDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	ID of Transaction. The `SMPU_BDTLS.ID` bit field provides the ID of the transaction that caused the bad address error.	
1 (R/NW)	RNW	Read/Write Status. The `SMPU_BDTLS.RNW` bit indicates whether the last transaction that caused the bad address error was a read or write.	
		0	Transaction that caused last bus error was a write
		1	Transaction that caused last bus error was a read
0 (R/NW)	SECURE	Secure Status Register. The `SMPU_BDTLS.SECURE` bit indicates whether the last transaction that caused the bad address error was secure or non-secure.	
		0	Transaction that caused last bus error was non-secure
		1	Transaction that caused last bus error was secure

SMPU Control Register

The `SMPU_CTL` register provides access to the locking control, error interrupts and SMPU violations.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

PBEDIS (R/W)
Protection Violation Bus Error Disable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LOCK (R/W)
Lock Bit

Figure 13-4: SMPU_CTL Register Diagram

Table 13-8: SMPU_CTL Register Fields

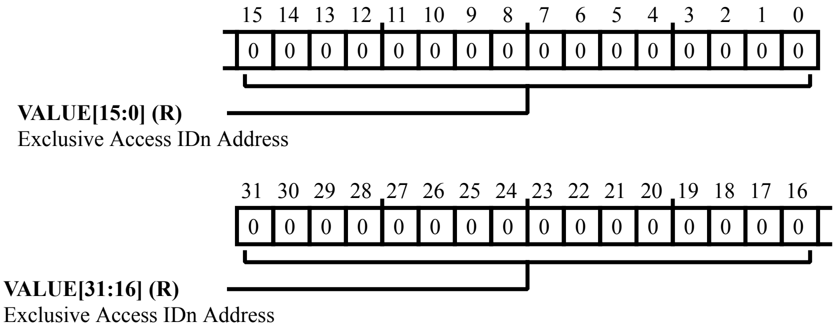
Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the `SMPU_CTL.LOCK` bit is set and the global lock signal is asserted from the SPU, the `SMPU_CTL` register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	CTL Global Lock Disable. The `SMPU_CTL` register is not write-protected.
		1	CTL Global Lock Enable. The `SMPU_CTL` register is write-protected.
4 (R/W)	RLOCK	RCTLn, RADDRn, RIDxn and RIDMxn Registers Lock Bit. When the `SMPU_CTL.RLOCK` bit is set, all the registers associated with region-based control (`SMPU_RCTL[n]`, `SMPU_RADDR[n]`, `SMPU_RIDA[n]`, `SMPU_RIDB[n]`, `SMPU_RIDMSKA[n]` and `SMPU_RIDMSKB[n]`) are write-protected when the global lock signal is active from the SPU. Write access is allowed again when the global lock signal is deasserted.	
		0	Region Registers Write-Protect Enable. All region registers are not write-protected.
		1	Region Registers Write-Protect Disable. All region registers are write-protected.

Table 13-8: SMPU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	PINTEN	Protection Violation Interrupt Enable. The `SMPU_CTL.PINTEN` bit controls whether or not an interrupt is generated when a protection violation occurs.	
		0	Protection Violation IRQ Disable. The protection violation interrupt is disabled.
		1	Protection Violation IRQ Enable. The protection violation interrupt is enabled.
2 (R/W)	PBETYPE	Protection Violation Bus Error Type. The `SMPU_CTL.PBETYPE` bit controls whether a protection violation produces a decode error or a slave error.	
		0	Decode Error Type. Decode error for transactions that violate the configured protection.
		1	Save Error Type. Slave Error for transactions which violate the configured protection
1 (R/W)	PBEDIS	Protection Violation Bus Error Disable. If set, the `SMPU_CTL.PBEDIS` bit blocks protection violations, but does not cause a bus error.	
		0	Bus Error Generation Enable. Transactions which violate the configured protection are blocked and cause a bus error.
		1	Bus Error Generation Disable. Transactions which violate the configured protection are blocked but do not cause a bus error.
0 (R/W)	RSDIS	Read Speculation Disable. The `SMPU_CTL.RSDIS` bit controls whether or not the read addresses are checked before being sent to the slave.	
		0	Read Speculation Enable. Read addresses are sent to the slave without checking.
		1	Read Speculation Disable. Read addresses are checked before being sent to the slave.

Exclusive Access IDn Address

The `SMPU_EXACADD[n]` register provides the address ID of an exclusive access.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit No. (Access)	Bit Name	Description/Enumeration
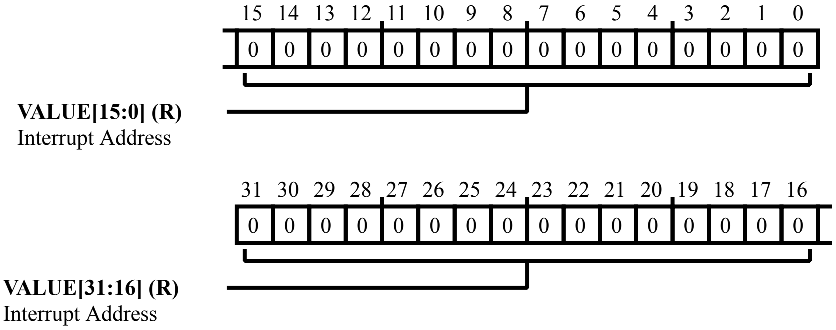
20:8 (R/NW)	ARID	Exclusive Access ID.
7:5 (R/NW)	ARSIZE	Exclusive Access Read Size.
4:1 (R/NW)	ARLEN	Exclusive Access Read Length.
0 (R/NW)	VALID	Valid Exclusive Access Read.

Interrupt Address Register

The `SMPU_IADDR` register indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The SMPU issues a bus error for this condition.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R)
Interrupt Address

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R)
Interrupt Address

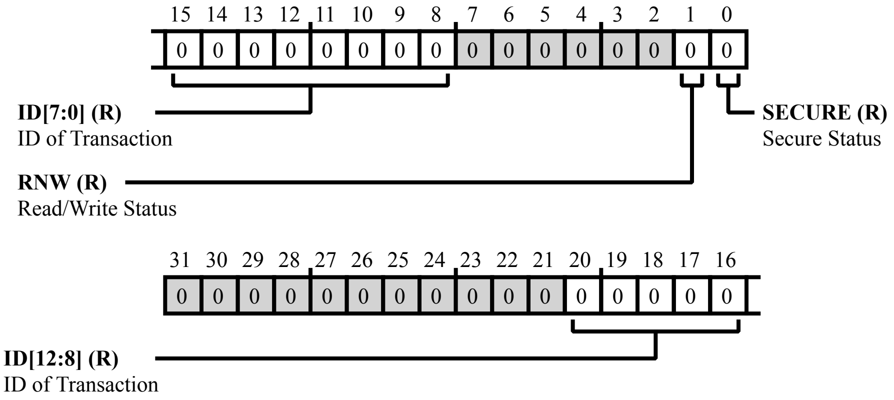
Figure 13-7: SMPU_IADDR Register Diagram

Table 13-11: SMPU_IADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Interrupt Address. The `SMPU_IADDR.VALUE` bit field is the address where an attempt to access an unimplemented address or a non-aligned access has occurred.

Interrupt Details Register

The `SMPU_IDTLS` register provides the ID of the last signaled interrupt, whether the interrupt was caused by a read or write, and whether the transaction that caused the last signaled interrupt was secure.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

ID[12:8] (R)
ID of Transaction

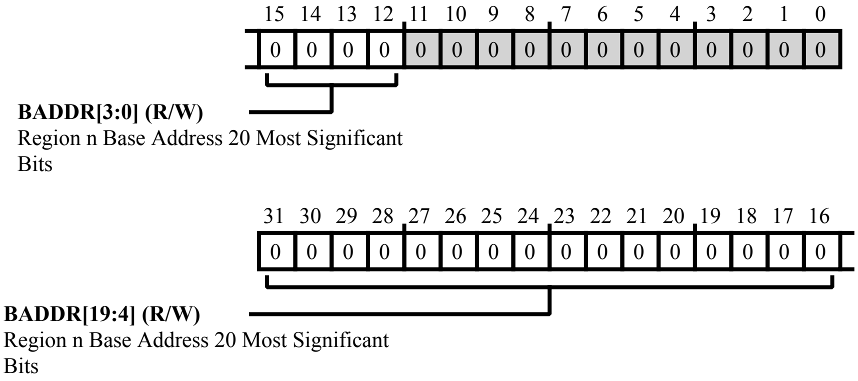
Figure 13-8: SMPU_IDTLS Register Diagram

Table 13-12: SMPU_IDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	ID of Transaction. The `SMPU_IDTLS.ID` bit field provides the ID of the transaction that caused the interrupt.	
1 (R/NW)	RNW	Read/Write Status. The `SMPU_IDTLS.RNW` bit indicates whether the last transaction that caused the interrupt was a read or write.	
		0	Transaction that caused last signaled interrupt was a write
		1	Transaction that caused last signaled interrupt was a read
0 (R/NW)	SECURE	Secure Status. The `SMPU_IDTLS.SECURE` bit indicates whether the last transaction that caused the interrupt was secure or non-secure.	
		0	Transaction that caused last signaled interrupt was non-secure
		1	Transaction that caused last signaled interrupt was secure

Region n Address Register

The `SMPU_RADDR[n]` register is used to define the base address for a memory region to be protected.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BADDR[19:4] (R/W)
Region n Base Address 20 Most Significant Bits

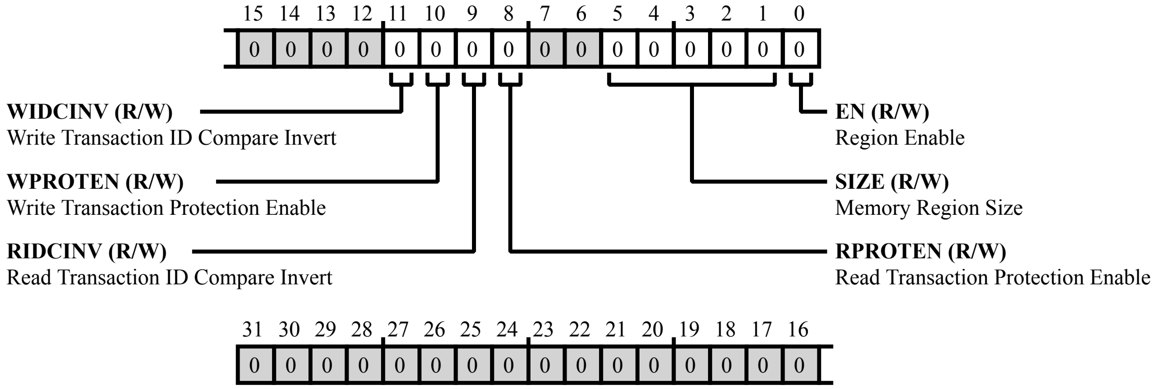
Figure 13-9: SMPU_RADDR[n] Register Diagram

Table 13-13: SMPU_RADDR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/W)	BADDR	Region n Base Address 20 Most Significant Bits. The `SMPU_RADDR[n].BADDR` bit field defines the base address for a memory region to be protected.

Region n Control Register

The `SMPU_RCTL[n]` register is used to define the level of protection for a region of memory. The protection of a region is controlled and defined by this register and the `SMPU_RADDR[n]`, `SMPU_RIDA[n]`, `SMPU_RIDB[n]`, `SMPU_RIDMSKA[n]`, and `SMPU_RIDMSKB[n]` registers.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

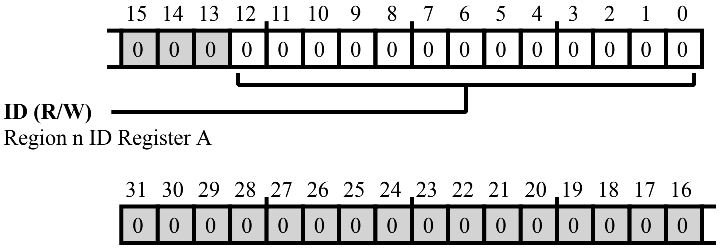
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

Region n ID A Register

The SMPU_RIDA[n] register is used for ID comparison 'A'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more detail, refer to the ID Comparison section.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	ID	Region n ID Register A. The `SMPU_RIDA[n].ID` bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID B Register

The `SMPU_RIDB[n]` register is used for ID comparison 'B'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more details, refer to the ID Comparison section.

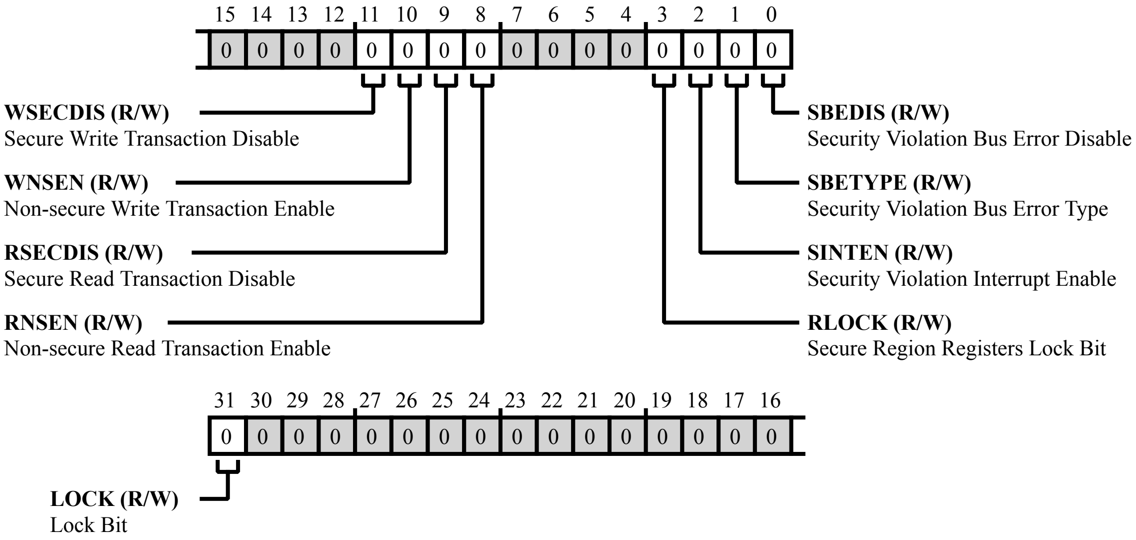
SMPU Control Secure Accesses Register

The `SMPU_SECURECTL` register provides the bits required to set up the security settings for the processor. These settings includes error generation and read/write security.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

LOCK (R/W)
Lock Bit

Figure 13-16: SMPU_SECURECTL Register Diagram

Table 13-20: SMPU_SECURECTL Register Fields

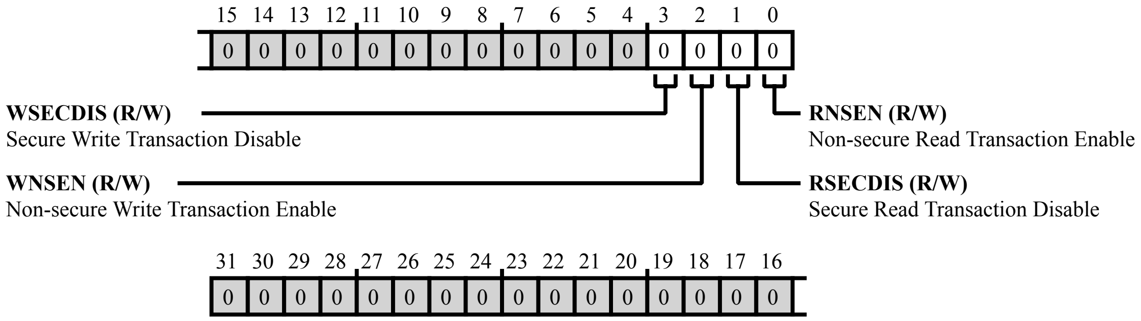
Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the `SMPU_SECURECTL.LOCK` bit is set and the global lock signal is asserted from the SPU, the `SMPU_SECURECTL` register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	`SMPU_SECURECTL` is not write-protected
		1	`SMPU_SECURECTL` is write-protected
11 (R/W)	WSECDIS	Secure Write Transaction Disable. The `SMPU_SECURECTL.WSECDIS` bit disables secure write transactions.	
		0	Enable secure write transactions
		1	Disable secure write transactions
10 (R/W)	WNSEN	Non-secure Write Transaction Enable. The `SMPU_SECURECTL.WNSEN` bit enables non-secure write transactions.	
		0	Disable non-secure writes
		1	Enable non-secure writes

Table 13-20: SMPU_SECURECTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RSECDIS	Secure Read Transaction Disable. The `SMPU_SECURECTL.RSECDIS` bit disables secure read transactions.	
		0	Enable secure read transactions
		1	Disable secure read transactions
8 (R/W)	RNSEN	Non-secure Read Transaction Enable. The `SMPU_SECURECTL.RNSEN` bit enables non-secure read transactions.	
		0	Disable non-secure read transactions
		1	Enable non-secure read transactions
3 (R/W)	RLOCK	Secure Region Registers Lock Bit. When the `SMPU_SECURECTL.RLOCK` bit is set, the secure region control registers, `SMPU_SECURERCTL[n]`, are write-protected when the global lock signal is active from the SPU. When the global lock signal is deasserted, write access is allowed again.	
		0	Disable write-protection on secure region registers
		1	Enable write-protection on secure region registers
2 (R/W)	SINTEN	Security Violation Interrupt Enable. The `SMPU_SECURECTL.SINTEN` bit enables interrupt generation when a security violation occurs.	
		0	Disable security settings violation interrupt
		1	Enable security settings violation interrupt
1 (R/W)	SBETYPE	Security Violation Bus Error Type. The `SMPU_SECURECTL.SBETYPE` bit controls whether a decode error or a slave error is returned when a security violation occurs.	
		0	Return a decode error error which violates the security settings
		1	Return a slave error which violates the security settings
0 (R/W)	SBEDIS	Security Violation Bus Error Disable. The `SMPU_SECURECTL.SBEDIS` bit controls whether or not a bus error is caused when a security violation occurs.	
		0	Enable bus error
		1	Disable bus error

Region n Control Secure Accesses Register

The `SMPU_SECURERCTL[n]` register contains bits that configure read/write security for a specific region.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 13-22: SMPU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The `SMPU_STAT.LWERR` bit is set when `SMPU_CTL.LOCK` bit =1, the global lock signal is asserted from the SPU and a read or write attempt was made to the SMPU_CTL MMR.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The `SMPU_STAT.ADRERR` bit is set when the SMPU MMR is accessed as an unaligned address, or when a read-only MMR is written to.	
		0	No Address Error
		1	Address Error
3 (R/W1C)	BEOVR	Bus Error Overrun. The `SMPU_STAT.BEOVR` bit indicates that another bus error had occurred. Any new information about the most recent violation which caused the bus error is not captured.	
		0	No Bus Error overrun
		1	Bus Error overrun has occurred

Table 13-22: SMPU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	BERR	Bus Error. This `SMPU_STAT.BERR` bit indicates if a bus error was generated.	
		0	No Bus Error since this bit has been cleared
		1	Bus Error has been generated
1 (R/W1C)	IOVR	Interrupt Overrun. The `SMPU_STAT.IOVR` bit indicates if another violation occurred while the previous violation interrupt was not finished being serviced. Information about the most recent violation is then not captured.	
		0	No Interrupt overrun
		1	Interrupt overrun has occurred
0 (R/W1C)	IRQ	Interrupt Request. The `SMPU_STAT.IRQ` bit provides an indication that an interrupt has been generated.	
		0	No Interrupt since this bit has been cleared
		1	Interrupt has been generated

14 General-Purpose Ports (PORT)

This section describes general-purpose ports, pin multiplexing, general-purpose input/output (GPIO) functionality, and pin interrupts. The general-purpose ports provide the following three functions:

- Pin multiplexing scheme
- GPIO functionality
- Pin interrupt requests

NOTE: In this chapter, the naming convention for registers and bits omits the alphabetic group enumeration to refer to any and all of the ports. For example, `PORT_FER` represents registers `PORTA_FER`, `PORTB_FER`, and so on. Likewise `PORT_FER.PX1` represents bits PA1, PB1, and so on.

Figure 14-1: Simplified GPIO and Pin Interrupt Signal Flow

PORT Features

The PORTs include the following features:

- Input mode, output mode, and open-drain mode of GPIO operation
- Port multiplexing controlled on a pin-by-pin basis
- No external glue hardware required for unused pins
- All port pins provide interrupt request functionality
- Byte-wide pin-to-interrupt request assignment

PORT Functional Description

The number of ports and each's composition are defined in the processor datasheet. Each port has a dedicated set of MMR registers that control pin functions and operates in general-purpose I/O (GPIO) mode by default, as controlled by the port-specific `PORT_FER` register. Each bit in this register, as well as the other PORT MMRs, represents a specific GPIO pin on the specified port.

Input Mode, Output Mode, and Open-Drain Mode of GPIO Operation

At reset, every GPIO pin defaults to input mode with the input drivers disabled. To enable any GPIO input driver, set the bits corresponding to the individual pins in the appropriate input enable register (`PORT_INEN`).

The GPIO output drivers are enabled by setting the corresponding bits in the direction registers (`PORT_DIR`).

The PORT can use every GPIO in open-drain mode by clearing the respective bit in the `PORT_DATA` register or setting the respective bit in the `PORT_DATA_CLR` register. Then, set the corresponding bit in the `PORT_INEN` register. Read from the `PORT_DATA` register to obtain the status from the pin.

Port Multiplexing Controlled on Pin-by-Pin Basis

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (`PORT_FER`) registers and the 32-bit port multiplexing (`PORT_MUX`) registers.

All Port Pins Provide Interrupt Functionality

Pin interrupts are completely decoupled from GPIO functionality. Pins are connected to the system event controller (SEC) via the PINTx modules, each of which is configurable in terms of which port pins are sensed for interrupt generation.

ADSP-SC58x PORT Register List

The PORT module (PORT) regulates the use of the multiplexable processor pins. Every port pin can operate in general-purpose I/O (GPIO) mode or as an alternate function. This GPIO operation is the default after processor reset and is controlled by a set of registers that control GPIO functionality. Every bit in these registers represents a certain GPIO pin of a specific port. For more information on PORT functionality, see the PORT register descriptions.

Table 14-1: ADSP-SC58x PORT Register List

ADSP-SC58x PINT Register List

The Pin Interrupt module (PINT) controls the pin-to-interrupt assignment in a byte-wide manner. The pin-interrupt assignment registers do not consist of 32 individual bits. They consist of four control bytes, each functioning as a multiplexer control. For more information, see the PINT register descriptions.

All PINT registers are 32 bits wide and can be accessed by 32-bit load/store instructions. They also support 16-bit operation where the upper 16 bits are ignored and the application uses the lower 16 bits only. Consequently, all PINT registers support 32-bit accesses as well as 16-bit accesses for the lower half words. Applications may use faster 16-bit accesses as long as they do not require functionality of upper register halves.

Table 14-2: ADSP-SC58x PINT Register List

PORT Architectural Concepts

These sections describe in more detail how the PORT module connects externally to pins and internally to the MMR bus. Ports are named alphabetically beginning with A.

- Internal Interfaces
- External Interfaces
- GPIO Functionality
- Port Multiplexing Control

Internal Interfaces

All of the pin multiplexing, GPIO, and pin interrupt control block MMRs can be accessed through the MMR bus. There is no DMA support. Each of the pin interrupt (PINTx) modules has its own dedicated interrupt request output signal that connects directly to the system event controller (SEC).

External Interfaces

The pin multiplexing hardware can be seen as a layer between the on-chip peripherals and the silicon pads connecting to the physical pins/balls or the package, as controlled by the PORT unit.

GPIO Functionality

By default, the PORT sets every GPIO pin to input mode. The input drivers are not enabled, which avoids the need for unnecessary current sinks and external termination resistors on unused pins.

Input Mode

The default mode of every GPIO pin after reset is input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the bits corresponding to the PORT pins in the appropriate input enable register (`PORT_INEN`). When enabled, a read from the `PORT_DATA` register returns the logical state of the input pins.

However, the input signal does not overwrite the state of the internal flip-flop used for providing output to the same pin. Only software can alter the state. If the input driver is enabled, a write to the `PORT_DATA` register can alter the state of the flip-flop, but the change cannot be read back.

Output Mode

Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the bits corresponding to the PORT pins in the appropriate direction register. The PORT implements direction registers as a pair of write-1-to-set (W1S) and write-1-to-clear (W1C) MMRs called `PORT_DIR_SET` and `PORT_DIR_CLR`, respectively. As such, software can alter the direction of the signal flow on individual GPIO pins without impacting other GPIOs on the same port.

Both the `PORT_DIR_SET` and `PORT_DIR_CLR` registers return the same value when read, and a logical 1 indicates an enabled output. The `PORT_DATA` registers control the state of output pins. A logical 0 drives the output low while a logical 1 drives the output high.

While writes to the `PORT_DATA` register can alter all of the GPIOs on a specific port at once, there are also a pair of W1S and W1C MMRs called `PORT_DATA_SET` and `PORT_DATA_CLR`, respectively. These registers enable the manipulation of individual GPIO outputs. The state of the outputs can be obtained by reading the `PORT_DATA` registers. Because the state of the GPIO output can be controlled before the output driver is enabled, set or clear the internal flip-flop first by programming this register to avoid volatile levels on the output pin.

Open-Drain Mode

Every GPIO can also be used in open-drain mode. First, either clear the respective bit in the `PORT_DATA` register or set the respective bit in the `PORT_DATA_CLR` register. Then, set the appropriate bit in the `PORT_INEN` register. Read from the `PORT_DATA` register to return the status from the pin rather than the state of the internal flip-flop.

By toggling the output driver through the `PORT_DIR_SET` and `PORT_DIR_CLR` register pair, the output signal can be pulled low or three-stated, as required. The polarity of the driven signal can be inverted when the internal flip-flop is set. When using a GPIO port in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pins.

Port Multiplexing Control

To configure pins properly, consult the processor datasheet to determine which bits in the `PORT_FER` and `PORT_MUX` register map to the pin of interest, and then set these registers appropriately for the desired function.

After reset, all port pins default to GPIO input mode with their output and input drivers disabled. As a result, all unused port pins can be left unconnected. Disabled pins appear as high-impedance to external circuits.

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (`PORT_FER`) registers and the 32-bit port multiplexing (`PORT_MUX`) registers.

The function enable register specifies whether the pin is used as a GPIO pin or allocated for use by a specific peripheral, but it does not specify what the peripheral function is. Each bit in the 16-bit `PORT_FER` register corresponds to an individual port pin. For example, if bit 1 (PA1) of the `PORTA_FER` register is cleared, the PA_01 pin is configured as a GPIO. When set, one of the available peripheral functions becomes active on the PA_01 pin instead.

Pairs of bits in the `PORT_MUX` register control the multiplexing between the peripheral functions available to an individual pin, as some PORT pins provide up to four possible peripheral functions.

Refer to the Signal Muxing table in the datasheet for the specific `PORT_MUX` settings.

PORT Event Control

The following sections describe event generation in the PORT module.

PORT Interrupt Signals

The pin interrupts are decoupled from GPIO functionality, providing the following advantages.

- Flexible mapping scheme enables pins from up to four different ports to be grouped into one common interrupt scheme.
- Interrupt requests work on input and output pins regardless of whether the pin is functioning as a GPIO or a peripheral.

The processor has a number of interrupt channels dedicated to pin interrupts, managed by a set of pin interrupt (PINTx) blocks. Each PINTx block can sense up to 32 GPIO pins, as described in the following list and figure.

- PINT0 can sense pin activity on PORTA and PORTB
- PINT1 can sense pin activity on PORTB and PORTC
- PINT2 can sense pin activity on PORTC and PORTD
- PINT3 can sense pin activity on PORTD and PORTE
- PINT4 can sense pin activity on PORTE and PORTF
- PINT5 can sense pin activity on PORTF and PORTG. Note that PORTF and PORTG are not available on the low pin count package.

The processor supports both 32-bit and 16-bit peripheral bus accesses to PINTx registers.

Figure 14-3: ADSP-SC57x/SC58x PINTx Block Diagram

As shown in the ***PINTx Block Diagram***, each port is subdivided into two 8-pin half ports, upper (`PxH`) and lower (`PxL`). The `PINT_ASSIGN` registers control the 8-bit multiplexers associated with these half ports, where the lower half units (eight pins) can be forwarded to either byte 0 or byte 2 of the PINTx blocks, and the upper half units (eight pins) can be forwarded to either byte 1 or byte 3 of the PINTx blocks.

When a half port is assigned to a byte in any PINTx block, the state of the eight pins appears in the `PINT_PINSTATE` register, regardless of whether the pin is enabled for GPIO or peripheral functions (input or output). When neither the input nor output drivers of the pin are enabled, the pin state is read as zero. The `PINT_PINSTATE` register reports the inverted state of the pin when the `PINT_INV_SET` register activates the signal inverter. The inverter can be enabled on an individual bit-by-bit basis. Each bit in the `PINT_INV_SET`/ `PINT_INV_CLR` register pair represents a pin signal.

By default, PORT interrupt request generation is level-sensitive, and an interrupt request occurs when the enabled pin is sensed as active high. Use the `PINT_EDGE_SET` register to change the interrupt request genearion scheme to instead be edge-sensitive (rising edge generates the interrupt request). Use the `PINT_INV_SET` register to invert the polarity such that the PINTx block generates the interrupt request on active-low signals or falling edges.

The PINTx modules also assist when both signal edges must generate unique interrupt requests. If two different interrupt requests are required, the `PINT_ASSIGN` registers can route a single input signal to two different PINTx blocks, where one block inverts the signal in the `PINT_INV_SET` register and the other one does not. In this fashion, a unique software routine is associated with the hardware PINTx block that is generating the unique interrupt request for each signal edge. When both signal edges can be serviced by the same interrupt request, each half port can be routed to two separate bytes within a single PINTx block using the `PINT_ASSIGN` register, and then one of the half ports needs to have the inversion enabled in the `PINT_INV_SET` register. The servicing software routine can then detect from the `PINT_LATCH` register whether a falling, rising, or both edges have occurred.

Regardless of whether level-sensitive or edge-sensitive mode is used, the hardware always latches an interrupt request. Latched signals can be read from the `PINT_LATCH` registers. Only a software or hardware reset clears the latches. To clear the latch, a W1C operation must be performed to the `PINT_REQ` or `PINT_LATCH` register. When in level-sensitive mode, the interrupt request remains asserted if the pin state does not change by the time the interrupt service routine exits.

Because every PINTx block groups up to 32 pin signals, the `PINT_MSK_SET`/ `PINT_MSK_CLR` register pair can control which of the signals can request an interrupt at the system level. Software can interrogate the `PINT_REQ` register for signaling pins. The `PINT_REQ` bits represent a logical AND between the mask and the latch. When any of these bits is set, the block output interrupt request is asserted.

PORT Programming Model

The ***GPIO Programming Model Flow (Part 1)***, ***GPIO Programming Model Flow (Part 2)***, and ***GPIO Programming Model Flow (Part 3)*** figures show the programming model for the general-purpose ports. This programming includes the GPIO input and output operation, open-drain mode, and the pin interrupt PINTx modules.

> **NOTE:** These process flow diagrams connect where call-out letters appear. For example, call-out A in the ***GPIO Programming Model Flow (Part 1)*** diagram connects to call-out A in the ***GPIO Programming Model Flow (Part 2)*** diagram.

The following flowcharts describe the processes for setting up pins for various functions. Begin the process from the start label in the ***GPIO Programming Model Flow (Part 1)*** figure. The first decision (GPIO or peripheral) determines how to program the `PORT_FER` register. Set the bit(s) corresponding to the pin(s) to 1 to enable peripheral functionality or to 0 to enable GPIO mode. For more information on setting up for peripheral functions, refer to Port Multiplexing Control.

If the pin is to be a GPIO pin, a subsequent series of decisions must be made that will impact how the `PORT_DATA`, `PORT_POL`, `PORT_DIR`, and `PORT_INEN` configuration registers must be programmed. Depending on the type of GPIO pin desired, some configurations do not apply and can have different meanings. The following paragraphs briefly describe the function of the different settings for each of the pin functions in the input, output, and open-drain GPIO modes. It is a best practice to use the SET or CLR versions of the PORT registers, where applicable, to effect changes on a pin-by-pin basis rather than on the full port.

For more detailed descriptions of the configurations, see PORT Register Descriptions.

For output mode, first clear the `PORT_DATA` register to set all the pins low. Then write the `PORT_DIR` register to define the direction of each pin (set the bits associated with the desired output pins to 1). In output mode, the other registers are not significant. The ***GPIO Programming Model Flow (Part 1)*** chart shows this flow starting at label 2.

Figure 14-4: GPIO Programming Model Flow (Part 1)

For input mode, first decide the polarity for each pin using the `PORT_POL` register. Program the `PORT_DIR` register to define the appropriate pins as inputs (write a 0 to the bit location associated with the pin). If interrupt requests are desired, configure the PINT module as shown in the ***GPIO Programming Model Flow (Part 3)*** figure starting at label B. Finally, write the `PORT_INEN` register to enable the associated input drivers. The ***GPIO Programming Model Flow (Part 2)*** chart shows this entire flow starting at label 3.

For open-drain mode, set all pins low by clearing the `PORT_DATA` register. Then, use the `PORT_INEN` register to enable the appropriate input drivers. Set the `PORT_DIR` register in this mode to indicate whether the pin is in an active state or not (active being 0). The ***GPIO Programming Model Flow (Part 2)*** chart shows this flow starting at label 4.

`PORT_POL_SET`	Port x GPIO Polarity Invert Set Register

Port x GPIO Data Register

The operation of the PORT_DATA register depends on whether the bit/pin is in output mode or input mode. In both modes, a set bit in the PORT_DATA register corresponds to a signal high on a GPIO pin. A cleared bit in the PORT_DATA register corresponds to a signal low on a GPIO pin.

The PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers control the state of GPIO pins in output mode. To enable output mode (and output drivers), use the PORT_DIR_SET and PORT_DIR_CLR registers.

Writes to the PORT_DATA register affect the state of all pins of the port that are in output mode. To set or clear specific pins without impacting other pins of the port, use the PORT_DATA_SET and PORT_DATA_CLR registers.

When the GPIO pins are in input mode (input driver is enabled with the PORT_INEN register), reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the state of the respective GPIO pins.

Note that when the input driver is not enabled, reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the value previously written to the registers.

Table 14-8: PORT_DATA Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Data. The `PORT_DATA.PX15` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
14 (R/W)	PX14	Port x Bit 14 Data. The `PORT_DATA.PX14` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
13 (R/W)	PX13	Port x Bit 13 Data. The `PORT_DATA.PX13` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
12 (R/W)	PX12	Port x Bit 12 Data. The `PORT_DATA.PX12` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
11 (R/W)	PX11	Port x Bit 11 Data. The `PORT_DATA.PX11` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
10 (R/W)	PX10	Port x Bit 10 Data. The `PORT_DATA.PX10` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
9 (R/W)	PX9	Port x Bit 9 Data. The `PORT_DATA.PX9` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Table 14-8: PORT_DATA Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PX8	Port x Bit 8 Data. The `PORT_DATA.PX8` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
7 (R/W)	PX7	Port x Bit 7 Data. The `PORT_DATA.PX7` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
6 (R/W)	PX6	Port x Bit 6 Data. The `PORT_DATA.PX6` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
5 (R/W)	PX5	Port x Bit 5 Data. The `PORT_DATA.PX5` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
4 (R/W)	PX4	Port x Bit 4 Data. The `PORT_DATA.PX4` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
3 (R/W)	PX3	Port x Bit 3 Data. The `PORT_DATA.PX3` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
2 (R/W)	PX2	Port x Bit 2 Data. The `PORT_DATA.PX2` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Port x GPIO Output Toggle Register

The `PORT_DATA_TGL` register permits toggling the state of output GPIO pins. Setting bits in the `PORT_DATA_TGL` register affects the state of specific pins without impacting other pins of the port.

Reading the `PORT_DATA_TGL` returns the state of the `PORT_DATA` register output pin state, but does not return the input pin/signal state.

Port x GPIO Direction Register

The `PORT_DIR`, `PORT_DIR_SET`, and `PORT_DIR_CLR` registers select output or input mode for GPIO pins and enable output drivers. Use the `PORT_INEN`, `PORT_INEN_SET`, and `PORT_INEN_CLR` registers to enable or disable input drivers.

Writes to the `PORT_DIR` register affect the state of all pins of the port. To select a direction for specific pins without impacting other pins of the port, use the `PORT_DIR_SET` and `PORT_DIR_CLR` registers.

Setting a bit in the `PORT_DIR` register enables output mode on the corresponding a GPIO pin. Clearing a bit in the `PORT_DIR` register disables output mode on the corresponding GPIO pin.

Input Mode - The default mode of every GPIO pin after reset is the input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the corresponding bits in the `PORT_INEN` register. When enabled, a read from the `PORT_DATA` register returns the logical state of the input pin. The input signal does not overwrite the state of the bit used for the output case. That state can only be altered by software. If the input driver is enabled, a write to the `PORT_DATA` register can alter the state of the bit, but the change cannot be read back.

Output Mode - Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the corresponding bits in the `PORT_DIR`, `PORT_DIR_SET`, or `PORT_DIR_CLR` registers. By using the `PORT_DIR_SET` and `PORT_DIR_CLR` registers, the direction of the signal flow of individual GPIO pins can be altered by separate software threads without mutually impacting other GPIOs on the same port. Both registers return the same value when read. Because the state of the GPIO output can already be controlled before the output driver is enabled, it is recommended to first set or clear the bit (using the `PORT_DATA`, `PORT_DATA_SET`, or `PORT_DATA_CLR` registers) to avoid any volatile levels on the output.

Open-Drain Mode - Every GPIO can also be used in open-drain mode. To accomplish this, first, clear the respective bit in the `PORT_DATA` or `PORT_DATA_CLR` register. Then, set the one bit in the `PORT_INEN` register. Reads from the `PORT_DATA` register then return the status from the pin and do not return the state of the internal flip-flop. By toggling the output driver through the `PORT_DIR_SET` and `PORT_DIR_CLR` register pair, the output signal can be pulled low or three-stated as required. Note that the polarity of the driven signal can be inverted when the internal flip-flop is set instead. When a GPIO port is used in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pin.

		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
5 (R/W)	PX5	Port x Bit 5 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
4 (R/W)	PX4	Port x Bit 4 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
3 (R/W)	PX3	Port x Bit 3 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
2 (R/W)	PX2	Port x Bit 2 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Table 14-12: PORT_DIR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	PX1	Port x Bit 1 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
0 (R/W)	PX0	Port x Bit 0 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Port x GPIO Direction Clear Register

The `PORT_DIR_CLR` register disables output mode and disables the output drivers for GPIO pins. For more information, see the `PORT_DIR` register description.

		0	No Effect
		1	Enable output mode/driver
1 (R/W1S)	PX1	Port x Bit 1 Direction Set. The `PORT_DIR_SET.PX1` bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
0 (R/W1S)	PX0	Port x Bit 0 Direction Set. The `PORT_DIR_SET.PX0` bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver

Port x Function Enable Register

The `PORT_FER` register bits indicate each port bit's operating mode: general purpose I/O mode or peripheral mode. After reset, all pins default to GPIO mode. Setting a bit in the `PORT_FER` registers enables a peripheral module to take ownership of the pin. The function enable bits impact output control only. Regardless of the setting of the function enable bits, both GPIO and peripherals can still sense the pin input. After a function is enabled, it is up to the `PORT_MUX` registers as to which peripheral takes control.

Port x Function Enable Clear Register

The `PORT_FER_CLR` register permits enabling GPIO mode for each bit and corresponding GPIO pin. Writing 1 to a bit in `PORT_FER_CLR` enables GPIO mode for the corresponding pin.

		0	No Effect
		1	Set Bit for Peripheral Mode

Port x GPIO Input Enable Register

The PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers enable or disable input drivers, which are required for using a GPIO pin in input mode.

Writes to the PORT_INEN register affect the input drivers for all pins of the port. To set or clear specific pin drivers without impacting other pin drivers of the port, use the PORT_INEN_SET and PORT_INEN_CLR registers.

If the input is enabled, reads from the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers return the state of the pins. However, the state of the output is not overwritten by the input. It is altered by software writes only. Input and output drivers can be enabled at the same time. In this case, a read of the data register returns the true value of the data register and not the pin state.

For more information, see the PORT_DATA register description and the PORT_DIR register description.

		0	Unlock MUX
		1	Lock MUX
0 (R/W)	FER	Function Enable Lock. The `PORT_LOCK.FER` disables write access to the `PORT_FER`, `PORT_FER_SET`, and `PORT_FER_CLR` registers.	
		0	Unlock FER
		1	Lock FER

Port x Multiplexer Control Register

When a pin is in peripheral mode (not GPIO mode), the `PORT_MUX` register controls which peripheral takes ownership of a pin. Ports may have multiple, different peripheral functions. Two bits are required to describe every multiplexer on an individual pin-by-pin scheme. For example, bit 0 and bit 1 of the `PORT_MUX` register control the multiplexer of pin 0, bit 2 and bit 3 of `PORT_MUX` control the multiplexer of pin 1, and so on. The value of any `PORT_MUX` bit has no effect on the port pins when the associated bit in the `PORT_FER` register is 0 (selects GPIO mode). Even if a port has only one function, the `PORT_MUX` register is still present. For single function ports (no multiplexing is needed), leave the `PORT_MUX` bits at 0 (default). For all `PORT_MUX` bit fields: 00 = default/reset peripheral option, 01 = first alternate peripheral option, 10 = second alternate peripheral option, and 11 = third alternate peripheral option.

See the processor data sheet for details regarding the peripheral options associated with each port.

1:0 (R/W)	MUX0	Mux for Port x Bit 0. The `PORT_MUX.MUX0` bit provides multiplexer control for port x bit 0.

Port x GPIO Polarity Invert Register

The `PORT_POL`, `PORT_POL_SET`, and `PORT_POL_CLR` registers enable or disable inverting polarity of GPIO signals. To invert polarity of peripheral signals, use the inversion selection programming in the signal's corresponding module.

Writes to the `PORT_POL` register affect the polarity inversion selection of all pins of the port. To enable or disable polarity inversion for specific pins without impacting other pins of the port, use the `PORT_POL_SET` and `PORT_POL_CLR` registers.

Setting a bit in the `PORT_POL` register enables polarity inversion on the corresponding inversion GPIO pin, making the pin active-low or falling-edge sensitive. Clearing a bit in the `PORT_POL` register disables polarity (default state) on the corresponding GPIO pin, making it active-high or rising-edge sensitive.

Table 14-23: PORT_POL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Polarity Invert. The `PORT_POL.PX15` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 14-23: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	PX14	Port x Bit 14 Polarity Invert. The `PORT_POL.PX14` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
13 (R/W)	PX13	Port x Bit 13 Polarity Invert. The `PORT_POL.PX13` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
12 (R/W)	PX12	Port x Bit 12 Polarity Invert. The `PORT_POL.PX12` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
11 (R/W)	PX11	Port x Bit 11 Polarity Invert. The `PORT_POL.PX11` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
10 (R/W)	PX10	Port x Bit 10 Polarity Invert. The `PORT_POL.PX10` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
9 (R/W)	PX9	Port x Bit 9 Polarity Invert. The `PORT_POL.PX9` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
8 (R/W)	PX8	Port x Bit 8 Polarity Invert. The `PORT_POL.PX8` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 14-23: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	PX7	Port x Bit 7 Polarity Invert. The `PORT_POL.PX7` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
6 (R/W)	PX6	Port x Bit 6 Polarity Invert. The `PORT_POL.PX6` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
5 (R/W)	PX5	Port x Bit 5 Polarity Invert. The `PORT_POL.PX5` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
4 (R/W)	PX4	Port x Bit 4 Polarity Invert. The `PORT_POL.PX4` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
3 (R/W)	PX3	Port x Bit 3 Polarity Invert. The `PORT_POL.PX3` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
2 (R/W)	PX2	Port x Bit 2 Polarity Invert. The `PORT_POL.PX2` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
1 (R/W)	PX1	Port x Bit 1 Polarity Invert. The `PORT_POL.PX1` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 14-23: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PX0	Port x Bit 0 Polarity Invert. The `PORT_POL.PX0` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Port x GPIO Polarity Invert Clear Register

The PORT_POL_CLR register disables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
0 (R/W1S)	PX0	Port x Bit 0 Polarity Invert Set. The `PORT_POL_SET.PX0` bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

ADSP-SC58x PINT Register Descriptions

The Pin Interrupt module (PINT) contains the following registers.

Table 14-26: ADSP-SC58x PINT Register List

Name	Description
PINT_ASSIGN	PINT Assign Register
PINT_EDGE_CLR	PINT Edge Clear Register
PINT_EDGE_SET	PINT Edge Set Register
PINT_INV_CLR	PINT Invert Clear Register
PINT_INV_SET	PINT Invert Set Register
PINT_LATCH	PINT Latch Register
PINT_MSK_CLR	PINT Mask Clear Register
PINT_MSK_SET	PINT Mask Set Register
PINT_PINSTATE	PINT Pin State Register
PINT_REQ	PINT Request Register

PINT Assign Register

The PINT_ASSIGN register controls the pin-to-interrupt request assignment in a byte-wide manner. This register consists of four control bytes that each function as a multiplexer control.

The PINT ports are subdivided into 8-bit half ports, resulting in lower and upper half 8-bit units. Using the multiplexers controlled by the PINT_ASSIGN register, the lower half units of eight pins can be forwarded to either byte 0 or byte 2 of either associated PINT block. The upper half units can be forwarded to either byte 1 or byte 3 of the PINT block, without further restrictions.

		0	B0MAP_PAL. Byte 0 = PA.L
		1	B0MAP_PBL. Byte 0 = PB.L

PINT Edge Clear Register

The `PINT_EDGE_CLR` register permits selecting level-sensitive interrupts. Writing 1 to a bit in `PINT_EDGE_CLR` enables level sensitivity for the corresponding pin interrupt.

20 (R/W1C)	PIQ20	Pin Interrupt 20 Level. Set the `PINT_EDGE_CLR.PIQ20` bit to enable level sensitivity.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Level. Set the `PINT_EDGE_CLR.PIQ19` bit to enable level sensitivity.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Level. Set the `PINT_EDGE_CLR.PIQ18` bit to enable level sensitivity.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Level. Set the `PINT_EDGE_CLR.PIQ17` bit to enable level sensitivity.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Level. Set the `PINT_EDGE_CLR.PIQ16` bit to enable level sensitivity.

Table 14-28: PINT_EDGE_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Level. Set the `PINT_EDGE_CLR.PIQ15` bit to enable level sensitivity.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Level. Set the `PINT_EDGE_CLR.PIQ14` bit to enable level sensitivity.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Level. Set the `PINT_EDGE_CLR.PIQ13` bit to enable level sensitivity.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Level. Set the `PINT_EDGE_CLR.PIQ12` bit to enable level sensitivity.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Level. Set the `PINT_EDGE_CLR.PIQ11` bit to enable level sensitivity.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Level. Set the `PINT_EDGE_CLR.PIQ10` bit to enable level sensitivity.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Level. Set the `PINT_EDGE_CLR.PIQ9` bit to enable level sensitivity.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Level. Set the `PINT_EDGE_CLR.PIQ8` bit to enable level sensitivity.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Level. Set the `PINT_EDGE_CLR.PIQ7` bit to enable level sensitivity.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Level. Set the `PINT_EDGE_CLR.PIQ6` bit to enable level sensitivity.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Level. Set the `PINT_EDGE_CLR.PIQ5` bit to enable level sensitivity.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Level. Set the `PINT_EDGE_CLR.PIQ4` bit to enable level sensitivity.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Level. Set the `PINT_EDGE_CLR.PIQ3` bit to enable level sensitivity.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Level. Set the `PINT_EDGE_CLR.PIQ2` bit to enable level sensitivity.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Level. Set the `PINT_EDGE_CLR.PIQ1` bit to enable level sensitivity.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Level. Set the `PINT_EDGE_CLR.PIQ0` bit to enable level sensitivity.

PINT Edge Set Register

The `PINT_EDGE_SET` register permits selecting edge-sensitive interrupts. Writing 1 to a bit in `PINT_EDGE_SET` enables edge sensitivity for the corresponding pin interrupt.

Table 14-29: PINT_EDGE_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Edge. Set the `PINT_EDGE_SET.PIQ31` bit to enable edge sensitivity.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Edge. Set the `PINT_EDGE_SET.PIQ30` bit to enable edge sensitivity.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Edge. Set the `PINT_EDGE_SET.PIQ29` bit to enable edge sensitivity.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Edge. Set the `PINT_EDGE_SET.PIQ28` bit to enable edge sensitivity.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Edge. Set the `PINT_EDGE_SET.PIQ27` bit to enable edge sensitivity.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Edge. Set the `PINT_EDGE_SET.PIQ26` bit to enable edge sensitivity.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Edge. Set the `PINT_EDGE_SET.PIQ25` bit to enable edge sensitivity.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Edge. Set the `PINT_EDGE_SET.PIQ24` bit to enable edge sensitivity.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Edge. Set the `PINT_EDGE_SET.PIQ23` bit to enable edge sensitivity.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Edge. Set the `PINT_EDGE_SET.PIQ22` bit to enable edge sensitivity.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Edge. Set the `PINT_EDGE_SET.PIQ21` bit to enable edge sensitivity.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Edge. Set the `PINT_EDGE_SET.PIQ20` bit to enable edge sensitivity.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Edge. Set the `PINT_EDGE_SET.PIQ19` bit to enable edge sensitivity.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Edge. Set the `PINT_EDGE_SET.PIQ18` bit to enable edge sensitivity.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Edge. Set the `PINT_EDGE_SET.PIQ17` bit to enable edge sensitivity.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Edge. Set the `PINT_EDGE_SET.PIQ16` bit to enable edge sensitivity.

Table 14-29: PINT_EDGE_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Edge. Set the `PINT_EDGE_SET.PIQ15` bit to enable edge sensitivity.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Edge. Set the `PINT_EDGE_SET.PIQ14` bit to enable edge sensitivity.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Edge. Set the `PINT_EDGE_SET.PIQ13` bit to enable edge sensitivity.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Edge. Set the `PINT_EDGE_SET.PIQ12` bit to enable edge sensitivity.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Edge. Set the `PINT_EDGE_SET.PIQ11` bit to enable edge sensitivity.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Edge. Set the `PINT_EDGE_SET.PIQ10` bit to enable edge sensitivity.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Edge. Set the `PINT_EDGE_SET.PIQ9` bit to enable edge sensitivity.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Edge. Set the `PINT_EDGE_SET.PIQ8` bit to enable edge sensitivity.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Edge. Set the `PINT_EDGE_SET.PIQ7` bit to enable edge sensitivity.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Edge. Set the `PINT_EDGE_SET.PIQ6` bit to enable edge sensitivity.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Edge. Set the `PINT_EDGE_SET.PIQ5` bit to enable edge sensitivity.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Edge. Set the `PINT_EDGE_SET.PIQ4` bit to enable edge sensitivity.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Edge. Set the `PINT_EDGE_SET.PIQ3` bit to enable edge sensitivity.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Edge. Set the `PINT_EDGE_SET.PIQ2` bit to enable edge sensitivity.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Edge. Set the `PINT_EDGE_SET.PIQ1` bit to enable edge sensitivity.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Edge. Set the `PINT_EDGE_SET.PIQ0` bit to enable edge sensitivity.

PINT Invert Clear Register

The `PINT_INV_CLR` register disables inverting input polarity. Writing 1 to a bit in `PINT_INV_CLR` disables an inverter for input on the corresponding pin.

17 (R/W1S)	PIQ17	Pin Interrupt 17 Invert. Set the `PINT_INV_SET.PIQ17` bit to enable inverted input.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Invert. Set the `PINT_INV_SET.PIQ16` bit to enable inverted input.

Table 14-31: PINT_INV_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Invert. Set the `PINT_INV_SET.PIQ15` bit to enable inverted input.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Invert. Set the `PINT_INV_SET.PIQ14` bit to enable inverted input.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Invert. Set the `PINT_INV_SET.PIQ13` bit to enable inverted input.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Invert. Set the `PINT_INV_SET.PIQ12` bit to enable inverted input.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Invert. Set the `PINT_INV_SET.PIQ11` bit to enable inverted input.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Invert. Set the `PINT_INV_SET.PIQ10` bit to enable inverted input.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Invert. Set the `PINT_INV_SET.PIQ9` bit to enable inverted input.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Invert. Set the `PINT_INV_SET.PIQ8` bit to enable inverted input.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Invert. Set the `PINT_INV_SET.PIQ7` bit to enable inverted input.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Invert. Set the `PINT_INV_SET.PIQ6` bit to enable inverted input.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Invert. Set the `PINT_INV_SET.PIQ5` bit to enable inverted input.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Invert. Set the `PINT_INV_SET.PIQ4` bit to enable inverted input.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Invert. Set the `PINT_INV_SET.PIQ3` bit to enable inverted input.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Invert. Set the `PINT_INV_SET.PIQ2` bit to enable inverted input.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Invert. Set the `PINT_INV_SET.PIQ1` bit to enable inverted input.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Invert. Set the `PINT_INV_SET.PIQ0` bit to enable inverted input.

PINT Latch Register

The `PINT_LATCH` register indicates the interrupt latch status for pin interrupts. When set, an interrupt request is latched. When cleared, there is no interrupt request latched.

Both the `PINT_REQ` and `PINT_LATCH` registers indicate whether an interrupt request is latched on the respective pin. The `PINT_LATCH` register is a latch that operates regardless of the interrupt masks. Bits of the `PINT_REQ` register depend on the mask register. The `PINT_REQ` register is a logical AND of the `PINT_LATCH` register and the interrupt mask.

Having two separate registers here enables the user to interrogate certain pins in polling mode while others work in interrupt mode. The `PINT_LATCH` registers can be used for edge detection or pin activity detection.

Both registers have W1C behavior. Writing a 1 to either register clears the respective bits in both registers. For interrupt operation, the user may prefer to W1C the `PINT_REQ` register (address still loaded in Px pointer). In polling mode, it might be cleaner to W1C the `PINT_LATCH` register.

Whether in edge-sensitive mode or level-sensitive mode, `PINT_LATCH` bits are never cleared by hardware except at system reset. Even in level-sensitive mode, the `PINT_LATCH` register functions as latch.

Table 14-32: PINT_LATCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Latch. If the `PINT_LATCH.PIQ31` bit is set, the request is latched.

Table 14-32: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Latch. If the `PINT_LATCH.PIQ30` bit is set, the request is latched.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Latch. If the `PINT_LATCH.PIQ29` bit is set, the request is latched.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Latch. If the `PINT_LATCH.PIQ28` bit is set, the request is latched.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Latch. If the `PINT_LATCH.PIQ27` bit is set, the request is latched.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Latch. If the `PINT_LATCH.PIQ26` bit is set, the request is latched.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Latch. If the `PINT_LATCH.PIQ25` bit is set, the request is latched.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Latch. If the `PINT_LATCH.PIQ24` bit is set, the request is latched.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Latch. If the `PINT_LATCH.PIQ23` bit is set, the request is latched.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Latch. If the `PINT_LATCH.PIQ22` bit is set, the request is latched.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Latch. If the `PINT_LATCH.PIQ21` bit is set, the request is latched.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Latch. If the `PINT_LATCH.PIQ20` bit is set, the request is latched.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Latch. If the `PINT_LATCH.PIQ19` bit is set, the request is latched.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Latch. If the `PINT_LATCH.PIQ18` bit is set, the request is latched.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Latch. If the `PINT_LATCH.PIQ17` bit is set, the request is latched.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Latch. If the `PINT_LATCH.PIQ16` bit is set, the request is latched.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Latch. If the `PINT_LATCH.PIQ15` bit is set, the request is latched.

Table 14-32: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Latch. If the `PINT_LATCH.PIQ14` bit is set, the request is latched.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Latch. If the `PINT_LATCH.PIQ13` bit is set, the request is latched.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Latch. If the `PINT_LATCH.PIQ12` bit is set, the request is latched.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Latch. If the `PINT_LATCH.PIQ11` bit is set, the request is latched.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Latch. If the `PINT_LATCH.PIQ10` bit is set, the request is latched.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Latch. If the `PINT_LATCH.PIQ9` bit is set, the request is latched.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Latch. If the `PINT_LATCH.PIQ8` bit is set, the request is latched.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Latch. If the `PINT_LATCH.PIQ7` bit is set, the request is latched.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Latch. If the `PINT_LATCH.PIQ6` bit is set, the request is latched.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Latch. If the `PINT_LATCH.PIQ5` bit is set, the request is latched.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Latch. If the `PINT_LATCH.PIQ4` bit is set, the request is latched.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Latch. If the `PINT_LATCH.PIQ3` bit is set, the request is latched.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Latch. If the `PINT_LATCH.PIQ2` bit is set, the request is latched.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Latch. If the `PINT_LATCH.PIQ1` bit is set, the request is latched.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Latch. If the `PINT_LATCH.PIQ0` bit is set, the request is latched.

PINT Mask Clear Register

The `PINT_MSK_CLR` register permits masking (disabling) of interrupt requests. Writing 1 to a bit in `PINT_MSK_CLR` masks the corresponding pin interrupt.

22 (R/W1C)	PIQ22	Pin Interrupt 22 Mask. Set the `PINT_MSK_CLR.PIQ22` bit to disable the interrupt.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Mask. Set the `PINT_MSK_CLR.PIQ21` bit to disable the interrupt.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Mask. Set the `PINT_MSK_CLR.PIQ20` bit to disable the interrupt.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Mask. Set the `PINT_MSK_CLR.PIQ19` bit to disable the interrupt.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Mask. Set the `PINT_MSK_CLR.PIQ18` bit to disable the interrupt.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Mask. Set the `PINT_MSK_CLR.PIQ17` bit to disable the interrupt.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Mask. Set the `PINT_MSK_CLR.PIQ16` bit to disable the interrupt.

Table 14-33: PINT_MSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Mask. Set the `PINT_MSK_CLR.PIQ15` bit to disable the interrupt.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Mask. Set the `PINT_MSK_CLR.PIQ14` bit to disable the interrupt.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Mask. Set the `PINT_MSK_CLR.PIQ13` bit to disable the interrupt.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Mask. Set the `PINT_MSK_CLR.PIQ12` bit to disable the interrupt.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Mask. Set the `PINT_MSK_CLR.PIQ11` bit to disable the interrupt.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Mask. Set the `PINT_MSK_CLR.PIQ10` bit to disable the interrupt.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Mask. Set the `PINT_MSK_CLR.PIQ9` bit to disable the interrupt.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Mask. Set the `PINT_MSK_CLR.PIQ8` bit to disable the interrupt.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Mask. Set the `PINT_MSK_CLR.PIQ7` bit to disable the interrupt.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Mask. Set the `PINT_MSK_CLR.PIQ6` bit to disable the interrupt.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Mask. Set the `PINT_MSK_CLR.PIQ5` bit to disable the interrupt.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Mask. Set the `PINT_MSK_CLR.PIQ4` bit to disable the interrupt.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Mask. Set the `PINT_MSK_CLR.PIQ3` bit to disable the interrupt.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Mask. Set the `PINT_MSK_CLR.PIQ2` bit to disable the interrupt.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Mask. Set the `PINT_MSK_CLR.PIQ1` bit to disable the interrupt.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Mask. Set the `PINT_MSK_CLR.PIQ0` bit to disable the interrupt.

PINT Mask Set Register

The `PINT_MSK_SET` register permits unmasking (enabling) of interrupt requests. Writing 1 to a bit in `PINT_MSK_SET` unmasks the corresponding pin interrupt.

11 (R/W1S)	PIQ11	Pin Interrupt 11 Unmask. Set the `PINT_MSK_SET.PIQ11` bit to enable the interrupt.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Unmask. Set the `PINT_MSK_SET.PIQ10` bit to enable the interrupt.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Unmask. Set the `PINT_MSK_SET.PIQ9` bit to enable the interrupt.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Unmask. Set the `PINT_MSK_SET.PIQ8` bit to enable the interrupt.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Unmask. Set the `PINT_MSK_SET.PIQ7` bit to enable the interrupt.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Unmask. Set the `PINT_MSK_SET.PIQ6` bit to enable the interrupt.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Unmask. Set the `PINT_MSK_SET.PIQ5` bit to enable the interrupt.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Unmask. Set the `PINT_MSK_SET.PIQ4` bit to enable the interrupt.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Unmask. Set the `PINT_MSK_SET.PIQ3` bit to enable the interrupt.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Unmask. Set the `PINT_MSK_SET.PIQ2` bit to enable the interrupt.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Unmask. Set the `PINT_MSK_SET.PIQ1` bit to enable the interrupt.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Unmask. Set the `PINT_MSK_SET.PIQ0` bit to enable the interrupt.

PINT Pin State Register

When a half port is assigned to a byte in any PINT block, the state of the eight pins (regardless of GPIO or function, input or output) can be seen in the `PINT_PINSTATE` register. While neither input nor output drivers of the pin are enabled, reads of the pin state in `PINT_PINSTATE` return zero. The `PINT_PINSTATE` register reports the inverted state of the pin if the signal inverter is activated by the `PINT_INV_SET` register. The inverter can be enabled on an individual bit-by-bit basis. Every bit in the `PINT_INV_SET` and `PINT_INV_CLR` register pair represents a pin signal.

The pin interrupt pin state registers enable the service routine to read the current state of the pin without reading from GPIO space. If there was an edge-sensitive interrupt, the service routine can check whether the state of the pin is still high or turned low.

17 (R/NW)	PIQ17	Pin Interrupt 17 State. A read of the `PINT_PINSTATE.PIQ17` bit returns the pin state.
16 (R/NW)	PIQ16	Pin Interrupt 16 State. A read of the `PINT_PINSTATE.PIQ16` bit returns the pin state.
15 (R/NW)	PIQ15	Pin Interrupt 15 State. A read of the `PINT_PINSTATE.PIQ15` bit returns the pin state.

Table 14-35: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	PIQ14	Pin Interrupt 14 State. A read of the `PINT_PINSTATE.PIQ14` bit returns the pin state.
13 (R/NW)	PIQ13	Pin Interrupt 13 State. A read of the `PINT_PINSTATE.PIQ13` bit returns the pin state.
12 (R/NW)	PIQ12	Pin Interrupt 12 State. A read of the `PINT_PINSTATE.PIQ12` bit returns the pin state.
11 (R/NW)	PIQ11	Pin Interrupt 11 State. A read of the `PINT_PINSTATE.PIQ11` bit returns the pin state.
10 (R/NW)	PIQ10	Pin Interrupt 10 State. A read of the `PINT_PINSTATE.PIQ10` bit returns the pin state.
9 (R/NW)	PIQ9	Pin Interrupt 9 State. A read of the `PINT_PINSTATE.PIQ9` bit returns the pin state.
8 (R/NW)	PIQ8	Pin Interrupt 8 State. A read of the `PINT_PINSTATE.PIQ8` bit returns the pin state.
7 (R/NW)	PIQ7	Pin Interrupt 7 State. A read of the `PINT_PINSTATE.PIQ7` bit returns the pin state.
6 (R/NW)	PIQ6	Pin Interrupt 6 State. A read of the `PINT_PINSTATE.PIQ6` bit returns the pin state.
5 (R/NW)	PIQ5	Pin Interrupt 5 State. A read of the `PINT_PINSTATE.PIQ5` bit returns the pin state.
4 (R/NW)	PIQ4	Pin Interrupt 4 State. A read of the `PINT_PINSTATE.PIQ4` bit returns the pin state.
3 (R/NW)	PIQ3	Pin Interrupt 3 State. A read of the `PINT_PINSTATE.PIQ3` bit returns the pin state.
2 (R/NW)	PIQ2	Pin Interrupt 2 State. A read of the `PINT_PINSTATE.PIQ2` bit returns the pin state.
1 (R/NW)	PIQ1	Pin Interrupt 1 State. A read of the `PINT_PINSTATE.PIQ1` bit returns the pin state.
0 (R/NW)	PIQ0	Pin Interrupt 0 State. A read of the `PINT_PINSTATE.PIQ0` bit returns the pin state.

PINT Request Register

The `PINT_REQ` register indicates the interrupt request status for pin interrupts. When set, an interrupt request is pending. When cleared, there is no interrupt request pending.

Both the `PINT_REQ` and `PINT_LATCH` registers indicate whether an interrupt request is latched on the respective pin. The `PINT_LATCH` register is a latch that operates regardless of the interrupt masks. Bits of the `PINT_REQ` register depend on the mask register. The `PINT_REQ` register is a logical AND of the `PINT_LATCH` register and the interrupt mask.

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	EMAC0	PTP Clock Source 0. The `PADS_PCFG0.EMAC0` selects the clock source for the PTP Block in EMAC0.	
		0	EMAC0_RMII CLK
		1	SCLK
		2	External Clock
		3	SCLK

15 Link Port (LP)

Link ports allow the processor to connect to other processors or peripheral link ports using a simple communication protocol for high-speed parallel data transfer. This peripheral allows various I/O peripheral interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes.

The link ports of the processor support 8-bit wide data transfers. The link port pins are multiplexed in the GPIO ports. For information on processor multiplexing, see the data sheet for the specific processor.

Link ports can operate independently and simultaneously, allowing glueless high-speed connectivity of up to four external processors.

LP Features

All link ports are identical in their design and have the following common features.

- Bidirectional ports with eight data signals (`LP0_D0` - `LP0_D7`), an acknowledge signal (`LP0_ACK`), and a clock signal (`LP0_CLK`).
- Provide high-speed, point-to-point data transfers to other processors, allowing different types of interconnections between multiple processors.
- Pack data into 32-bit words. The processor can directly read this data or transfer it through DMA to or from on-chip memory.
- Support for data buffering through a 2-deep FIFO for transmit and a 4-deep FIFO for receive.
- Programmable clock and acknowledge based handshake mechanism for efficient communication.
- A dedicated DMA channel.

LP Functional Description

This section provides a description of the link port, including a list of its registers and a functional block diagram.

ADSP-SC58x LP Register List

The Link Port LP is an 8-bit wide parallel port that can connect to another processor's LP or another LP-compatible device. This port allows a variety of interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes. A set of registers governs LP operations. For more information on LP functionality, see the LP register descriptions.

Table 15-1: ADSP-SC58x LP Register List

Name	Description
`LP_CTL`	Control Register
`LP_DIV`	Clock Divider Value Register
`LP_RX`	Receive Buffer Register
`LP_STAT`	Status Register
`LP_TX`	Transmit Buffer Register
`LP_TXIN_SHDW`	Shadow Input Transmit Buffer Register
`LP_TXOUT_SHDW`	Shadow Output Transmit Buffer Register

External Connections

As shown in the ***Link Port Pin Connections*** figure, a link port has eight data lines (`LP_D0` – `LP_D7`), a clock line (`LP_CLK`), and an acknowledge line (`LP_ACK`). A link port can act as either a transmitter or a receiver but not both at the same time.

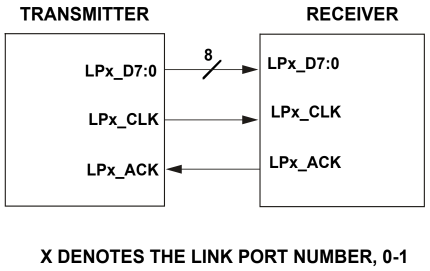

Figure 15-2: Link Port Pin Connections

Use external pull-downs for the `LP_CLK` and `LP_ACK` pins so that the link port can enable the transmitter and receiver, irrespective of the state of the other.

Internal Blocks

As shown in the block diagram, the link ports have independent modules for transmit and receive. If enabled as transmitter, the link port uses a 2 deep 32-bit FIFO. If enabled as a receiver, the port uses a 4 deep 32-bit FIFO. The core MMR access bus interfaces with these FIFOs. The distributed DMA engines (DDE) use the system cross bar (SCB) interface to access the FIFO. The link port uses the `LP_CTL.TRAN` bit to determine whether the module is enabled for transmit or receive operation.

Architectural Concepts

The following sections describe the architectural concepts of the link port.

- Link Port Protocol
- FIFO Buffers
- Handshake for Link Port Enable Process
- Clocking
- Multi-Processor Connectivity

Link Port Protocol

A link port transmitted word consists of 4 bytes and the communication proceeds as follows.

1. The transmitter asserts the link port clock (`LP_CLK`) with each byte of data. The receiver uses the falling edge of `LP_CLK` driven by the transmitter to latch the byte.
2. When the receiver is ready to accept another word in the receive buffer it asserts the acknowledge signal, `LP_ACK`.
3. The transmitter samples `LP_ACK` driven by the receiver at the beginning of each word transmission. If `LP_ACK` is deasserted, then the transmitter does not transmit the next word.
4. The transmitter leaves `LP_CLK` high and continues to drive the first byte of the next word until `LP_ACK` is asserted.

5. When this assertion occurs, the transmitter drives `LP_CLK` low. The transmission of the next word starts. If the transmit buffer is empty, `LP_CLK` remains low until the buffer refills, regardless of the state of `LP_ACK`.

The `LP_ACK` signal can deassert when it anticipates that the buffer could fill. The receiver reasserts the `LP_ACK` signal as soon as the internal DMA grant signal has occurred or the core reads the receive buffer. Either of these actions frees a buffer location.

NOTE: The `LP_ACK` signal inhibits transmission of the next word and not of the current byte.

The `LP_ACK` signal provides a handshake between the receiver and transmitter in the following configurations.

- When configured as a transmitter, the port drives both the data and the clock while `LP_ACK` is three-stated. In this mode, `LP_CLK` is always synchronous with CDU0_CLKO4.
- When configured as a receiver, the link port drives the acknowledge signal and the data and clock lines are three-stated. In this case, the external `LP_CLK` signal can either be synchronous or asynchronous with CDU0_CLKO4.
- When the link port is disabled, the data, clock, and acknowledge signals are three-stated.

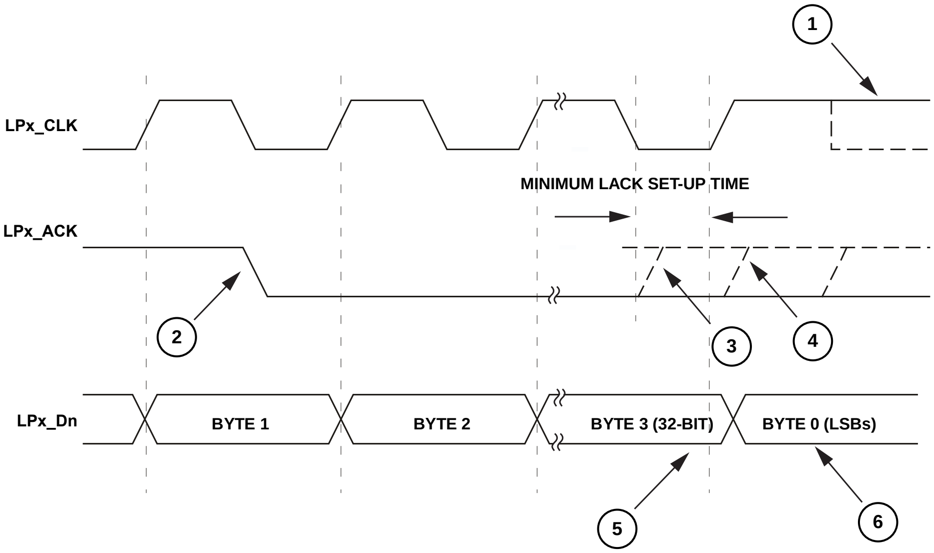

Figure 15-3: Link Port Communication and Handshake Waveform

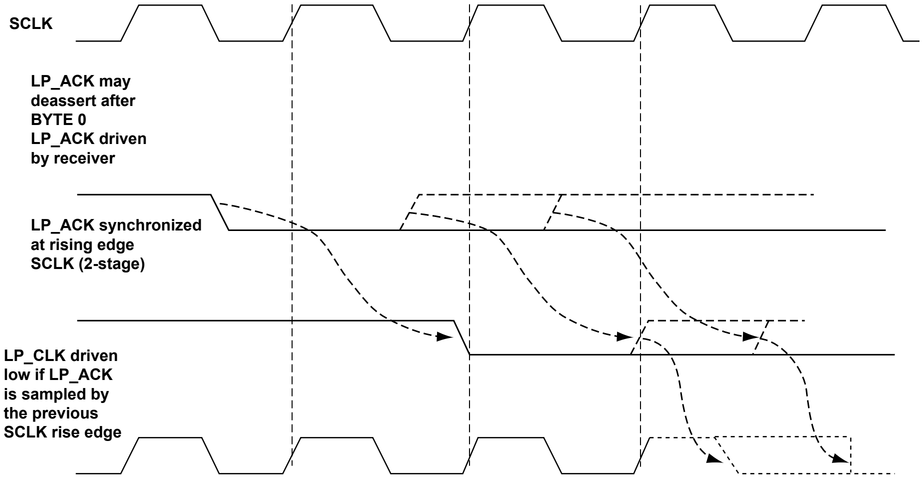
The following list describes the stages shown in the ***Link Port Communication and Handshake Waveform*** figure.

1. `LP_CLK` stays high at byte 0 when `LP_ACK` is sampled low on the previous `LP_CLK` rising edge. `LP_CLK` high indicates a stall.
2. The `LP_ACK` signal can deassert after byte 0.
3. The `LP_ACK` signal reasserts as soon as the link buffer is not full (depending on Rx FIFO conditions).
4. The transmitter samples `LP_ACK` to determine whether to transmit the next word.

5. The receiver accepts the remaining word even if `LP_ACK` is deasserted. The transmitter does not send the following word.
6. Transmission of data for next word is held until `LP_ACK` is asserted.

The transmitter samples the `LP_ACK` signal. If the signal is high, the transmitter gives out the falling edges of `LP_CLK` for data sampling. The `LP_ACK` signal is first sampled at the rising edge of CDU0_CLKO4. One more CDU0_CLKO4 stage synchronizes the signal further. This synchronized signal is given to the subsequent logic. The `LP_CLK` falling edge is aligned with CDU0_CLKO4 falling edge in a 1:1 clock ratio mode and with the *SCLK* rising edge for the rest of the clock ratios. The following figures explain how the synchronization is maintained between the `LP_ACK` and `LP_CLK` signals.

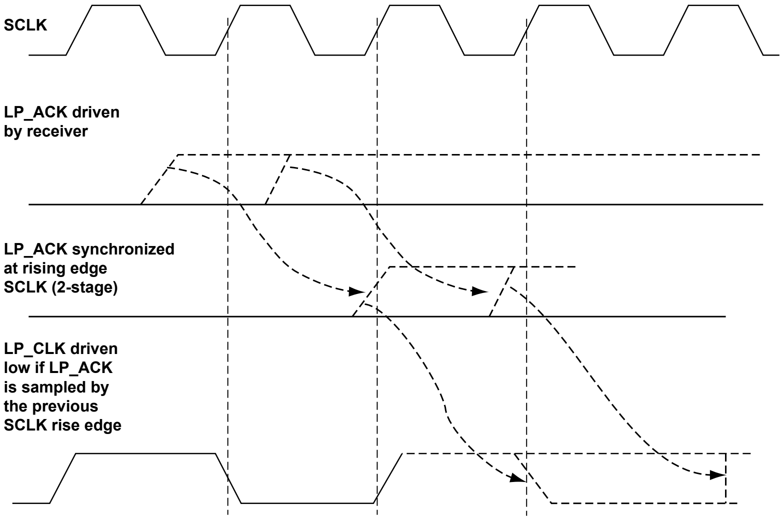
In the following figure, synchronizing time is guaranteed to be 1.5 CDU0_CLKO4 cycles.



SCLK
LP_ACK may deassert after BYTE 0 LP_ACK driven by receiver
LP_ACK synchronized at rising edge SCLK (2-stage)
LP_CLK driven low if LP_ACK is sampled by the previous SCLK rise edge

Figure 15-4: `LP_ACK` Synchronization for SCLK:`LP_CLK`=1:1

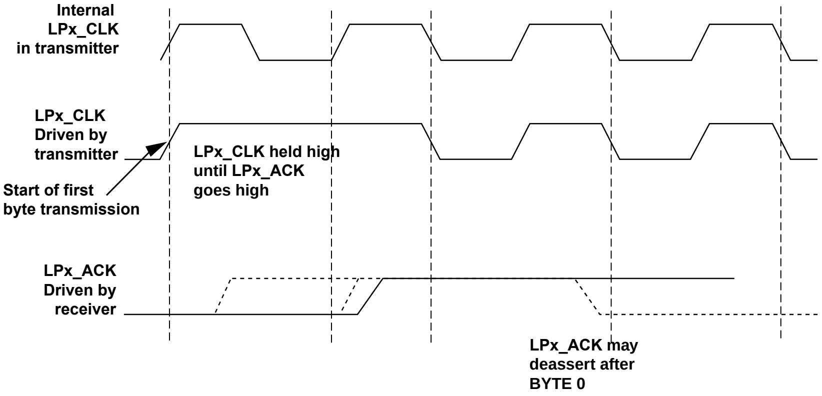
In the following figure, synchronizing time is guaranteed to be 2 CDU0_CLKO4 cycles.



SCLK
LP_ACK driven by receiver
LP_ACK synchronized at rising edge SCLK (2-stage)
LP_CLK driven low if LP_ACK is sampled by the previous SCLK rise edge

Figure 15-5: `LP_ACK` Synchronization for SCLK: `LP_CLK`=1:2, 1:4 and Up

The link port uses the value programmed in the `LP_DIV` register at the transmitter to determine the frequency of the link port clock (`LP_CLK`). However, the signal appearing on the `LP_CLK` pin is also dependent on the status of the `LP_ACK` pin driven by the receiver. The ***Relationship Between Internal Link Port Clock and Link Port Clock at the Pins*** figure shows this relationship.



Internal LPx_CLK in transmitter
LPx_CLK Driven by transmitter
Start of first byte transmission
LPx_CLK held high until LPx_ACK goes high
LPx_ACK Driven by receiver
LPx_ACK may deassert after BYTE 0

Figure 15-6: Relationship Between Internal Link Port Clock and Link Port Clock at the Pins

FIFO Buffers

When a link port is configured as transmitter, the link port uses a 2-deep FIFO buffer. A shift register unpacks the single 32-bit word to four 8-bit data bytes. As the FIFO has space for more data, the link port makes a new DMA request. If the FIFO becomes empty, the `LP_CLK` signal is deasserted. The core can access FIFO through the `LP_TX` register.

The core or DMA makes three writes (2-stage FIFO and 1 shift register) to the transmit buffer before it signals a full condition. The link port uses the `LP_STAT.FFST` bit field to reflect the status of the FIFO but not the shift register full or empty condition. However, the program can poll the `LP_STAT.LPBS` bit to discover whether the link port is driving data from the shift register to the pins. The `LP_STAT.LPBS` bit is also set when receiver has held off transmission by driving `LP_ACK` low.

NOTE: When the 2-deep FIFO and the output shift-register overflow, any further write to the link port buffer overwrites the input stage of the FIFO.

NOTE: The core can also read the transmit FIFO through the data `LP_TX` register.

NOTE: If the transmitter is disabled while performing writes to the transmit FIFO, a FIFO full condition is signaled after two writes.

The transmit buffer registers have shadow registers. Using these shadow registers, both stages of the 2-deep FIFO can be read without updating the status registers. The `LP_TXIN_SHDW` register corresponds to the input stage of the FIFO. The `LP_TXOUT_SHDW` register corresponds to the output stage of the FIFO as shown in the ***Transmit FIFO path*** figure.

FIFO INPUT STAGE
SHADOW REGISTER FOR INPUT STAGE
WRITE ACCESS VIA DATA REGISTER

Figure 15-7: Transmit FIFO path

When a link port is configured as receiver, data transfers to the core or DMA from the full 4-deep receive FIFO. An internal packing register packs data to 32 bits. Four reads can occur from the receive buffer by the core or DMA before it signals an empty condition. The link port uses the `LP_STAT.FFST` bits to reflect the status of the 4-deep read buffer FIFO. The core can access this FIFO through the `LP_RX` register.

NOTE: When receive FIFO overflows (`LP_STAT.ROVF` bit=1), any further data from the transmitter is lost. Only the data retained in the receive FIFO can be retrieved further.

The receiver drives the `LP_ACK` output signal low, after the first byte of data for the next-to-last empty slot (in the 4-deep FIFO) is received. This functionality prevents data loss due to the transmitter starting transmission of the next word before the `LP_ACK` signal reaches the transmitter. (The timing is due to the larger delay in synchronization.) This functionality guarantees that even after allowing for the extra synchronization cycle in the transmitter and receiver, there is no overflow in the receive FIFO. The ***LACK Generation Based on Receive FIFO Status*** figure shows how FIFO slots influence the acknowledge signal generation. The grayed sections show received data. The white sections show empty locations where the decision to pull `LP_ACK` high is taken.

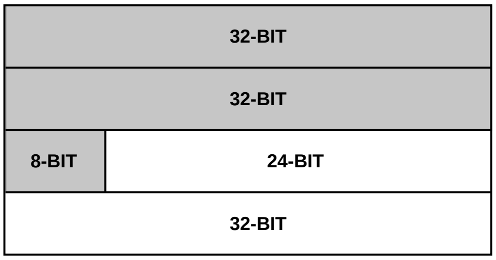

Figure 15-8: LACK Generation Based on Receive FIFO Status

> **NOTE:** The link port uses a 4-deep receive FIFO only under a worst case situation, as mentioned. In all other cases, respond as if the FIFO has only a 3-deep stage. The `LP_ACK` signal is pulled high before the last stage of the FIFO.

The link port has memory-mapped buffers for both receive and transmit operations. A JTAG-based emulator can read the FIFO which can cause unexpected problems in data transfers. This activity can only happen during an emulation event (typically hitting a breakpoint or single-stepping). The emulator issues core reads through JTAG. To work around this issue, see the tools documentation for more information.

Handshake for Link Port Enable Process

In a link port-based system, the transmitter and the receiver can be enabled at different times. Use external pull-downs for the `LP_CLK` and `LP_ACK` signals.

If the receiver is enabled before the transmitter, the external pull-down holds the `LP_CLK` signal of the transmitter low. The receiver is held off. The receiver can wait for a rising edge on the `LP_CLK` signal to assert its receive service request interrupt. This rising edge occurs only when transmitter starts driving the first data on to the bus, after the application enables it.

If the transmitter is enabled before the receiver, the external pull-down holds the `LP_ACK` signal of the receiver low. Transmission is held off. Refer to the ***Enable the Transmitter Before the Receiver*** figure. The transmitter can wait for a rising edge on the `LP_ACK` signal to assert its transmit service request interrupt. This rising edge is asserted as soon as the receiver is enabled after the hardware drives the `LP_ACK` high.

Figure 15-9: Enable the Transmitter Before the Receiver

NOTE: Service request interrupts or status are asserted only when the link port (receiver or transmitter) is disabled.

Clocking

The link port clock (`LP_CLK`) is derived from the internal system clock (CDU0_CLKO4). The link port clock to system clock ratio can be configured in the `LP_DIV` register. This value applies to the transmitter only. The receiver can operate at any asynchronous frequency up to the maximum frequency, independent of the ratio programmed. The following formula describes the relationship between the frequency of the link port clock, the CDU0_CLKO4 frequency, and the `LP_DIV` value.

- $f_{LP\_CLK} = f_{SCLK} <$ or $= f_{LP\_CLK\text{-}MAX}$ if DIV = 0
- $f_{LP\_CLK} = f_{SCLK}/(2 \times \text{DIV})$ if DIV > 0

Where: f_{LP_CLK} = link clock frequency, $f_{LP\_CLK\text{-}MAX}$ = link clock maximum frequency, and f_{SCLK} = system clock frequency.

While programming the `LP_DIV` register to select the clock ratio, ensure that the `LP_CLK` frequency does not exceed the maximum frequency supported for the device. For example, if the CDU0_CLKO4 frequency is 125 MHz and the limit for `LP_CLK` operation is 83 MHz, `LP_DIV` must be greater than or equal to 1. The resulting `LP_CLK` frequency is less than or equal to 83 MHz. For supported frequencies, see the product-specific data sheet.

NOTE: The link ports on this processor have a flexible system clock assignment where their CDU0_CLKO4 is derived from the CLKO8 output of the CDU. For information on clock programming, see CDU Programming Model.

Multi-Processor Connectivity

Link ports can operate independently, allowing glueless connection with external processors. Link ports have dedicated DMA channels, allowing independent data transfers. The following group of figures shows some examples of different bus connection topology that can be used in multi-processor system design. The inter-connection methods are not limited to these examples.

Figure 15-12: Link Port Ring Model

The link port protocol does not include built-in support for multiple masters. However, there can be situations where multiple devices try to become the bus master at the same time. Multi-master conflicts can be resolved using token passing. In token passing, the token is a software flag that passes between processors.

At reset, the token is set to reside in the link port of one device, making it the master and the transmitter. When a receiver (slave) wants to become the master, it can assert its `LP_ACK` signal to get the attention of the master. The master knows, through the software protocol, whether to respond with actual data or whether the token is requested. If the master wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag.

Simultaneously, the slave sets its token and can thereafter transmit. The token release word can be any user-defined value. Because the transmitter and receiver expect a code word, this word does not need to be exclusive of normal data transmission. If the master wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag. Simultaneously, the slave examines the data sent back and if it is the token release word, the slave sets its token, and can thereafter transmit.

The link port protocol includes handshake mechanism to inform the other end of transfer (transmit or receive) of an enable instance. However, it does not support handshakes to inform a disable instance, while a chunk of data transfers. The application must assume the disabled state of the other end, and take appropriate action.

For example, in a multi-processing environment, a receiver did not read its full FIFO for an extended time due to internal bus arbitrations. The transmitter can require software or a peripheral timer-based timeout to inform the application that the `LP_ACK` signal is low for an extended time period.

LP Operating Modes

The link port does not have particular modes of operation, as the peripheral is based on a simple protocol. The following sections explain the data transfer modes, using the core and using DMA.

- Core Data Transfers
- DMA Data Transfers

LP Data Transfer Modes

This section describes link port DMA and core data transfers.

Core Data Transfers

If DMA is disabled for a link port buffer, the processor core can write or read internal FIFO buffers as a memory-mapped register through the MMR access bus. In order to avoid FIFO overflow or underflow, the core can access the FIFO registers in one of the two following ways.

1. Access link port registers using an interrupt service routine (ISR) mapped to the data request interrupt of the link port. The interrupt request remains high only if the FIFO is accessible (if the FIFO is not full in transmit mode and not empty in receive mode).
2. Poll the FIFO status bits of the `LP_STAT` register. Write to the transmit FIFO if not full or read from the receive FIFO if not empty.

DMA Data Transfers

Dedicated DMA channels are available for each link port. DMA-related activity is explained in the following steps.

1. Data Receive – Once the DMA channel and link port module are configured and enabled, the external device begins writing data to the FIFO through the data pins of the link port. The FIFO detects this activity and in turn sends a DMA request. After the request is granted, the DMA transfer progresses until the FIFO is empty.
2. Data Transmit – Once the DMA channel and link port module are configured and enabled, setting the `LP_CTL.EN` bit automatically asserts a DMA request when the transmit FIFO is empty. After the request is granted, DMA fills the FIFO. The external device begins reading data from the FIFO through the data pins of

the link port. The FIFO detects that there is room in the buffer and asserts another DMA request, continuing the process.

LP Event Control

This section describes how the link port uses interrupts and status signals.

Interrupt Signals

Each link port has two dedicated interrupt lines registered with the system event controller—a data request interrupt and a status interrupt. Data request interrupts are asserted based on FIFO conditions for data transfer. Status interrupts are asserted when a service request status or an overflow status is set. The following list explains each of these interrupts.

- *Data Request Interrupt.* Asserted if the FIFO is not full in transmission mode and the FIFO is not empty in reception mode. This functionality serves as a core triggered interrupt in non-DMA mode and as the DMA interrupt request in DMA mode. Generation of this interrupt is based on the `LP_STAT.FFST` (status bit of the link port buffer).
- *Link Port Transmit Service Request Interrupt (LTRQ)*. Allow a disabled link port to generate an interrupt when an external access is attempted. When a link port is configured as transmitter, the transmit service request interrupt is enabled by setting the `LP_CTL.TRQMSK` bit. When set, an external receiver can indicate to the disabled transmitter that it must receive data through the connected link port. The receiver does so by driving a high level on the `LP_ACK` line. When the `LP_ACK` of the disabled transmitter link port is detected high, a `LP_STAT.LTRQ` interrupt is generated. The transmitter can enable itself for data transfer with the receiver. The link port needs a pull-down on `LP_ACK` for this feature to function properly.
- *Link Port Receive Service Request Interrupt (LRRQ)*. When a link port is configured as receiver, this interrupt is enabled by setting the `LP_CTL.RRQMSK` bit. When set, an external transmitter can indicate to the disabled receiver that it must receive data through the connected link port. The transmitter does so by driving out the first data. When the `LP_CLK` of the disabled receiver link port is detected high, a `LP_STAT.LRRQ` interrupt is generated. The receiver can further enable itself for data transfer with the transmitter. The link port needs a pull-down on the `LP_CLK` signal for this feature to function properly.
- *Link Port Receive Overflow Interrupt (LPOVF)*. Generated when the receiver FIFO overflows and is enabled by setting the `LP_CTL.ROVFMSK` bit. This interrupt can happen if the transmitter continues to transmit data even though the receiver has deasserted `LP_ACK` signal causing the receive FIFO to overflow.

Enabling Link Port Interrupts

A data request interrupt is fed to the system event controller directly and can be controlled separately from the application.

To mask the interrupt, set the mask bits in `LP_CTL` register corresponding to service interrupts and the overflow interrupt. These interrupts are OR'ed and fed to the SIC as a single `LP_STAT` interrupt. These interrupts are latched and stored in the associated bits of `LP_STAT` register. If an `LP_STAT` interrupt occurs, in the ISR, programs can read the `LP_STAT` register bits to determine the type of interrupt. These bits are write-one-to-clear (W1C); writing one to the bit resets the bit and disables the corresponding interrupt.

Status and Error Signals

This section explains the various status signals in the `LP_STAT` register.

- *Transfer Status signals*. The link port uses the bus status bit (`LP_STAT.LPBS`) to give the status of the bus condition (busy or idle), when the link port is configured as transmitter. The `LP_STAT.LPBS` is high if the link port drives data into the link port pins. Programs can poll this bit after polling the `LP_STAT.FFST` bit to disable the link port safely.

  The link buffer status (`LP_STAT.FFST`) field directly indicates the status of the FIFO (including empty or full conditions) during data transfer. Software can poll this field in the `LP_STAT` register before writing to the FIFO (in case of transmission) or reading from the FIFO (in case of reception). The `LP_STAT.FFST` bit is automatically cleared when the link port is disabled.

- *Transfer Request Status signals*. The link port uses the receive request status (`LP_STAT.LRRQ`) bit to indicate that an external receiver wants to receive data (in case the link port is a disabled transmitter). The link port uses the transmit request status (`LP_STAT.LTRQ`) bit to indicate that an external transmitter wants to send data (in case the link port is a disabled receiver). Software can poll these bits to enable the transmitter or receiver accordingly.

- *Error Status signals*. In receive mode 32-bit data is received in four chunks of 8-bit data. This data is then packed to a single 32-bit data before loading the FIFO. The link buffer error status (`LP_STAT.LPACK`) bit is high during this packing process and goes low after packing.

  The link port overflow status (`LP_STAT.ROVF`) bit is set when the receive FIFO overflows. This event can occur if the transmitter continues to transmit data even though the receiver has deasserted `LP_ACK` causing the receiver FIFO to overflow.

LP Programming Model

The following sections provide information on configuring the operating mode and enabling the link ports.

- Setting Up a DMA Transmit Operation
- Setting Up a DMA Receive Operation
- Setting Up a Core Transmit Operation
- Setting Up a Core Receive Operation

Setting Up a DMA Transmit Operation

This following procedure describes the typical steps for configuring the link ports in DMA transmit mode.

1. Enable the link port pins in the GPIO port mux using the appropriate `PORT_FER` and `PORT_MUX` registers.

2. Install interrupt handlers for DMA and for transfer status (service request interrupt).
3. Configure the link port to transmit by setting the `LP_CTL` bit and enable the transmit request interrupt mask by setting the `LP_CTL.TRQMSK` bit.
4. Program the link port clock divider by writing a value to the `LP_DIV` register.
5. If using DMA stop mode or auto buffer mode, program the appropriate DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: `DMA_ADDRSTART`, `DMA_XCNT`, `DMA_XMOD`, and `DMA_CFG` registers (Stop/Auto, `DMA_CFG.PSIZE` =1, `DMA_CFG.MSIZE` =4, interrupt generation and memory read).
6. Wait for the link port receiver (connected externally) to be enabled. The application can wait for the transmit service request interrupt to assert.
7. Clear the transmit service request interrupt status by writing 1 to the `LP_STAT.LTRQ` bit.
8. Enable DMA by setting the `DMA_CFG.EN` bit.
9. Enable the link port by setting the `LP_CTL.EN` bit.
10. Wait for DMA to assert a transfer completion interrupt.
11. Clear the DMA interrupt source by writing 1 to the `DMA_STAT.IRQDONE` bit.

Setting Up a DMA Receive Operation

This section describes the typical steps for using the link ports in DMA receive mode.

1. Enable the link port pins in GPIO port mux using the appropriate `PORT_FER` and `PORT_MUX` registers.
2. Install interrupt handlers for DMA and for transfer status (service request interrupt).
3. Configure the link port for reception (clear the `LP_CTL.TRAN` bit) and enable the receive request interrupt mask by setting the `LP_CTL.RRQMSK` bit.
4. If using DMA stop mode or auto buffer mode, program the DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: `DMA_ADDRSTART`, `DMA_XCNT`, `DMA_XMOD`, and `DMA_CFG` registers (Stop/Auto, `DMA_CFG.PSIZE=1`, `DMA_CFG.MSIZE=4`, interrupt generation and memory write).
5. If using DMA array mode or list mode, create DMA configuration data structures filled with components.

   ADDITIONAL INFORMATION: An example configuration is: `DMA_ADDRSTART`, `DMA_XCNT`, `DMA_XMOD`, and `DMA_CFG` registers (Array/List, `DMA_CFG.PSIZE` =1, `DMA_CFG.MSIZE` =4, interrupt generation, memory write and fetch =4/5) and `DMA_DSCPTR_NXT` register (if list mode). Further, program DMA configuration register (Array/List, `DMA_CFG.PSIZE` =1, `DMA_CFG.MSIZE` =4, Memory Write and Fetch =4/5) and program the `DMA_DSCPTR_NXT` register (if list mode).

6. Wait for the link port transmitter (connected externally) to be enabled with subsequent data transmission. The application can wait for the receive service request interrupt to assert.
7. Clear the receive service request interrupt status by writing 1 to the `LP_STAT.LRRQ` bit.
8. Enable DMA by setting the `DMA_CFG.EN` bit.
9. Enable the link port by setting the `LP_CTL.EN` bit.
10. Wait for DMA to assert the transfer complete interrupt.
11. Clear the DMA interrupt source by writing 1 to the `DMA_STAT.IRQDONE` bit of the DMA status register.

Setting Up a Core Transmit Operation

This section describes the typical steps for using the link ports in processor core based transmission.

1. Enable the link port pins in the GPIO port mux using the appropriate `PORT_FER` and `PORT_MUX` registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC.
3. Configure the link port for transmission by setting the `LP_CTL.TRAN` bit) and enable the transmit request interrupt mask by setting the `LP_CTL.TRQMSK` bit).
4. Program the link port clock divider by writing a value in to the `LP_DIV` register.
5. Wait for the link port receiver (connected externally) to be enabled. The application can wait for a transmit service request interrupt to assert.
6. Clear the transmit service request interrupt status by writing 1 to the `LP_STAT.LTRQ` bit.
7. Enable the link port by setting the `LP_CTL.EN` bit.
8. The data request interrupt is asserted whenever there is free space in the FIFO. The application can write to the `LP_TX` register based on the FIFO conditions (half or empty) reflected in the `LP_STAT.FFST` bit field.

Setting Up a Core Receive Operation

This section describes the typical steps for using the link ports in processor core-based reception.

1. Enable the link port pins in the GPIO port mux using the appropriate `PORT_FER` and `PORT_MUX` registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC).
3. Configure link port for reception (clear `LP_CTL.TRAN` bit). Enable the receive request interrupt mask bit (set `LP_CTL.RRQMSK`).
4. Wait for the link port transmit (connected externally) to be enabled with subsequent transmission of data. The application can wait for receive service request interrupt to be asserted.

5. Clear the receive service request interrupt status by writing 1 to the `LP_STAT.LRRQ` bit.
6. Enable the link port by setting the `LP_CTL.EN` bit.
7. The data request interrupt is asserted whenever there is free space in the FIFO. The application can read from the `LP_RX` register based on the FIFO conditions (1 or 2 or 3 data available) which is reflected in the `LP_STAT.FFST` bit field.

ADSP-SC58x LP Register Descriptions

Link Port (LP) contains the following registers.

Table 15-6: ADSP-SC58x LP Register List

Name	Description
`LP_CTL`	Control Register
`LP_DIV`	Clock Divider Value Register
`LP_RX`	Receive Buffer Register
`LP_STAT`	Status Register
`LP_TX`	Transmit Buffer Register
`LP_TXIN_SHDW`	Shadow Input Transmit Buffer Register
`LP_TXOUT_SHDW`	Shadow Output Transmit Buffer Register

Control Register

The `LP_CTL` register provides LP interrupt masking, selection of transfer direction, and link port enable.

		0	Disable Disable linkport
		1	Enable linkport Enable linkport

Clock Divider Value Register

The `LP_DIV` register selects the divisor for ratio between the internal LP clock (LCLK) and system clock (CDU0_CLKO8). This programming is applicable only for the transmitter. The receiver can operate at any asynchronous frequency up to the maximum frequency independent of the ratio programmed.

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Divisor Value. The `LP_DIV.VALUE` bits select the clock divider (relating the LP' internally generated clock (LCLK) to the system clock (CDU0_CLKO8). The `LP_DIV.VALUE` should be programmed prior to LP enable. For `LP_DIV.VALUE` = 0, LCLK = CDU0_CLKO8 For `LP_DIV.VALUE` = xxxxxxxx, LCLK = CDU0_CLKO8 / (2 x DIV)

Receive Buffer Register

The `LP_RX` register buffers the receive data flow through the LP. The receive buffer is a four-location deep FIFO. In the receive buffer, data is transferred to the core or DMA from the receive FIFO where an internal register does the packing. This packing register is not software accessible. For more information on LP buffer features and operations, see the LP functional description.

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	LPBS	Bus Status. The `LP_STAT.LPBS` bit indicates the LPDAT bus status. `LP_STAT.LPBS` is kept high if data is being driven by the link port into the `LP_D[n]` pins.	
		0	Bus is Idle Link Port Bus is idle
		1	Bus Busy Link Port Bus is busy
7 (R/NW)	LPACK	Buffer Pack Status. The `LP_STAT.LPACK` bit indicates packing status. In receive mode, 32-bit data is received in 4 blocks of 8-bit data. Then, the data is packed to get a single 32-bit data before loading the FIFO. The `LP_STAT.LPACK` bit is high during this packing process and goes low after packing. In transmit mode, 32-bit data in the FIFO is unpacked to 4 blocks of 8-bit data before sending. The `LP_STAT.LPACK` is high during unpacking.	
		0	Packing Complete Packing done
		1	Packing Incomplete Packing is in progress
6:4 (R/NW)	FFST	FIFO Status. The `LP_STAT.FFST` bits indicate the FIFO status. These bits are cleared when the LP is disabled.	
		0	TX - Empty; RX - Empty Link buffer (TX OR RX) empty

Table 15-10: LP_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	TX - Reserved ; RX - Has 1 data word RX has 1 word of data. TX reserved
		2	TX - Reserved; RX - Has 2 data words RX has 2 word of data. TX reserved.
		3	TX - Reserved; RX - Has 3 data words RX has 3 word of data. TX reserved.
		4	TX - One Word; RX -Has 4 data words RX has 4 word of data. TX 1 word of data.
		5	Reserved
		6	TX - FIFO Full; RX - Reserved RX reserved. TX reserved.
		7	Reserved
3 (R/W1C)	ROVF	Receive FIFO Overflow Interrupt. This interrupt is generated when the receiver FIFO overflows. This overflow may happen if the transmitter continues to transmit data even though the receiver has de-asserted the `LP_ACK` pin.	
1 (R/W1C)	LRRQ	Receive Request. The LP generates this interrupt when the `LP_CLK` pin of a disabled link port (the receiver) is forced high by another link port (the transmitter).	
0 (R/W1C)	LTRQ	Transmit Request. The LP generates this interrupt when the `LP_ACK` pin of a disabled link port (the transmitter) is forced high by another link port (the receiver).	

Transmit Buffer Register

The LP_TX register buffers the transmit data flow through the LP. The transmit buffer is two words deep. In the transmit buffer, the input stage of the FIFO is used to accept core data or DMA data from internal memory, and the data is transferred to the link port interface from the output stage of the FIFO. The output stage performs the unpacking in the transmit buffer. The least significant byte is transmitted first. As each word is unpacked and transmitted, the next location in FIFO becomes available and a new DMA request is made if DMA is enabled. If the register becomes empty, the LP asserts the `LP_CLK` signal. For more information on LP buffer features and operations, see the LP functional description.

16 Serial Peripheral Interface (SPI)

The serial peripheral interface is an industry-standard synchronous serial link that supports communication with multiple SPI-compatible devices. The baseline SPI peripheral is a synchronous, four-wire interface consisting of two data pins, one device select pin, and a gated clock pin. The two data pins allow full-duplex operation to other SPI-compatible devices. Two extra (optional) data pins are provided on specific SPIs to support quad SPI operation. Enhanced modes of operation such as flow control, fast mode, and dual-I/O mode (DIOM) are also supported. In addition, a direct memory access (DMA) mode allows for transferring several words with minimal CPU interaction.

With a range of configurable options, the SPI ports provide a glueless hardware interface with other SPI-compatible devices in master mode, slave mode, and multimaster environments. The SPI peripheral includes programmable baud rates, clock phase, and clock polarity. The peripheral can operate in a multimaster environment by interfacing with several other devices, acting as either a master device or a slave device. In a multimaster environment, the SPI peripheral uses open-drain outputs to avoid data bus contention. The flow control features enable slow slave devices to interface with fast master devices by providing an SPI ready pin which flexibly controls the transfers.

NOTE: All SPI peripherals (SPI0, SPI1 and SPI2) on the ADSP-SC58x/ADSP-2158x processors operate on the SCLK1_0 domain. The term SCLK in this chapter is a generic reference to SCLK1_0. For more details on SCLK1_0 programming refer the *Clock Generation Unit (CGU)* chapter.

SPI Features

The SPI module supports the following features:

- Full-duplex, synchronous serial interface
- 8, 16-bit and 32-bit word sizes
- Programmable baud rate, clock phase, and polarity
- Programmable inter-frame latency
- Flow control
- Support for Fast and DIOM modes
- Quad and memory-mapped modes are supported by SPI2 only
- Independent receive and transmit DMA channels

- Burst transfer mode for non-DMA write accesses

SPI Functional Description

This section provides information on the function of the SPI module.

Shift register functionality

The SPI is essentially a shift register that serially transmits and receives data bits to or from other SPI devices. During an SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line synchronizes shifting and sampling of the information on the two serial data lines.

Master slave functionality

During a data transfer, one SPI system acts as the link master which controls the data flow. The other system acts as the slave, which has data shifted into and out of it by the master. Different devices can take turn being masters, and one master can simultaneously shift data into multiple slaves (broadcast mode). However, only one slave can drive its output to write data back to the master at any given time. This rule must be enforced in the broadcast mode. Several slaves can be selected to receive data from the master in this mode. But only one slave can be enabled to send data back to the master.

Enhanced operating modes

SPI supports enhanced modes of operation like fast mode, DIOM, and Quad-SPI, and optional flow control. In fast mode, received data is sampled on the transmit edge instead of the standard receive edge, thus enabling a full-cycle path for the received data. In DIOM, both MOSI and MISO are configured as input or output pins, and 2 bits are shifted in or out on each receive or transmit edge. In Quad-SPI mode, SPI_D3:0 are configured as input or output pins and 4 bits are shifted in or out on each receive or transmit edge. A slower slave can use flow control to stall a faster master device.

Single and multi-master use

The SPI can be used in a single master as well as multi-master environment. The `SPI_MOSI`, `SPI_MISO`, and the `SPI_CLK` signals are all tied together in both configurations. SPI transmission and reception can be enabled simultaneously or individually, depending on `SPI_RXCTL` and `SPI_TXCTL` settings. In broadcast mode, several slaves can be enabled to receive, but only one slave must be in transmit mode and driving the `SPI_MISO` line.

ADSP-SC58x SPI Register List

The Serial Peripheral Interface (SPI) provides a full-duplex, synchronous serial interface, which supports both master/slave modes and multi-master environments. The SPI's baud rate and clock phase/polarities are programmable, and it has integrated DMA channels for both transmit and receive data streams. A set of registers governs SPI operations. For more information on SPI functionality, see the SPI register descriptions.

Transfer Protocol

The SPI module implements two channels that are independent of each other. The SPI module uses the `SPI_RXCTL` and `SPI_TXCTL` dedicated control registers to control these channels. Except in dual and quad modes, SPI can enable and use both channels simultaneously.

The SPI protocol supports four different combinations of serial clock phase and polarity. These combinations are selected through the `SPI_CTL.CPOL` and `SPI_CTL.CPHA` bits.

The ***SPI Transfer Protocol*** figures demonstrate the two basic transfer formats as defined by the CPHA bit. Two waveforms are shown for `SPI_CLK`; one for `SPI_CTL.CPOL`=0 and the other for `SPI_CTL.CPOL`=1. The diagrams can be interpreted as master or slave timing diagrams since the `SPI_CLK`, `SPI_MISO`, and `SPI_MOSI` pins are directly connected between the master and the slave. The `SPI_MISO` signal is the output from the slave (slave transmission), and the `SPI_MOSI` signal is the output from the master (master transmission). The master generates the `SPI_CLK` signal. The `SPI_SS` signal is the slave device select input to the slave from the master. The diagrams represent an 8-bit transfer (`SPI_CTL.SIZE`=0) with the MSB first (`SPI_CTL.LSBF`=0). Any combination of the `SPI_CTL.SIZE` and `SPI_CTL.LSBF` bits is permissible. For example, a 16-bit transfer with the LSB first is another possible configuration.

The clock polarity and the clock phase could be identical for the master device and the slave device involved in the communication link. The transfer format from the master can be changed between transfers to adjust for various requirements of a slave device.

The SPI module uses the `SPI_CTL.ASSEL` bit to determine when the SPI hardware or software control the `SPI_SEL[n]` line. When `SPI_CTL.ASSEL`=1, the slave select line must be set to the polarity set in the `SPI_CTL.SELST` field between each serial transfer. The actual behavior of `SPI_SEL[n]` also depends on the parameters programmed into the `SPI_DLY` register. The SPI hardware logic automatically controls this functionality. When `SPI_CTL.ASSEL`=0, `SPI_SEL[n]` can either remain active between successive transfers or be inactive. The software must control this activity through manipulation of the `SPI_SLVSEL` register.

The ***SPI Transfer Protocol*** pair of figures illustrates the case when `SPI_CTL.ASSEL` = 1 and the `SPI_SEL[n]` line is inactive between frames. If `ASSEL` = 0, the `SPI_SEL[n]` line can remain active between frames; however, the first bit is only driven when an active transition of `SPI_CLK` occurs.

Clock Considerations

The `SPI_CLK` signal is a gated clock that is only active during data transfers, for the time of the transferred word. In normal mode, the number of active edges is equal to the number of bits to be transmitted or received. In dual-I/O mode, it is half of the number of bits to be transmitted or received, and in quad-SPI mode it is one-fourth of the number. The clock rate can be as high as the SCLK1_0 rate, and both even and odd dividers from SCLK1_0 are supported. For master devices, the SPI uses the `SPI_CLK` register value to determine the clock rate, whereas this value is ignored for slave devices.

When the SPI controller is a master, `SPI_CLK` is an output signal. Conversely, when the SPI controller is a slave, `SPI_CLK` is an input signal. Slave devices ignore the SPI clock when the slave select input is driven inactive. The SPI uses the `SPI_CLK` signal to shift out and shift in the data driven onto the `SPI_MISO` and `SPI_MOSI` lines. The data is always shifted out on one edge of the clock (the active edge) and sampled on the opposite edge of the clock (the sampling edge). Clock polarity and clock phase relative to data are programmable through the `SPI_CTL` register and define the transfer format.

Controlling Delay Between Frames

The ***SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing using the `SPI_DLY.LEADX` and `SPI_DLY.LAGX` programming. The SPI uses the `SPI_DLY.LAGX` bits to control the timing between the slave select (`SPI_SS`) signal assertion and the first `SPI_CLK` edge. The SPI uses the `SPI_DLY.LEADX` bits to control the timing between the last `SPI_CLK` edge and deassertion of the `SPI_SS` signal. The lead and lag timing can be extended by a 1 `SPI_CLK` duration to ease timing restrictions on the slave device.

1 SPI_CLK
SPI_CLK Pol – 0
SPI_CLK Pol – 1

Figure 16-4: SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)

The *SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)* figure illustrates SPI timing with STOP programming. The SPI module uses this timing to insert multiples of `SPI_CLK` period delays between transfers. The `SPI_SS` line is deasserted for the duration specified in the `SPI_DLY.STOP` bit field, assuming the `SPI_CTL.SELST` bit is configured for deassertion between transfers.

If the `SPI_DLY.STOP` bit =0, the master operates in a *continuous mode*. This mode causes an immediate start of the second word after the last bit is transferred from the first word. During this mode of operation, the slave select line is continuously asserted.

MSB
SPI_CLK Pol=0
SPI_CLK Pol=1

Figure 16-5: SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)

When the `SPI_DLY.STOP` bit =0 and initial conditions for a transfer are not met, the interface pauses before the next transfer. During this pause, the SPI uses the `SPI_CTL.SELST` bit to determine the state of the slave select pin. The SPI uses the `SPI_DLY.LEADX` and `SPI_DLY.LAGX` bits to determine the timing between `SPI_CLK` edges and the slave select line.

Flow Control

In master mode, the slave device must drive the `SPI_RDY` pin. The pin acts as an input signal. The slave can deassert the `SPI_RDY` pin to stop the master from initiating any new transfer. If `SPI_RDY` is deasserted in the middle of a transfer, the current transfer continues, and the next transfer will not start unless the slave asserts the `SPI_RDY` signal. Whenever the slave deasserts `SPI_RDY` and stalls the master, the SPI controller goes into a waiting state, and the `SPI_STAT.FCS` bit is set. When the slave asserts `SPI_RDY`, the SPI controller resumes operation, and the `SPI_STAT.FCS` bit is cleared.

In slave mode, the `SPI_RDY` pin acts as an output signal. Flow control can be configured on either the TX channel or the RX channel. The SPI uses the `SPI_CTL.FCCH` bit to control this configuration. If flow control is configured on the TX channel, as the `SPI_TFIFO` status nears the empty condition, the `SPI_RDY` pin is deasserted. If flow control is configured on the RX channel, as the `SPI_RFIFO` status nears the full condition, the `SPI_RDY` pin is deasserted. The SPI uses the `SPI_CTL.FCWM` bits to control the FIFO status at which `SPI_RDY` deassertion takes place. Flow control in slave mode is purely based on the FIFO status and does not depend on the word counters.

The ***SPI Flow Control Timing in Master Mode*** figure illustrates this timing.

Figure 16-6: SPI Flow Control Timing in Master Mode.

Slave Select Operation

If the SPI is in slave mode, `SPI_SS` acts as the slave select input. When SPI is enabled as a master, `SPI_SS` can serve as an error detection input for the SPI in a multi-master environment. The `SPI_CTL.PSSE` bit enables this feature. When `SPI_CTL.PSSE`=1, the `SPI_SS` input is the master mode error input. Otherwise, `SPI_SS` is ignored.

The `SPI_SS` signal is an active-low signal. The master asserts the signal during the transfer. The signal can be deasserted or remain asserted between transfers. When `SPI_SS` is deasserted, `SPI_CLK` and inputs are ignored, and outputs are three-stated.

The slave select bits (`SPI_SLVSEL.SSEL1` – `SPI_SLVSEL.SSEL7`) are used in a multiple-slave SPI environment. For example, if there are eight SPI devices in the system including a processor master, the master processor can support the SPI mode transactions across the other seven devices. This configuration requires only one master processor in this multi-slave environment.

For example, assume that the SPI of the processor is the master. The `SPI_SLVSEL.SSEL1` – `SPI_SLVSEL.SSEL7` bits on the processor can be connected to the slave select pin of each slave device. In this configuration, the slave select bits can be used in three ways. In cases 1 and 2, the processor is the master and the seven microcontrollers or peripherals with SPI interfaces are slaves. The processor can do one of the following:

1. Transmit to all seven SPI devices at the same time in a broadcast mode. Here, all slave select bits are set.
2. Receive and transmit from one SPI device by enabling only one slave SPI device at a time.
3. If all the slaves are also processors, then the requester can receive data from only one processor at a time. (The functionality is enabled by clearing the `SPI_CTL.EMISO` bit in the six other slave processors.) The requestor can transmit broadcast data to all seven at the same time. This MISO enabling feature is available in some other microcontrollers. Therefore, it is possible to use the MISO enabling feature with any other SPI device that includes this functionality.

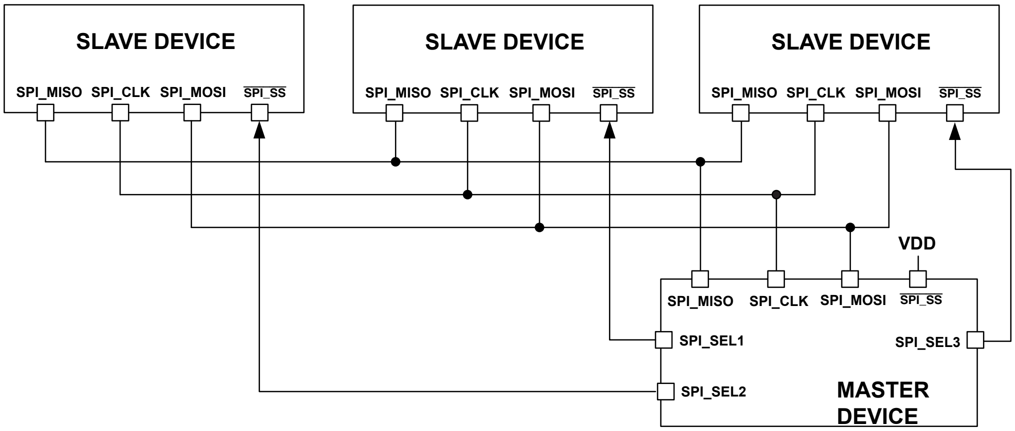

Figure 16-7: Single-Master, Multiple-Slave Configuration

Beginning and Ending a Non-DMA SPI Transfer

The start and finish of a non-DMA SPI transfer depend on the following settings.

1. Whether the device is configured as a master or a slave.
2. The state of the `SPI_CTL.ASSEL` bit, which selects between hardware and software control over `SPI_SLVSEL`.

When `SPI_CTL.CPHA`=0, the enabled slave select outputs are driven active. However, the `SPI_CLK` signal remains inactive for the first half of the first cycle of `SPI_CLK`. For a slave with `SPI_CTL.CPHA`=0, the transfer starts as soon as the `SPI_SS` input goes low.

When `SPI_CTL.CPHA`=1, a transfer starts with the first active edge of `SPI_CLK` for both slave and master devices. For a master device, a transfer is complete after it sends the last data and simultaneously receives the last data bit. A transfer for a slave device ends after the last sampling edge of `SPI_CLK`. If `SPI_CTL.ASSEL`=0, the hardware maintains responsibility for toggling `SPI_SS` between frames. If `SPI_CTL.ASSEL`=1, software controls the `SPI_SS` line and can keep it active between frames.

The `SPI_STAT.RFE` bit defines when the receive buffer can be read, indicating that `SPI_RFIFO` is not empty. The `SPI_STAT.TFF` bit defines when the transmit buffer can be written, indicating that the `SPI_TFIFO` is not full. The end of a single word transfer occurs when the `SPI_STAT.RFE` bit is cleared. The status indicates that a new word has been received and written into the receive FIFO. The `SPI_STAT.RFE` bit remains cleared as long as the receive FIFO has valid data.

To maintain software compatibility with other SPI devices, the `SPI_STAT.SPIF` bit is also available for polling. This bit can have a slightly different behavior from other commercially available devices.

In master mode with the `SPI_CTL.ASSEL` bit cleared, software manually asserts the required slave select signal before starting the transaction. After all data transfers, software typically releases the slave select line.

When the receive or transmit word counters are enabled in the `SPI_TXCTL` or `SPI_RXCTL` registers, the SPI generates a finish interrupt at the end of the transfer. It signals the end of all transfers related to that transaction.

Transmit Operation in Non-DMA Mode

The transmit operation in non-DMA mode is enabled through the `SPI_TXCTL.TEN` bit. It can be enabled independently from the receive operation, and the transmit channel can become the initiating channel based on the `SPI_TXCTL.TTI` bit setting.

Transmit underrun is not possible in this mode, as no new transfer initiates unless the transmit FIFO is empty (in the case that `SPI_TXCTL.TTI` =1). A receive overflow is detected when data from a new frame transfer replaces older data in a full receive FIFO. This event can occur if `SPI_TXCTL.TTI` =1 and the receive channel is enabled in a non-initiating capacity.

An SPI transmit interrupt request is signaled once the transmit channel has been enabled and the transmit FIFO is not full. The SPI uses the `SPI_TXCTL.TDR` bit setting to control the frequency of the interrupt request.

Receive Operation in Non-DMA Mode

The receive operation in non-DMA mode is enabled through the `SPI_RXCTL.REN` bit. It can be enabled independently from the transmit operation, and the receive channel can become the initiating channel based on the `SPI_RXCTL.RTI` bit setting.

Receive overflow is not possible in this mode, as no new transfer initiates when the receive FIFO is full (in the case of `SPI_RXCTL.RTI` =1). A transmit underrun can occur (`SPI_TXCTL.TDU` bit) when no valid data is in the `SPI_TFIFO` register when a transfer is initiated. This event can occur if `SPI_RXCTL.RTI` =1 and the transmit channel is enabled in a non-initiating capacity.

An SPI receive interrupt request is signaled once the receive channel has been enabled and there is data waiting to be read. The SPI uses the `SPI_RXCTL.RDR` bit setting to control the frequency of the interrupt request.

Dual I/O Mode

In Dual I/O mode, the `SPI_MISO` and `SPI_MOSI` pins are configured to operate in the same direction which doubles bandwidth. The SPI uses the `SPI_CTL.SOSI` bit to determine the order of bits on the pins. When set, the processor sends the first bit on the `SPI_MOSI` pin and the second bit on the `SPI_MISO` pin. If the

`SPI_CTL.SOSI` bit is cleared, the order is reversed. Since dual I/O mode uses both pins to transmit or receive data, only one channel can be enabled, either transmit or receive. Flow control through the `SPI_RDY` pin is supported. Interrupt request generation is unaffected by dual I/O mode. However, the interrupt service interval is reduced, since the individual transfer latency is halved.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

Quad I/O Mode (SPI2 only)

In quad SPI mode, the `SPI_MISO` and `SPI_MOSI` pins, in tandem with the `SPI_D2` and `SPI_D3` pins, are configured to operate in the same direction. The SPI uses the `SPI_CTL.SOSI` bit to determine the order of bits on the pins. When set, the processor sends:

- The first bit on the `SPI_MOSI` pin
- The second bit on the `SPI_MISO` pin
- The third bit on the `SPI_D2` pin
- The fourth bit on the `SPI_D3` pin

If the `SPI_CTL.SOSI` bit is cleared, the order is reversed. Since quad SPI mode uses all four pins to transmit or receive data, only one channel can be enabled as either transmit or receive. Flow control through the `SPI_RDY` pin is supported. Interrupt generation is unaffected by quad SPI mode.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

While using dual or quad I/O mode for communicating with flash devices, program the `SPI_CTL.CPHA` and the `SPI_CTL.CPOL` bits =1. This programming avoids bus contention during read operations, because the flash device starts driving out the bits immediately after dummy cycles in read header.

NOTE: The SPI does support quad SPI 8-bit transfer in slave continuous mode of operation with an SCLK:`SPI_CLK` ratio of less than 1:2. A minimum of 2 SCLK cycles is required between transfers in 8-bit quad SPI slave mode with an SCLK:`SPI_CLK` ratio of less than 1:2.

Fast Mode

Fast mode is similar to the normal mode of operation when transmitting. When receiving, data is sampled at the next transmit edge allowing a full cycle of timing in the receive direction. This mode is valid in master mode operation only. When the SPI operates in fast mode, the slave drives the data for one full cycle.

Memory-Mapped Mode (SPI2 only)

The SPI supports direct memory-mapped read accesses from a SPI memory device, enabled by setting the `SPI_CTL.MMSE` bit. This mode allows for direct execution of instructions from a SPI memory device without the need for a low-level software driver, as hardware handles all overhead tasks (for example, transmission of the read header, pin turnaround timing, and receive data sizing). The SPI features configurable options in the memory-mapped read header register (`SPI_MMRDH`) to provide compatibility with a wide range of SPI memory devices.

In non-memory-mapped mode, the software is responsible for providing the command and required dummy words for the read response, whereas this is all handled by hardware when the SPI is in memory-mapped mode. The memory of the SPI device is accessible directly through reads of the processor address space. The read accesses can be code or data accesses in core mode or when using memory DMA (MDMA). These accesses allow code to execute directly from SPI memory devices (true eXecute-In-Place operations), and the contents can be cached to improve performance. It is not necessary to access the SPI data buffer registers nor poll status bits; however, the hardware does not support peripheral DMA accesses nor write operations to the SPI memory space.

The *Types of Operations* table is a comparison of the permitted operations in the non-memory-mapped and memory-mapped modes supported by the SPI controller.

Table 16-6: Types of Operations

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
Core data write	Yes	No
Core data read	Yes	Yes
Code fetch: Execute-In-Place (XIP)	No	Yes
Read/Write accesses using SPI Peripheral DMA	Yes	No
Read/Write accesses by other peripheral DMA channels	No	No
MDMA read	No	Yes

Table 16-6: Types of Operations (Continued)

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
MDMA write	No	No

Memory-Mapped Description of Operation

Memory-mapped mode is enabled by setting the `SPI_CTL.MMSE` bit. When enabled, the SPI (if ready) accepts the read requests through a dedicated on-chip slave interface. The memory subsystem master drives this dedicated interface through the SCB fabric.

In a typical scenario, the memory subsystem master issues read requests to the fabric, and the fabric routes these requests to the slave port of the SPI peripheral. The master describes the read access using a number of parameters such as starting address, transfer size, and burst type. The SPI responds to this read access request when it is ready for a new transfer. It loads the opcode, a specified number of address bytes, and an optional mode byte into the transmit FIFO. The SPI memory state machine begins when both the transmit and receive channels of the SPI are enabled:

- the transmit transfer initiation bit is set (`SPI_TXCTL.TTI`=1), *and*
- the receive initiation bit is cleared (`SPI_RXCTL.RTI`=0)

The SPI memory read sequence starts with the assertion of `SPI_SEL1`. If the SPI memory state machine is in the reset state, it looks for a command. The SPI hardware then sends the specific 8-bit read command (which can be optionally skipped), followed by the SPI memory read address. After this, a dummy period is inserted, in which a mode byte is optionally sent and the pins are held or three-stated during the dummy clocking period.

NOTE: This read header is transmitted over the SPI standard protocol pins (`SPI_CLK`, `SPI_MOSI`, `SPI_MISO`, `SPI_SEL1`) or over the extended SPI protocol pins (`SPI_CLK`, `SPI_MOSI`, `SPI_MISO`, `SPI_D2`, `SPI_D3`, `SPI_SEL1`), based on the `SPI_MMRDH.CMDPINS`, `SPI_MMRDH.ADRPINS`, and `SPI_CTL.MIOM` bit settings. SPI memory devices usually support communication in MSB-first mode. In dual mode, the SPI typically uses `SPI_MISO` as IO1 and `SPI_MOSI` as IO0. In quad mode, the SPI typically uses `SPI_D3` pin as IO3, `SPI_D2` as IO2, `SPI_MISO` as IO1, and `SPI_MOSI` as IO0.

When all I/O data pins are three-stated, the SPI continues clocking the SPI memory device, which drives out the data bits at the addressed location, until all bytes are received. The SPI hardware reads the data as configured by the `SPI_CTL.MIOM` bit setting. Upon reception of the last byte, the SPI typically deasserts `SPI_SEL1` to prepare for the next requested read header.

Application code must ensure that the opcode sent is consistent with multiple I/O programming and that the parameters specified in the memory-mapped read header register are consistent with flash read access timing.

The ***SPI Memory-Mapped Register Operations Flow*** diagram shows how the fields of the `SPI_MMRDH` register determine the read header while initiating transfers in memory-mapped mode.

Memory-Mapped Architectural Concepts

In memory-mapped mode, the SPI accepts read requests through a dedicated on-chip slave interface. The SPI (if ready) accepts these requests and begins the process of assembling the read header based on access attributes described in both the `SPI_MMRDH` register and the internal bus request. After the read header transmission is complete, a pin turnaround period is timed and the receiver is enabled. The SPI continues clocking the SPI memory device until all bytes are received.

The SPI memory-mapped hardware accommodates various memory devices with different read timing. The capabilities include extra mode bits, flexible dummy period timing, and three-state control, as configured in the `SPI_MMRDH` register.

The *Memory-Mapped Protocol* figure shows the protocol for the SPI controller in memory-mapped mode.

Figure 16-14: Memory-Mapped Protocol

As shown in the figure, the COMMAND field (`SPI_MMRDH.OPCODE`) is transmitted upon assertion of the `SPI_SEL[n]` signal. The SPI memory interprets this 8-bit value as a read command. Any 8-bit read opcode whose timing is compliant with the processor SPI and features provided by memory-mapped hardware is allowed, the most common being:

- Standard Read (0x03)
- Fast Read (0x0B)
- Fast Read Dual Output (0x3B)
- Fast Read Dual I/O (0x6B)
- Fast Read Quad Output (0xBB)
- Fast Read Quad I/O (0xEB)
- Word Read Quad I/O (0xE7)
- Octal Word Read Quad I/O (0xE3)

NOTE: The SPI hardware does not validate the content of the `SPI_MMRDH.OPCODE` field prior to transmitting.

DMYSIZE (Number of Dummy Bytes)

When operating at a high clock frequency in multi-IO modes, most flash devices require some dummy clocks after the address bits. These dummy clock cycles allow the internal circuits of the device extra time for setting up the initial address. These bits specify the number of bytes separating address transmission and read data return.

The number of dummy cycles required varies per manufacturer, the read command used, and the SPI access time. The SPI hardware allows dummy cycles to be programmed in bytes in the `SPI_MMRDH.DMYSIZE` field, the value of which is a function of the number of pins used to transmit the address (`SPI_MMRDH.ADRPINS`), as shown in the *Pins Used to Transmit the Address (ADRPINS)* table.

Table 16-7: Pins Used to Transmit the Address (ADRPINS)

	Dummy clock cycles		
SPI_MMRDH.DMYSIZE	(**SPI_MMRDH.ADRPINS**=0, **SPI_CTL.MIOM**=x) Dummy bytes elapse over 1-pin	(**SPI_MMRDH.ADRPINS**=1, **SPI_CTL.MIOM**=1) Dummy bytes elapse over 2-pins	(**SPI_MMRDH.ADRPINS**=1, MIOM=2) Dummy bytes elapse over 4-pins
000	0	0	0
001	8	4	2
010	16	8	4
011	24	12	6
100	32	16	8
101	40	20	10
110	48	24	12
111	56	28	14

This dummy clocking period allows the mode bits to be sent, the pins to be three-stated, and the pins to be turned around in preparation for the receive data.

Memory-Mapped Read Accesses

The SPI hardware supports the most commonly used read operations.

- Two standard SPI reads (read and read fast), which use the unidirectional `SPI_MOSI` and `SPI_MISO` pins in addition to `SPI_SEL[n]` and `SPI_CLK`
- Four extended SPI multiple I/O reads: dual output, quad output, dual I/O, and quad I/O reads

The *SPI Read Operations* table and *SPI Flash Fast Read Sequence* figures summarize the types of read operations. Program each read operation in a way that is compatible with the description given in the SPI flash data sheet.

Table 16-8: SPI Read Operations

Operation	Read Command (Opcode)	CMDPIN	ADRPIN	DMYSIZE	Three-state	Multiple I/O Mode	Data Pins
Read	0x03	1	1	Zero	No	No	1
Fast Read	0x0B	1	1	Non-Zero	Yes	No	1
Dual Output Read	0x3B	1	1	Non-Zero	Yes	Yes(IO0-1)	2
Quad Output Read	0x6B	1	1	Non-Zero	Yes	Yes(IO0-3)	4
Dual I/O Read	0xBB	1, 2	2	Non-Zero	Yes	Yes (IO0-1)	2

Table 16-8: SPI Read Operations (Continued)

Operation	Read Command (Opcode)	CMDPIN	ADRPIN	DMYSIZE	Three-state	Multiple I/O Mode	Data Pins
Quad I/O Read	0xEB	1, 4	4	Non-Zero	Yes	Yes (IO0-3)	4

Some memory devices also support word quad I/O read (0xE7) and octal quad I/O read (0xE3) operations. These operations require fewer dummy cycles than normal quad I/O read operations.

Figure 16-19: SPI Flash Quad I/O Read Sequence

SPI memory-mapped reads can be made cacheable in the core's internal memory by properly configuring the region as cacheable memory without bypass (see the related core's cache configuration documentation for details). In the figures, the number of read data bytes (N) is based on the following:

- For an instruction fetch by core (when in XIP mode); the number of instruction bytes to fetch depends the cache line size of the cache.
- For a data fetch by the core (data read), the number of data bytes to fetch depends on the cache line size of the cache.

Although the minimum size of a memory-mapped data read transfer is 4 bytes, applications can fetch a single byte or a 2-byte data. (For example, it can fetch an unsigned char or short access in C code). In this case, only the required bytes are provided to the core and the other bytes are cached.

The on-chip memory subsystem master provides a starting address for the burst and the SPI hardware issues this address as part of the read header. The address provided is N-byte aligned. For example, to read the 30th byte from SPI memory, then the typical address to provide is:

- 28 (0x0000_001C) for a 32-bit cache line
- 24 (0x0000_0018) for a 64-bit cache line
- 16 (0x0000_0010) for a 128-bit cache line
- 0 (0x0000_0000) for a 256-bit cache line

The read data is returned to the memory subsystem in the order provided by the SPI memory. There can be considerable delay for the expected data provided to the master.

To minimize this delay, the wrap feature can be used where the memory subsystem provides the address of the critical word.

- For MDMA reads, the number of read data bytes (N) is always equal to 4 bytes. The MDMA read does not depend on the cache setting. For MDMA reads, limit the `DMA_CFG.MSIZE` field to 1, 2 or 4 bytes. The address provided by the memory subsystem master to the SPI hardware is always 4 byte-aligned.

Memory-Mapped High-Performance Features

In addition to automating the SPI memory read accesses, the memory-mapped hardware also provides some features to improve SPI memory fetches and increase the system performance. The following sections describe these features.

Merged Read Accesses

It is common for the memory subsystem to fetch two or more cache lines from consecutive addresses (the address sequencing is linear without any jumps). To take advantage of this situation, the SPI memory-mapped hardware provides a feature called merging. Enable merging by setting the `SPI_MMRDH.MERGE` bit.

When enabled, the hardware compares the address of an incoming read request to the address of a request the SPI memory is actively servicing. It can decide to merge two accesses when the address for the second access is incremental. For example, if the first address of a 32-byte cache line fetch is 0x0000_0000 and the second fetch is to address 0x0000_0020, then these two accesses can be merged. Merging increases efficiency and overall fetch bandwidth by eliminating the read header for those accesses which only require continuation of the SPI clock.

Wrap Around Accesses

Many SPI flash memory devices support wrapping which is used to enhance critical word fetching of cache lines. In this mode, the SPI device automatically wraps the read address to the base of a cache line once the end of the cache line is reached.

Wrap around accesses are enabled by setting the `SPI_MMRDH.WRAP` bit.

Some flash devices require programs to send a ***Set Wrap*** command to place the device in wrap mode. Other flash devices provide a configuration register which must be programmed to set the flash in wrap mode. Since the SPI memory-mapped hardware does not support any write operations to flash, perform this step in non-memory-mapped mode (`SPI_CTL.MMSE`=0) by accessing the SPI registers.

Table 16-9: Wrap Modes

Cache Line Size	Wrap Mode	Comments
4-byte	Not applicable	Usually flash does not support 4-byte wrapping.
8-byte	8 byte wrapping	Read data wraps within an aligned 8-byte boundary starting from the specified address.
16-byte	16 byte wrapping	Read data wraps within an aligned 16-byte boundary starting from the specified address.
32-byte	32 byte wrapping	Read data wraps within an aligned 32-byte boundary starting from the specified address.

Data access is limited to 8-byte, 16-byte, or 32-byte sections of flash page in wrap mode. The ARM core uses the Wrap 4 access (64-bit data) for L1 cache. The ARM core uses Wrap 4 and Wrap 8 accesses (64-bit data) for L2 cache. The cores use the Wrap 8 accesses for unaligned accesses. During the read request to the SPI memory-mapped hardware, the memory subsystem master of the processor provides the address of a critical word instead of the line base. The read-data starts at the address specified in the instruction. Once it reaches the end boundary of the 8, 16, or 32-byte section, the output automatically wraps around to the beginning boundary to the line base address. The data fetch continues. It is not necessary to deassert the SPI `SPI_SEL[n]` signal or resend the read header to wrap to the cache line base when servicing misaligned cache fill requests.

The ***Byte Sequence in Wrap Modes*** table shows byte sequences in various wrap modes.

Table 16-10: Byte Sequence in Wrap Modes

Starting Address	8-Byte Wrap (cache_line = 8 byte)
0	0-1-2- . . . -6-7
1	1-2- 3-. . . -7-0
7	7-0-1- . . . -5-6
15	15-8-9- . . . -13-14
31	31-24-25-. . . .-29-30

The burst with wrap feature allows applications to fetch a critical address quickly. Applications then fill the cache afterwards within a fixed length (8/16/32-byte) of data without issuing multiple read commands. Certain applications can benefit from this feature to improve cache fill efficiency and overall performance of system code execution.

NOTE: Do not use the merge and wrap feature together. Using wrap bursts can unintentionally disable merging (merging cannot occur for unaligned wrapping bursts). A wrap burst can start fetching data words in the middle of the cache line and cannot be merged with the next access.

Execute-In-Place (XIP, SPI2 only)

Execute-In-Place, most commonly known as XIP, allows software code to execute directly from an SPI flash device rather than downloading the code and executing it out of RAM. XIP, also known as Command Skip mode, is a general term and can be applied to fetching data as well.

There is a difference between XIP mode and standard mode. In XIP mode, after the SPI memory device is selected (CS# =LOW), the memory device does not decode the first input byte as command code. Instead, it expects the read header to directly start with address bytes. In standard mode, the memory decodes the first input byte it receives as a command code.

The XIP mode dramatically reduces random access time for applications that require fast code execution without shadowing the memory content on a RAM. The SPI memory-mapped hardware provides a control bit, `SPI_MMRDH.CMDSKIP` to skip the command from read header.

Some SPI memory devices require configuration of their control register to enable the XIP mode of operation, using the non-memory-mapped mode of the processor SPI. Typically, during the dummy cycle period, the mode bits are used to confirm the XIP operation and the `SPI_MMRDH.MODE` field must be set appropriately. A dummy memory-mapped access may be needed before setting the `SPI_MMRDH.CMDSKIP` bit in order to set the SPI memory device in Command Skip mode.

For more details about how to configure SPI memories into XIP mode, refer to the device data sheet.

> **NOTE:** When configuring the flash to XIP mode from the SHARC+ core, ensure that the routine that configures flash to XIP is not routed through the L2CC. This is accomplished by first configuring the flash to XIP mode, then enabling the L2CC from the core.

Memory-Mapped Mode Error Status Bits

The SPI memory-mapped hardware provides bits in the `SPI_STAT` register to report errors. It provides these bits for notification only and their state has no effect on SPI operations. The status register bits are sticky. A W1C (write-1-to-clear) operation clears the bits.

- Memory-Mapped Write Error (`SPI_STAT.MMWE`). This bit is set (=1) if an attempt is made to write to address space that is reserved for memory-mapped SPI memory. The SPI memory-mapped hardware does not support automated write access to SPI memory space.
- Memory-Mapped Read Error (`SPI_STAT.MMRE`). This bit is set (=1) if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (`SPI_CTL.MMSE` =0).
- Memory-Mapped Access Error (`SPI_STAT.MMAE`). This bit is set (=1) if an attempt is made to access either the TX or RX FIFO while memory-mapped access of SPI memory is enabled. In this case, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric error responses. Legacy methods include any direct access made to the TX and RX FIFOs, whether by DMA or processor MMR.
- Memory-Mapped Write Error Mask (`SPI_CTL.MMWEM`) bit specifies whether an error response is returned to the fabric on write attempts to address space that is reserved for memory-mapped SPI memory reads. Regardless of whether a write error response is masked using this bit, the memory-mapped write error (`SPI_STAT.MMWE`) sticky notification bit is still set.

> **NOTE:** Unlike other bits in the `SPI_STAT` register, these memory-mapped mode error bits do not have associated bits in the SPI interrupt mask (`SPI_IMSK`) and SPI interrupt condition (`SPI_ILAT`) registers.

The memory-mapped top register (`SPI_MMTOP`) is used to specify the upper limit of the SPI memory address. The memory-mapped accesses to SPI memory addresses equal to or above this range are considered illegal. The accesses are blocked and a bus error response is generated.

This register is useful to block the invalid SPI memory address accesses. Some SPI memory vendors do not clearly specify (guarantee) that overrange address bits are ignored (address spaces can be wrapped).

Memory-Mapped Programming Guidelines

Seting the `SPI_CTL.MMSE` bit enables SPI memory-mapped mode. When enabled, the SPI interface is forced to be consistent with SPI memory requirements regardless the settings of certain control bits. The following tables specify typical settings for configuring the SPI in memory-mapped mode:

Table 16-11: SPI Control (SPI_CTL) Register

Bits	Typical values to set	Description	Comments
`SPI_CTL.MSTR`	1	Master mode enable	
`SPI_CTL.PSSE`	0	Protected slave select enable	
`SPI_CTL.ODM`	0	Open-drain mode enable	
`SPI_CTL.CPHASPI_CTL.CPOL`	0–0 or 1–1	SPI mode of communication	Flash dependent, usually SPI flash supports mode-0 (CPHA=CPOL=0) and mode-3 (CPHA=CPOL=1)
`SPI_CTL.ASSEL`	1	Hardware slave select pin control	
`SPI_CTL.SELST`	1	Slave select asserted between transfers	
`SPI_CTL.EMISO`	1	MISO pin enable	
`SPI_CTL.SIZE`	2	32-bit transfer size	
`SPI_CTL.LSBF`	0	MSB bit first mode	Flash dependent, usually SPI flash communicates in MSB bit first mode

`SPI_CTL.FCEN`
`SPI_CTL.FCCH`
`SPI_CTL.FCPL`
`SPI_CTL.FCWM`
	0	Hardware flow control related bits	

`SPI_CTL.FMODE`	1	Fast mode enable	Typically set to 1 for full cycle timing, 0 only works at low speed
`SPI_CTL.SOSI`	0	Treat `SPI_MOSI` pin as IO0 pin.	

Table 16-12: SPI Receive Control Register

Bits	Typical values to set	Description
`SPI_RXCTL.REN`	1	Receive channel enable
`SPI_RXCTL.RTI`	0	Receive transfer initiation disable
`SPI_RXCTL.RWCEN`	0	Receive word counter disable
`SPI_RXCTL.RDR`	0	Receive data request disable
`SPI_RXCTL.RDO`	0	Discard incoming data if RFIFO is full
`SPI_RXCTL.RRWM`	0	Receive FIFO regular watermark
`SPI_RXCTL.RUWM`	0	Receive FIFO urgent watermark disable

Table 16-13: SPI Transmit Control Register

Bits	Typical values to set	Description
`SPI_TXCTL.TEN`	1	Transmit channel enable
`SPI_TXCTL.TTI`	1	Transmit transfer initiation disable
`SPI_TXCTL.TWCEN`	0	Transmit word counter disable
`SPI_TXCTL.TDR`	0	Transmit data request disable
`SPI_TXCTL.TDU`	0	Send last word when TFIFO is empty
`SPI_TXCTL.TRWM`	0	Transmit FIFO regular watermark
`SPI_TXCTL.TUWM`	0	Transmit FIFO urgent watermark disable

Table 16-14: SPI DLY Control Register

Bits	Typical values to set	Description	Comments See Flash data sheet for CS (for example. SSEL) timing specs
`SPI_DLY.LAGX`	1	Extended lag timing	
`SPI_DLY.LEADX`	1	Extended lead timing	
`SPI_DLY.STOP`	3	Stop bit between the transfers	Can be set to 1 at lower SPI clock frequencies.

The multiple I/O mode (`SPI_CTL.MIOM`) bits are partially ignored:

- The command (opcode) is transmitted using either just one or the number of pins specified by the `SPI_CTL.MIOM` bits, depending on `SPI_MMRDH.CMDPINS` bit setting.
- The address is then transmitted using either just one or the number of pins specified by the `SPI_CTL.MIOM` bits, depending on `SPI_MMRDH.ADRPINS` bit setting.
- The data is always read with the number of pins specified by the `SPI_CTL.MIOM` bits.

NOTE: Set the SPI module enable bits `SPI_CTL.EN` last after configuring all registers.

Use the following programming guidelines for memory-mapped mode:

- The SPI memory-mapped hardware does not check the flash status before initiating the access. It assumes that SPI memory is always able to respond to a read access. Befor enabling memory-mapped mode (for example, setting the `SPI_CTL.MMSE` bit) ensure that SPI flash is ready for a read access. When using non-memory-mapped mode, a write-complete status can be examined prior to enabling the SPI in memory-mapped mode. (See the write in progress bit in the SPI flash memory status register.) Also, immediately after initial power-up, SPI memory devices can be inaccessible for a vendor-specified period.
- When SPI is enabled in memory-mapped mode, attempts to communicate with the SPI device using legacy methods are blocked. Legacy methods include any direct access made to the transmit or receive FIFOs, whether initiated by DMA or by a processor MMR access.

- To use some of the features offered by SPI memory devices, programs can first configure the SPI memory device by setting its control word or sending some commands. Since SPI memory-mapped hardware does not allow any type of SPI write operations, configure the SPI in non-memory-mapped mode prior to enabling memory-mapped mode.
- The memory-mapped hardware does not interpret the opcode. It does not check the validity of the timing that is specified in the `SPI_MMRDH` register for a particular opcode. Programs must set the fields of the `SPI_MMRDH` register to be consistent with the read-type selected.
- When the core requests the data or code fetch, the memory-mapped transfer depends on cache settings. The cache configuration register in the SPI memory device must be appropriately configured before enabling memory-mapped mode. Some of the high performance modes like merge, wrap, and transfer size depend on cache parameters.
- SPI memory-mapped MDMA reads do not support wrapping. For MDMA reads, limit the `DMA_CFG.MSIZE` field to 1 byte, 2 bytes or 4 bytes.
- There is not always tool support to change the SPI memory-mapped hardware setting or cache settings on-the-fly. Changing these settings can optimize the performance of code that accesses SPI memory in memory-mapped mode. It is expected that the SPI memory, SPI peripheral, and cache are programmed to one specific set of control settings for the whole application. Profiling or benchmarking of the actual application can be done to find the setting that works best.

SPI Interrupt Signals

The SPI controller supports three types of interrupt request signals that correspond to data, status, and error conditions.

Data Interrupts

The SPI peripheral supports two data interrupt channels – receive and transmit. These interrupt signals are multiplexed into the DMA request lines. Since the peripheral interfaces with separate read and write interfaces with DMA, the read and write data interrupts are independent. When the DMA channels are not used, the interrupts are routed directly to the system event controller. The interrupts occupy the same vector locations as the corresponding DMA channels.

Each of the data interrupt requests can be individually controlled. Program the `SPI_RXCTL.RDR` and `SPI_TXCTL.TDR` bit fields for receive and transmit, respectively. When receive is enabled, the RX interrupt request is issued whenever there is data available in the receive datapath for reading. (The event occurs according to the `SPI_RXCTL.RDR` bit setting.) When transmit is enabled, the TX interrupt request is issued whenever the transmit datapath can be written. (The event occurs according to the `SPI_TXCTL.TDR` setting.) DMA data interrupts are compatible with second-generation DMA to incorporate urgent data requests and transfer finish interrupt requests apart from the usual data request interrupts. Transmit interrupt requests operate independently from the word counter-value in the `SPI_TWC` register.

Status Interrupts

The SPI controller supports several status interrupt requests to indicate different conditions of the receiver and transmitter. All status interrupt requests can be masked. Status interrupt requests are signaled directly through a single SPI status IRQ line. The line cannot be combined with the SPI error IRQ line for some processors. The ***SPI Status Interrupts*** table describes the status interrupt requests that are available for the SPI controller.

Table 16-15: SPI Status Interrupts

SPI_STAT Bit	Description
`SPI_STAT.RUWM`	Receive FIFO urgent watermark interrupt request. Issued when the level of the RFIFO breaches the watermark set in the `SPI_RXCTL.RUWM` field. It is cleared when the level of the RFIFO reaches the watermark set in the `SPI_RXCTL.RRWM` field. If the RX channel is configured in DMA mode, `SPI_RXCTL.RUWM` is multiplexed with the data request.
`SPI_STAT.TUWM`	Receive FIFO urgent watermark interrupt request. Issued when the level of the TFIFO breaches the watermark set using the `SPI_TXCTL.TUWM` bit. It is cleared when the level of the TFIFO reaches the watermark set in the `SPI_TXCTL.TRWM` field. If the TX channel is configured in DMA mode, `SPI_STAT.TUWM` is multiplexed with the data request.
`SPI_STAT.TS`	Transmit start interrupt request. Issued when the start of a transmit burst is detected by loading of the `SPI_TWC` register with the contents of the `SPI_TWCR` register.
`SPI_STAT.RS`	Receive start interrupt request. Issued when the start of a receive burst is detected by the loading of `SPI_RWC` with the contents of `SPI_RWCR`.
`SPI_STAT.TF`	Transmit finish interrupt request. Issued when a transmit burst completes (`SPI_TWC` decrements to zero).
`SPI_STAT.RF`	Receive finish interrupt request. Issued when a receive burst completes (`SPI_RWC` decrements to zero).

Error Conditions

The SPI controller supports interrupt requests upon several different error conditions. All interrupt requests are maskable. The individual error indications combine into a single SPI error IRQ signal, which can be multiplexed on some processors with the aggregated SPI status IRQ signal. The ***SPI Error Interrupts*** table details the possible error indications.

Error conditions arise depending on which of the channels (transmit or receive) are enabled. If a channel is disabled, all errors related to it are ignored. When both channels are enabled, errors from both channels are enabled.

Table 16-16: SPI Error Interrupts

Bit	Description
`SPI_STAT.MF`	Mode fault. Signaled when another device also tries to be a master in a multi-master system and drives the `SPI_SS` input low. This error is signaled in master mode operation.
`SPI_STAT.TUR`	Transmission error. Signaled when an underflow condition occurs on the transmit channel. This event occurs when a new transfer starts but `SPI_TFIFO` is empty. This error does not occur in master transmit initiating mode since `SPI_TFIFO` *Not Empty* is one of the conditions for transfer initiation.

Table 16-16: SPI Error Interrupts (Continued)

Bit	Description
`SPI_STAT.ROR`	Reception error. Signaled when an overflow condition occurs on the receive channel. This event occurs when a new data word is received, but the `SPI_RFIFO` is full. This error condition does not occur in master receive initiating mode since `SPI_RFIFO` *Not Full* is one of the conditions for transfer initiation.
`SPI_STAT.TC`	Transmit collision error. Signaled when loading data to the transmit shift register happens near the first transmitting edge of `SPI_CLK`. In slave mode of operation, the SPI controller is unaware of when the next transfer starts. Loading of data to the transmit shift register can happen just after the transmitting edge. This event results in the setup time not being met for the first bit transmitted. The transmitted data is corrupt. In `SPI_CTL.CPHA` 1 mode, the first `SPI_CLK` edge is taken as the first transmitting edge. If `SPI_CTL.CPHA` =0, then the last `SPI_CLK` edge of the last transmission (`SPI_CTL.SELST` =1) or slave select deassertion (`SPI_CTL.SELST` =0) is taken as the first transmitting edge. This error is signaled only in the slave mode of operation. In master mode of operation, loading of data happens before the first transmitting edge of `SPI_CLK`.

SPI Programming Concepts

The following sections provide general programming guidelines and procedures.

Programming Guidelines

It is acceptable to program `SPI_RXCTL` and `SPI_TXCTL` registers after programming the `SPI_CTL` register. However, program the initiating mode register and its counter-register, if enabled, after the non-initiating mode register. For example, if transmit is the initiating mode and receive is the non-initiating mode, then program the `SPI_RXCTL` and `SPI_RWC` registers before the `SPI_TXCTL` and `SPI_TWC` registers. If enabling both transmit and receive in initiating mode, enable the `SPI_CTL` register after programming both the `SPI_RXCTL` and `SPI_TXCTL` registers.

These programming guidelines prevent SPI from starting a transfer when SPI registers are not fully programmed. Other ways of programming are also allowed as long as the initiating conditions prevent the start of communication until after programming of SPI registers is complete.

Take precautions to avoid data corruption when changing the SPI module configuration. Do not change the configuration during a data transfer. Additionally, change the clock polarity only when no slaves are selected. However, an exception to this rule exists. When an SPI communication link consists of a single master and slave, `SPI_CTL.ASSEL` = 0. The slave select input of the slave is permanently tied low. In this case, the slave is always selected. Avoid data corruption by enabling the slave only after both the master and slave devices are configured.

The module supports 8, 16-bit and 32-bit word sizes. To ensure correct operation, configure both the master and slave with the same word size.

Master Operation in Non-DMA Modes

This section describes the operation of the SPI as a master in non-DMA mode.

1. Write to the `SPI_SLVSEL` register, setting one or more of the SPI select enable bits. This operation ensures that the desired slaves are properly deselected while the master is configured.
2. The `SPI_RXCTL.RTI` and `SPI_TXCTL.TTI` bits determine the SPI initiating mode. The initiating mode defines the primary transfer channel, and also the initiating condition for the transfer.
3. Write to the `SPI_CLK`, `SPI_CTL`, `SPI_RXCTL`, and `SPI_TXCTL` registers. This operation enables the device as a master and configures the SPI system. It specifies the transfer modes and channels, appropriate word length, transfer format, baud rate, and other control information.

   ADDITIONAL INFORMATION: If `SPI_RXCTL.RTI` is enabled and `SPI_TXCTL.TTI` is not, write to the `SPI_RXCTL` register after writing into `SPI_CTL`, `SPI_TXCTL`, and `SPI_TFIFO` registers to prevent a transmit underrun for the first transfer.
4. If `SPI_CTL.ASSEL`=0, activate the desired slaves by clearing one or more of the `SPI_SLVSEL` flag bits. Otherwise, the SPI hardware performs slave activation.
5. The SPI controller then generates the programmed clock pulses on `SPI_CLK` and simultaneously shifts data out of `SPI_MOSI` while shifting data in from `SPI_MISO`. Before a shift, the shift register is loaded with the contents of the `SPI_TFIFO` register. At the end of the transfer, the contents of the shift register are loaded into `SPI_RFIFO`.
6. Whenever the initiating conditions are satisfied, the SPI continues to send and receive words. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the `SPI_TXCTL.TDU` and `SPI_RXCTL.RDO` bits.
7. It is possible to program a secondary channel in addition to the initiating channel. This feature allows usage of available channel resources for receives or transmits simultaneously with the initiating channel.

Slave Operation in Non-DMA Modes

When a device is enabled as a slave in a non-DMA mode, a transition of the $\overline{\texttt{SPI\_SS}}$ select signal to the active state (low) triggers the the start of a transfer. Or, the first active edge of `SPI_CLK` triggers the start, depending on the state of `SPI_CTL.CPHA` bit. The interface operates in the following manner.

1. The core writes to the `SPI_CTL`, `SPI_RXCTL`, and `SPI_TXCTL` registers. The operation defines the mode of the serial link to be the same as the mode setup in the SPI master.
2. To prepare for the data transfer, the core writes data to be transmitted into `SPI_TFIFO`.
3. Once the $\overline{\texttt{SPI\_SS}}$ falling edge is detected, the slave starts sending data on active `SPI_CLK` edges and sampling data on inactive `SPI_CLK` edges.
4. Reception or transmission continues until $\overline{\texttt{SPI\_SS}}$ is released or until the slave has received the proper number of clock cycles.
5. The slave device continues to receive or transmit with each new falling edge transition on $\overline{\texttt{SPI\_SS}}$ or active `SPI_CLK` edge. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the `SPI_TXCTL.TDU` and `SPI_RXCTL.RDO` bits.

Configuring DMA Master Mode

The SPI interface supports a write DMA channel and a read DMA channel. It can use these functions individually or in a lock-step manner in duplex mode (`SPI_TXCTL.TTI`= `SPI_RXCTL.RTI`=1).

1. Write to the appropriate DMA registers to enable the SPI DMA channel and to configure the necessary work units, access direction, word count, and so on.
2. Write to the `SPI_SLVSEL` register, setting one or more of the SPI flag select bits.
3. Write to the `SPI_CLK` and `SPI_CTL` registers, enabling the device as a master and configuring the SPI system by specifying the appropriate word length, transfer format, baud rate, and so forth.
4. Write to `SPI_RXCTL` to configure SPI master receive mode, or write to `SPI_TXCTL` to configure SPI master transmit mode.
5. Finally, write to the `SPI_RXCTL.REN` bit to enable the receive channel, or write to `SPI_TXCTL.TEN` to enable the transmit channel.
6. If the `SPI_RXCTL.RTI` bit is enabled, a receive transfer is initiated upon enabling `SPI_CTL.EN` bit. If the receive word counter is enabled (`SPI_RXCTL.RWCEN`), then the `SPI_RWC` register must be non-zero for a transfer to initiate.

   ADDITIONAL INFORMATION: If enabling both receive and transmit DMA channels, but not enabling `SPI_TXCTL.TTI`, write to the `SPI_RXCTL` register after writing the `SPI_CTL` and `SPI_TXCTL` registers. In this way, a transmit underrun can be prevented for the first transfer. Subsequent transfers are initiated as the SPI reads data from the receive shift register and writes to the SPI receive FIFO. The SPI then requests a write from DMA to memory. Upon a DMA grant, the DMA engine reads a word from the SPI receive FIFO and writes to memory. New requests continue to be initiated as long as the receive FIFO does not fill up, when `SPI_RWC` does not become zero while `SPI_RXCTL.RWCEN`=1.

7. If `SPI_TXCTL.TTI` is enabled, the SPI controller requests DMA reads from memory as long as there is space for more data in the transmit pipe. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO. As long as transmit data is available in the FIFO, and the `SPI_TWC` register is non-zero when `SPI_TXCTL.TWCEN`=1, the SPI continues to initiate transfers until disabled.
8. If both the `SPI_TXCTL.TTI` and `SPI_RXCTL.RTI` bits are enabled, the SPI controller requests a DMA read from memory. However, there must be space for more data in the transmit pipe and the number of words written into the SPI must be less than `SPI_TWC` if `SPI_TXCTL.TWCEN`=1. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

   ADDITIONAL INFORMATION: As the SPI writes data from the transmit FIFO into the transmit shift register, it initiates a transfer on the SPI link. Data received from the transfer is moved from the SPI receive shift register to the receive FIFO. The SPI controller requests a write from DMA to memory. Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory. Transfer continues to be initiated as long as both receives and transmits can accommodate new data.

9. If the receive pipe fills up due to unavailability of DMA grants, the transmit pipe stalls until the pipe is drained. If the transmit pipe fills up, the SPI stops requesting for DMA writes. If the value in `SPI_RWC` expires, further write-requests to DMA stop. However, data already written into the transmit FIFO is sent, and read requests to DMA continue until the receive data is read from the receive FIFO.
10. The SPI then generates the programmed clock pulses on `SPI_CLK` and simultaneously shifts data out of `SPI_MOSI` while shifting data in from `SPI_MISO`. For receive transfers, the value in the shift register is loaded into the `SPI_RFIFO` register at the end of the transfer. For transmit transfers, the value in the `SPI_TFIFO` register is loaded into the shift register at the start of the transfer.

Configuring DMA Slave Mode Operation

This mode occurs when the SPI is enabled as a slave and the DMA engine is configured to transmit or receive data. A transition of the `SPI_SS` signal to the active-low state triggers the start of a transfer. Or, the first active edge of `SPI_CLK` triggers the start of a transfer, depending on the state of the `SPI_CTL.CPHA` bit. The following steps illustrate the SPI receive or transmit DMA sequence in an SPI slave (in response to a master command). The SPI supports a receive DMA channel and a transmit DMA channel.

1. Write to the appropriate DMA registers to enable the SPI DMA channel and configure the necessary work units, access direction, word count, and so on.
2. Write to the `SPI_CTL`, `SPI_RXCTL`, and `SPI_TXCTL` registers to define the mode of the serial link to be the same as the mode configured in the SPI master.
3. If the receive channel is enabled (`SPI_RXCTL.REN` is asserted), the following actions occur:
    a. Once the slave select input is active, the slave starts receiving and transmitting data on active `SPI_CLK` edges.
    b. The value in the shift register is loaded into the `SPI_RFIFO` register at the end of the transfer.
    c. Once `SPI_RFIFO` has valid data, it requests a write from DMA to memory.
    d. Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory.
    e. As long as there is data in the receive FIFO, the SPI slave continues to request a DMA write to memory. The DMA engine continues to read a word from the FIFO and writes to memory until the `SPI_RWC` counts to zero. The SPI slave continues receiving words on active `SPI_CLK` edges as long as the `SPI_SS` input is active.
    f. If the data collected in the receive pipe breaches the set level, and the DMA engine cannot keep up with the receive rate, the slave can deassert the `SPI_RDY` signal. This signaling throttles the master. The receive pipe level is set according to the `SPI_CTL.FCWM` field. The signal is deasserted as the DMA drains the receive FIFO. Alternatively, the SPI can use the `SPI_RXCTL.RDO` bit to decide when the incoming data is discarded or overwritten into the receive FIFO (when `SPI_CTL.FCEN` is inactive).
4. If the transmit channel is enabled (`SPI_TXCTL.TEN` is asserted), the following actions occur:
    a. The SPI requests a DMA read from memory.

   b. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.
   c. The SPI then reads DMA data from the transmit FIFO and writes to the transmit shift register, awaiting the start of the next transfer.
   d. Once the slave select input is active, the slave starts receiving and transmitting data on active `SPI_CLK` edges.
   e. As long as there is room in the transmit FIFO, the SPI slave continues to request a DMA read from memory. The DMA engine continues to read a word from memory and write to the transmit FIFO until the `SPI_TWC` register value counts down to 0. The SPI slave continues transmitting words on active `SPI_CLK` edges as long as the $\overline{\texttt{SPI\_SS}}$ input is active.
   f. If the number of outstanding data entries in the transmit pipe breaches the level set and the DMA cannot keep up with the transmit rate, the slave deasserts the `SPI_RDY` signal. This signaling throttles the master. The transmit pipe level is set according to the `SPI_CTL.FCWM` field. The signal is deasserted as the DMA fills the transmit FIFO. Alternately, the `SPI_TXCTL.TDU` bit decides the state of the transmit data (when `SPI_CTL.FCEN` is deasserted).

5. If both receive and transmit channels are enabled, the following actions occur after the actions for each channel. Transfers continue as long as both receive and transmit channels can accommodate new data.
   a. If the receive pipe fills up due to the unavailability of DMA grant, the SPI interface stalls the master by asserting the `SPI_RDY` pin. This signal is deasserted as the DMA drains the receive FIFO. Alternately, the SPI uses the `SPI_RXCTL.RDO` bit to decide when the incoming data is discarded or overwritten in the receive FIFO (when `SPI_CTL.FCEN` is deasserted).
   b. If the transmit pipe fills up, the SPI stops requesting DMA writes until the pipe clears.
   c. If there is an underflow problem in the transmit pipe, the slave stalls the master by deasserting `SPI_RDY` while the DMA fills the transmit FIFO. Alternately, the SPI uses the `SPI_TXCTL.TDU` bit to decide the state of the transmit data (when `SPI_CTL.FCEN` is deasserted).

ADSP-SC58x SPI Register Descriptions

Serial Peripheral Interface (SPI) contains the following registers.

Table 16-17: ADSP-SC58x SPI Register List

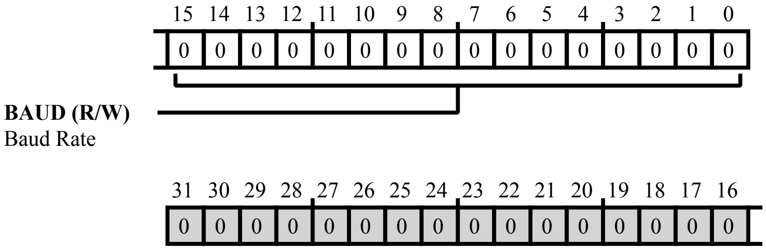
Name	Description
`SPI_CLK`	Clock Rate Register
`SPI_CTL`	Control Register
`SPI_DLY`	Delay Register
`SPI_ILAT`	Masked Interrupt Condition Register
`SPI_ILAT_CLR`	Masked Interrupt Clear Register

Table 16-17: ADSP-SC58x SPI Register List (Continued)

Name	Description
`SPI_IMSK`	Interrupt Mask Register
`SPI_IMSK_CLR`	Interrupt Mask Clear Register
`SPI_IMSK_SET`	Interrupt Mask Set Register
`SPI_MMRDH`	Memory Mapped Read Header (Only on SPI2)
`SPI_MMTOP`	SPI Memory Top Address (Only on SPI2)
`SPI_RFIFO`	Receive FIFO Data Register
`SPI_RWC`	Received Word Count Register
`SPI_RWCR`	Received Word Count Reload Register
`SPI_RXCTL`	Receive Control Register
`SPI_SLVSEL`	Slave Select Register
`SPI_STAT`	Status Register
`SPI_TFIFO`	Transmit FIFO Data Register
`SPI_TWC`	Transmitted Word Count Register
`SPI_TWCR`	Transmitted Word Count Reload Register
`SPI_TXCTL`	Transmit Control Register

Clock Rate Register

The `SPI_CLK` register selects the baud rate for SPI data transfers, relating this rate to the SPI serial clock (SPI clock) and the system clock (SCLK1_0).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 16-21: SPI_CTL Register Diagram

Table 16-19: SPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	MMSE	Memory-Mapped SPI Enable (Only on SPI2). When the `SPI_CTL.MMSE` bit is asserted, communication to an SPI memory device is automated such that the memory it contains is accessible directly through the read of processor address space assigned to it. (As far as the SPI peripheral is concerned, this includes all read accesses received by the SPI peripherals system crossbar slave port.) Note that when memory-mapped access of SPI memory is enabled, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric error responses are generated. Legacy methods include any direct access made to the Tx and Rx FIFOs, whether initiated by DMA or processor MMR access.	
		0	Hardware automated access of memory-mapped SPI memory disabled.
		1	Hardware-automated access of memory-mapped SPI memory enabled.
30 (R/W)	MMWEM	Memory Mapped Write Error Mask (Only on SPI2). The `SPI_CTL.MMWEM` bit specifies whether an error response is returned to the fabric upon write attempts to address space reserved for memory-mapped reads of SPI memory.	
		0	Write error response returned upon write attempts to memory-mapped SPI memory
		1	Write error response masked (not returned) upon write attempts to memory-mapped SPI memory
22 (R/W)	SOSI	Start on MOSI (Only on SPI2). The `SPI_CTL.SOSI` bit is valid only when `SPI_CTL.MIOM` is enabled for either DIOM or QIOM, and this bit selects the starting pin and the bit placement on pins for these modes. In DIOM, by default, (`SPI_CTL.SOSI` =0) SPI sends the first bit on the `SPI_MISO` pin and the second bit on the `SPI_MOSI` pin. In QIOM, by default, the SPI sends the first bit on the `SPI_D3` pin, the second bit on the `SPI_D2` pin, the third bit on the `SPI_MISO` pin and the fourth bit on the `SPI_MOSI` pin. This order can be reversed by setting the `SPI_CTL.SOSI` bit. When this bit is set, the SPI sends the first bit on the `SPI_MOSI` pin. The first bit referred to here depends on the `SPI_CTL.LSBF` bit setting (MSB bit or LSB bit).	
		0	Start on MISO (DIOM) or start on SPI_D3 (Only on SPI2)
		1	Start on MOSI

Table 16-19: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	MIOM	Multiple I/O Mode (Only on SPI2). The `SPI_CTL.MIOM` bits enable SPI operation in dual I/O mode (DIOM) or quad I/O mode (QIOM). These bits can only be changed when the SPI is disabled (`SPI_CTL.EN` =0).	
		0	No MIOM (disabled)
		1	DIOM operation
		2	QIOM operation (Only on SPI2)
		3	Reserved
18 (R/W)	FMODE	Fast-Mode Enable. The `SPI_CTL.FMODE` bit enables fast mode operation for SPI receive transfers. SPI transmit operations in fast mode are the same as normal mode.	
		0	Disable
		1	Enable
17:16 (R/W)	FCWM	Flow Control Watermark. The `SPI_CTL.FCWM` bits select the watermark level of the transmit channel (`SPI_TFIFO` buffer) or receive channel (`SPI_RFIFO` buffer) that triggers flow control operation. These bits are applicable only when the SPI is a slave (`SPI_CTL.MSTR` = 0) and flow control is enabled (`SPI_CTL.FCEN` =1). When the watermark condition is met, the SPI slave deasserts the `SPI_RDY` pin.	
		0	TFIFO empty or RFIFO full
		1	TFIFO 75% or more empty, or RFIFO 75% or more full
		2	TFIFO 50% or more empty, or RFIFO 50% or more full
		3	Reserved
15 (R/W)	FCPL	Flow Control Polarity. The `SPI_CTL.FCPL` bit selects flow control polarity for the `SPI_RDY` pin when flow control is enabled. When the `SPI_RDY` pin is active, the SPI is indicating it is ready for data transfer.	
		0	Active-low RDY
		1	Active-high RDY

Table 16-19: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	FCCH	Flow Control Channel Selection. The `SPI_CTL.FCCH` bit selects whether the SPI applies flow control to the transmit channel (`SPI_TFIFO` buffer) or receive channel (`SPI_RFIFO` buffer). This bit is applicable only when the SPI is a slave and flow control is enabled.	
		0	Flow control on RX buffer
		1	Flow control on TX buffer
13 (R/W)	FCEN	Flow Control Enable. The `SPI_CTL.FCEN` bit enables SPI flow control operation, which permits slow slave devices to interface with fast master devices. This bit controls the operation of the `SPI_RDY` pin. Note that options for flow control operation are available using the `SPI_CTL.FCCH`, `SPI_CTL.FCPL`, and `SPI_CTL.FCWM` bits.	
		0	Disable
		1	Enable
12 (R/W)	LSBF	Least Significant Bit First. The `SPI_CTL.LSBF` bit selects whether the SPI transmits/receives data as LSB first (little endian) or MSB first (big endian). This bit can only be changed when the SPI is disabled.	
		0	MSB sent/received first (big endian)
		1	LSB sent/received first (little endian)
10:9 (R/W)	SIZE	Word Transfer Size. The `SPI_CTL.SIZE` bits select the SPI transfer word size as 8, 16 or 32 bits. To ensure correct operation, both the master and slave must be configured with the same word size. This bit can only be changed when the SPI is disabled (`SPI_CTL.EN` =0).	
		0	8-bit word
		1	16-bit word
		2	32-bit word
		3	Reserved
8 (R/W)	EMISO	Enable MISO. The `SPI_CTL.EMISO` bit enables master-in-slave-out (MISO) mode. This SPI mode is applicable only when the SPI is a slave.	
		0	Disable
		1	Enable

Table 16-19: SPI_CTL Register Fields (Continued)

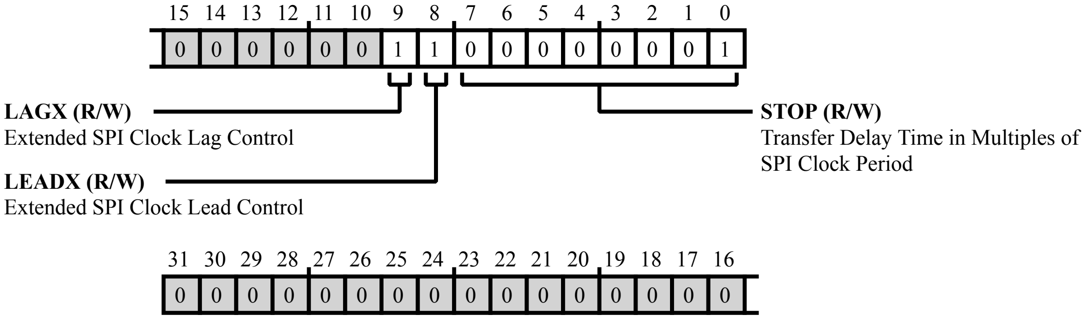
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SELST	Slave Select Polarity Between Transfers. The `SPI_CTL.SELST` bit selects the state (polarity) for the $\overline{\texttt{SPI\_SEL[n]}}$ pin between SPI transfers when the SPI is a master and hardware slave select assertion is enabled (`SPI_CTL.ASSEL` =1). In slave mode, this bit affects the detection of both transmit collision (`SPI_STAT.TC` and underrun (`SPI_STAT.TUR`) errors.	
		0	Deassert slave select (high)
		1	Assert slave select (low)
6 (R/W)	ASSEL	Slave Select Pin Control. The `SPI_CTL.ASSEL` bit selects whether the SPI hardware sets the $\overline{\texttt{SPI\_SEL[n]}}$ pin output value (ignoring the slave select `SPI_SLVSEL.SSEL1` - `SPI_SLVSEL.SSEL7` bits) or whether software control of the slave select bits set the $\overline{\texttt{SPI\_SEL[n]}}$ pin output value. This feature is applicable only when the SPI is a master. When hardware control is enabled, the $\overline{\texttt{SPI\_SEL[n]}}$ pin output is asserted during the transfers, and the pin polarity between transfers is selected by the `SPI_CTL.SELST` bit. When software control is enabled, the $\overline{\texttt{SPI\_SEL[n]}}$ pin output value is set through software control of the slave select bits, and as such, the pin may either remain asserted (low) or be deasserted between transfers.	
		0	Software slave select control
		1	Hardware slave select control
5 (R/W)	CPOL	Clock Polarity. The `SPI_CTL.CPOL` bit selects whether the SPI uses an active-low or active-high signal for the SPI clock (`SPI_CLK`). This bit works with the `SPI_CTL.CPHA` bit to select combinations of clock phase and polarity for the `SPI_CLK` pin. This bit can only be changed when the SPI is disabled.	
		0	Active-high SPI CLK
		1	Active-low SPI CLK
4 (R/W)	CPHA	Clock Phase. The `SPI_CTL.CPHA` bit selects whether the SPI starts toggling the signal for the SPI clock (`SPI_CLK`) from the start of the first data bit or from the middle of the first data bit. The `SPI_CTL.CPHA` bit works with the `SPI_CTL.CPOL` bit to select combinations of clock phase and polarity for the `SPI_CLK` pin. This bit can only be changed when the SPI is disabled.	
		0	SPI CLK toggles from middle
		1	SPI CLK toggles from start

Table 16-19: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	ODM	Open Drain Mode. The `SPI_CTL.ODM` bit configures the data output pins (`SPI_MOSI` and `SPI_MISO`) to behave as open drain outputs, which prevents contention and possible damage to pin drivers in multi-master or multi-slave SPI systems. When `SPI_CTL.ODM` is enabled and the SPI is a master, the SPI three-states the `SPI_MOSI` pin when the data driven out on MOSI is a logic-high. The SPI does not three-state the `SPI_MOSI` pin when the driven data is a logic-low. When `SPI_CTL.ODM` is enabled and the SPI is a slave, the SPI three-states the `SPI_MISO` pin when the data driven out on `SPI_MISO` is a logic-high. Note that an external pull-up resistor is required on both the `SPI_MOSI` and `SPI_MISO` pins when `SPI_CTL.ODM` is enabled.	
		0	Disable
		1	Enable
2 (R/W)	PSSE	Protected Slave Select Enable. The `SPI_CTL.PSSE` bit enables the $\overline{\texttt{SPI\_SS}}$ pin to provide error detection input in a multi-master environment when the SPI is in master mode. If some other device in the system asserts the $\overline{\texttt{SPI\_SS}}$ pin while SPI is enabled as master (and `SPI_CTL.PSSE` is enabled), this condition causes a mode fault error.	
		0	Disable
		1	Enable
1 (R/W)	MSTR	Master/Slave. The `SPI_CTL.MSTR` bit toggles the SPI between master mode and slave mode. This bit can only be changed when the SPI is disabled.	
		0	Slave
		1	Master
0 (R/W)	EN	Enable. The `SPI_CTL.EN` bit enables SPI operation.	
		0	Disable SPI module
		1	Enable

Delay Register

The `SPI_DLY` register selects a transfer delay and the lead/lag timing between slave select signals and SPI clock edge assertion/deassertion.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 16-20: SPI_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	LAGX	Extended SPI Clock Lag Control. The `SPI_DLY.LAGX` bit enables insertion of a 1-SPI_CLK cycle lag (extend lag) in the timing between the slave select (`SPI_SEL[n]`) assertion and first SPI clock edge.	
		0	Disable
		1	Enable
8 (R/W)	LEADX	Extended SPI Clock Lead Control. The `SPI_DLY.LEADX` bit enables insertion of a 1-SPI_CLK cycle lead (extend lead) in the timing between the slave select (`SPI_SEL[n]`) deassertion and last SPI clock edge.	
		0	Disable
		1	Enable
7:0 (R/W)	STOP	Transfer Delay Time in Multiples of SPI Clock Period. The `SPI_DLY.STOP` bits select a delay (number of stop bits in multiples of SPI clock duration) at the end of each SPI transfer. The default delay is the minimum value required to comply with the SPI protocol (1-bit duration). The `SPI_DLY.STOP` bits can be programmed with smaller delay values, resulting in continuous operation (for example, stop bits =0).	

Masked Interrupt Condition Register

The SPI_ILAT register latches interrupts, queuing the interrupt requests for service. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in SPI_ILAT.

		1	Clear mask bit

Interrupt Mask Register

The `SPI_IMSK` register unmasks (enables) or masks (disables) SPI interrupt requests. When a condition is indicated by a bit in the `SPI_STAT` register and the corresponding interrupt request is unmasked in `SPI_IMSK`, the SPI latches the interrupt request bit in the `SPI_ILAT` register, queuing the interrupt request for service.

		1	Set mask bit

Memory Mapped Read Header (Only on SPI2)

The `SPI_MMRDH` register enables the use of memory-mapped mode. This mode allows direct memory-mapped read accesses of an SPI memory device and is primarily used to directly execute instructions from an SPI FLASH memory without using a low-level software driver. All overhead tasks such as transmission of the read header, pin turnaround timing and receive data sizing are handled in hardware.

The memory-mapped access mode is enabled by setting the `SPI_CTL.MMSE` bit. The features within the `SPI_MMRDH` register include a command skip mode, variable length byte addressing, and independent multi-pin support for command transmission, address transmission and data reception. In addition, the command opcode and mode bytes are fully programmable.

Figure 16-28: SPI_MMRDH Register Diagram

Table 16-26: SPI_MMRDH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	CMDPINS	Pins Used for Command. The `SPI_MMRDH.CMDPINS` bit specifies the number of pins to be used for command transmission. This bit must be set consistent with the expectations established by the read opcode. Hardware does not interpret `SPI_MMRDH.OPCODE`, but rather relies on this bit to specify behavior. When cleared, it overrides the `SPI_CTL.MIOM` bits. When set, it uses bits specified by the `SPI_CTL.MIOM` bit setting.	
		0	Use only one pin: MOSI (overrides `SPI_CTL.MIOM` bits)
		1	Use pins specified by `SPI_CTL.MIOM` bits

Table 16-26: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	CMDSKIP	Command Skip Enable. The `SPI_MMRDH.CMDSKIP` bit enables command skip mode where the address is sent first and the OPCODE field is not sent (`SPI_MMRDH.CMDSKIP` bit =1). This mode is useful for supporting XIP (Execute-In-Place) operation where only the address is sent and the same read command is assumed. The SPI flash device must be primed with an initial read command, before the `SPI_MMRDH.CMDSKIP` bit is set.	
		0	OPCODE field is sent first followed by address
		1	OPCODE field is not sent; address is sent first
27 (R/W)	WRAP	SPI Memory Wrap Indicator. The `SPI_MMRDH.WRAP` bit must be set by software if software places a connected SPI memory device into a 8-byte, 16-byte or 32-byte wrap mode based on the ILINE and DLINE field setting of the cache configuration register address wrap mode. Software achieves this by transmitting a vendor specified command to the SPI memory device while the `SPI_CTL.MMSE` bit =0. If the `SPI_MMRDH.WRAP` bit =1, the SPI does not need to deassert the SPI slave select signal and resend the read header in order to wrap to the cache line base when servicing misaligned cache fill requests. Although this improves cache fill efficiency, it requires that the SPI deassert the SPI slave select pin and resend the read header whenever a DMA burst requests crosses 32 byte alignments. Setting this bit improves cache throughput but decreases DMA throughput.	
		0	SPI Memory auto increments address purely sequentially
		1	SPI Memory auto increments address but wraps within 32 Byte lines
26 (R/W)	MERGE	Merge Enable. When the `SPI_MMRDH.MERGE` bit is set, SPI hardware combines the two successive transfers. This increases the throughput rate when accessing a large number of sequential memory locations. For more information refer to the Merged Read Accesses section.	

Table 16-26: SPI_MMRDH Register Fields (Continued)

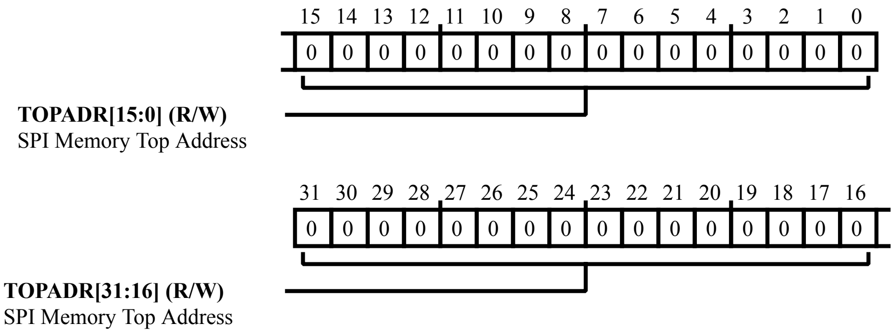
Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRIDMY	Tristate Dummy Timing. The `SPI_MMRDH.TRIDMY` bits specify whether and when output pins are three-stated during the interval of time specified by the `SPI_MMRDH.DMYSIZE` bits. Output pins potentially three-stated include all pins which were used to transmit the address	
		0	Tristate outputs immediately
		1	Tristate outputs after 4 bits of dummy/mode are transmitted
		2	Tristate outputs after 8 bits of dummy/mode are transmitted
		3	Never tristate outputs (previously specified output state is held)
23:16 (R/W)	MODE	Mode Field. These bits specify up to a leading byte to be transmitted during the interval of time specified by the `SPI_MMRDH.DMYSIZE` bit field. This first byte, or a portion of it, is interpreted as mode bits when certain opcodes are used in conjunction with certain SPI memory devices. Mode bits are sent using the same number of pins which were used to transmit the address. Once sent, output pins will be held in their final resultant state until the conclusion of all dummy byte periods, unless three-stating the outputs is specified first by the `SPI_MMRDH.TRIDMY` bits.	
14:12 (R/W)	DMYSIZE	Bytes of Dummy/Mode. The `SPI_MMRDH.DMYSIZE` bit field specifies the number of bytes separating address transmission and read data return. Dummy bytes elapse assuming dummy bits are transmitted using the same number of pins which were used to transmit address.	
		0	0 Bytes
		1	1 Bytes
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
		5	5 Bytes
		6	6 Bytes
		7	7 Bytes

Table 16-26: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ADRPINS	Pins Used for Address. The `SPI_MMRDH.ADRPINS` bit specifies the number of pins to be used for address transmission. This bit must be set consistent with expectations established by read opcode. Hardware does not interpret the `SPI_MMRDH.OPCODE`, but rather relies on this bit to specify behavior.	
		0	Use only one pin: MOSI (overrides `SPI_CTL.MIOM` bits)
		1	Use pins specified by `SPI_CTL.MIOM` bits
10:8 (R/W)	ADRSIZE	Bytes of Read Address. The `SPI_MMRDH.ADRSIZE` bit field defines the number of bytes used to specify the read address. The read address is sent immediately following the transmission of opcode. Unlike opcode bits, address bits may be sent using either one or multiple pins. The number of pins is selected using the `SPI_MMRDH.ADRPINS` bit. The address sent to a connected SPI memory device is an echo of the read address received by the SPI peripheral slave port. The least significant bytes of address are sent when the entire address is not sent.	
		0	1 Byte
		1	1 Byte
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
7:0 (R/W)	OPCODE	Read Opcode. The `SPI_MMRDH.OPCODE` bit field specifies the initial bits transmitted in response to a read request of SPI memory. Although any opcode may be sent, values 0x03, 0x0B, 0x3B, 0x6B, 0xBB, and 0xEB are likely to be the most commonly used. `SPI_MMRDH.OPCODE` is sent by the SPI without interpretation; the states of these bits have no effect beyond specifying what is initially shifted across the SPI interface.	

SPI Memory Top Address (Only on SPI2)

The `SPI_MMTOP` register specifies the top populated address of a connected SPI memory device.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TOPADR[15:0] (R/W)
SPI Memory Top Address
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TOPADR[31:16] (R/W)
SPI Memory Top Address

Figure 16-29: SPI_MMTOP Register Diagram

Table 16-27: SPI_MMTOP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TOPADR	SPI Memory Top Address. The `SPI_MMTOP.TOPADR` bit field specifies the top populated address of a connected SPI memory device. Attempts to access SPI memory are not blocked if this address is exceeded and an error is generated as part of the read response.

Receive FIFO Data Register

The SPI_RFIFO register has an interface to the receive shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit SPI_RFIFO register, but the size (number of word locations) of the receive FIFO is actually flexible with transfer word size. The size of the receive FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both masters and slaves may stop or stall receive transfers based on FIFO status. When the receive FIFO is full, the SPI master stops initiating new transfers on the SPI if `SPI_RXCTL.RTI` is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data reception continues after SPI_RFIFO is full, the data in the receive FIFO is invalid. The SPI indicates this condition with receive overrun (`SPI_STAT.ROR`) error. This condition is possible when `SPI_RXCTL.RTI` =0 and `SPI_RXCTL.REN` =1 for a master, or for a slave that does not exercise flow control.

Note that the receive FIFO is reset (cleared) when the SPI is disabled after being enabled.

Table 16-28: SPI_RFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Receive FIFO Data. The `SPI_RFIFO.DATA` bit field contains the FIFO receive data.

Received Word Count Register

The `SPI_RWC` register holds a count of the number of words remaining to be received by the SPI. To start the decrement of the word count in `SPI_RWC`, enable the receive word counter (`SPI_RXCTL.RWCEN` =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the receive finish interrupt (`SPI_ILAT.RF`). In DMA mode, the SPI uses the `SPI_RWC` register to ensure that the number of frames received during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the `SPI_RWC` registers should match the word count in the DMA configuration. The `SPI_RWC` register maintains the number of frames to be received in a transfer. The `SPI_RWC` should only be changed when the counter is disabled.

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count. The `SPI_RWC.VALUE` bits hold the receive transfer word count.

Received Word Count Reload Register

The `SPI_RWCR` register holds the receive word count value that the SPI loads into the `SPI_RWC` register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The `SPI_RWCR` register should only be changed when the counter is disabled.

RUWM (R/W)
Receive FIFO Urgent Watermark

Figure 16-33: SPI_RXCTL Register Diagram

Table 16-31: SPI_RXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	RUWM	Receive FIFO Urgent Watermark. The SPI_RXCTL.RUWM bits select the receive FIFO (SPI_RFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.RUWM interrupt. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Disabled
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
		5	Reserved
		6	Reserved
		7	Reserved

Table 16-31: SPI_RXCTL Register Fields (Continued)

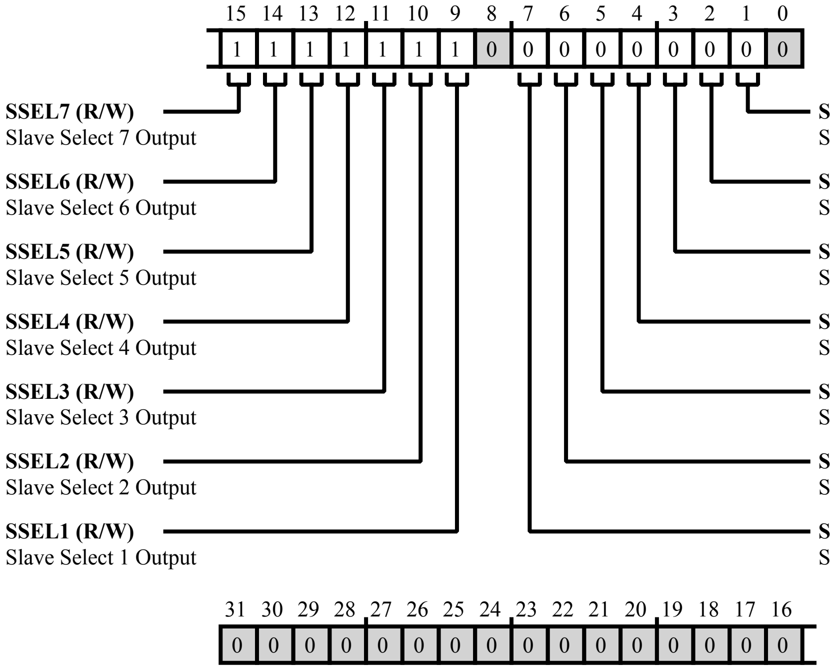
Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	RRWM	Receive FIFO Regular Watermark. The `SPI_RXCTL.RRWM` bits select the receive FIFO (`SPI_RFIFO`) watermark level for regular data bus requests. When an urgent `SPI_RFIFO` watermark is enabled with `SPI_RXCTL.RUWM`, the `SPI_RXCTL.RRWM` selection is used as the deassertion condition for any `SPI_ILAT.RUWM` interrupts that are latched.	
		0	Empty RFIFO
		1	RFIFO less than 25% full
		2	RFIFO less than 50% full
		3	RFIFO less than 75% full
8 (R/W)	RDO	Receive Data Overrun. The `SPI_RXCTL.RDO` bit selects handling for receive data requests when the receive buffer (`SPI_RFIFO`) is full. If enabled and `SPI_RFIFO` is full, the SPI overwrites old data in the buffer with incoming data. If disabled and `SPI_RFIFO` is full, the SPI keeps old data in the buffer and discards incoming data.	
		0	Discard incoming data if SPI_RFIFO is full
		1	Overwrite old data if SPI_RFIFO is full
6:4 (R/W)	RDR	Receive Data Request. The `SPI_RXCTL.RDR` bits select receive FIFO (`SPI_RFIFO`) watermark conditions that direct the SPI to generate a receive data request.	
		0	Disabled
		1	Not empty RFIFO
		2	25% full RFIFO
		3	50% full RFIFO
		4	75% full RFIFO
		5	Full RFIFO
		6	Reserved
		7	Reserved
3 (R/W)	RWCEN	Receive Word Counter Enable. The `SPI_RXCTL.RWCEN` bit enables the decrement of the `SPI_RWC` register when the count is not zero and `SPI_RXCTL.RTI` is enabled. Enabling `SPI_RXCTL.RWCEN` prevents receive overrun errors from occurring. The `SPI_RXCTL.RWCEN` bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable

Table 16-31: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	RTI	Receive Transfer Initiate. The `SPI_RXCTL.RTI` bit enables initiation of receive transfers if the receive FIFO (`SPI_RFIFO`) is not full. The bit also enables this initiation if `SPI_RWC` is not zero when `SPI_RXCTL.RWCEN` is enabled. Enabling `SPI_RXCTL.RTI` prevents receive overrun errors from occurring. The `SPI_RXCTL.RTI` bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable
0 (R/W)	REN	Receive Enable. The `SPI_RXCTL.REN` bit enables SPI receive channel operation.	
		0	Disable
		1	Enable

Slave Select Register

The SPI_SLVSEL register enables the SPI_SEL[n] pins for output and indicates the state (high or low) of these pins when enabled.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 16-34: SPI_SLVSEL Register Diagram

Table 16-32: SPI_SLVSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SSEL7	Slave Select 7 Output. The SPI_SLVSEL.SSEL7 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
14 (R/W)	SSEL6	Slave Select 6 Output. The SPI_SLVSEL.SSEL6 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High

Table 16-32: SPI_SLVSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	SSEL5	Slave Select 5 Output. The `SPI_SLVSEL.SSEL5` bit state indicates the value driven on the related `SPI_SEL[n]` pin.	
		0	Low
		1	High
12 (R/W)	SSEL4	Slave Select 4 Output. The `SPI_SLVSEL.SSEL4` bit state indicates the value driven on the related `SPI_SEL[n]` pin.	
		0	Low
		1	High
11 (R/W)	SSEL3	Slave Select 3 Output. The `SPI_SLVSEL.SSEL3` bit state indicates the value driven on the related `SPI_SEL[n]` pin.	
		0	Low
		1	High
10 (R/W)	SSEL2	Slave Select 2 Output. The `SPI_SLVSEL.SSEL2` bit state indicates the value driven on the related `SPI_SEL[n]` pin.	
		0	Low
		1	High
9 (R/W)	SSEL1	Slave Select 1 Output. The `SPI_SLVSEL.SSEL1` bit state indicates the value driven on the related `SPI_SEL[n]` pin.	
		0	Low
		1	High
7 (R/W)	SSE7	Slave Select 7 Enable. The `SPI_SLVSEL.SSE7` bit enables the related `SPI_SEL[n]` pin for output. If disabled, the SPI three-states the related `SPI_SEL[n]` pin. When the SPI is a slave, the master (not the SPI) asserts the input during the transfer. The input may be deasserted or remain asserted between transfers. While the input is deasserted, the SPI ignores the SPI clock, ignores inputs, and three-states outputs.	
		0	Disable
		1	Enable

Table 16-32: SPI_SLVSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SSE6	Slave Select 6 Enable. The `SPI_SLVSEL.SSE6` bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the `SPI_SLVSEL.SSE7` bit description for more information.	
		0	Disable
		1	Enable
5 (R/W)	SSE5	Slave Select 5 Enable. The `SPI_SLVSEL.SSE5` bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the `SPI_SLVSEL.SSE7` bit description for more information.	
		0	Disable
		1	Enable
4 (R/W)	SSE4	Slave Select 4 Enable. The `SPI_SLVSEL.SSE4` bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the `SPI_SLVSEL.SSE7` bit description for more information.	
		0	Disable
		1	Enable
3 (R/W)	SSE3	Slave Select 3 Enable. The `SPI_SLVSEL.SSE3` bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the `SPI_SLVSEL.SSE7` bit description for more information.	
		0	Disable
		1	Enable
2 (R/W)	SSE2	Slave Select 2 Enable. The `SPI_SLVSEL.SSE2` bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the `SPI_SLVSEL.SSE7` bit description for more information.	
		0	Disable
		1	Enable
1 (R/W)	SSE1	Slave Select 1 Enable. The `SPI_SLVSEL.SSE1` bit enables the related $\overline{\texttt{SPI\_SEL[n]}}$ pin for output. See the `SPI_SLVSEL.SSE7` bit description for more information.	
		0	Disable
		1	Enable

Status Register

The `SPI_STAT` register indicates SPI status including FIFO status, error conditions, and interrupt conditions. When an interrupt condition from this register is unmasked (enabled) by the corresponding bit in the `SPI_IMSK` register, the interrupt request is latched into the corresponding bit in the `SPI_ILAT` register.

Table 16-33: SPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MMAE	Memory Mapped Access Error. The `SPI_STAT.MMAE` bit =1 if an attempt is made to access either the Tx or Rx FIFO while memory-mapped access of SPI memory is enabled (see the `SPI_CTL.MMSE` bit). The `SPI_STAT.MMAE` bit =0 when a 1 is written to it. The `SPI_STAT.MMAE` bit is provided for software notification only. Its state has no further effect.

Table 16-33: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W1C)	MMRE	Memory Mapped Read Error. The `SPI_STAT.MMRE` bit =1 if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (see the `SPI_CTL.MMSE` bit). The `SPI_STAT.MMRE` bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
28 (R/W1C)	MMWE	Memory Mapped Write Error. The `SPI_STAT.MMWE` bit =1 if an attempt is made to write address space reserved for memory-mapped SPI memory. The `SPI_STAT.MMWE` bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
23 (R/NW)	TFF	SPI_TFIFO Full. The `SPI_STAT.TFF` bit indicates whether the `SPI_TFIFO` is full or not full.	
		0	Not full Tx FIFO
		1	Full Tx FIFO
22 (R/NW)	RFE	SPI_RFIFO Empty. The `SPI_STAT.RFE` bit indicates whether the `SPI_RFIFO` is empty or not empty.	
		0	Rx FIFO not empty
		1	Rx FIFO empty
20 (R/NW)	FCS	Flow Control Stall Indication. The `SPI_STAT.FCS` bit indicates whether a slave has deasserted the `SPI_RDY` pin to stall the SPI master while the slave is unable to service the SPI masters request. This bit is valid only when the SPI is a master (`SPI_CTL.MSTR` =1) and flow control is enabled (`SPI_CTL.FCEN` =1).	
		0	No Stall (RDY pin asserted)
		1	Stall (RDY pin deasserted)
18:16 (R/NW)	TFS	SPI_TFIFO Status. The `SPI_STAT.TFS` bits indicate the status of the `SPI_TFIFO`. The SPI uses this status when evaluating transmit watermark conditions.	
		0	Full TFIFO
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 16-33: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/NW)	RFS	SPI_RFIFO Status. The `SPI_STAT.RFS` bits indicate the status of the `SPI_RFIFO`. The SPI uses this status when evaluating receive watermark conditions.	
		0	Empty RFIFO
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
11 (R/W1C)	TF	Transmit Finish Indication. The `SPI_STAT.TF` bit indicates that the SPI has detected the finish of a transmit burst transfer (the `SPI_TWC` count decrements to zero). This condition can only occur when `SPI_TXCTL.TTI` and `SPI_TXCTL.TWCEN` are enabled.	
		0	No status
		1	Transmit finish detected
10 (R/W1C)	RF	Receive Finish Indication. The `SPI_STAT.RF` bit indicates that the SPI has detected the finish of a receive burst transfer (the `SPI_RWC` count decrements to zero). This condition can only occur when `SPI_RXCTL.RTI` and `SPI_RXCTL.RWCEN` are enabled.	
		0	No status
		1	Receive finish detected
9 (R/W1C)	TS	Transmit Start. The `SPI_STAT.TS` bit indicates that the SPI has detected the start of a transmit burst transfer. A transmit bursts starts with the load of `SPI_TWC` from the `SPI_TWCR`. This condition can only occur when `SPI_TXCTL.TTI` and `SPI_TXCTL.TWCEN` are enabled.	
		0	No status
		1	Transmit start detected
8 (R/W1C)	RS	Receive Start. The `SPI_STAT.RS` bit indicates that the SPI has detected the start of a receive burst transfer. A receive bursts starts with the load of `SPI_RWC` from the `SPI_RWCR`. This condition can only occur when `SPI_RXCTL.RTI` and `SPI_RXCTL.RWCEN` are enabled.	
		0	No status
		1	Receive start detected

Table 16-33: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	MF	Mode Fault Indication. The `SPI_STAT.MF` bit, when SPI is a master and `SPI_CTL.PSSE` is enabled, indicates that multiple masters have asserted slave select inputs.	
		0	No status
		1	Mode fault occurred
6 (R/W1C)	TC	Transmit Collision Indication. The `SPI_STAT.TC` bit, when SPI is a slave, indicates that the load of data into the shift register has occurred too close to the first transmitting edge of the SPI clock.	
		0	No status
		1	Transmit collision occurred
5 (R/W1C)	TUR	Transmit Underrun Indication. The `SPI_STAT.TUR` bit, when the transmit FIFO (`SPI_TFIFO`) is empty, indicates that the last word in the transmit FIFO has been re-sent as transmit data. Alternately, it indicates that zero has been sent as transmit data.	
		0	No status
		1	Transmit underrun occurred
4 (R/W1C)	ROR	Receive Overrun Indication. The `SPI_STAT.ROR` bit, when the receive FIFO (`SPI_RFIFO`) is full, indicates that a word in the receive FIFO has been overwritten with incoming receive data. Alternately, it indicates that incoming receive data has been discarded.	
		0	No status
		1	Receive overrun occurred
2 (R/NW)	TUWM	Transmit Urgent Watermark Breached. The `SPI_STAT.TUWM` bit indicates that the transmit urgent watermark (`SPI_TXCTL.TUWM`) has been reached. This condition is cleared when the transmit FIFO fills enough to reach the transmit regular watermark (`SPI_TXCTL.TRWM`).	
		0	Tx regular watermark reached
		1	Tx urgent watermark breached
1 (R/NW)	RUWM	Receive Urgent Watermark Breached. The `SPI_STAT.RUWM` bit indicates that the receive urgent watermark (`SPI_RXCTL.RUWM`) has been reached. This condition is cleared when the receive FIFO empties enough to reach the receive regular watermark (`SPI_RXCTL.RRWM`).	
		0	Rx regular watermark reached
		1	Rx urgent watermark breached

Table 16-33: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SPIF	SPI Finished. The `SPI_STAT.SPIF` bit indicates that a single word transfer is complete.	
		0	No status
		1	Completed single word transfer

Transmit FIFO Data Register

The `SPI_TFIFO` register has an interface to the transmit shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit `SPI_TFIFO` register, but the size (number of word locations) of the transmit FIFO is actually flexible with transfer word size. The size of the transmit FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both masters and slaves may stop or stall transmit transfers based on FIFO status. When the transmit FIFO is empty, the SPI master stops initiating new transfers on the SPI if `SPI_TXCTL.TTI` is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data transmit requests continue after `SPI_TFIFO` is empty, the data sent from the transmit FIFO is invalid, and the SPI indicates this condition with transmit underrun (`SPI_STAT.TUR`). This condition is possible when `SPI_TXCTL.TTI` =0 and `SPI_TXCTL.TEN` =1 for a master, or for a slave that does not exercise flow control.

Note that the transmit FIFO is reset (cleared) when the SPI is disabled after being enabled.

Transmitted Word Count Register

The `SPI_TWC` register holds a count of the number of words remaining to be transmitted by the SPI. To start the decrement of the word count in `SPI_TWC`, enable the transmit word counter (`SPI_TXCTL.TWCEN` =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the transmit finish interrupt request. In DMA mode, the SPI uses the `SPI_TWC` to ensure that the number of frames transmitted during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the `SPI_TWC` registers should match the word count in the DMA configuration. The `SPI_TWC` maintains the number of frames to be transmitted in a transfer. The `SPI_TWC` should only be changed when the counter is disabled.

17 Universal Asynchronous Receiver/Transmitter (UART)

The UART module is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word lengths, stop bits, bit rates, and parity-generation options. Multiple events can generate interrupts.

The UART is logically compliant to EIA-232E, EIA-422, EIA-485 and LIN standards, but usually requires external transceiver devices to meet electrical requirements. In IrDA (Infrared Data Association) mode, the UART meets the half-duplex IrDA SIR (9.6/115.2 Kbps rate) protocol. In multi-drop bus mode, the UART meets the full-duplex MDB/ICP v2.0 protocol.

The UART module supports partial modem status and control functionality to allow for hardware flow control.

The UART is a DMA-capable peripheral with separate transmit and receive DMA master channels. The use of DMA requires minimal software intervention as the DMA engine moves the data. The UART can also use a programmed core mode of operation. The core mode requires software management of the data flow using either interrupts or polling.

The UART can use one of the peripheral timers for a hardware-assisted auto-baud detection mechanism. The timers are external to the UART.

UART Features

Each UART includes the following features.

- 5–8 data bits
- Programmable extra stop bit and programmable extra half-stop bit
- Even, odd, and sticky parity bit options
- Extra 8-stage receive FIFO with programmable threshold interrupt request
- Flexible transmit and receive interrupt request timing
- Three interrupt outputs for receive, transmit, and status

- Independent DMA operation for receive and transmit
- Programmable automatic request to send (RTS)/clear to send (CTS) hardware flow control
- False start bit detection
- SIR IrDA operation mode
- MDB/ICP v2.0 operation mode
- Internal loopback
- Improved bit rate granularity
- LIN break command/Inter-frame gap transmission support

UART Architectural Concepts

The following sections provide information about the UART architecture.

Internal Interface

The UART is a DMA-capable peripheral with support for separate transmit and receive DMA master channels. It operates in either DMA or programmed core modes. The core mode requires software management of the data flow using either interrupts or polling. The DMA method requires minimal software intervention, as the DMA engine itself moves the data. The `UART_RBR` and `UART_THR` registers also connect to one of the peripheral DMA buses.

All UART registers are 32 bits wide and the registers connect to the peripheral MMR bus. Not all MMRs can be used and unused bits are zero-filled. The UART has three interrupt outputs described as follows.

- The transmit and receive request outputs can function as DMA requests and connect to the DMA controller. Therefore, if the DMA is not enabled, the DMA controller simply forwards the request to the system event controller (SEC).
- The status interrupt output connects directly to the SEC. On many processors, the alternative capture input (`TIMER_ACI[n]`) of one of the GP timers also senses the `UART_RX` pin. When configured in capture mode, the processor can then use the GP timer to detect the bit rate of the received signal.

External Interface

Each UART features a `UART_RX` (receive) pin and a `UART_TX` (transmit) pin available through the general-purpose ports. These two pins usually connect to an external transceiver device that meets the electrical requirements of full-duplex or half-duplex standards. For example, EIA-232, EIA-422, 4-wire EIA-485 for full-duplex or 2-wire EIA-485, LIN for half-duplex. Additionally, the UART features a pair of clear-to-send, input pins (`UART_CTS`), and request-to-send, output pins (`UART_RTS`) for hardware flow control. UART signals are multiplexed with other functions at the pin level.

Hardware Flow Control

To prevent the UART transmitter from sending data while the receiving counterpart is not ready, the UART features a `UART_RTS`/`UART_CTS` hardware flow control mechanism. The `UART_RTS` signal is an output that connects to the `UART_CTS` input of the communication partner. If data transfer is bidirectional, the figure shows the ***UART Hardware Flow Control*** handshake.

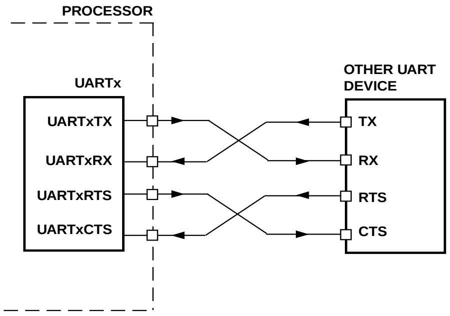

Figure 17-2: UART Hardware Flow Control

In both DMA and core mode, the receiver can deassert the `UART_RTS` signal to indicate that its receive buffer is almost full. Continued data transfers can cause an overrun error. The transmitter pauses when the `UART_CTS` input is in a deasserted state. In this state, the transmitter completes transmission of the data currently held in the transmit shift register (`UART_TSR`) but it does not continue with the data in the transmit hold register (`UART_THR`). If the `UART_CTS` pin is asserted again, the transmitter resumes and loads the content of `UART_THR` register into the `UART_TSR` register.

Bit Rate Generation

The peripheral clock (SCLK0_0) and the 16-bit divisor in the `UART_CLK` register characterize the sample clock. The UART uses the `UART_CTL.EN` bit to enable the clock. By default, every serial bit is oversampled 16 times.

The bit clock is 1/16th of the sample clock. If not in IrDA mode, the bit clock can equal the sample clock if the `UART_CLK.EDBO` bit is set, so that the following equation applies:

$\text{Bit Rate} = \text{SCLK0\_0}/16^{(1-\text{EDBO})} \times \text{Divisor}$

ADSP-SC5xx Processor Example

The ***UART Bit Rate Examples with 100 MHz*** SCLK0_0 table provides example divide factors required to support standard baud rates at an SCLK0_0 of 100 MHz.

Table 17-7: UART Bit Rate Examples with 100 MHz SCLK0_0

Bit Rate (bits/ sec)	D Factor = 16			D Factor = 1		
	DL	Actual	% Error	DL	Actual	% Error
2400	2604	2400.15	0.006	41667	2399.98	0.001
4800	1302	4800.31	0.006	20833	4800.08	0.002
9600	651	9600.61	0.006	10417	9599.69	0.003
19200	326	19171.78	0.147	5208	19201.23	0.006
38400	163	38343.56	0.147	2604	38402.46	0.006
57600	109	57339.45	0.452	1736	57603.69	0.006
115200	54	115740.74	0.469	868	115207.37	0.006
921600	7	892857.14	3.119	109	917431.19	0.452
1500000	4	1562500	4.167	67	1492537.31	0.498
3000000	2	3125000	4.167	33	3030303.03	1.01
6250000	1	6250000	0	16	6250000	0

NOTE: Careful selection of SCLK0_0 frequencies—that is, even multiples of desired bit rates— can result in lower error percentages.

Setting the bit clock equal to the sample clock (`UART_CLK.EDBO` =1) improves bit rate granularity and enables the bit clock to more closely match the bit rate of the communication partner. The disadvantage to this configuration is that the power dissipation is higher and the sample points are not always as accurate. Therefore, use `UART_CLK.EDBO` =1 mode only when bit rate accuracy is not acceptable in `UART_CLK.EDBO` =0 mode.

The `UART_CLK.EDBO` =1 mode is not intended to increase operation speed beyond the electrical limitations of the UART transfer protocol.

Autobaud Detection

At the chip level, the `UART_RX` pin is typically routed to an alternate capture input (`TIMER_ACI[n]`) of a general-purpose timer. When working in width capture mode, the processor uses this general-purpose timer to detect the bit rate applied to the $\overline{\texttt{UART\_RX}}$ pin automatically by an external device. It often uses the capture capabilities of the timer to supervise the bit rate at run time. If the UART communicates with any device supplied by a weak clock oscillator that drifts over time, the processor can then readjust its UART bit rate dynamically, as required.

Often, the processor uses autobaud detection for initial bit rate negotiations where it is most likely a slave device waiting for the host to send a predefined autobaud character. This situation is common for UART booting. Do not enable the `UART_CTL.EN` bit while autobaud detection is in-process, to prevent the UART from starting a receive operation with incorrect bit rate matching. Alternatively, set the `UART_CTL.LOOP_EN` bit to disconnect the UART from its $\overline{\texttt{UART\_RX}}$ pin.

A software routine can detect the pulse widths of serial stream bit cells. The sample base of the timer is synchronous with the UART operation (all derived from the same SCLK0_0). The UART uses pulse widths to calculate the bit rate divider as follows:

Divisor = `TIMER_TMR[n]_WID`/$16^{(1-\mathrm{EDBO})}$ × Number of captured UART bits

To increase the number of timer counts and the resolution of the captured signal, do not measure just the pulse width of a single bit. Instead, enlarge the pulse of interest over more bits. Traditionally, a NULL character (ASCII 0x00) is used in autobaud detection, as shown in the ***Autobaud Detection*** figure.

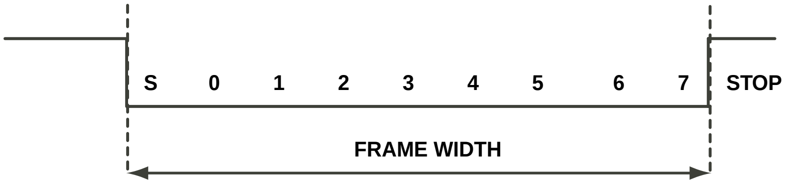

Figure 17-3: Autobaud Detection

Because the example frame encloses 8 data bits and 1 start bit, apply the following formula:

Divisor = `TIMER_TMR[n]_WID`/$16^{(1-\mathrm{EDBO})}$ × 9

> **NOTE:** For processor-specific mapping of timer alternate capture inputs to the UARTs of the processor, see "Width Capture (WIDCAP) Mode" in the "*General-Purpose Timer (TIMER)*" chapter.

Real receive signals often have asymmetrical falling and rising edges, and the sampling logic level is not exactly in the middle of the signal voltage range. At higher bit rates, such pulse-width-based autobaud detection does not always return adequate results without extra conditioning of the analog signal. Measure signal periods to work around this issue.

For example, predefine the ASCII character “@” (0x40) as the autobaud detection character and measure the period between two subsequent falling edges. As shown in the ***Autobaud Detection Character 0x40*** figure, measure the period between the falling edge of the start bit and the falling edge after bit 6. Since this period encloses 8 bits, apply the following formula:

Divisor = `TIMER_TMR[n]_PER`/$16^{(1-\mathrm{EDBO})}$ × 8

or:

- Divisor = `TIMER_TMR[n]_PER`>> 7, if `UART_CLK.EDBO`=0

- Divisor = TIMER_TMR[n]_PER>> 3, if UART_CLK.EDBO=1

The ***Autobaud Detection Character 0x40*** figure shows the ASCII "@" (0x40) detection character.

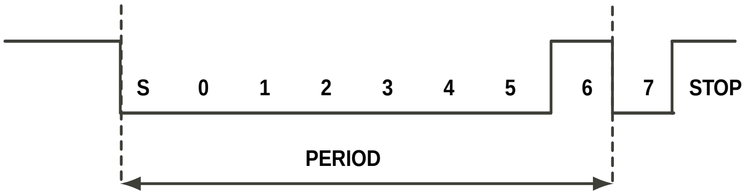

Figure 17-4: Autobaud Detection Character 0x40

UART Debug Features

The UART can automatically calculate and transmit a parity bit. The ***UART Parity*** table summarizes parity behavior assuming 8-bit data words (UART_CTL.WLS=b#11).

Table 17-8: UART Parity

PEN	STP	EPS	Data (hex)	Data (binary, LSB first)	Parity
0	x	x	x	x	None
1	0	0	0x60	0000 0110	1
1	0	0	0x57	1110 1010	0
1	0	1	0x60	0000 0110	0
1	0	1	0x57	1110 1010	1
1	1	0	x	x	1
1	1	1	x	x	0

The two force error bits, UART_CTL.FPE and UART_CTL.FFE, are intended for test purposes. They are useful for debugging software, especially in loopback mode.

The UART can be set to internal loopback mode (UART_CTL.LOOP_EN=1). Loopback mode disconnects the input of the receiver from the receive pin and internally redirects the transmit output to the receiver. The transmit pin remains active and continues to transmit data externally as well. Loopback mode also forces the UART_RTS pin to deassert, disconnects the UART_STAT.CTS bit from the UART_CTS input pin, and connects the internal version of UART_RTS to the UART_STAT.CTS bit.

Additionally, the UART_TX pin can be forced to zero asynchronously using the UART_CTL.SB bit.

UART Operating Modes

The following sections describe the main operating modes of the UART.

- UART Mode
- IrDA SIR Mode

- Multi-Drop Bus Mode

UART Mode

The UART mode follows an asynchronous serial communication protocol with these options:

- 1 start bit
- 5–8 data bits
- Address bit (available in MDB mode only)
- None, even, odd or sticky parity
- 1, 1½, or 2 stop bits (1½ stop bits valid only in 5-bit word length)

The `UART_CTL` register controls the format of received and transmitted character frames. Data is always transmitted and received with the least significant bit (LSB) first.

The ***Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)*** figure shows a typical physical bit stream measured on a `UART_TX` pin.

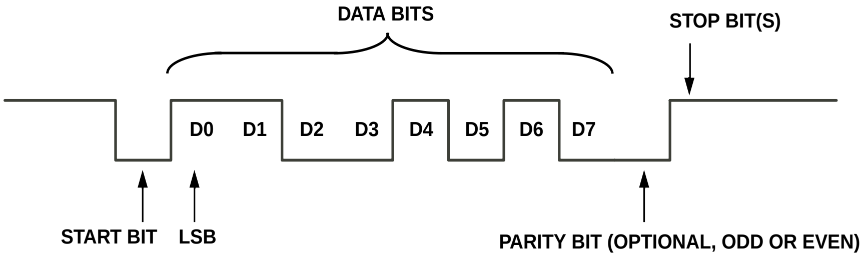

Figure 17-5: Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)

IrDA SIR Mode

The UART also supports serial data communication by way of infrared signals, according to the recommendations of the Infrared Data Association (IrDA). The physical layer known as IrDA SIR (9.6/115.2 Kbps rate) is based on return-to-zero-inverted (RZI) modulation. The UART does not support pulse position modulation.

Using the 16x data rate clock, RZI modulation is achieved by inverting and modulating the non-return-to-zero (NRZ) code normally transmitted by the UART. On the receive side, the UART uses a 16x clock to determine an IrDA pulse sample window, from which it recovers the RZI modulated NRZ code.

NOTE: The `UART_CLK.EDBO` bit is not valid in IrDA mode. Clear (=0) this bit in this mode.

Multi-Drop Bus Mode

The UART uses a protocol for point-to-point connections as well as in networks where the EIA-485 standard is representative of UART-based bus systems. The EIA-232 standard defines point-to-point connections. In such networks, node addressing is important.

In a multidrop bus (MDB) network, for example, an address bit enhances the UART frame. The address bit is inserted between the data bits and the optional parity bit. To configure the UART for MDB mode, set the mode of operation bits (`UART_CTL.MOD` [5:4]) to 01.

By convention, the address bit is transmitted low for regular data bytes. When set, it marks special address bytes that require the attention of all nodes on the network.

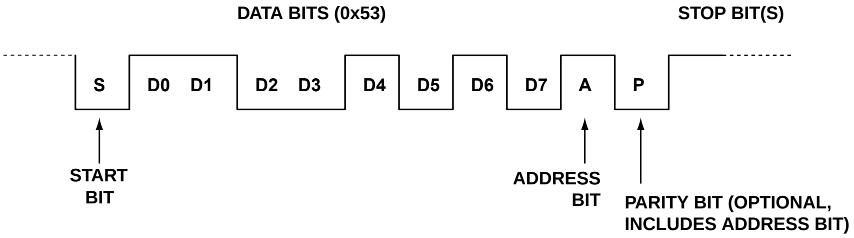

Figure 17-6: UART Frame with Address Bit

All transmit operations are processed through the transmit buffer register (`UART_THR`), so all DMA data transmissions clear the address bit. If data is written to the transmit address or insert pulse register (`UART_TAIP`) instead, the same transmit operation is initiated with the only exception that the address bit is sent high.

The UART uses the `UART_STAT.ADDR` bit of the receiver to signal whether the previously received frame had the address bit set or not. Hardware updates it every time a new frame is received. When the enable address word interrupt bit (`UART_IMSK.EAWI`) is set, the reception of an address byte triggers a special status interrupt request.

The address sticky bit (`UART_STAT.ASTKY`) is the sticky version of the `UART_STAT.ADDR` bit. Hardware sets it whenever the `UART_STAT.ADDR` bit is set. Software can clear the `UART_STAT.ASTKY` bit with a W1C operation.

In MDB mode, only address bytes progress to the receive FIFO by default. Data bytes are gated unless the `UART_STAT.ASTKY` bit is set. The receiver ignores all traffic on the UART bus. This way, the processor can go into low-power mode and interrupt activity does not load the processor every time a frame is transmitted on the UART bus. If, however, an address frame is transmitted, the receiver immediately samples all further traffic. A software routine can analyze the received data, decide whether it was of relevance for the local network node, and W1C the `UART_STAT.ASTKY` bit if it was not.

Software can overrule of the hardware address frame detection by setting the `UART_STAT.ADDR` bit and (indirectly) the `UART_STAT.ASTKY` bit with a W1S operation.

The MDB mode follows an asynchronous serial communication protocol with the following options.

- 1 start bit
- 5–8 data bits
- Address bit
- None, even, odd or sticky parity
- 1, 1½, or 2 stop bits (1½ stop bits are valid only in 5-bit word length)

NOTE: If the address bit and parity bit are both enabled, the parity check and generation includes the address bit in its parity calculation.

UART Data Transfer Modes

The UART can transfer data using both the core and DMA. Receive and transmit paths operate independently except that the bit rate and the frame format are identical for both transfer directions. Transmit and receive channels are both buffered. The `UART_THR` register buffers the transmit shift register (`UART_TSR`) and the `UART_RBR` register buffers the receive shift register (`UART_RSR`).

UART Mode Transmit Operation (Core)

In core mode, the processor core moves data to and from the UART. A write to the `UART_THR` register initiates the transmit operation. If no former operation is pending, the `UART_THR` register passes the data immediately to the `UART_TSR` register. There, it is shifted out at the bit rate characterized by the `UART_CTL` register, with start, stop, and parity bits appended as defined by the `UART_CTL` register.

The `UART_THR` register and the `UART_TSR` register can be modeled as a two-stage transmit buffer. The least significant bit (LSB) always transmits first. This bit is bit 0 of the value written to the `UART_THR` register.

UART Mode LIN Break Command

Some UART-based protocols demand synchronization methods that are not native to standard UART implementations. For example, the Local Interconnect Network (LIN) protocol requires a low-pulse of well-defined transmit length as a prologue to every multi-byte message. Its length must be at least 13 bit-times.

With previous UARTs, there were two options to implement this protocol:

- A null byte is transmitted with a temporarily lowered bit rate, or
- A software counter generates the period and the asynchronous set break (SB) mechanisms pull the transmit pin low

Since both methods have their disadvantages, the newer UART introduces a new inter-frame gap technique.

The feature is not available in MDB or IrDA operating modes. However, in standard UART mode (bits `UART_CTL.MOD` [5:4] =00), a write to the `UART_TAIP` register initiates the transmission of an inter-frame pulse. If the transmit buffer is not empty, the UART first transmits all bytes in the queue. It only initiates with pulse generation after the last stop bit of the last byte has been shifted out.

The value written into the `UART_TAIP` register defines the nature and the duration of the transmitted pulse. Bits [6:0] control the duration in bit-times and bit [7] controls the value (duration = `UART_TAIP`[6:0] / `UART_CLK`[15:0]). If `UART_TAIP`[7] is set, and an active high pulse is issued, the number of stop bits is extended. If `UART_TAIP`[7] is cleared, a low pulse is generated. Invert the polarity using the `UART_CTL.FCPOL` bit. Writing a value of 13 into the `UART_TAIP` register generates the break command as required by the LIN protocol.

NOTE: If the `UART_CTL.TPOLC` bit is enabled, an inverted most-significant bit can be transmitted.

NOTE: If another transmission is pending (in the UART_TSR register), the UART_TAIP initiated pulse is queued until after all pending operations have finished and all stop bits are transmitted.

The transmission of break command/inter-frame gap precedes transmission of the number of stop bits as set in the UART_CTL.STB and UART_CTL.STBH bit fields.

The UART receiver can detect break commands through the break indicator (UART_STAT.BI) flag. This flag reports that an entire UART frame has been received in low state. It does not report whether the duration of the received low pulse was exact or at least 13 bit-times as LIN masters transmit. Typically, the break indicator meets LIN requirements. The processor can use GP timers to determine the pulse width more precisely, if necessary.

Each UART_RX pin is also routed to a GP timer through its alternate capture input (TACI). This functionality is not only useful for bit rate detection (*autobaud*) but also helps to measure the pulse widths precisely on the UART_RX input. Additionally, the GP timers can issue an interrupt request or a fault condition when the received pulse width is shorter than a bit time or longer than the worst-case break condition. The windowed watchdog width mode of the GP timers controls this functionality.

UART Mode Receive Operation (Core)

The receive operation uses the same data format as the transmit configuration except that one valid stop bit is always sufficient. The UART_CTL.STB and UART_CTL.STBH bits have no impact on the receiver.

The UART receiver senses the falling edges of the receive input. When it detects an edge, the receiver starts sampling the input according to settings in the UART_CLK register. The receiver samples the start bit (majority sampling) close to its midpoint. If sampled low, it assumes a valid start condition. Otherwise, it discards the detected falling edge.

After detection of the start bit, the received word is shifted into the UART_RSR register.

After the corresponding stop bit is received, the content of the UART_RSR register is transferred to the 8-deep receive FIFO and is accessible by reading the UART_RBR register.

The receive FIFOs and the UART_RBR register act as a 9-stage receive buffer. If the stop bit of the ninth word is received before software reads the UART_RBR register, an overrun error is reported. Overruns protect data in the UART_RBR register and the receive FIFO from being overwritten by further data until the software clears the UART_STAT.OE bit. However, the data in the UART_RSR register is immediately destroyed as soon as the overrun occurs.

The sampling clock is 16 times faster than the bit clock. The receiver oversamples every bit 16 times and makes a majority-decision based on the middle three samples. This functionality improves immunity against noise and hazards on the line. The receiver disregards spurious pulses of less than two times the sampling clock period.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th and 9th sample clock. If, however, the UART_CLK.EDBO bit is set to 1, the receiver samples bits roughly at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy as required at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

Reception starts when the UART receiver detects a falling edge on the $\overline{\texttt{UART\_RX}}$ input pin. The receiver attempts to see a start bit. The data is shifted into the UART_RSR register. After the ninth sample of the first, the receiver processes the stop bit and copies the received data to the 8-stage receive FIFO. The UART_RSR recovers for further data reception.

The receiver samples data bits close to their midpoint. Because the receiver clock is typically asynchronous to the data rate of the transmitter, the sampling point can drift relative to the center of the data bits. The sampling point is synchronized again with each start bit, so the error accumulates only over the length of a single word. The polarity of received data is selectable, using the UART_CTL.RPOLC bit.

NOTE: The receiver checks for only a single stop bit. After the third sample of the first stop bit has been received (at time 9/16th of the stop bit duration), the receiver immediately acts (status update). It then prepares for new falling edge detection (start detection).

IrDA Transmit Operation

To generate the IrDA pulse transmitted by the UART, the normal NRZ output of the transmitter is first inverted if the UART_CTL.TPOLC bit is configured for active-low operation. In this configuration, a zero is transmitted as a high pulse of 16 UART clock periods and a one is transmitted as a low pulse for 16 UART clock periods. Then, six UART clock periods delay the leading edge of the pulse. Similarly, eight UART clock periods truncate the trailing edge of the pulse. For a 16-cycle UART clock period, this operation results in the final representation of the original zero as a high pulse of only 3/16 clock periods. The ***IrDA Transmit Pulse*** figure shows how the pulse is centered around the middle of the bit time. The final IrDA pulse is fed to the off-chip infrared driver.

This modulation approach ensures a pulse width output from the UART of three cycles high out of every 16 UART clock cycles. As shown in the ***IrDA Transmit Pulse*** figure, the error terms associated with the bit rate generator are small and well within the tolerance of most infrared transceiver specifications.

NOTE: In IrDA mode, writes to the UART_TAIP register are equivalent to writes to the UART_THR register.

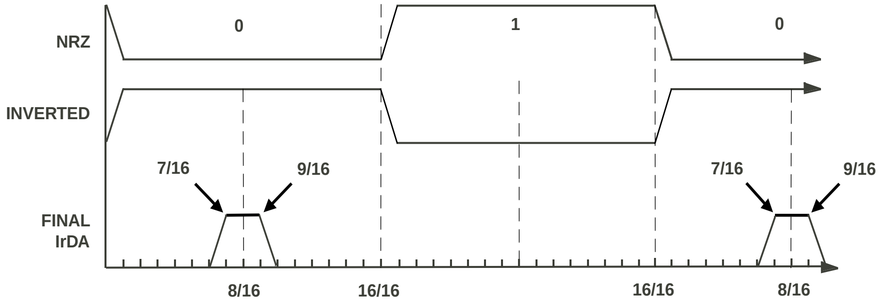

Figure 17-7: IrDA Transmit Pulse

IrDA Receive Operation

The IrDA receiver function is more complex than the transmit function. The receiver must discriminate the IrDA pulse and reject noise. The receiver looks for the IrDA pulse in a narrow window centered around the middle of the expected pulse.

Glitch filtering is accomplished by counting 16 system clocks from the time the receiver detects an initial pulse. If the pulse is absent when the counter expires, the receiver interprets it as a glitch. Otherwise, the receiver interprets it as a zero. This assessment is acceptable because glitches originating from on-chip capacitive cross-coupling typically do not last for more than a fraction of the system clock (SCLK0_0) period. Appropriate shielding avoids sources outside of the chip and not part of the transmitter. The only other source of a glitch is the transmitter itself. The processor relies on the transmitter to perform within specification. If the transmitter violates the specification, unpredictable results can occur. The 4-bit counter adds an extra level of protection at a minimal cost.

NOTE: Because SCLK0_0 can change across systems, the longest glitch tolerated is inversely proportional to the SCLK0_0 frequency.

A counter that is clocked at the 16x bit-time sample clock determines the receive sampling window. The sampling window is resynchronized with each start bit by centering the sampling window around the start bit.

The polarity of receive data is selectable, using the `UART_CTL.RPOLC` bit. The ***IrDA Receiver Pulse Detection*** figure provides examples of each polarity type.

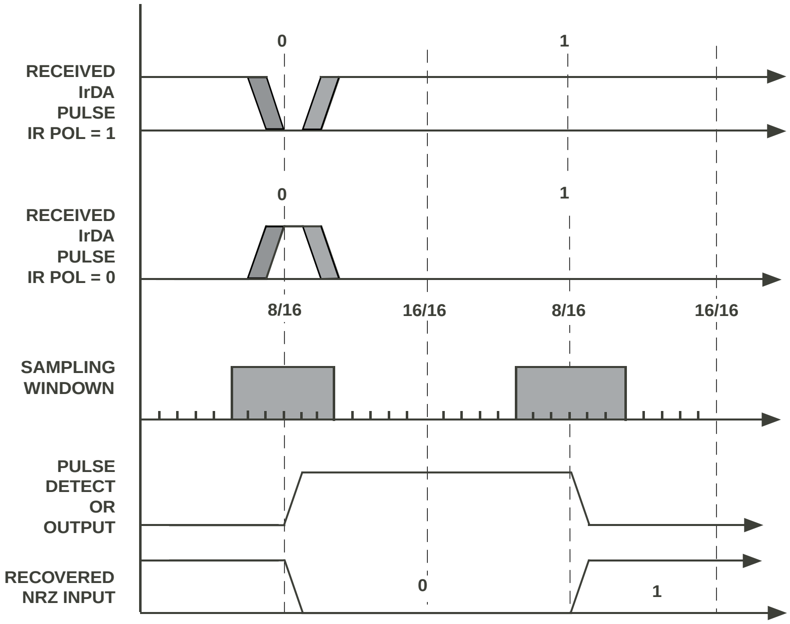

Figure 17-8: IrDA Receiver Pulse Detection

MDB Transmit Operation

In MDB mode, receive and transmit paths operate independently from each other, except for sharing bit rate and frame formats for both transfer directions.

Transmit operation is initiated by writing the `UART_THR` or `UART_TAIP` registers. A write to the `UART_THR` register transmits the written word with the appending address bit set low. A write to the `UART_TAIP` register transmits the written word with the appended address bit set high. The data is moved into the `UART_TSR` register, where it is shifted out at the bit rate programmed by the `UART_CLK` register, with start, stop, address, and parity bits appended, as required.

If DMA is enabled, the DMA engine always writes the data into the UART_THR register, and the written word is transmitted with the appending address bit set low.

The polarity of transmit data is selectable, using the UART_CTL.TPOLC bit.

MDB Receive Operation

Receive operations use the same data format as the transmit configuration, except that the number of stop bits is always assumed to be 1. After detection of the start bit, the received word is shifted into the UART_RSR register at the programmed bit.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th and 9th sample clock. If, however, the UART_CLK.EDBO bit is set, the receiver samples the bits roughly at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy needed at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

After the appropriate number of bits (including address, parity, and stop bits) is received, the UART_RSR register is transferred to the receive FIFO and accessible through the UART_RBR register.

The polarity of receive data is selectable, using the UART_CTL.RPOLC bit.

DMA Mode

In DMA mode, separate receive and transmit DMA channels move data between the UART and memory. The software does not have to move data; it just has to set up the appropriate transfers either through the descriptor mechanism or through autobuffer mode.

DMA channels provide a 4-deep FIFO, resulting in total buffer capabilities of 6 words at the transmit side and 9 words at the receive side. In DMA mode, the bus activity and arbitration mechanism determine the latency. The processor loading and interrupt priorities do not determine the latency.

To enable UART DMA, first set up the system DMA control registers. Then, enable the UART_IMSK.ERBFI or UART_IMSK.ETBEI interrupts. This sequence is necessary because these interrupt request lines double as DMA request lines. With DMA enabled, once these requests are received, the DMA control unit generates a direct memory access. If DMA is not enabled, the UART interrupt is passed on to the system interrupt handling unit. The status interrupt for the UART goes directly to the system event controller (SEC), bypassing the DMA unit completely.

For transmit DMA, programs must set the DMA_CFG.SYNC bit. With this bit set, interrupt generation is delayed until the entire DMA FIFO is drained to the UART module. The UART transmit DMA interrupt service routine can disable the DMA or to clear the UART_IMSK.ETBEI control bit only when the DMA_CFG.SYNC bit is set. Otherwise, up to four data bytes can be lost.

When the UART_IMSK.ETBEI bit is set, an initial transmit DMA request is issued immediately. The program then clears the UART_IMSK.ETBEI bit through the DMA service routine.

In DMA transmit mode, the UART_IMSK.ETBEI bit enables the peripheral request to the DMA FIFO. The DMA_CFG.EN bit enables the strobe on the memory side. If the DMA count is less than the DMA FIFO depth, which is 4, then the DMA interrupt can be requested before the UART_IMSK.ETBEI bit is set. If this behavior is unwanted, set the DMA_CFG.SYNC bit.

Regardless of the `DMA_CFG.SYNC` setting, the DMA stream has not left the UART transmitter completely at the time the interrupt request is generated. Transmission can abort in the middle of the stream, causing data loss, when the UART clock was disabled without extra synchronization with the `UART_STAT.TEMT` bit.

The UART provides functionality to avoid resource-consuming polling of the `UART_STAT.TEMT` bit. The `UART_IMSK_SET.EDTPTI` bit enables the `UART_STAT.TEMT` bit to trigger a DMA interrupt. To delay the DMA completion interrupt until the last data word of a STOP DMA has left the UART, keep the `DMA_CFG.INT` bit cleared and set the `UART_IMSK_SET.EDTPTI` bit instead. Then, the normal DMA completion interrupt is suppressed. Later, the `UART_STAT.TEMT` event triggers a DMA interrupt after the last word of the DMA has left the UART transmit buffers. If `DMA_CFG.INT` and `UART_IMSK.EDTPTI` are set, when finishing STOP mode, the DMA requests two interrupts.

The DMA of the UART module supports 8-bit and 16-bit operation, but not 32-bit operation. It does not support sign-extension.

Mixing DMA and Core Modes

Switching from DMA mode to core operation dynamically requires some consideration, especially for transmit operations. By default, the interrupt timing of the DMA is synchronized with the memory side of the DMA FIFOs. Normally, the transmit DMA completion interrupt is generated after the last byte is copied from the memory into the DMA FIFO. The transmit DMA interrupt service routine is not yet permitted to disable the `DMA_CFG.EN` bit. The interrupt is requested when the `DMA_STAT.IRQDONE` bit is set. The `DMA_STAT.RUN` bit, however, remains set until the data has completely left the transmit DMA FIFO.

When planning to switch from a DMA to core mode, set the `DMA_CFG.SYNC` bit in the word of the last descriptor or work unit before handing over control. Then, after the interrupt request occurs, software can write new data into the `UART_THR` register as soon as the `UART_STAT.THRE` bit permits. If the `DMA_CFG.SYNC` bit cannot be set, software can poll the `DMA_STAT.RUN` bit instead. Alternatively, using the `UART_IMSK.EDTPTI` bit can avoid expensive status bit polling.

When switching from core to DMA operation, ensure that the first DMA request is issued properly. If the DMA is enabled while the UART is still transmitting, no precaution is required. If, however, the DMA is enabled after the `UART_STAT.TEMT` bit is high, pulse the `UART_IMSK.ETBEI` bit to initiate DMA transmission.

Setting Up Hardware Flow Control

Use the following steps to set up UART hardware flow control.

1. Configure automatic or manual hardware flow control for the receiver through the `UART_CTL.ARTS` bit, or the transmitter through the `UART_CTL.ACTS` bit.
2. Configure $\overline{\texttt{UART\_CTS}}$ and $\overline{\texttt{UART\_RTS}}$ polarity through the `UART_CTL.FCPOL` bit.

On reset, when the UART is not yet enabled and the port multiplexing has not been programmed, the $\overline{\texttt{UART\_RTS}}$ pin is not driven. Some applications require a resistor pull the `UART_RTS` signal to either state during reset.

UART Event Control

Status flags in the `UART_STAT` register are available to signal data reception, parity, and error conditions, if necessary.

DMA and Interrupt Multiplexing

See the *Direct Memory Access (DMA)* chapter on for information on DMA multiplexing. Several interrupts and DMA channels in thr UART can be multiplexed.

> **NOTE:** To operate in interrupt mode without using DMA channels, set the `UART_IMSK.ELSI` bit. This configuration redirects receive and transmit requests to the status interrupt output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Masks

Each UART features a set of interrupt mask registers: `UART_IMSK`, `UART_IMSK_SET`, and `UART_IMSK_CLR`. The `UART_IMSK` register supports read/write operations. Writing ones to the `UART_IMSK_SET` register enables interrupts, writing ones to the `UART_IMSK_CLR` register disables them. Reads from either register return the enabled bits. This way, different interrupt service routines can control transmit, receive, and status interrupt requests independently and easily.

The UART module uses the `UART_IMSK` registers to enable requests for system handling of empty or full states of data registers. Unless polling is used as a means of action, the `UART_IMSK.ERBFI` and `UART_IMSK.ETBEI` bits in this register are normally set.

Each UART module has three interrupt outputs. It uses one for transmission, one for reception, and one for reporting status events. The UART module routes transmit and receive requests through the DMA controller. The status request goes directly to the system event controller (SEC).

If the associated DMA channel is enabled, the request functions as a DMA request. If the DMA channel is disabled, it simply forwards the request to the SEC. A DMA channel must be associated with the UART module to enable transmit and receive interrupts. Otherwise, transmit and receive requests cannot be forwarded.

> **NOTE:** To operate in interrupt mode without using DMA channels, set the `UART_IMSK.ELSI` bit. This configuration redirects receive and transmit requests to the status interrupt request output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Servicing

Interrupt service routines (ISRs) perform UART writes and reads. Separate interrupt lines are provided for transmit, receive, and status. The `UART_IMSK` register group enables the independent interrupts individually. To enable UART transmit interrupts, set the `UART_CTL.EN` bit.

The ISRs evaluate the status bits in the `UART_STAT` register to determine the signaling interrupt source. The system event controller for the processor assigns and unmasks interrupts. The ISRs must clear the interrupt latches explicitly. To reduce interrupt frequency on the receive side in core mode, use the `UART_IMSK.ERFCI` status interrupt as an alternative to the regular UART_IMSK.ERBFI receive interrupt. Hardware must ensure that at least two (if UART_CTL.RFIT=0) or four (if UART_CTL.RFIT=1) words are available in the receive buffer by the time the interrupt is requested.

Transmit Interrupts

The UART module uses the UART_IMSK_SET.ETBEI bit to enable transmit interrupt requests.

The UART_THR and UART_TAIP registers are the same physical register, and both affect the signaling of the UART_STAT.TEMT, UART_STAT.TFI, and UART_STAT.THRE bits similarly.

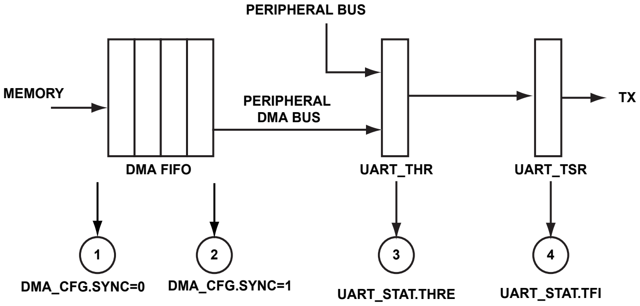

Figure 17-9: Transmit Interrupts

The UART module asserts the transmit request along with the UART_STAT.THRE bit, indicating that the transmit buffer is ready for new data. The UART_STAT.THRE bit resets to 1. When the UART_IMSK_SET.ETBEI bit is set, the UART module immediately issues an interrupt or DMA request. This way, no special handling of the first character is required when transmission of a string is initiated. Set the UART_IMSK_SET.ETBEI bit and let the interrupt service routine load the first character from memory and write it to the UART_THR register in the normal manner. ISRs can clear the UART_IMSK.ETBEI bit through the UART_IMSK_CLR register when the string transmission has completed.

Hardware clears the UART_STAT.THRE bit when new data is written to the UART_THR register. These write operations also clear the transmit interrupt request. However, they also initiate further transmission. If continued transmission is undesirable, the UART module can alternatively clear the transmit request through the UART_IMSK_CLR.ETBEI bit register. Transfers of data from the UART_THR register to the UART_TSR register reset this status flag in the UART_STAT register.

ISRs can interrogate the UART_STAT.TEMT bit to discover any ongoing transmission. The sticky counterpart of the UART_STAT.TEMT bit, UART_STAT.TFI, indicates when the transmit buffer has drained and can trigger a status interrupt. When data is pending in either one of these registers, the UART_STAT.TEMT flag is low. As soon as all data has left the UART_TSR register, the UART_STAT.TEMT bit goes high again and indicates that all pending transmit operations (including stop bits) have finished. Then, it is safe to disable the UART_CTL.EN bit or to three-state off-chip line drivers. Then, the UART module can generate an interrupt either through the status interrupt channel when the UART_IMSK.ETFI bit is set, or through the DMA controller when enabled by the UART_IMSK.EDTPTI bit.

When enabled by the `UART_IMSK.ETBEI` bit, the `UART_STAT.THRE` flag requests data along the peripheral command lines to the DMA controller (referred to as TXREQ). This signal is routed through the DMA controller. If the associated DMA channel is enabled, the TXREQ signal functions as a DMA request, otherwise the DMA controller simply forwards it to the SEC. Alternatively the `UART_IMSK.ETXS` bit can redirect the transmit interrupts to the UART status interrupt.

With interrupts disabled, the UART module can poll the status flags to determine when data is ready to move. Because polling is processor intensive, it is not typically used in real-time signal processing environments. Since read operations from `UART_STAT` registers have no side effects, different software threads can interrogate these registers without mutual impacts.

Polling the `SEC_SSTAT[n]` register without enabling the interrupts by the `SEC_CCTL[n]` register is an alternate method of operation to consider. Software can write up to two words into the `UART_THR` register before enabling the UART clock. As soon as the `UART_CTL.EN` bit is set, the UART module sends those two words.

Receive Interrupts

The UART module uses the `UART_IMSK_SET.ERBFI` bit to enable receive interrupt requests. If set, the `UART_STAT.DR` flag requests an interrupt on the dedicated RXREQ output, indicating that new data is available in the `UART_RBR` register. This signal is routed through the DMA controller. If the associated DMA channel is enabled, the RXREQ signal functions as a DMA request; otherwise the DMA controller simply forwards it to the SEC. Alternatively, if no DMA channel is assigned to the UART, the `UART_IMSK.ERXS` bit can redirect the receive interrupts to the UART status interrupt. When software reads the `UART_RBR` register, hardware clears the `UART_STAT.DR` bit again, which, in turn, clears the receive interrupt request.

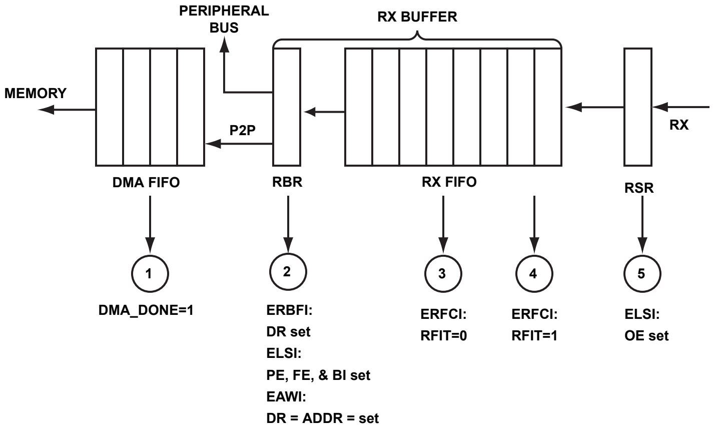

Figure 17-10: Receive Interrupts

Hardware updates the following:

- `UART_STAT.DR` bits
- `UART_STAT.ADDR` bits
- `UART_STAT.ASTKY` bits
- `UART_STAT.PE` bits

- `UART_STAT.FE` bits
- `UART_STAT.BI` bits
- `UART_RBR` register

The `UART_STAT.OE` bit is updated as soon as an overflow condition occurs (for example when a stop bit for a frame is received and the receive FIFO is full). When software does not read the `UART_RBR` register in time, the received data is protected from being overwritten by new data until software clears the `UART_STAT.OE` bit. Only the content of the `UART_RSR` register can be overwritten in the overrun case.

The UART module uses the `UART_STAT.RFCS` bit to monitor the state of the 8-deep receive FIFO. It uses the `UART_CTL.RFIT` bit to control the behavior of the buffer. If `UART_CTL.RFIT` is zero, the `UART_STAT.RFCS` bit is set when the receive buffer holds four or more words. If `UART_CTL.RFIT` is set, the `UART_STAT.RFCS` bit is set when the receive buffer holds seven or more words. Hardware clears the `UART_STAT.RFCS` bit when a core or DMA reads the `UART_RBR` register and when the buffer is flushed below the level of four (`UART_CTL.RFIT`=0) or seven (`UART_CTL.RFIT`=1). If the associated interrupt bit `UART_IMSK.ERFCI` is enabled, a status interrupt request is reported when the `UART_STAT.RFCS` bit is set.

If errors are detected during reception, an interrupt can be requested from the status interrupt output. This status interrupt request goes directly to the SEC. The bit enables status interrupt requests.

The controller detects the following error conditions, shown with their associated bits in the `UART_STAT` register.

- Overrun error (`UART_STAT.OE` bit)
- Parity error (`UART_STAT.PE` bit)
- Framing error or invalid stop bit (`UART_STAT.FE` bit)
- Break indicator (`UART_STAT.BI` bit)

Status Interrupts

The UART module uses status interrupt channels for the following purposes:

- Line status interrupt requests
- Flow control interrupt requests
- Receive FIFO threshold interrupt requests
- Transmission finished interrupt request

The UART module uses the `UART_IMSK.ELSI` bit to enable the line status interrupts. If set, the status interrupt request is asserted with one of the `UART_STAT.BI`, `UART_STAT.FE`, `UART_STAT.PE`, or `UART_STAT.OE` receive errors bits. A W1C operation to the `UART_STAT` register clears the error bits. Once all error conditions are cleared, the interrupt request deasserts.

The UART module uses the `UART_IMSK_SET.ERFCI` bit to enable the receive FIFO count interrupt. If set, a status interrupt request is generated when the `UART_STAT.RFCS` is active. The `UART_STAT.RFCS` bit indicates a receive buffer threshold level. If the `UART_CTL.RFIT` bit is cleared, software can safely read two words out of the `UART_RBR` register by the time the `UART_STAT.RFCS` interrupt occurs.

If the `UART_CTL.RFIT` bit is set, software can safely read four words. The interrupt request and the `UART_STAT.RFCS` bit are cleared when the `UART_RBR` is read enough of times, so that the receive buffer drains below the threshold of two (`UART_CTL.RFIT`=0) or four (`UART_CTL.RFIT`=1). Because in DMA mode a status service routine may not be permitted to read `UART_RBR`, this interrupt is only recommended in core mode. In DMA mode, use this functionality for error recovery only.

The UART module uses the `UART_IMSK_SET.EDSSI` bit to enable the flow control interrupts. If active, a status interrupt is generated when the sticky `UART_STAT.SCTS` bit register is set, indicating that the `UART_CTS` input of the transmitter been reasserted. A W1C operation to the `UART_STAT.SCTS` bit clears the interrupt request.

The UART module uses the `UART_IMSK_SET.ETFI` bit to enable the transmission finished interrupt. If active, a status interrupt request is asserted when the `UART_STAT.TFI` bit is set. The `UART_STAT.TFI` is the sticky version of the `UART_STAT.TEMT` bit, indicating that a byte that started transmission has finished. A W1C operation to the `UART_STAT.TFI` bit clears the interrupt request.

Multi-Drop Bus Events

Several status bits and interrupt features in the `UART_STAT` and `UART_IMSK` registers facilitate efficient data handling in multi-drop bus mode. These features include the address (`UART_STAT.ADDR`) bit, the address sticky (`UART_STAT.ASTKY`) bit and the enable address word interrupt (`UART_IMSK.EAWI`). One of the key features of the multi-drop bus protocol is its address bit. The address bit signifies to the slaves that the master is transmitting an address word (all read it) or a data word (only the addressed slave reads its). The UART hardware provides an efficient method of handling the situation described with the use of `UART_STAT.ASTKY` bit.

NOTE: The UART module uses the `UART_STAT.ASTKY` bit in multi-drop bus mode to indicate when an address operation for a peripheral is occurring. The `UART_STAT.ASTKY` bit is a sticky version of the `UART_STAT.ADDR` bit. Hardware sets the bit whenever the `UART_STAT.ADDR` bit is set. Only software clears it with a W1C operation. With the `UART_STAT.ASTKY` bit set, words are received irrespective of the mode bit or address bit setting. With the `UART_STAT.ASTKY` bit cleared, only address words (mode bit =1) are received and words with mode bit =0 are ignored in MDB mode. This bit does not affect reception in non-MDB modes. (Words with mode bit =0 are not moved from the `UART_RSR` register to the receive FIFO.)

UART Programming Model

The following sections provide basic procedures for configuring various UART operations.

Detecting Autobaud

Refer to Autobaud Detection section for more information. The required steps are:

1. Ensure that the timer is disabled.

2. Configure the following bits: `UART_CTL.MOD` =00, `UART_CTL.LOOP_EN` =1, `UART_CTL.WLS` =11 (8-bit data), and `UART_CTL.EN` =1
3. Configure the following bits: `TIMER_TMR[n]_CFG.TMODE` =1101, `TIMER_TMR[n]_CFG.OUTDIS` =1, `TIMER_TMR[n]_CFG.IRQMODE` =10 and enable the timer.
4. Send test data through the host device and wait for the timer interrupt and disable the timer.

   The bit rate can be derived from the timer period register value according to the formula provided in the Auto-baud Detection section.

Using Common Initialization Steps

When using the core or the DMA to execute transfers, the following steps are common to all UART modes.

1. All UART signals are multiplexed and compete with other functions at pin level. First, program the port registers according to the guidelines in the PORT chapter.
2. Program the `UART_CLK` register. Refer to Bit Rate Generation topic.
3. Program the `UART_CTL` register and enable the UART clock.

Using Core Transfers

Write data into the `UART_THR` register, when the `UART_STAT.THRE` bit is set, to initiate a core transmit operation. If the `UART_STAT.DR` bit is set, received data can be read from the `UART_RBR` register.

Using DMA Transfers

1. Make sure that the `UART_IMSK.ETBEI` or the `UART_IMSK.ERBFI` bits are cleared before configuring the DMA.
2. Configure the dedicated DMA channel.
3. Set the `UART_IMSK.ETBEI` or `UART_IMSK.ERBFI` bits to start the transfer.

Using Interrupts

Each UART features three interrupt signal outputs.

1. Enable individual interrupts in the system event controller (SEC).
2. Register IRQ handlers.
3. Use the interrupts mask registers to enable specific IRQ events.

Setting Up Hardware Flow Control

1. Configure automatic or manual hardware flow control for the receiver through the `UART_CTL.ARTS` bit, or the transmitter through the `UART_CTL.ACTS` bit.
2. Configure $\overline{\texttt{UART\_CTS}}$ and $\overline{\texttt{UART\_RTS}}$ polarity through the `UART_CTL.FCPOL` bit.

ADSP-SC58x UART Register Descriptions

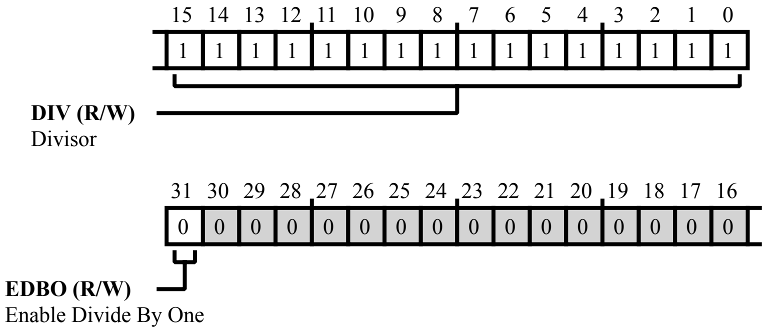
UART (UART) contains the following registers.

Table 17-9: ADSP-SC58x UART Register List

Name	Description
UART_CLK	Clock Rate Register
UART_CTL	Control Register
UART_IMSK	Interrupt Mask Register
UART_IMSK_CLR	Interrupt Mask Clear Register
UART_IMSK_SET	Interrupt Mask Set Register
UART_RBR	Receive Buffer Register
UART_RSR	Receive Shift Register
UART_RXCNT	Receive Counter Register
UART_SCR	Scratch Register
UART_STAT	Status Register
UART_TAIP	Transmit Address/Insert Pulse Register
UART_THR	Transmit Hold Register
UART_TSR	Transmit Shift Register
UART_TXCNT	Transmit Counter Register

Clock Rate Register

The `UART_CLK` register divides the system clock (SCLK0_0) down to the bit clock.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 17-10: UART_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EDBO	Enable Divide By One. The `UART_CLK.EDBO` bit enables the bypassing of the divide-by-16 prescaler in bit clock generation. This functionality improves bit rate granularity, especially at high bit rates. Do not set this bit in IrDA mode.	
		0	Bit clock prescaler = 16
		1	Bit clock prescaler = 1
15:0 (R/W)	DIV	Divisor. The `UART_CLK.DIV` provides the divisor for the UART's clock bit rate calculation. The bit rate is defined by: Bit Rate = SCLK0_0 / ($16^{(1\text{-EDBo})}$ x `UART_CLK.DIV`)	

Control Register

The `UART_CTL` register provides enable and disable control for internal UART and for the IrDA mode of operation. This register also provides UART line control, permitting selection of the format of received and transmitted character frames. Modem feature control also is available from this register, including partial modem functionality to allow for hardware flow control and loopback mode.

Figure 17-12: UART_CTL Register Diagram

Table 17-11: UART_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	RFRT	Receive FIFO RTS Threshold. The `UART_CTL.RFRT` bit controls `UART_RTS` pin assertion and deassertion timing. This bit is ignored if `UART_CTL.ARTS` is cleared. If set, the `UART_RTS` pin is deasserted when the receive buffer already holds seven words and an eighth start bit is detected. It is reasserted when the FIFO contains seven words or less. If cleared, the `UART_RTS` pin is deasserted when the RX buffer already holds four words and a fifth start bit is detected. The `UART_RTS` pin is reasserted when the RX buffer contains no more than 4 words.	
		0	Deassert RTS if RX FIFO word count > 4; assert if <= 4
		1	Deassert RTS if RX FIFO word count > 7; assert if <= 7
29 (R/W)	RFIT	Receive FIFO IRQ Threshold. The `UART_CTL.RFIT` bit controls the timing of the `UART_STAT.RFCS` bit. If `UART_CTL.RFIT` is cleared, the receive threshold is two. If `UART_CTL.RFIT` is set, the threshold is four words in the receive buffer.	
		0	Set RFCS=1 if RX FIFO count >= 4
		1	Set RFCS=1 if RX FIFO count >= 7
28 (R/W)	ACTS	Automatic CTS. The `UART_CTL.ACTS` bit must be set to enable the `UART_CTS` input pin for `UART_TX` handshaking. If enabled, the `UART_STAT.CTS` bit holds the value (if `UART_CTL.FCPOL` is set) or complement value (if `UART_CTL.FCPOL` is cleared) of the `UART_CTS` input pin. The `UART_STAT.CTS` bit can be used to determine whether the external device is ready to receive data (if `UART_STAT.CTS` is set) or whether it is busy (if `UART_STAT.CTS` is cleared). If `UART_CTL.ACTS` is cleared, the `UART_TX` handshaking protocol is disabled, and the `UART_TX` line transmits data whenever there is data to send, regardless of the value of `UART_CTS`. Software can pause ongoing transmission by setting the `UART_CTL.XOFF` bit.	
		0	Disable TX handshaking protocol
		1	Enable TX handshaking protocol
27 (R/W)	ARTS	Automatic RTS. The `UART_CTL.ARTS` bit must be set to enable the `UART_RTS` input pin for `UART_TX` handshaking. If set, the hardware guarantees a minimal `UART_RTS` pin deassertion pulse width of at least the number of data bits defined by the `UART_CTL.WLS` bit field. If cleared, the `UART_RTS` pin is not generated automatically by hardware. The `UART_RTS` pin can still be manually controlled by the `UART_CTL.MRTS` bit, and software is responsible for `UART_RTS` pulse width control (if needed).	
		0	Disable RX handshaking protocol.
		1	Enable RX handshaking protocol.

Table 17-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	XOFF	Transmitter off. The `UART_CTL.XOFF` bit (if set) turns off transmission (XOFF) by preventing the content of THR from being continued to TSR. When set, this bit turns on transmission (XON). The state of the `UART_CTL.XOFF` bit is ignored if the `UART_CTL.ACTS` bit is set.	
		0	Transmission ON, if ACTS=0
		1	Transmission OFF, if ACTS=0
25 (R/W)	MRTS	Manual Request to Send. The `UART_CTL.MRTS` bit controls the state of the `UART_RTS` output pin when the `UART_CTL.ARTS` bit is cleared. When `UART_CTL.MRTS` is cleared, the UART deasserts the `UART_RTS` pin, signaling to the external device that the UART is not ready to receive. When `UART_CTL.MRTS` is set, the UART asserts the `UART_RTS` pin, signaling to the external device that the UART is ready to receive.	
		0	Deassert RTS pin when ARTS=0
		1	Assert RTS pin when ARTS=0
24 (R/W)	TPOLC	IrDA TX Polarity Change. The `UART_CTL.TPOLC` bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the `UART_TX` pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the `UART_TX` pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low TX polarity setting
		1	Active-high TX polarity setting
23 (R/W)	RPOLC	IrDA RX Polarity Change. The `UART_CTL.RPOLC` bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the `UART_RX` pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the `UART_RX` pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low RX polarity setting
		1	Active-high RX polarity setting

Table 17-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	FCPOL	Flow Control Pin Polarity. The `UART_CTL.FCPOL` bit selects the polarities of the `UART_CTS` and `UART_RTS` pins. When the `UART_CTL.FCPOL` bit is cleared, the `UART_RTS` and `UART_CTS` pins are active low, and the UART is halted when the `UART_RTS` and `UART_CTS` pin state is high. When `UART_CTL.FCPOL` bit is set, the `UART_RTS` and `UART_CTS` pins are active high, and the UART is halted when the `UART_RTS` and `UART_CTS` pin state is low.	
		0	Active low CTS/RTS
		1	Active high CTS/RTS
19 (R/W)	SB	Set Break. If set, the `UART_CTL.SB` bit forces the `UART_TX` pin to low asynchronously, regardless of whether or not data is currently transmitted. This bit functions even when the UART clock is disabled. Because the `UART_TX` pin normally drives high, it can be used as a flag output pin, if the UART is not used. (For example, if `UART_CTL.TPOLC` is cleared, drive `UART_TX` pin low; or if `UART_CTL.TPOLC` is set, drive `UART_TX` pin high.)	
		0	No force
		1	Force TX pin to 0
18 (R/W)	FFE	Force Framing Error on Transmit. The `UART_CTL.FFE` bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force error
17 (R/W)	FPE	Force Parity Error on Transmit. The `UART_CTL.FPE` bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force parity error

Table 17-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	STP	Sticky Parity. The `UART_CTL.STP` bit controls whether the parity is generated by hardware based on the data bits or whether it is set to a fixed value. If this bit is cleared, the hardware calculates the parity bit value based on the data bits. Then, the EPS bit determines whether odd or even parity mode is chosen. If this bit is set, odd parity is used. That means that the total count of logical-1 data bits including the parity bit must be an odd value. Even parity is chosen by `UART_CTL.STP` cleared and `UART_CTL.EPS` set. Then, the count of logical-1 bits must be a even value. If the `UART_CTL.STP` bit is set, hardware parity calculation is disabled. In this case, the sent and received parity equals the inverted `UART_CTL.EPS` bit.	
		0	No forced parity
		1	Force (Stick) parity to defined value (if PEN=1)
15 (R/W)	EPS	Even Parity Select.	
		0	Odd parity
		1	Even parity
14 (R/W)	PEN	Parity Enable. The `UART_CTL.PEN` bit enables parity transmission and parity check. The `UART_CTL.PEN` bit inserts one additional bit between the most significant data bit and the first stop bit. The polarity of this so-called parity bit depends on data and the `UART_CTL.STP` and `UART_CTL.EPS` control bits. Both transmitter and receiver calculate the parity value. The receiver compares the received parity bit with the expected value and issues a parity error if they do not match. If the `UART_CTL.PEN` bit is cleared, the `UART_CTL.STP` and the `UART_CTL.EPS` bits are ignored.	
		0	Disable
		1	Enable parity transmit and check
13 (R/W)	STBH	Stop Bits (Half Bit Time).	
		0	0 half-bit-time stop bit
		1	1 half-bit-time stop bit
12 (R/W)	STB	Stop Bits. The `UART_CTL.STB` bit controls how many stop bits are appended to transmitted data.	
		0	1 stop bit
		1	2 stop bits

Table 17-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	WLS	Word Length Select. The `UART_CTL.WLS` field determines whether the transmitted and received UART word consists of 5, 6, 7, or 8 data bits.	
		0	5-bit word
		1	6-bit word
		2	7-bit word
		3	8-bit word
5:4 (R/W)	MOD	Mode of Operation. The `UART_CTL.MOD` selects the UART operation mode (UMOD).	
		0	UART mode
		1	MDB mode
		2	IrDA SIR mode
1 (R/W)	LOOP_EN	Loopback Enable. The `UART_CTL.LOOP_EN` bit enables UART loopback mode. When set, this bit disconnects the input of the receiver from the `UART_RX` pin, and internally redirects the transmit output to the receiver. The `UART_TX` pin remains active and continues to transmit data externally as well. Loopback mode also forces the `UART_RTS` pin to its deassertive state, disconnects the `UART_CTS` bit from the `UART_CTS` input pin, and directly connects the `UART_CTL.MRTS` bit to the `UART_STAT.CTS` bit. In loopback mode, setting the `UART_CTL.MRTS` bit sets the `UART_STAT.CTS` bit and enables the transmitter of the UART. Clearing the `UART_CTL.MRTS` bit clears the `UART_STAT.CTS` bit and disables the transmitter of the UART.	
		0	Disable
		1	Enable
0 (R/W)	EN	Enable UART. The `UART_CTL.EN` enables the UART clocks. This bit also resets the state machine and control registers when cleared. Using this bit to disable the UART -- when not used -- reduces power consumption.	
		0	Disable
		1	Enable

Interrupt Mask Register

The `UART_IMSK` register indicates the interrupt mask status (unmasked, if set, or masked, if cleared) of the UART status interrupt requests. This register is not a data register. Instead, it is controlled by the `UART_IMSK_SET` and `UART_IMSK_CLR` register pair. Writing ones to the `UART_IMSK_SET` register enables (unmasks) interrupt requests, and writing ones to the `UART_IMSK_CLR` register disables (masks) them. Reads from either register return the enabled bits.

The `UART_IMSK` register is used to enable requests for system handling of empty or full states of UART data registers. Unless polling is used as a means of action, the `UART_IMSK.ERBFI` and `UART_IMSK.ETBEI` bits are normally set. Setting this register without enabling system DMA causes the UART to notify the processor of the data inventory state using interrupts. For proper operation in this mode, system interrupts must be enabled, and appropriate interrupt handling routines must be present.

Each UART features three separate interrupt channels to handle the data transmit, data receive, and line status events independently, regardless of whether DMA is enabled or not. If no DMA channels are assigned to the UART, set the `UART_IMSK.ELSI` bit to reroute the transmit and receive interrupts to the status interrupt request output.

With system DMA enabled, the UART uses DMA to transfer data to or from the processor. Dedicated DMA channels are available for receive and transmit operations. Line error handling can be configured independently from the receive or transmit setup.

The DMA of the UART is enabled by first setting up the system DMA control registers and then enabling the `UART_IMSK.ERBFI` and `UART_IMSK.ETBEI` interrupts. This configuration is because the interrupt request lines double as DMA request lines. Depending on whether DMA is enabled or not, upon receiving these requests, the DMA control unit either generates a direct memory access or passes the UART interrupt on to the system interrupt handling unit(s). However, the error interrupt for the UART goes directly to the system interrupt handling unit(s), bypassing the DMA unit completely.

Figure 17-13: UART_IMSK Register Diagram

Table 17-12: UART_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ETXS	Enable TX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ETXS` bit indicates re-direction of the TX interrupt requests to status interrupt output. If cleared, TX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked
8 (R/W)	ERXS	Enable RX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ERXS` bit indicates re-direction of RX interrupt requests to status interrupt output. If cleared, RX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 17-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	EAWI	Enable Address Word Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.EAWI` bit indicates generation of a status interrupt request when an Address word in MDB-mode is present in the `UART_RBR`. A received word is an address word if the `UART_STAT.ADDR` bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
6 (R/W)	ERFCI	Enable Receive FIFO Count Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ERFCI` bit indicates enabling of the receive buffer threshold interrupt request if signaled by the `UART_STAT.RFCS` bit. Read the `UART_RBR` register sufficient times to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
5 (R/W)	ETFI	Enable Transmission Finished Interrupt Mask Status. If set (interrupt unmasked) the `UART_IMSK.ETFI` bit indicates enabling of interrupt generation on the status interrupt channel when the transmit buffer register, the transmit address register, and the transmit shift register are all empty as indicated by the `UART_STAT.TFI`. The `UART_IMSK.ETFI` interrupt can be used to avoid expensive polling of the `UART_STAT.TEMT` bit, when the UART clock or line drivers should be disabled after transmission has completed. W1C the `UART_STAT.TFI` bit to clear the interrupt request. In DMA operation, the `UART_IMSK.ETFI` bits functionality might be preferred.	
		0	Interrupt is masked
		1	Interrupt is unmasked
4 (R/W)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.EDTPTI` bit indicates enabling of the DMA completion interrupt request to be delayed until the data has left the UART completely. This bit is required for DMA transmit operation only. If set, the UART can generate a DMA interrupt request by the time the `UART_STAT.TEMT` bit goes high after the last DMA data word is transmitted. When `UART_IMSK.EDTPTI` is set, usually the `DMA_CFG.INT` field is cleared to 00 in a STOP mode DMA. This set up suppresses the normal completion interrupt request, and the `UART_STAT.TEMT` event is signaled through the DMA controller and triggers the DMA interrupt. If both (`DMA_CFG.INT` not 00 and `UART_IMSK.EDTPTI` set), two interrupts are requested at the end of a STOP mode DMA.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 17-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	EDSSI	Enable Modem Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.EDSSI` bit indicates enabling of a modem status interrupt request on the same status interrupt channel when the `UART_STAT.SCTS` bit is set. This indicates `UART_CTS` pin re-assertion. Write-1-to-clear (W1C) the `UART_STAT.SCTS` bit to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
2 (R/W)	ELSI	Enable Line Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ELSI` bit indicates that redirection of TX and RX interrupt requests to the status interrupt output of the UART by OR'ing them with the `UART_STAT.OE`, `UART_STAT.PE`, `UART_STAT.FE`, and `UART_STAT.BI` interrupt requests. Set this bit when no DMA channel is associated with the UART. Enabling `UART_IMSK.ELSI` disables the RX/TX interrupt channels and negates the `UART_IMSK.EDTPTI` bit.	
		0	Interrupt is masked
		1	Interrupt is unmasked
1 (R/W)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ETBEI` bit indicates generation of a TX interrupt request if the `UART_STAT.THRE` bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
0 (R/W)	ERBFI	Enable Receive Buffer Full Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ERBFI` indicates generation of an RX interrupt request if the `UART_STAT.DR` bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Interrupt Mask Clear Register

The UART_IMSK indicates interrupt mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

Interrupt Mask Set Register

The UART_IMSK indicates interrupt request mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

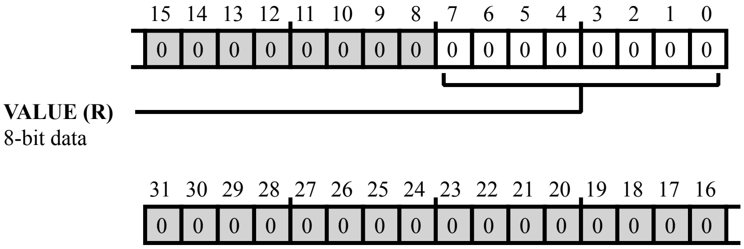
Receive Buffer Register

The read-only `UART_RBR` register is the UART's receive buffer. It is updated when there is pending data in the receive FIFO. Newly available data is signaled by the `UART_STAT.DR` bit.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 17-15: UART_RBR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	VALUE	8-bit data.

Receive Shift Register

The read only UART_RSR register which returns the content of the UART's receive shift register.

The frame data is moved into this shift register after polarity inversion, if any (including the native polarity inversion in the IrDA case).

In the case of the longest frame (MDB, with parity mode, and 8 bit data word-length), the start bit may be shifted out and not available for reading at the end of the frame reception. This register is NOT reset at the start of frame. If read, in the middle of a frame reception, data corresponding the previous frame may not have entirely shifted out (for example, the read data that have been read may NOT correspond entirely to the frame being received).

Because the UART is receiving only 1 stop bit, the UART_RSR contains only 1 stop bit even if more than one stop bit is present in the actual transfer. This register may be considered as storing the 10 most recently received bits (taking into consideration the stop bit receive limitation above).

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	VALUE	Contents of RSR.

Receive Counter Register

The `UART_RXCNT` register returns the content of 16-bit counter in the UART receiver. This count is used for baud rate clock generation (the lower [15:0] is the count data).

Scratch Register

The `UART_SCR` registers contain 8-bit scratch pad data. These registers are used for general purpose data storage and do not control the UART hardware in any way.

Status Register

The UART_STAT register contains the UART line status and UART modem status, as indicated by the current states of the UART's UART_CTS pin and internal receive buffers. Writes to this register can perform write-one-to-clear (W1C) operations on most status bits. Reading this register has no side effects.

Figure 17-20: UART_STAT Register Diagram

Table 17-19: UART_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	RFCS	Receive FIFO Count Status. The UART_STAT.RFCS bit is set when the receive buffer holds more or equal entries than a certain threshold. The threshold is controlled by the UART_CTL.RFIT bit. If UART_CTL.RFIT is cleared, the threshold is four entries. If UART_CTL.RFIT is set, the threshold is seven entries. The UART_STAT.RFCS bit is cleared when the UART_RBR register is read sufficient times until the buffer is drained below the threshold. The UART_STAT.RFCS bit can trigger a status interrupt request if enabled by the UART_IMSK_SET.ERFCI bit.	
		0	RX FIFO has less than 4 (7) entries when RFIT=0 (1)
		1	RX FIFO has at least 4 (7) entries when RFIT=0 (1)

Table 17-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	CTS	Clear to Send. The `UART_STAT.CTS` bit holds the value (if `UART_CTL.FCPOL` set) or the complement value (if `UART_CTL.FCPOL` cleared) of the `UART_CTS` input pin. The `UART_CTL.ACTS` bit must be set to enable this feature. The core can read the value of the `UART_STAT.CTS` bit to determine whether the external device is ready to receive (`UART_STAT.CTS` set) or if it is busy (`UART_STAT.CTS` cleared). If `UART_CTL.ACTS` is cleared, the `UART_TX` handshaking protocol is disabled, and the UART transmits data as long as there is data to transmit, regardless of the value of `UART_STAT.CTS`. When `UART_CTL.ACTS` is cleared, the software can pause transmission temporarily by setting the XOFF bit. Note that in loopback mode (`UART_CTL.LOOP_EN` set), the `UART_STAT.CTS` bit is disconnected from the `UART_CTS` input pin. Instead, the bit is directly connected to the `UART_CTL.MRTS` bit.	
		0	Not clear to send (External device not ready to receive)
		1	Clear to send (External device ready to receive)
12 (R/W1C)	SCTS	Sticky CTS. The `UART_STAT.SCTS` bit is a sticky bit that is set when `UART_STAT.CTS` transitions from 0 to 1. The `UART_STAT.SCTS` bit is cleared by software with a W1C operation. This bit can trigger a line status interrupt request if enabled by the `UART_IMSK_SET.EDSSI` bit.	
		0	CTS has not transitioned from low to high
		1	CTS has transitioned from low to high
11 (R/NW)	RO	Reception On-going.	
		0	No data reception in progress
		1	Data reception in progress
10 (R/W1S)	ADDR	Address Bit Status. The `UART_STAT.ADDR` bit is used to mirror the address bit of the word in `UART_RBR` in multi-drop bus protocol, and is enabled only in MDB mode. The `UART_STAT.ADDR` bit is updated by hardware upon detecting a received word with the address bit in `UART_RBR` set or cleared. Additionally, software can set the ADDR bit with a write-1-to-set (W1S) operation.	
		0	Address bit is low
		1	Address bit is high

Table 17-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ASTKY	Address Sticky. The `UART_STAT.ASTKY` bit is used in multi-drop bus mode to indicate whether a peripheral is currently being addressed. This bit is a sticky version of the `UART_STAT.ADDR` bit and is set by hardware when setting the `UART_STAT.ADDR` bit. The `UART_STAT.ASTKY` bit can only be cleared by software with a write-one-to-clear (W1C) operation. With the `UART_STAT.ASTKY` bit set, words will be received irrespective of the `UART_CTL.MOD` bit or `UART_STAT.ADDR` bit selection. With the `UART_STAT.ASTKY` bit cleared, only address words (`UART_CTL.MOD` bit set) will be received and words with `UART_CTL.MOD` bit cleared are ignored (not moved from the RSR to the RX FIFO) in MDB mode. The `UART_STAT.ASTKY` bit does not affect reception in non-MDB modes.	
		0	ADDR bit has not been set
		1	ADDR bit has been set
8 (R/W1C)	TFI	Transmission Finished Indicator. The `UART_STAT.TFI` bit is a sticky version of the `UART_STAT.TEMT` bit. While `UART_STAT.TEMT` is automatically cleared by hardware when new data is written to the `UART_THR` register, the sticky `UART_STAT.TFI` bit remains set, until it is cleared by software (W1C). The `UART_STAT.TFI` bit enables more flexible transmit interrupt request timing.	
		0	TEMT did not transition from 0 to 1
		1	TEMT transition from 0 to 1
7 (R/NW)	TEMT	TSR and THR Empty. The `UART_STAT.TEMT` bit indicates that the `UART_THR` and `UART_TAIP` registers and the `UART_TSR` register are empty. In this case, the program is permitted to write to the `UART_THR` and `UART_TAIP` registers twice without losing data. The `UART_STAT.TEMT` bit can also be used as indicator that pending UART transmission is completed. At that time, it is safe to disable the `UART_CTL.EN` bit or to three-state the off-chip line driver.	
		0	Not empty TSR/THR
		1	TSR/THR Empty

Table 17-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	THRE	Transmit Hold Register Empty. The UART_STAT.THRE bit indicates that the UART transmit channel is ready for new data and software can write to the UART_THR and UART_TAIP registers. Writes to the UART_THR and UART_TAIP registers clear the UART_STAT.THRE. The bit is set again when the UART_THR and UART_TAIP registers are empty and ready to accept data.	
		0	Not empty THR/TAIP
		1	Empty THR/TAIP
4 (R/W1C)	BI	Break Indicator. The UART_STAT.BI bit indicates that the first stop bit is sampled low and the entire data word, including parity bit, consists of low bits only. (This condition indicates that UART_RX was held low for more than the maximum word length.) The UART_STAT.BI bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The bit is sticky and can be cleared by W1C operations.	
		0	No break interrupt
		1	Break interrupt this indicates UARTxRX was held low(RPOLC=0) / high (RPOLC=1) for more than the maximum word length
3 (R/W1C)	FE	Framing Error. The UART_STAT.FE bit indicates that the first stop bit is sampled. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.FE bit is sticky and can be cleared by W1C operations. Note that invalid stop bits can be simulated by setting the UART_CTL.FFE bit.	
		0	No error
		1	Invalid stop bit error
2 (R/W1C)	PE	Parity Error. The UART_STAT.PE bit indicates that the received parity bit does not match the expected value. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.PE bit is sticky and can be cleared by W1C operations. Note that invalid parity bits can be simulated by setting the UART_CTL.FPE bit.	
		0	No parity error
		1	Parity error

Table 17-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	OE	Overrun Error. The `UART_STAT.OE` bit indicates that further data is received while the internal receive buffer was full. This bit is set when sampling the stop bit of the sixth data word. To avoid overruns, read the `UART_RBR` register in time. In DMA receive mode, overruns are very unlikely to happen ever. After an overrun occurs, the `UART_RBR` and receive FIFO are protected from being overwritten by new data until the `UART_STAT.OE` bit is cleared by software. The content of the `UART_RSR` register is lost as soon as the overrun occurs. The `UART_STAT.OE` bit is sticky and can be cleared by W1C operations.	
		0	No overrun
		1	Overrun error
0 (R/NW)	DR	Data Ready. The `UART_STAT.DR` bit indicates that data is available in the receiver and can be read from the `UART_RBR` register. The bit is set by hardware when the receiver detects the first valid stop bit. The bit is cleared by hardware when the `UART_RBR` register is read.	
		0	No new data
		1	New data in RBR

Transmit Address/Insert Pulse Register

The `UART_TAIP` register and the `UART_THR` register share the same physical register, but `UART_TAIP` has different effect than the `UART_THR` register when `UART_TAIP` is written to in MDB and UART modes.

In MDB mode, data written to the `UART_TAIP` register is transmitted as an address frame (as with the `UART_CTL.MOD` bit set).

In UART mode, a write to `UART_TAIP` causes a pulse of value `UART_TAIP` [7] for a duration of `UART_TAIP` [6:0] x bit time. (There is additional inversion if the `UART_CTL.TPOLC` bit is set).

Bit time is defined by the `UART_CLK` register. The transmission of the pulse is followed by stop bit transmission as specified by the `UART_CTL.STB` and `UART_CTL.STBH` bits. This could be used for supporting line break command and inter-frame gap.

In IrDA mode, writes to `UART_TAIP` is treated the same as writes to `UART_THR`.

Accesses to the `UART_TAIP` register have the same affects as the `UART_THR` register with respect to the `UART_STAT.THRE`, `UART_STAT.TEMT`, and `UART_STAT.TFI` flags.

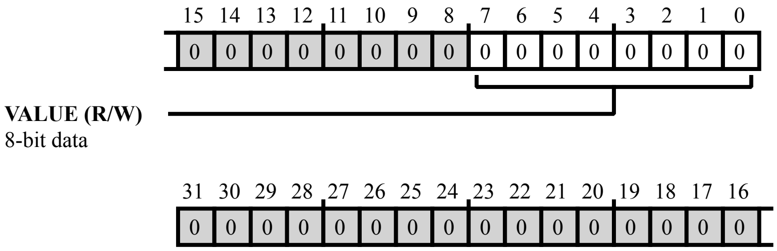

Figure 17-21: UART_TAIP Register Diagram

Table 17-20: UART_TAIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8-bit data.

Transmit Hold Register

The write-only `UART_THR` register is the UART's transmit buffer. The `UART_STAT.THRE` bit indicates whether data can be written to `UART_THR`. Writes to this register automatically propagate to the internal `UART_TSR` register as soon as `UART_TSR` is ready. Then, transmit operation is initiated immediately.

18 Enhanced Parallel Peripheral Interface (EPPI)

The Enhanced Parallel Peripheral Interface (EPPI) is a half-duplex, bidirectional port with a dedicated clock pin and three frame sync (FS) pins. It can support direct connections to active TFT LCDs, parallel A/D and D/A converters, video encoders and decoders, image sensor modules and other general-purpose peripherals. Each EPPI has two DMA channels associated with it. Moreover, in some modes, an EPPI can use an extra DMA channel.

EPPI Features

The EPPI module supports the following features.

- Programmable data length from 8 bits to up to 24 bits per clock cycle (depending on the product model)
- Bidirectional and half-duplex port
- Internal or external clock source
- Clock gating by an external device asserting the clock gating control signal
- Various framed and non-framed operating modes, as well as internal or external frame syncs
- Various general-purpose modes with 0, 1, 2, and 3 frame sync modes for both receive and transmit
- Ignores premature external frame syncs for data consistency
- SMPTE274M and SMPTE 296M high definition format support
- ITU-656, SMPTE 296M and SMPTE 274M status word error detection and correction for ITU-656 receive modes
- ITU-656, SMPTE 296M and SMPTE 274M receive modes – active video only, vertical blanking only, and entire field
- ITU-656, SMPTE 296M and SMPTE 274M preamble and status word decode
- Optional packing and unpacking of data to or from 32 bits from or to 8, 16 bits and 24 bits. If packing or unpacking is enabled, endianness can be altered to change the order of packing or unpacking of bytes/words
- Optional sign extension or zero-fill and alternate even or odd data sample filter for receive modes

- RGB888 to RGB666 or RGB565 conversion for transmit modes
- 4:2:2 YCrCb data Tx/Rx interleaving or de-interleaving modes
- Configurable LCD data enable (DEN) output available on frame sync 3
- Delayed start of PPI frame syncs
- Data clipping and mirroring
- Horizontal and vertical windowing for general purpose 2 and 3 frame sync modes
- Preamble, blanking and stripping support
- Multiplexing dual input

EPPI Functional Description

The EPPI has the following functionality.

RGB data formats

For transmit modes, the EPPI can convert RGB888 data in memory to either RGB565 or RGB666 at the output using bits in the Control register.

Data clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. This functionality is used for clipping data values during 8-bit, 10-bit, 12-bit or 16-bit transmit modes.

Data mirroring

A data mirroring feature is available which mirrors the EPPI data bits 15–0. This functionality is available in both transmit and receive modes.

Windowing

The EPPI supports windowing for general-purpose input modes.

Preamble, blanking and stripping support

The EPPI can embed blanking information and clip active data to be transmitted. This functionality is available for single channel data, interleaved data, and parallel data and supports data lengths equal to 16 bits, 20 bits or 24 bits.

ADSP-SC58x EPPI Register List

The EPPI is a half-duplex, bidirectional parallel port. It comprises a clock pin, 3 frame sync pins, and a set of data pins. For more information on EPPI functionality, see the EPPI register descriptions.

Table 18-1: ADSP-SC58x EPPI Register List

Name	Description
`EPPI_CLKDIV`	Clock Divide Register
`EPPI_CTL`	Control Register
`EPPI_CTL2`	Control Register 2 Register
`EPPI_EVENCLIP`	Clipping Register for EVEN (Luma) Data Register
`EPPI_FRAME`	Lines Per Frame Register
`EPPI_FS1_DLY`	Frame Sync 1 Delay Value Register

47	`EPPI0_CH1_DMA`	EPPI0 Channel 1 DMA	Pulse

RGB Data Formats

For transmit modes, the EPPI can convert RGB888 data in memory to RGB666 at the output when the `EPPI_CTL.RGBFMTEN` bit is set and the `EPPI_CTL.DLEN` value is equal to 18 bits. Similarly, the EPPI can convert RGB888 data in memory to RGB565 at the output when the `EPPI_CTL.RGBFMTEN` bit is set and `EPPI_CTL.DLEN` is equal to 16 bits.

This conversion is performed as follows:

- If `EPPI_CTL.PACKEN` =1, the EPPI first unpacks according to the `EPPI_CTL.SWAPEN` bit setting, and the three 32-bit data words from the DMA are broken into four 24-bit data words to be transmitted out, as described earlier.
- If `EPPI_CTL.PACKEN` =0, the EPPI takes the lower 24 bits of the 32-bit DMA as the data to be transmitted. Then, the EPPI truncates this 24-bit data word to the required data width. It removes the lower 2 bits of G and the lower 2 bits or 3 bits of R and B.

Data Clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. It uses these registers for clipping data values during 8-bit, 10-bit, 12-bit or 16-bit transmit modes. All data values for odd samples which are less than the value in the `EPPI_ODDCLIP.LOWODD` bit field are replaced with the value in the `EPPI_ODDCLIP.LOWODD` field. All data values for even samples which are less than the value in the `EPPI_EVENCLIP.LOWEVEN` field are replaced with the value in the `EPPI_EVENCLIP.LOWEVEN` field.

In the same manner, all data values for odd samples which are more than the value in the `EPPI_ODDCLIP.HIGHODD` bit field are replaced with the value in the `EPPI_ODDCLIP.HIGHODD` field. All data values for even samples which are more than the values in the `EPPI_EVENCLIP.HIGHEVEN` field are replaced with the values in the `EPPI_EVENCLIP.HIGHEVEN` field.

Depending on the programmed EPPI length, only the corresponding bits (least aligned) are considered for clipping. For example, if the EPPI is programmed in 10-bit mode, bits 9:0 and bits 25:16 constitute the clipping thresholds. The higher bits are ignored. The EPPI supports 8-bit, 10-bit, 12-bit, and 16-bit clipping thresholds.

For the 4:2:2 YCrCb color space, Luma and Chroma typically have different lower and upper thresholds. Separate thresholds can be required for even and odd data samples. For monochrome (Y only) or some non-video clipping applications, the value in the `EPPI_ODDCLIP.LOWODD` field can be the same as the value in the `EPPI_EVENCLIP.LOWEVEN` field. The value in the `EPPI_ODDCLIP.HIGHODD` field can be the same as the value in the `EPPI_EVENCLIP.HIGHEVEN` field.

In GP 0 FS mode with internal blanking generation, clipping is valid only for the active video part of the transmitted data. ITU-R 656 preambles, status words, and blanking data bypass the clipping logic.

If the EPPI is programmed in 16, 20-bit or 24-bit mode with the `EPPI_CTL.SPLTWRD` bit set, the YDATA (luma data) gets the clipping threshold levels of the `EPPI_EVENCLIP` register. The CDATA (chroma data) gets the clipping threshold levels of the `EPPI_ODDCLIP` register.

The clipping registers are ignored when the `EPPI_CTL.RGBFMTEN` bit is set.

Data Mirroring

To increase the pin multiplexing options for the EPPI data pins, a data mirroring feature is available which mirrors the EPPI data bits 15:0. This feature is available in both transmit and receive modes. It is enabled by setting the `EPPI_CTL.DMIRR` bit.

Windowing

The EPPI supports windowing for general-purpose input modes. The module can be configured to bring in a region of interest instead of the entire frame of data, which helps reduce bandwidth requirements.

Preamble, Blanking and Stripping Support

The EPPI supports embedding blanking information and clipping of active data for transmission. This functionality is available for single-channel data, interleaved data, and parallel data and supports a data length (`EPPI_CTL.DLEN`) of 16, 20 bits or 24 bits.

Support of preamble generation or detection and stripping of blanking information is also provided for ITU656 mode and the SMPTE 274M and 296M HD formats. The ***Video Mode Comparison*** table shows the SMPTE standards in comparison with the ITU656 modes. Preambles for SMPTE and ITU656 modes are identical. Extension of preamble to 12 bits is also supported.

Table 18-5: Video Mode Comparison

Video Mode	Frame Rate	Frame Resolution	Active Video Resolution	Sampling Frequency (MHz)	Remarks
ITU656 (NTSC)	30	1716x525	720x480	27.02	Y-C interleaved
ITU656 (PAL)	25	1728x625	720x576	27.00	Y-C interleaved
SMPTE 296M	30	3300x750	1280x720	74.25	Y,C separate
	60	1650x750	1280x720	74.25	Y,C separate

Table 18-5: Video Mode Comparison (Continued)

Video Mode	Frame Rate	Frame Resolution	Active Video Resolution	Sampling Frequency (MHz)	Remarks
SMPTE 274M	30	2200x1125	1920x1080	74.25	Y,C separate
	60	2200x1125	1920x1080	148.50	Y,C separate
	25	2640x1125	1920x1080	74.25	Y,C separate
	50	2640x1125	1920x1080	148.50	Y,C separate
	24	2750x1125	1920x1080	74.25	Y,C separate

See the clock operating conditions section of the data sheet for the maximum sampling frequency for this product.

EPPI Definitions

The following definitions are helpful when using the EPPI module.

ITU-R BT.-656

Description of a digital video protocol for interfaces and data stream format required to send uncompressed PAL or NTSC standard definition TV (525 or 625 lines) signals.

YUV422

YUV is a color space where luminance (Y) and chrominance (UV) components define the pixels. The suffix signifies how the chrominance components have been decimated and provide formatting information. In this case, the YUV422 format has the chrominance decimated by two, meaning only half of each chrominance component is available. Typical YUV422 formatting interleaves the luminance and chrominance (for example, U1Y1V1Y2U2Y3V2Y4).

RGB888

RGB is a color space where three color values, one red (R), one green (G) and one blue (B), define the pixels. The suffix signifies the bit widths for these color components. In this case, RGB888 means that each red, green, and blue value is 8 bits.

RGB565

RGB is a color space where three color values, one red (R), one green (G) and one blue (B) define the pixels. The suffix signifies the bit widths for these color components. In this case, RGB565 means that the red (R) and blue (B) are 5 bits each while the green (G) is 6 bits. When packed together, each RGB565 pixel can be represented in a 16-bit data word. LCD display panels commonly use this format.

SMPTE 274M

An HD standard defining the spatial resolution (image sample structure) and frame rates for 1920x1080.

SMPTE 296M

An HD standard for defining the spatial resolution (image sample structure) and frame rates fro 1280x720.

Reset Operation

On a hardware reset, the entire EPPI is reset. All MMRs return to their default values. EPPI interrupt and DMA requests become inactive and internally generated `EPPI_CLK` and frame syncs are aborted.

In software, write 0 to the `EPPI_CTL.EN` bit to reset and reconfigure the EPPI. When disabled in this manner, only the `EPPI_STAT` register is cleared to its reset value. Interrupts and DMA requests become inactive and internally generated clock and frame syncs are aborted.

Frame Sync Polarity and Sampling Edge

The `EPPI_CTL.POLS` and `EPPI_CTL.POLC` bits provide a mechanism to select the active level of the frame syncs and the sampling or driving edge of the EPPI clock, respectively. This functionality allows the EPPI to connect to data sources and receivers with a wide array of control signal polarities. Often, the remote data source or receiver also offer configurable signal polarities. In these cases, the `EPPI_CTL.POLS` and `EPPI_CTL.POLC` bits add flexibility.

Table 18-6: Frame Sync Polarity Selections and Frame Sync Pin States

Bit Setting	Frame Sync 2	Frame Sync 1
POLS = b#00	Active high	Active high
POLS = b#01	Active high	Active low
POLS = b#10	Active low	Active high
POLS = b#11	Active low	Active low

POLC = b#01	Falling edge	Rising edge	Rising edge	Falling edge
POLC = b#10	Rising edge	Falling edge	Falling edge	Rising edge
POLC = b#11	Rising edge	Rising edge	Falling edge	Falling edge

Direct Memory Access (DMA)

The EPPI has a native DMA controller with two channels. A local arbiter arbitrates between these channels and requests are forwarded to the system crossbar. The EPPI has one connection to the fabric.

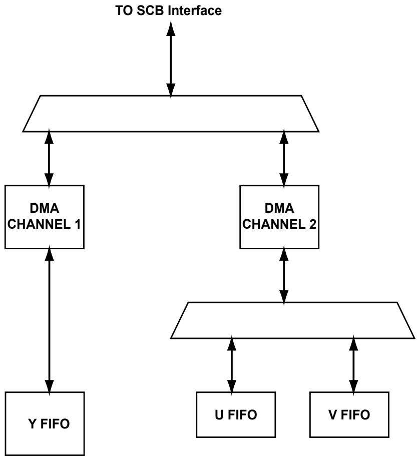

Figure 18-7: EPPI DMA Interface

The EPPI must be used with DMA. Configuring the EPPI DMA channels is a necessary step toward using the EPPI interface. The channels can be configured for either transmit or receive operation, and have a maximum throughput of (`EPPI_CLK`) x (32 bits/transfer). In modes where data lengths permit, packing can increase transfer bandwidth.

The DMA engine generates interrupts at the completion of a row, frame, or partial-frame transfer. The DMA engine also coordinates the source or destination point for the data that is transferred through the EPPI.

The 2D DMA capability allows the processor to be interrupted at the end of a line or after a frame of video is transferred, or if a DMA error occurs. The `DMA_XCNT` and `DMA_YCNT` registers allow for flexible data interrupt points. For example, assume the `DMA_XMOD` = `DMA_YMOD` =1. If a data frame contains 320 × 240 bytes (240 rows of 320 bytes each), the following conditions hold.

- Setting `DMA_XCNT` =320, `DMA_YCNT` = 240, and `DMA_CFG.INT` =1 interrupts on every row transferred, for the entire frame.
- Setting `DMA_XCNT` =320, `DMA_YCNT` =240, and `DMA_CFG.INT` =2 interrupts only on the completion of the frame (when 240 rows of 320 bytes have been transferred).

- Setting `DMA_XCNT` =38,400 (320 x 120), `DMA_YCNT` =2, and `DMA_CFG.INT` =1 causes an interrupt when half of the frame is transferred, and again when the whole frame is transferred.

The following is the general procedure for setting up DMA operation with the EPPI.

1. Configure the DMA registers as appropriate for the desired DMA operating mode.
2. Enable the DMA channel for operation.
3. Configure appropriate EPPI registers.
4. Enable the EPPI by writing 1 to the `EPPI_CTL.EN` bit.

EPPI Clock

The EPPI can be supplied with an external clock, or the clock can be generated internally and supplied to external devices. For information on the maximum PPI_CLK specification in internal and external clock modes, see the product-specific data sheet.

When using an external `EPPI_CLK`, there can be up to two cycles latency before valid data is received or transmitted.

The internal clock can be generated from SCLK1_0 when the `EPPI_CTL.ICLKGEN` bit is set. The value in the `EPPI_CLKDIV` register determines the generated clock frequency. The internally generated EPPI clock frequency is:

$f_{PCLK} = f_{SCLK0}/(\texttt{EPPI\_CLKDIV} + 1)$

where:

f_{PCLK} – frequency of internally generated EPPI clock

f_{SCLK} – frequency of SCLK1_0

`EPPI_CLKDIV` – Clock division value programmed in the `EPPI_CLKDIV` register.

The ***Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock*** table gives a few examples.

Table 18-8: Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock

0x0003	1:4
0x0004	1:5
0x0005	1:6
...	...

EPPI Operating Modes

The EPPI supports various receive and transmit modes of operation which include the detection and generation of preamble data. Specifically, the EPPI supports data formats described in the specifications ITU656, SMPTE 274M and SMPTE 296M. In addition to these modes, the EPPI also supports general-purpose receive and transmit using up to three frame syncs (FS).

The control register (`EPPI_CTL`) includes most of the bits used for configuring operating modes. The “Register Descriptions” section of this chapter provides complete descriptions of these bits.

ITU-R 656 Modes

The EPPI supports three input modes and one output mode for ITU-R 656 framed data. This section describes these modes.

ITU-R 656 Background

In ITU-R 656 mode, the horizontal (H), vertical (V), and field (F) signals are sent as an embedded part of the video data stream. The signals are sent in a series of bytes that form a control word. ITU-R 656 was formerly known as CCIR-656.

The letter H is used to distinguish between the *start of active video* (SAV) and *end of active video* (EAV) signals. These signals indicate the beginning and end of active video data in each line. The SAV occurs on a 1-to-0 transition of H, and EAV occurs on a 0-to-1 transition of H. The space between EAV and SAV is filled with horizontal blanking data. Therefore, H = 1 during the horizontal blanking portion of the data stream, and H = 0 during the active video portion of the data stream.

The letter V is used to denote the vertical blanking portion of the data stream. A transition in V can occur only in the EAV sequence. When V = 1, the data stream contains vertical blanking data, and when V = 0, the data stream contains active video data.

The letter F is used to distinguish Field 1 from Field 2. Interlaced video has two fields in a frame of data. It requires each field to be handled uniquely, and alternate rows of each field combined to create the actual video image.

For interlaced video, F = 0 represents Field 1 (*Odd Field*) and F = 1 represents Field 2 (*Even Field*). Progressive video makes no distinction between Field 1 and Field 2, and F is always 0 for progressive video. Interlaced video requires each field to be handled uniquely because alternate rows of each field combine to create the actual video image.

An entire field of video is comprised of active video plus horizontal blanking (the space between an EAV and SAV code) and vertical blanking (the space where V = 1). A field of video commences on a transition of the F bit.

Figure 18-9: ITU-R 656 8-Bit Parallel Data Stream from NTSC (PAL) Systems

NOTE: Refer to the ***Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video*** table. There is a defined preamble of three data elements (for example, in the case of 8-bit video: 0xFF, 0x00, 0x00), followed by the XY status word. The status word contains four protection bits for error detection and correction excluding the F (field), V (vertical blanking), and H (horizontal blanking) bits. F and V are only allowed to change as part of EAV sequences (that is, transition from H = 0 to H = 1).

The bit definitions are as follows:

- F = 0 for field 1
- F = 1 for field 2

- V = 1 during vertical blanking
- V = 0 when not in vertical blanking
- H = 0 at SAV
- H = 1 at EAV
- P3 = V XOR H
- P2 = F XOR H
- P1 = F XOR V
- P0 = F XOR V XOR H

P3–P0 are protection bits that enable 1-bit and 2-bit error detection, and 1-bit error correction at the receiver. The EPPI corrects the error if it detects 1-bit errors in F, V, or H. Errors in the protection bits themselves are detected but not corrected.

Table 18-9: Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video

	8-Bit Data								**10-Bit Data**	
	D9 (MSB	**D8**	**D7**	**D6**	**D5**	**D4**	**D3**	**D2**	**D1**	**D0**
Preamble	1	1	1	1	1	1	1	1	1	1
	0	0	0	0	0	0	0	0	0	0
	0	0	0	0	0	0	0	0	0	0
Control Byte	1	F	V	H	P3	P2	P1	P0	0	0

The `EPPI_STAT` register contains 2 bits, `EPPI_STAT.ERRDET` and `EPPI_STAT.ERRNCOR`, that are used to report the status of error detected and error not corrected, respectively.

The `EPPI_STAT.ERRDET` bit is set whenever an error is detected in the status word. However, this bit does not generate an interrupt. The `EPPI_STAT.ERRNCOR` bit is set when more than a 1-bit error is detected in the status word. An interrupt is generated when the `EPPI_STAT.ERRNCOR` bit is set. It can be cleared by clearing the `EPPI_STAT.ERRNCOR` and `EPPI_STAT.ERRDET` bits. Both bits are sticky and W1C.

In many applications, video streams other than the standard NTSC/PAL formats (for example, CIF, QCIF) can be employed. The processor interface is flexible enough to accommodate different row and field lengths. In general, as long as the incoming video has the proper EAV/SAV codes, the EPPI can read it in. A CIF image could be formatted to be 656-compliant, where EAV and SAV values define the range of the image for each line. The V and F codes are used to delimit fields and frames.

The following sections provide descriptions of EPPI operations.

Table 18-10: Operating Modes and Generic EPPI Operation

		How to configure	Useful for	How to configure in ITU R 656 Tx Mode

	Rx	DIR = 0 XFRTYPE = b#11 FSCFG = b#11		

ITU-R 656 Input Modes

In the ITU-R 656 input modes, the video source provides the clock or the system supplies it externally.

As shown in the ***ITU-R 656 Input Submodes*** figure and described in the following sections, there are three submodes supported for ITU-R 656 inputs: entire field, active video only, and vertical blanking interval only.

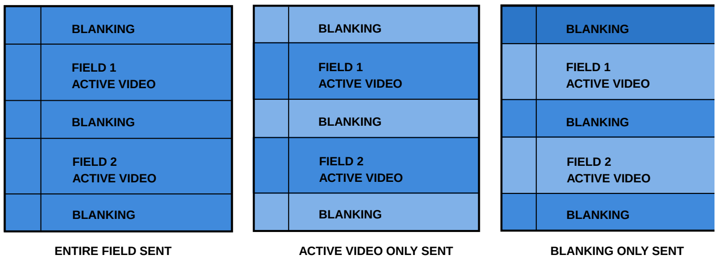

Figure 18-10: ITU-R 656 Input Submodes

Entire Field

In this mode, the EPPI reads the entire incoming bit stream. This stream includes active video as well as control byte sequences and ancillary data that can be embedded in horizontal and vertical blanking intervals.

Data transfer starts immediately after Field 1 synchronization occurs. The transfer does not include the first EAV code that contains the F = 0 assignment for interlaced video or the V = 0 assignment for progressive video.

Active Video

The EPPI uses this mode when only the active video portion of a field is of interest. The EPPI ignores (does not read in) all data between EAV and SAV, as well as all data present when V = 1. Furthermore, the control byte sequences are not stored to memory. The EPPI filters the sequences. After the start of Field 1 synchronizes, the EPPI ignores incoming samples until it sees an SAV.

In active video mode, programs must specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` register. Programs must specify the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` register.

In this mode, any input data sequence that is considered part of the preamble is not sent to memory such as in 8-bit ITU mode. If 0xFF or 0x00 appear in the input data stream, these values are considered part of the preamble. The part of the preamble can appear individually and not be tagged along with the preamble sequence FF, 00, 00. This functionality also applies to vertical blanking interval mode.

Vertical Blanking Interval (VBI)

In this mode, data transfer is only active while V = 1 is in the control byte sequence. This functionality indicates that the video source is in the midst of the vertical blanking interval (VBI), which is sometimes used for ancillary data transmission. The ITU-R 656 recommendation specifies the format for these ancillary data packets, but the EPPI is not equipped to decode the packets themselves. Software must handle this task. Horizontal blanking data is logged where it coincides with the rows of the VBI.

The VBI is split into two regions within each field. The EPPI considers these two separate regions as one contiguous space. However, frame synchronization begins at the start of Field 1, which does not necessarily correspond to the start of vertical blanking. For instance, in 525/60 systems, the start of Field 1 (F = 0) corresponds to line 4 of the VBI.

In VBI mode, the program must specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` register. The program must specify the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` register.

In this mode, any input data sequence that is considered as part of the preamble is not sent to memory such as in 8-bit ITU mode. If 0xFF or 0x00 appears in the input data stream, these values are considered part of the preamble. The part of the preamble can appear individually, and not be tagged along with the preamble sequence FF, 00, 00. This functionality applies to active video mode too.

ITU-R 656 Output in General-Purpose Transmit Modes

In GP transmit mode, the EPPI frames an ITU-R 656 output stream with the proper preambles and blanking intervals by setting the `EPPI_CTL.BLANKGEN` bit. The EPPI fetches active data from memory through the DMA channel, saving DMA bandwidth. The EPPI generates and embeds the proper preamble, status word (EAV and SAV sequences), and blanking data along with the active video from memory. Program the `EPPI_FS1_PASPL`, `EPPI_FS2_WLVB`, `EPPI_FS2_PALPF`, and `EPPI_FS1_WLHB` registers to perform the desired functions. The EPPI can also drive out the frame syncs using the `EPPI_CTL.FSCFG` bit setting.

The ***16-Bit Transmit with Internal Blanking Generation*** figure shows the bit stream format in 16-bit transmit modes with blanking generation (`EPPI_CTL.BLANKGEN` enabled). Each 16-bit data sample consists of 8-bit luma (Y) and 8-bit chroma (Cr or Cb) components. During transmission, the chroma data and blanking bytes of value 0x80 are placed on the upper half (MSBs) of the data lines. The luma data and blacking bytes of value 0x10 are placed on the lower half (LSBs) of the data lines.

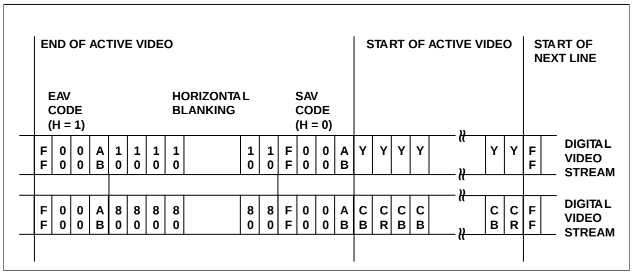

Figure 18-11: 16-Bit Transmit with Internal Blanking Generation

The ***Generated Blanking Preamble Sequence*** figure shows the data transmitted by the EPPI in this mode. After the EPPI is enabled, and if the EPPI FIFO is not empty, the transmission starts by sending out an EAV sequence for a vertical blanking line. For interlaced video, F starts at 1. For progressive video, F is always 0.

NOTE: Internal blanking generation functionality is valid only when the data length is 8, 10, or 16 bits and when the EPPI is in GP transmit modes. The `EPPI_CTL.BLANKGEN` bit generates preambles even in GP 2FS mode.

The internal blanking generation functionality of the ITU-R 656 output mode can also be bypassed by clearing the `EPPI_CTL.BLANKGEN` bit. (For example, if sending ancillary data in the blanking interval). The `EPPI_CTL.BLANKGEN` bit generates preambles even in GP 2FS mode.

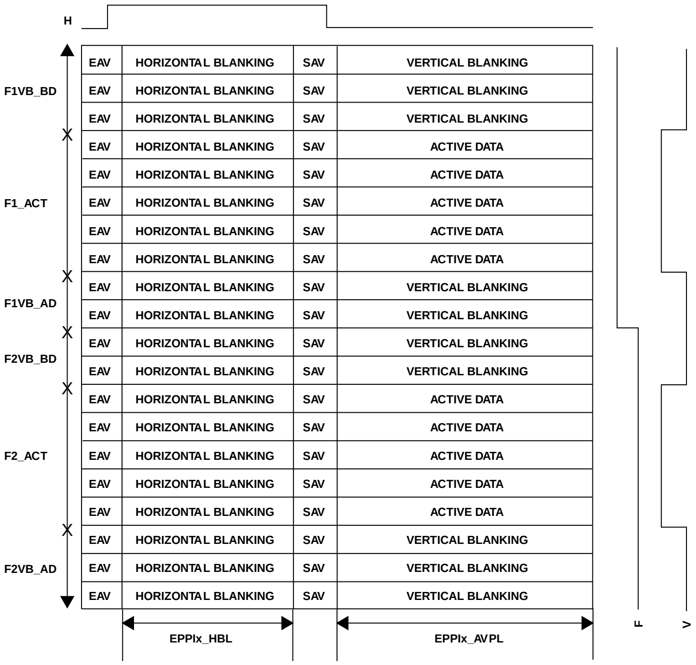

Figure 18-12: Generated Blanking Preamble Sequence

Frame Synchronization in ITU-R 656 Modes

For interlaced video, the start of frame synchronization occurs when a high-to-low transition is detected in F, the field indicator. For progressive video, the start of frame synchronization occurs when a high-to-low transition is detected in V, the vertical blanking indicator. These transitions in F and V can occur only in the EAV sequence. A start of line is detected on a low-to-high transition in H, the horizontal blanking indicator, which occurs in the EAV sequence as well.

For interlaced video, the start of frame corresponds to the start of field 1. Therefore, up to two fields can be ignored before the EPPI receives data. (For example, if field 1 started before the EPPI-to-camera channel was established). For progressive video, the start of frame corresponds to the start of active video.

Because all H and V signaling is embedded in the data stream in ITU-R 656 modes, the EPPI ignores the count registers (`EPPI_HCNT`, `EPPI_VCNT`). However, the EPPI still uses the `EPPI_FRAME` register to check for synchronization errors. Therefore, program this MMR with the number of lines expected in each frame of video.

The EPPI monitors the number of EAV-to-SAV transitions that occur from the start of a frame until it decodes the end of frame condition. (For example, a transition from F = 1 to F = 0 for interlaced video and a transition from V = 1 to V = 0 for progressive video).

At the end of frame condition, the actual number of lines processed is compared against the value in `EPPI_FRAME`. If there is a mismatch, a frame track error is asserted in the `EPPI_STAT` register. For example, if an SAV transition was missed, the current field only has NUM_ROWS – 1 rows. But, resynchronization occurs at the start of the next frame. When the EPPI receives the entire field, the field status bit is toggled in the `EPPI_STAT` register. This way, an interrupt service routine (ISR) can discern which field was previously read in.

General-Purpose EPPI Modes

The general-purpose (GP) EPPI modes accommodate a wide variety of data capture and transmission applications.

Each EPPI has three bidirectional frame sync pins. The EPPI internally generates frame syncs, or an external device communicating with the EPPI generates them.

GP modes differ based on the number of frame syncs used and the EPPI supports GP 0 FS—GP 3 FS modes.

All the GP modes, except 0 FS mode, support horizontal windowing. GP modes with 2 and 3 frame syncs also support vertical windowing.

For GP transmit modes with internal clock or frame syncs, the EPPI starts generating the clock or frame syncs only when the EPPI FIFO is full for the first time. For GP 0 FS transmit mode, the EPPI only starts transmitting when the EPPI FIFO is full for the first time.

General-Purpose 0 Frame Sync Mode

This mode is useful for applications where periodic frame syncs are not used to frame the data.

After the initial trigger, the EPPI receives or transmits data samples on every clock cycle. However, if the `EPPI_CTL.SKIPEN` bit is set for receive mode, the EPPI receives only alternate data samples.

The `EPPI_LINE`, `EPPI_FRAME`, `EPPI_HCNT`, `EPPI_HDLY`, `EPPI_VCNT`, and `EPPI_VDLY` registers are not valid for GP 0 FS mode. Therefore, windowing is not possible in this mode. Also, line and frame track errors are not applicable in this mode.

GP 0 FS receive mode is further divided into two submodes; internal trigger (`EPPI_CTL.FLDSEL` bit =0) and external trigger (`EPPI_CTL.FLDSEL` bit =1). The submodes are based on how the processor initiates data transmission or reception. GP 0 FS transmit mode is always internally triggered. DMA handles all subsequent data manipulation.

- ***Frame synchronization in GP 0 FS external trigger mode.*** When the EPPI is programmed in external trigger mode, it does not generate the `EPPI_FS1` signal and the external device must provide a trigger. The EPPI starts receiving the data as soon as an `EPPI_FS1` signal assertion is detected. After that, the DMA handles all subsequent data manipulation and any activity on `EPPI_FS1` is ignored.
- ***Frame synchronization in GP 0 FS internal trigger mode.*** When the EPPI is programmed in internal trigger mode, it starts receiving or transmitting data as soon as the EPPI clock is enabled and synchronized. There can be up to four PPI clock cycles of latency before valid data is received or transmitted.

General-Purpose 1 Frame Sync Mode

This mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs), and other general-purpose devices. This mode works for both transmit and receive.

The `EPPI_FRAME`, `EPPI_VDLY`, and `EPPI_VCNT` registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not available.

General-Purpose 2 Frame Sync Mode

This mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC signal can be connected to `EPPI_FS1` and the VSYNC signal can be connected to `EPPI_FS2`.

Data Enable in General-Purpose 2 Frame Sync Transmit Mode

The `EPPI_FS3` pin functions as a data enable (DEN) pin, when EPPI is configured in GP 2 FS transmit mode and generating the frame sync internally. The bits `EPPI_CTL.MUXSEL` and `EPPI_CTL.CLKGATEN` are not enabled. The functionality of the DEN pin is described in the following two cases.

Case 1

Blanking generation is configured using the `EPPI_CTL.BLANKGEN` bit. EPPI data length (`EPPI_CTL.DLEN` bit) is configured for 8, 10, or 16-bit transfers. The `EPPI_FS3` pin asserts during the *active data* regions, aligned with `EPPI_CLK` according to the clock polarity (`EPPI_CTL.POLC` bit) settings. For this mode, the pin `EPPI_FS3` is driven based on the `EPPI_CTL.POLC` setting. The pin `EPPI_FS3` is driven out on the same EPPI clock edge that drives out data. The frame sync polarity (`EPPI_CTL.POLS`) setting does not apply here—`EPPI_FS3` is always active high in this mode.

Case 2

Blanking generation (`EPPI_CTL.BLANKGEN` =0) is disabled. Or blanking generation is enabled, but the EPPI data length (`EPPI_CTL.DLEN` bit) is configured for a transfer size other than 8, 10, or 16 bits. The `EPPI_FS3` pin asserts at the start of the active data region on each line, aligned with `EPPI_CLK` according to the `EPPI_CTL.POLC` bit settings. For this mode, the pin `EPPI_FS3` is driven based on the `EPPI_CTL.POLC` setting. The `EPPI_FS3` signal is driven out on the same EPPI clock edge that drives out data.

The `EPPI_CTL.POLS` bit setting does not apply for case 2. The `EPPI_FS3` signal is always active high in this mode. Once asserted, `EPPI_FS3` stays asserted for the number of clock cycles per line configured in the `EPPI_HCNT` register, then it deasserts. This behavior on each line continues for the total number of lines programmed in the `EPPI_VCNT` register per frame. The behavior repeats at the start of subsequent video frames.

In case 2, if transmission of valid data is held off due to delays programmed in the `EPPI_HDLY` or `EPPI_VDLY` registers, the assertion of `EPPI_FS3` is also held off. The delay is on a per-line or per-frame basis.

General-Purpose 3 Frame Sync Mode

This mode is useful for video applications that use three synchronization signals for hardware: HSYNC, VSYNC, and FIELD. The HSYNC connects to the `EPPI_FS1` pin, VSYNC connects to the `EPPI_FS2` pin, and FIELD connects to the `EPPI_FS3` pin.

GP 3 FS mode is similar in operation to GP 2 FS mode. However, the start of frame synchronization in GP 3 FS also considers the state of the `EPPI_FS3` pin. All the windowing register settings (`EPPI_FRAME`, `EPPI_LINE`, `EPPI_HDLY`, `EPPI_HCNT`, `EPPI_VDLY`, and `EPPI_VCNT` registers), as well as data reception or transmission and error generation are the same as for GP 2 FS mode. In addition, for GP 3 FS mode with internal frame syncs, the `EPPI_CTL.FLDSEL` bit setting specifies the condition under which the transfer begins.

The EPPI generates the `EPPI_FS3` signal and toggles during every assertion of `EPPI_FS2` or a combination of `EPPI_FS2` and `EPPI_FS1`. The toggle depends on the `EPPI_CTL.FLDSEL` bit setting. The EPPI skips an `EPPI_FS2` signal when the `EPPI_FS3` value is high. Because of this condition, program the `EPPI_FS2` period value to half of the total number of pixels in the frame as in GP 3 FS mode. When in GP 2 FS mode, program the `EPPI_FS2` period with the value equal to the number of pixels per frame.

Supported Data Formats

The following sections describe EPPI receive and transmit data formats.

Receive Data Formats

The ***EPPI Receive Data Formats*** table provides information about EPPI configuration for specific use models for receive data.

Table 18-11: EPPI Receive Data Formats

Input Data Width	Use Model	Splitting/Packing Options
8	NTSC/PAL data	`EPPI_CTL.SPLTEO` =1 `EPPI_CTL.SUBSPLTODD` =1 if necessary to separate chroma components
	RGB sensor	No splitting possible. `EPPI_CTL.PACKEN` =1 – Four EPPI words are packed to 32-bit DMA data. `EPPI_CTL.PACKEN` =0 – Each EPPI word is sent as 8-bit data on the 32-bit DMA bus. This transfer consumes 4 times the DMA bandwidth of the 8-bit case with `EPPI_CTL.PACKEN` =1;
	ADCs	Gives I (in phase) and Q (quadrature) components. `EPPI_CTL.SPLTEO` =1 `EPPI_CTL.SUBSPLTODD` =0 since there are only two components.

Table 18-11: EPPI Receive Data Formats (Continued)

Input Data Width	Use Model	Splitting/Packing Options
10	NTSC/PAL data	Each EPPI word is zero filled or sign extended to 16 bits. `EPPI_CTL.SPLTEO` =1. `EPPI_CTL.SUBSPLTODD` =1 if necessary to separate chroma components.
	RGB sensor	No splitting possible. `EPPI_CTL.PACKEN` =1. Two EPPI words are zero filled or sign extended to 16 bits and packed to 32-bit DMA data. `EPPI_CTL.PACKEN` =0. Each EPPI word can be zero filled or sign extended to 16 bits and sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 10-bit case with `EPPI_CTL.PACKEN` =1;
	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. `EPPI_CTL.SPLTEO` =1 S`EPPI_CTL.SUBSPLTODD` = 0 since there are only two components.
12	RGB sensor	No splitting possible. `EPPI_CTL.PACKEN` =1. Two EPPI words are zero filled or sign extended to 16 bits and packed to 32-bit DMA data. `EPPI_CTL.PACKEN` =0. Each EPPI word can be zero filled or sign extended to 16 bits and sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 12-bit case with `EPPI_CTL.PACKEN` =1;
	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. `EPPI_CTL.SPLTEO` =1 `EPPI_CTL.SUBSPLTODD` =0 since there are only two components.
14	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. `EPPI_CTL.SPLTEO` =1 `EPPI_CTL.SUBSPLTODD` =0 since there are only two components.

Table 18-11: EPPI Receive Data Formats (Continued)

Input Data Width	Use Model	Splitting/Packing Options
16	8-bit luma/chroma pair for NTSC or HD	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SPLTWRD` =1, `EPPI_CTL.SUBSPLTODD` =1 if necessary to separate chroma components.
	16-bit luma/chroma pair for NTSC or HD	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SPLTWRD` =0, `EPPI_CTL.SUBSPLTODD` =1 if necessary to separate chroma components.
	RGB565 sensor	No splitting possible. `EPPI_CTL.PACKEN` =1. Two EPPI words are packed to a 32-bit DMA data. `EPPI_CTL.RGBFMTEN` is valid only in transmit modes. So, RGB565 cannot be byte aligned in memory. `EPPI_CTL.PACKEN` =0. Each EPPI word is sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 16-bit case with `EPPI_CTL.PACKEN` =1
	8-bit ADCs I/Q pair	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SPLTWRD` =1, `EPPI_CTL.SUBSPLTODD` =0.
	16-bit ADCs I/Q pair	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SPLTWRD` =0, `EPPI_CTL.SUBSPLTODD` =0.

Transmit Data Formats

The ***EPPI Transmit Data Formats*** table provides information about EPPI configuration for specific use models for transmit data.

Table 18-12: EPPI Transmit Data Formats

Output Data Width	Use Model	Splitting/Packing Options
8	NTSC/PAL data	`EPPI_CTL.SPLTEO` =1 `EPPI_CTL.SUBSPLTODD` =1 if the chroma components (U and V) come in separate DMA words.
	Serial RGB for lower-resolution LCDs	No splitting possible. `EPPI_CTL.PACKEN` =1. The 32-bit DMA data is unpacked to drive four EPPI words. `EPPI_CTL.PACKEN` =0. The lowest 8 bits of the DMA data is driven on the EPPI data and the rest of the 24 bits are discarded. This transfer consumes 4 times the DMA bandwidth of the 8-bit case with `EPPI_CTL.PACKEN` =1.
10	NTSC/PAL data	`EPPI_CTL.SPLTEO` =1 `EPPI_CTL.SUBSPLTODD` =1 if the chroma components (U and V) come in separate DMA words.
	DACs	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SUBSPLTODD` =0.

Table 18-12: EPPI Transmit Data Formats (Continued)

Output Data Width	Use Model	Splitting/Packing Options
12	DACs	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SUBSPLTODD` =0.
14	DACs	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SUBSPLTODD` =0.
16	8-bit luma/chroma pair for NTSC or HD	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SPLTWRD` =1, `EPPI_CTL.SUBSPLTODD` =1 if the chroma components (U and V) come in separate DMA words.
	16-bit luma/chroma pair for NTSC or HD	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SPLTWRD` =0, `EPPI_CTL.SUBSPLTODD` =1 if the chroma components (U and V) come in separate DMA words.
	RGB565 LCD	No splitting possible. `EPPI_CTL.RGBFMTEN` =1. Takes RGB888 data from the memory and drops the LSBs from each component to drive out RGB565 data.
	8-bit ADCs I/Q pair	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SPLTWRD` =1, `EPPI_CTL.SUBSPLTODD` = 0
	16-bit ADCs I/Q pair	`EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SPLTWRD` =0, `EPPI_CTL.SUBSPLTODD` =1
18	RGB666 LCD	No splitting possible. `EPPI_CTL.RGBFMTEN` =1. Takes RGB888 data from the memory and drops the 2 LSBs from each component to drive out RGB666 data.

Data Transfer Modes

The following sections describe EPPI data transfer modes, including receive or transmit data packing, sign extension, zero fill, receive or transmit split modes, clock gating, delayed start, and data consistency management.

Data Packing for Receive Modes

For receive modes, if the `EPPI_CTL.PACKEN` bit =1 and the DMA is 32 bits, the EPPI packs the incoming data into 32-bit words based on the `EPPI_CTL.DLEN` and `EPPI_CTL.SWAPEN` bit settings. When `EPPI_CTL.SWAPEN` =0, the EPPI puts the first data in the least significant bits and when `EPPI_CTL.SWAPEN` =1, the EPPI puts the first data in the most significant bits. The packing options for the `EPPI_CTL.DLEN` bits are as follows.

- When `EPPI_CTL.DLEN` =8, four 8-bit words can be packed into one 32-bit word.
- When `EPPI_CTL.DLEN` =16, two 16-bit words can be packed into one 32-bit word.
- For `EPPI_CTL.DLEN` values that are more than 8 bits but less than 16 bits, two such words are either sign-extended or zero-filled to 16 bits, and packed into one 32-bit word.
- When `EPPI_CTL.DLEN` =18, the EPPI sign-extends or zero-fills the 18-bit data to 24 bits and packs four 24-bit words into three 32-bit words.

- When `EPPI_CTL.DLEN` =24, the EPPI packs four 24-bit words into three 32-bit words.

When `EPPI_CTL.PACKEN` =0, the EPPI receives the incoming data and sends it on the bus as-is. If `EPPI_CTL.DLEN` is less than or equal to 16 bits, the DMA is a 16-bit DMA; otherwise it is a 32-bit DMA.

Data Packing for Transmit Modes

For transmit modes, if the `EPPI_CTL.DLEN` bit =1 and the DMA is a 32-bit DMA, the EPPI unpacks the 32-bit word according to the `EPPI_CTL.DLEN` and `EPPI_CTL.SWAPEN` bit settings.

If `EPPI_CTL.SWAPEN` =1, the EPPI transmits the most significant bits as the first data, and if `EPPI_CTL.SWAPEN` =0, the EPPI transmits the least significant bits as the first data. The unpacking options for the `EPPI_CTL.DLEN` bits are as follows.

- When `EPPI_CTL.DLEN` =8, the EPPI transmits one 32-bit word from memory as four 8-bit data words.
- For `EPPI_CTL.DLEN` values greater than 8 bits but less than or equal to 16 bits, the EPPI transmits one 32-bit word from memory as two 16-bit data words.
- When `EPPI_CTL.DLEN` =18 or 24, the EPPI transmits three 32-bit words from memory as four data words.

Sign-Extended and Zero-Filled Data

The following list describes the bit settings and functionality for sign-extending and zero-filling data.

- For `EPPI_CTL.DLEN` equal to 10, 12 or 14, data is zero-filled or sign-extended to 16 bits.
- For `EPPI_CTL.DLEN` equal to 18 bits, data is zero-filled or sign-extended to 24 bits if packing is enabled, and zero-filled or sign-extended to 32 bits if packing is disabled.
- For `EPPI_CTL.DLEN` equal to 24 bits, data is zero-filled or sign-extended to 32 bits if packing is disabled.
- For `EPPI_CTL.DLEN` equal to 8 bits, data is zero-filled or sign-extended to 16 bits if packing is disabled.
- If `EPPI_CTL.SIGNEXT` =1, then the data is sign-extended, otherwise it is zero-filled.

Split Receive Modes

The control register has three control bits for split receive modes: `EPPI_CTL.SPLTEO`, `EPPI_CTL.SUBSPLTODD`, and `EPPI_CTL.DMACFG`. Packing is not valid in split modes.

- If `EPPI_CTL.SPLTEO` =1, the EPPI splits the incoming data stream into two substreams, an even stream, and an odd stream, and packs them separately.
- The `EPPI_CTL.SUBSPLTODD` bit is available only when `EPPI_CTL.SPLTEO` =1. When `EPPI_CTL.SUBSPLTODD` =1, the EPPI subsplits the odd substream, and packs the streams separately.
- The `EPPI_CTL.DMACFG` bit is also available only if `EPPI_CTL.SPLTEO` =1. If `EPPI_CTL.DMACFG` =1, the EPPI uses two DMA channels and if `EPPI_CTL.DMACFG` =0, the EPPI uses only one DMA channel.

Split Transmit Modes

The `EPPI_CTL` register has three control bits for split transmit modes: `EPPI_CTL.SPLTEO`, `EPPI_CTL.SUBSPLTODD`, and `EPPI_CTL.DMACFG`. The DMA is always a 32-bit DMA. Packing is not valid in split modes.

- If `EPPI_CTL.SPLTEO` =1, the EPPI receives the Luma (Y3Y2Y1Y0) and interleaved Chroma (Cr1Cb1Cr0Cb0) data as 32 bits from the DMA channel. The EPPI interleaves the data to form a 4:2:2 YCrCb data stream to transmit.
- The `EPPI_CTL.SUBSPLTODD` bit is available only when `EPPI_CTL.SPLTEO` =1. In this case, if `EPPI_CTL.SUBSPLTODD` =1, the EPPI receives the Luma (Y3Y2Y1Y0) and deinterleaved Chroma (Cb3Cb2Cb1Cb0 and Cr3Cr2Cr1Cr0). The EPPI interleaves the data to form a 4:2:2 YCrCb data stream to transmit. (The EPPI does not decimate the chroma data when formatting it into 4:2:2.)
- The `EPPI_CTL.DMACFG` bit is also valid only if `EPPI_CTL.SPLTEO` =1. If `EPPI_CTL.DMACFG` =1, the EPPI uses two DMA channels and if `EPPI_CTL.DMACFG` =0, the EPPI uses only one DMA channel.

Clock Gating

In ITU-R BT.656 and GP 0/1/2 FS modes, `EPPI_FS3` becomes a clock-gating input. This functionality is valid for both internally and externally sourced `EPPI_CLK`, in both receive and transmit modes. This clock gating signal must be synchronous with `EPPI_CLK`. The external device on the rising edge of `EPPI_CLK` must drive the clock gating signal. Its function is to hold the sync and data lines in their current state until `EPPI_FS3` is driven low. There are no additional latency cycles upon coming out of clock gating mode.

If clock gating is not required, the `EPPI_FS3` pin must either be tied to ground, or configured to operate as another of its multiplexed functions.

In GP 2 FS transmit mode with internally generated frame syncs, the `EPPI_FS3` pin functions as a data enable signal.

Support for Delayed Start of EPPI Frame Syncs

The EPPI supports a delayed start of the `EPPI_FS1` and `EPPI_FS2` frame syncs. The `EPPI_FS1_DLY` and `EPPI_FS2_DLY` registers are programmable registers corresponding to `EPPI_FS1` (HSYNC) and `EPPI_FS2` (VSYNC).

The delay programmed in these registers applies to the first active edge of the internally generated frame sync. The delay starts from the first `EPPI_CLK` edge. The delay counter runs only for the first time and then shuts off until the EPPI is reenabled. (The delay counter is the period counter itself, since they do not run together.) Program the delay registers prior to the first `EPPI_CLK` edge (similar to the width and period registers). The ***EPPI Delayed Frame Sync Generation*** figure shows the functioning of `EPPI_FS1` and `EPPI_FS2`.

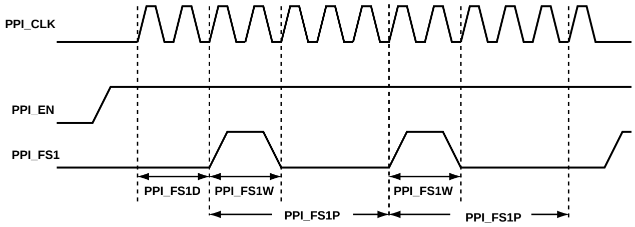

Figure 18-13: EPPI Delayed Frame Sync Generation

Ignoring Premature External Frame Syncs for Data Consistency

Once a frame has started with a VSYNC followed by an HSYNC (or both coming together), a line is tracked. When the count expires, the state machine waits at the end of line for an HSYNC to come. With the arrival of the HSYNC, the state machine starts tracking the next line, and so on.

The number of lines tracked is counted separately. Once the end of a frame is reached, the state machine waits there for the next VSYNC/HSYNC combination. The next frame starts once they are sampled. Unfortunately, every incoming FS (VSYNC or HSYNC) resets the respective counters and the tracking starts all over (even if the FS signals are premature). The result is incomplete data (or frames) to enter into memory through the PxP interface.

To correct this problem, the EPPI waits for a frame or line completion before considering any incoming FS as valid.

- Single FS mode and line tracking in dual FS mode – When a line is in progress, when HSYNC is detected prematurely, it is ignored. A line track underflow event is generated.
- Dual FS mode – If a VSYNC is received when a frame is in progress, it is ignored. A frame track underflow error (`EPPI_STAT.FTERRUNDR`) is generated.

Ignoring the FS ensures that once a frame starts, the amount of data that goes into the memory/PxP interface corresponds exactly to the programmed data size in a frame.

NOTE: Even if the premature FS is a valid FS, the state machine loses at most one frame and it recovers in the subsequent FS. The FS to number of data going into the memory relationship is always maintained as programmed.

When data underflow errors occur at the DMA interface, the EPPI does the following.

- If a premature line sync is detected, an LT underflow error is generated (`EPPI_STAT.LTERRUNDR` =1). All further line track errors are ignored until the EPPI detects the next valid line sync.
- If a premature frame sync is detected, an FT underflow error is generated (`EPPI_STAT.FTERRUNDR` =1). All further frame track and line track errors are ignored until the EPPI detects the next valid frame sync.

EPPI Event Control

The following sections describe how EPPI manages events.

EPPI Status, Error, and Interrupt Signals

The EPPI generates error interrupts (flagged in the `EPPI_STAT` register) when any one of the following error conditions occur.

- `EPPI_STAT.YFIFOERR` (YFIFO underflow or overflow)
- `EPPI_STAT.CFIFOERR` (CFIFO underflow or overflow)
- `EPPI_STAT.LTERROVR` (line track overflow error)
- `EPPI_STAT.LTERRUNDR` (line track underflow error)
- `EPPI_STAT.FTERROVR` (frame track overflow error)
- `EPPI_STAT.FTERRUNDR` (frame track underflow error)
- `EPPI_STAT.ERRNCOR` (ITU preamble error not corrected)

A W1C (write-1-to-clear) operation clears the error conditions. Each of the individual conditions which cause an EPPI error interrupt can be masked. The interrupt mask register (`EPPI_IMSK`) allows the masking of individual conditions which cause error interrupts.

There is only one interrupt line from each EPPI so all interrupts are internally OR'ed and sent as a single interrupt to the core. The `EPPI_STAT` register must then be read to discover specific errors. The following sections describe these errors in detail.

Frame and Line Track Errors

In external frame sync mode, the EPPI uses line track error (`EPPI_STAT.LTERROVR` and `EPPI_STAT.LTERRUNDR`) and frame track error (`EPPI_STAT.FTERROVR` and `EPPI_STAT.FTERRUNDR`) status bits to monitor the line and frame synchronization errors. The EPPI updates the bits when there is a mismatch detected in the HSYNC and VSYNC as compared to the programmed values in `EPPI_LINE` and `EPPI_FRAME` count registers.

Line Track Errors

The line track overflow (`EPPI_STAT.LTERROVR`) and underflow errors (`EPPI_STAT.LTERRUNDR`) generate a maskable interrupt as soon as the EPPI identifies them and not at the next frame sync.

- If the frame sync has not arrived when the `EPPI_LINE` counter expires, then the `EPPI_STAT.LTERROVR` error is generated.
- When the `EPPI_LINE` counter is running and a frame sync is detected, the `EPPI_STAT.LTERRUNDR` error is generated. A W1C operation clears boths interrupts.

Frame Track Errors

The frame track overflow (`EPPI_STAT.FTERROVR`) and underflow errors (`EPPI_STAT.FTERRUNDR`) generate a maskable interrupt as soon as the EPPI identifies them. When the `EPPI_FRAME.VALUE` counter expires, the `EPPI_STAT.FTERROVR` error is reported before the next frame sync arrives.

When the `EPPI_FRAME` counter is running and a frame sync is detected, then an `EPPI_STAT.FTERRUNDR` is reported.

Both errors generate an error interrupt. Perform a W1C operation to clear the interrupts at their respective locations in the status register.

A premature frame sync results in a frame track under run error. But, the error is logged (register bit set) only after the subsequent blanking period (if any) elapses.

Preamble Error Not Corrected Error

The EPPI supports data embedded frame syncs in ITU and SMPTE formats. In these formats, the module can receive an erroneous preamble which is not correctable. The `EPPI_STAT.ERRNCOR` error signals when this event occurs.

EPPI Programming Model

The following sections describe programming techniques, including receiving or transmitting ITU-R 656 frames; configuring transfers in GP0, GP1, GP2, and GP3 modes; and managing EPPI mode configurations.

Receiving ITU-R 656 Frames

The EPPI supports the reception of ITU-R 656 compliant frames.

1. Configure the EPPI to receive either full ITU-R 656 frame, active video, or blanking information by configuring the `EPPI_CTL.XFRTYPE` bits.
2. In both active video mode and in VBI (vertical blanking information) mode, specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` register. Specify the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` register.
3. Configure DMA descriptors to move the data to memory.
4. Enable DMA.
5. Enable the EPPI.
6. To program the EPPI in internal clock mode, follow the procedure above with the `EPPI_CTL.ICLKGEN` bit =0. After enabling the EPPI, add a delay of 200 SCLK1_0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the `EPPI_CTL.ICLKGEN` bit =1.

Depending on the EPPI configuration, either the full ITU-R 656 frame is moved to memory or only the active video or only the blanking information.

Transmitting ITU-R 656 Frames in GP Transmit Modes

The EPPI can take active video from memory and generate the proper preambles and blanking information to produce valid ITU-R 656 video frames for transmission.

1. Provide active data frame in memory.
2. Set the `EPPI_CTL.BLANKGEN` bit so the EPPI generates blanking information.
3. Configure the `EPPI_FS1_WLHB`, `EPPI_FS1_PASPL`, `EPPI_FS2_WLVB`, `EPPI_FS2_PALPF` registers accordingly.
4. Configure the rest of the EPPI settings.
5. Configure DMA to fetch active frame data from memory buffers.
6. Enable DMA.
7. Enable the EPPI.
8. To program the EPPI in internal clock mode, follow the procedure above with the `EPPI_CTL.ICLKGEN` bit =0. After enabling the EPPI, add a delay of 200 SCLK1_0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the `EPPI_CTL.ICLKGEN` bit =1.

The EPPI takes the active data from memory, generates the blanking information, and transmits an ITU-R 656 frame

Configuring Transfers in GP 0 FS Mode

The EPPI can be configured to not use periodic frame syncs to frame the data.

1. Configure the EPPI to operate in GP 0 FS mode by setting `EPPI_CTL.XFRTYPE` = b#11 and `EPPI_CTL.FSCFG` = b#00.
2. When receiving, configure the EPPI to trigger on internally or externally by setting the `EPPI_CTL.FLDSEL` field appropriately. When transmitting, the EPPI always generates a trigger internally.
3. Configure DMA to move the data to or from memory.
4. Enable DMA.
5. Enable EPPI.
6. To program the EPPI in internal clock mode, follow the procedure above with the `EPPI_CTL.ICLKGEN` bit =0. After enabling the EPPI, add a delay of 200 SCLK1_0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the `EPPI_CTL.ICLKGEN` bit =1.

The DMA descriptions control the amount of data transferred. The frame syncs from the EPPI do not control the amount.

Configuring Transfers in GP 1 FS Mode

The GP 1 FS mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs), and other general-purpose devices. This mode works for both transmit and receive.

NOTE: The `EPPI_FRAME`, `EPPI_VDLY`, and `EPPI_VCNT` registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not possible in this mode.

1. Configure GP 1 FS mode by setting the `EPPI_CTL.XFRTYPE` bit =b#11 and the `EPPI_CTL.FSCFG` bit =b#01. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Program the `EPPI_LINE` register to contain the number clock cycles expected between two assertions of the `EPPI_FS1` signal to monitor the line track errors. Program the `EPPI_LINE` register before the `EPPI_HCNT` register.
3. Program the `EPPI_HDLY` register to contain the number of clock cycles to wait after the assertion of `EPPI_FS1`. For example, the start of frame.
4. Program the `EPPI_HCNT` register to contain the number of data samples to receive or transmit for each frame.
5. Configure DMA to move the data to or from memory.
6. Enable DMA.
7. Enable the EPPI.
8. To program the EPPI in internal clock mode, follow the procedure above with the `EPPI_CTL.ICLKGEN` bit =0. After enabling the EPPI, add a delay of 200 SCLK1_0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then, switch to internal clock mode by setting the `EPPI_CTL.ICLKGEN` bit =1.

Data moves in or out of memory. A frame sync frames the data for every line.

Configuring Transfers in GP 2 FS Mode

GP 2 FS mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC connects to the `EPPI_FS1` signal and VSYNC connects to the `EPPI_FS2` signal.

1. Configure the EPPI to operate in GP 0 FS mode by setting the `EPPI_CTL.XFRTYPE` bit =b#11 and the `EPPI_CTL.FSCFG` bit =b#10. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Program the `EPPI_FRAME` register to contain the number of expected lines per frame. The value can be equal to the number of `EPPI_FS1` signal assertions expected between the start of each frame sync. The EPPI uses the value to monitor frame track errors. Program the `EPPI_FRAME` register before the `EPPI_VCNT` register.
3. Program the `EPPI_LINE` register to contain the number of clock cycles expected between two assertions of the `EPPI_FS1` signal to monitor line track errors. Program the `EPPI_LINE` register before the `EPPI_HCNT` register.
4. Program the `EPPI_HDLY` register to configure the number of clock cycles to wait after the assertion of the `EPPI_FS1` signal. (For example, the start of the line).
5. Program the `EPPI_HCNT` register to contain the number of data samples to receive or transmit for each line.

6. Program the `EPPI_VDLY` register to contain the number of lines to wait after the start of frame is detected.
7. Program the `EPPI_VCNT` register to contain the number of lines to receive or transmit.
8. If setting up the EPPI for transmit, the data enable (DEN) pin behaves according to the enabling of the blanking generation and the data length setting (DLEN). See Data Enable in General-Purpose 2 Frame Sync Transmit Mode for more details.
9. Enable DMA.
10. Enable the EPPI.
11. To program the EPPI in internal clock mode, follow the procedure above with the `EPPI_CTL.ICLKGEN` bit =0. After enabling the EPPI, add a delay of 200 SCLK1_0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the `EPPI_CTL.ICLKGEN` bit =1.

Data moves in or out of memory. A frame sync frames the data for every line and frame.

Configuring Transfers in GP 3 FS Mode

GP 3 FS mode is useful for video applications that use three synchronization signals for hardware: HSYNC, VSYNC, and FIELD. The HSYNC connects to `EPPI_FS1`, VSYNC connects to `EPPI_FS2`, and FIELD connects to `EPPI_FS3`.

1. Configure the EPPI to operate in GP 3 FS mode by setting the `EPPI_CTL.XFRTYPE` bit =b#11 and the `EPPI_CTL.FSCFG` bit =b#11. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Configure the windowing registers according to steps in GP 2 FS mode.
3. Enable DMA.
4. Enable the EPPI.
5. To program the EPPI in internal clock mode, follow the procedure above with the `EPPI_CTL.ICLKGEN` bit =0. After enabling the EPPI, add a delay of 200 SCLK1_0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the `EPPI_CTL.ICLKGEN` bit =1.

Data moves in or out of memory. A frame sync frames the data for every line and frame. Operation and result are similar to operation in GP 2 FS mode but the EPPI also uses the `EPPI_FS3` signal.

Configuring the EPPI to Use the Windowing Feature

Windowing is a useful feature for applications where the region of interest is smaller than the active video stream (for example, sensor calibration, auto-focusing, and others). It can result in significant DMA bandwidth reduction. The EPPI supports windowing for GP input modes.

1. Program the `EPPI_FRAME` register with the number of lines the frame contains.

2. Program the `EPPI_LINE` register with the number of samples per line in the frame.
3. Program the `EPPI_VDLY` register with the number of lines to wait after the start of a new frame before starting to read or transmit data.
4. Program the `EPPI_VCNT` register with the number of lines to read in or write out after `EPPI_VDLY` number of lines from the start of the frame.
5. Program the `EPPI_HDLY` register with the number of clock cycles to delay after the assertion of `EPPI_FS1` is detected for the start of a new line.
6. Program the `EPPI_HCNT` register with the number of samples to read in or write out after `EPPI_HDLY` number of cycles have expired since the assertion of `EPPI_FS1`.

EPPI Mode Configuration

This section describes EPPI mode configurations, including support for all EPPI transmit and receive modes.

Configuring 8-Bit Receive Mode

For 8-bit non-split receive mode and if `EPPI_CTL.PACKEN` =1, the EPPI packs 4 bytes of incoming data into a 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and `EPPI_CTL.SKIPEO` bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the `EPPI_CTL.SWAPEN` bit setting.

Table 18-13: 8-Bit Receive Mode with Packing Enabled

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO =X SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=1 SIGNEXT=X
0x11						
0x22						
0x33						
0x44	0x4433 2211	0x1122 3344				
0x55						
0x66						
0x77			0x7755 3311		0x1133 5577	
0x88	0x8877 6655	0x5566 7788		0x8866 4422		0x2244 6688
0x99						
0xAA						
0xBB						

Table 18-13: 8-Bit Receive Mode with Packing Enabled (Continued)

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO =X SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=1 SIGNEXT=X
0xCC	0xCCBB AA99	0x99AA BBCC

0xFF			0xFFDD BB99		0x99BB DDFF	
0x00	0x00FF EEDD	0xDDE EFF00		0x00EE CCAA		0xAACC EE00

If `EPPI_CTL.PACKEN`=0, the DMA is a 16-bit DMA and the EPPI either sign-extends or zero-fills the bytes of incoming data into a 16-bit word. The `EPPI_CTL.SWAPEN` bit has no effect if `EPPI_CTL.PACKEN`=0.

Table 18-14: 8-Bit Receive Mode with Packing Disabled

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=X SIGNEXT=0	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=X SIGNEXT=1	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=X SIGNEXT=0	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=X SIGNEXT=1

0xBB	0x00BB	0xFFBB		0xFFBB

Configuring 10/12/14-Bit Receive Modes

For 10, 12, or 14-bit non-split receive modes, the EPPI first either zero-fills or sign-extends the incoming data into a 16-bit word. The action depends on the setting of the `EPPI_CTL.SIGNEXT` bit. If `EPPI_CTL.PACKEN` =1, the EPPI then packs two of these words into one 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and `EPPI_CTL.SKIPEO` bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the `EPPI_CTL.SWAPEN` bit setting.

Configuring 16-Bit Receive Mode

For 16-bit non-split receive mode, if `EPPI_CTL.PACKEN` =1, the EPPI packs two 16-bit incoming data into one 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and

`EPPI_CTL.SKIPEO` bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the `EPPI_CTL.SWAPEN` bit setting.

Configuring 18-Bit Receive Mode

For 18-bit non-split receive mode, if `EPPI_CTL.PACKEN` =0, the EPPI zero-fills or sign-extends the incoming data into a 32-bit word. If `EPPI_CTL.PACKEN` =1, the EPPI first zero-fills or sign-extends the incoming data to 24 bits, and then packs four such 24-bit data words into three 32-bit words. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and `EPPI_CTL.SKIPEO` bits. The `EPPI_CTL.SWAPEN` bit has no effect.

Configuring 8-Bit Split Receive Mode

For 8-bit split receive mode, the `EPPI_CTL.PACKEN` and `EPPI_CTL.SIGNEXT` bits are not valid. The EPPI always packs 4 bytes of data into one 32-bit word.

Table 18-23: 8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 0

When the bits settings are `EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SUBSPLTODD` =1 and `EPPI_CTL.DMACFG` =0, the EPPI packs the second Chroma component sent over the DMA bus completely before the Luma component. However, it is intentionally held until that previous word is moved out. This functionality allows the separation of Luma and Chroma values into individual buffers when using 2D-DMA. The second Chroma component is U0U1U2U3 in the ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 0*** and ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 1*** tables. The Luma component is Y4Y5Y6Y7 in the ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 1*** table.

Configuring 10/12/14/16-Bit Split Receive Mode with SPLTWRD=0

For 16-bit split receive mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always packs two 16-bit words into one 32-bit word. For 10, 12, or 14-bit split receive modes, the EPPI first either sign-extends or zero-fills the incoming data into a 16-bit word. The EPPI then packs two of these words into one 32-bit word to send to the DMA.

Table 18-25: 16-bit Split Receive Mode with SPLTWRD = 0, SKIPEN = 0 and SWAPEN = 0

Configuring 16-Bit Split Receive Mode with SPLTWRD=1

For 16-bit split receive mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always packs two 16-bit words into one 32-bit word. The `EPPI_CTL.SPLTWRD` bit is only valid when the `EPPI_CTL.DLEN` bit =16 bits.

Table 18-27: 16-bit Split Receive Mode with SPLTWRD = 1, SKIPEN = 0 and SWAPEN = 0

Pin Data (16 bits)	SPLTEO=1 SUBSPLTODD=0 SWAPEN=0 SKIPEN=0 SKIPEO=X			SPLT_EVEN_ODD=1 SUBSPLTODD=1 SWAPEN=0 SKIPEN=0 SKIPEO=X

Configuring 8-Bit Transmit Mode

For 8-bit non-split transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory into 4 bytes to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If `EPPI_CTL.PACKEN` =0, the DMA is a 16-bit DMA and the EPPI transmits the lower 8 bits. The `EPPI_CTL.SWAPEN` bit has no effect when `EPPI_CTL.PACKEN` =0.

Table 18-28: 8-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x11223344	0x44	0x11
0x55667788	0x33	0x22
	0x22	0x33
	0x11	0x44
	0x88	0x55
	0x77	0x66
	0x66	0x77

Table 18-28: 8-bit Transmit Mode with Packing Enabled (Continued)

	0x55	0x88

Table 18-29: Data Sent in 8-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x34
0x2345	0x45
0x3456	0x56

Configuring 10/12/14-Bit Transmit Modes

For 10, 12, or 14-bit non-split transmit modes, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA. The EPPI unpacks the 32-bit word from memory into two 16-bit data words. The EPPI then transmits the required LSBs from each data word. The EPPI transmits either the most significant word or the least significant word as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If `EPPI_CTL.PACKEN` =0, the DMA is a 16-bit DMA and the EPPI transmits the required LSBs. The `EPPI_CTL.SWAPEN` bit has no effect when the `EPPI_CTL.PACKEN` bit =0.

Table 18-30: 10-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x1111 2222	0x222	0x111
0x3333 4444	0x111	0x222
	0x044	0x333
	0x333	0x044

0x1234	0x234
0x2345	0x345
0x3456	0x056
0x4567	0x167

Configuring 16-Bit Transmit Mode

For 16-bit non-split transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA. The EPPI unpacks the 32-bit word from memory into two 16-bit data words to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If the `EPPI_CTL.PACKEN` bit =0, the DMA is a 16-bit DMA and the EPPI transmits the data as is. The `EPPI_CTL.SWAPEN` has no effect when `EPPI_CTL.PACKEN` bit =0.

Table 18-32: 16-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x1111 2222	0x2222	0x1111
0x3333 4444	0x1111	0x2222
	0x4444	0x3333
	0x3333	0x4444

Table 18-33: 16-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x1234
0x2345	0x2345
0x3456	0x3456

Configuring 18-Bit Transmit Mode

For 18-bit transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory. In this mode, when `EPPI_CTL.RGBFMTEN` is set, the least significant 2 bits of R, G, and B are dropped.

Table 18-34: 18-bit Transmit Mode with Packing Enabled

DMA Data	Pin Data (18-bits)	
	RGBFMTEN=0	RGBFMTEN=1
0x0123 4567	0x3 4567	0x0 8459
0x89AB CDEF	0x1 EF01	0x3 3EC0
0x0123 4567	0x3 89AB	0x1 98AA
	0x1 2345	0x0 0211

Table 18-35: 18-bit Transmit Mode with Packing Disabled

Configuring 10/12/14/16-Bit Transmit Mode with SPLTWRD=0

For 16-bit split transmit mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always unpacks the 32-bit DMA data into two 16-bit words to transmit. For 10, 12, or 14-bit split transmit modes, the EPPI first unpacks the data in the same way as for 16-bit transmit mode. But, the EPPI transmits only the required number of LSBs.

Table 18-40: 16-bit Split Transmit Mode with SPLTEO = 1, SUBSPLTODD = 0, and SWAPEN = 0

EPPI Programming Concepts

This section provides information on SMPTE programming.

SMPTE Modes Programming

The programming model of SMPTE modes is similar to ITU Modes. All programming modes pertaining to ITU modes like XFRTYPE, FSCFG, FLDSEL, and BLANKGEN hold true for SMPTE modes as well. The only difference is that since ITU modes use Y-Cr/Cb interleaved data and SMPTE use parallel Y-Cr/Cb data, SPLTWRD could be set while operating in SMPTE modes. The ***Programming Modes for SMPTE Formats*** table describes the programming modes for different SMPTE formats.

Table 18-46: Programming Modes for SMPTE Formats

SMPTE Format	SMPTE Channel Width	EPPI Input Bit Width	EPPI Mode	Remarks
296M	8	16 Cr/Cb - [15:8] Y - [7:0]	DLEN = 16 bits SPLTWRD = 1	SIGNEXT not supported
	8	16 Cr/Cb - [15:8] Y - [7:0]	DLEN = 16 bits SPLTWRD = 1	SIGNEXT not supported

ADSP-SC58x EPPI Register Descriptions

Enhanced Parallel Peripheral Interface (EPPI) contains the following registers.

Table 18-47: ADSP-SC58x EPPI Register List

Name	Description
`EPPI_CLKDIV`	Clock Divide Register
`EPPI_CTL`	Control Register
`EPPI_CTL2`	Control Register 2 Register
`EPPI_EVENCLIP`	Clipping Register for EVEN (Luma) Data Register
`EPPI_FRAME`	Lines Per Frame Register
`EPPI_FS1_DLY`	Frame Sync 1 Delay Value Register
`EPPI_FS1_PASPL`	FS1 Period Register / EPPI Active Samples Per Line Register
`EPPI_FS1_WLHB`	FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register
`EPPI_FS2_DLY`	Frame Sync 2 Delay Value Register
`EPPI_FS2_PALPF`	FS2 Period Register / EPPI Active Lines Per Field Register
`EPPI_FS2_WLVB`	FS2 Width Register / EPPI Lines Of Vertical Blanking Register
`EPPI_HCNT`	Horizontal Transfer Count Register
`EPPI_HDLY`	Horizontal Delay Count Register
`EPPI_IMSK`	Interrupt Mask Register
`EPPI_LINE`	Samples Per Line Register
`EPPI_ODDCLIP`	Clipping Register for ODD (Chroma) Data Register
`EPPI_STAT`	Status Register
`EPPI_VCNT`	Vertical Transfer Count Register
`EPPI_VDLY`	Vertical Delay Count Register

Clock Divide Register

The `EPPI_CLKDIV` register provides the divisor for EPPI internal clock generation. The generated clock frequency is given by following formula:

`EPPI_CLK` = (SCLK1_0) / (`EPPI_CLKDIV` + 1)

Note that a value of 0xFFFF is invalid for the `EPPI_CLKDIV` register.

Figure 18-15: EPPI_CTL Register Diagram

Table 18-49: EPPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKGATEN	Clock Gating Enable. The `EPPI_CTL.CLKGATEN` bit enables using the `EPPI_FS3` pin as a clock gating pin. When `EPPI_CTL.CLKGATEN` is set, the `EPPI_FS3` pin acts as a clock gating signal, and both the internal and external clock are gated. Note that the `EPPI_FS3` pin gating signal is active low, and the `EPPI_CTL.CLKGATEN` selection is ignored if `EPPI_CTL.MUXSEL` is set or `EPPI_CTL.FSCFG` equals 0x3.	
		0	Disable
		1	Enable
30 (R/W)	MUXSEL	MUX Select. The `EPPI_CTL.MUXSEL` bit enables multiplexing of a primary and alternate camera using the EPPI main data and clock lines. For more information on this feature, see the EPPI functional description.	
		0	Normal Operation
		1	Multiplexed Operation
29 (R/W)	DMAFINEN	DMA Finish Enable. The `EPPI_CTL.DMAFINEN` bit selects whether or not the EPPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.	
		0	No Finish Command
		1	Enable Send Finish Command
28 (R/W)	DMACFG	One or Two DMA Channels Mode. The `EPPI_CTL.DMACFG` bit is valid only if `EPPI_CTL.SPLTEO` is set. If `EPPI_CTL.DMACFG` is set, the EPPI uses two DMA channels. And, if `EPPI_CTL.DMACFG` is cleared, the EPPI uses only one DMA channel.	
		0	PPI Uses One DMA Channel
		1	PPI Uses Two DMA Channels
27 (R/W)	RGBFMTEN	RGB Formatting Enable. For 16- or 18-bit transmit modes only, the `EPPI_CTL.RGBFMTEN` bit enables conversion of RGB888 from memory into RGB666 output data (18-bit transmit) or enables conversion of RGB888 from memory into RGB565 output data (16-bit transmit). Note that `EPPI_CTL.SPLTEO` and `EPPI_CTL.RGBFMTEN` should never be set simultaneously.	
		0	Disable RGB Formatted Output
		1	Enable RGB Formatted Output

Table 18-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	

26
(R/W)
	SPLTWRD	Split Word.
		The `EPPI_CTL.SPLTWRD` bit selects split word data placement when the data length (`EPPI_CTL.DLEN`) selects 16-, 20-, or 24-bit data words. For all other `EPPI_CTL.SPLTWRD` values, the set or clear selections for `EPPI_CTL.SPLTWRD` produce the same result (act as though `EPPI_CTL.SPLTWRD` is cleared). For `EPPI_CTL.SPLTWRD` set, the `EPPI_CTL.DLEN` values below result in the following combinations of split words:
		`DLEN     Cr/Cb data       Y data`
		` 16   PPI_DATA[15:8]   PPI_DATA[7:0]`
		` 20   PPI_DATA[19:10]  PPI_DATA[9:0]`
		` 24   PPI_DATA[23:12]  PPI_DATA[11:0]`	

		0	PPI_DATA has (DLEN-1) bits of Y or Cr or Cb
		1	PPI_DATA Contains 2 Elements per Word
25 (R/W)	SUBSPLTODD	Sub-Split Odd Samples. The `EPPI_CTL.SUBSPLTODD` bit is valid only if `EPPI_CTL.SPLTEO` is set. If `EPPI_CTL.SUBSPLTODD` is set, the EPPI sub-splits the odd sub-stream, and packs them separately.	
		0	Disable
		1	Enable
24 (R/W)	SPLTEO	Split Even and Odd Data Samples. If `EPPI_CTL.SPLTEO` is set, the EPPI splits the incoming data stream into two sub-streams, an even stream and an odd stream, and packs them separately.	
		0	Do Not Split Samples
		1	Split Even/Odd Samples
23 (R/W)	SWAPEN	Swap Enable. The `EPPI_CTL.SWAPEN` selects whether or not to swap the order of the first data (most-significant bits versus least-significant bits) of the DMA word. For receive modes, the EPPI puts the first data in the most significant bits (if set) or puts the first data in the least significant bits (if cleared) of the DMA word. For transmit modes, the EPPI transmits the most significant bits in the DMA word as the first data (if set) or transmits the least significant bits in the DMA word as the first data (if cleared).	
		0	Disable
		1	Enable

Table 18-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	PACKEN	Pack/Unpack Enable. The `EPPI_CTL.PACKEN` select whether or not packing is enabled (for receive modes) and unpacking is enabled (for transmit modes). When this bit is set, EPPI transfer DMA is 32-bits wide. When this bit is cleared and the `EPPI_CTL.DLEN` is less than or equal to 16 bits, EPPI transfer DMA is 16-bits wide. For receive modes, if this bit is set, then the EPPI packs the incoming data into 32-bit words. If this bit is cleared, then the EPPI does not do any packing. For transmit modes, if this bit is set, then the EPPI always unpacks the 32-bit data from DMA. If this bit is not set, the EPPI does not do any unpacking.	
		0	Disable
		1	Enable
21 (R/W)	SKIPEO	Skip Even or Odd. The `EPPI_CTL.SKIPEO` bit selects whether even (if set) or odd (if cleared) samples are skipped if sample skipping is enabled (`EPPI_CTL.SKIPEN` is set). This feature only is useful for receive modes.	
		0	Skip Odd Samples
		1	Skip Even Samples
20 (R/W)	SKIPEN	Skip Enable. The `EPPI_CTL.SKIPEN` bit enables skipping alternate samples. This feature only is useful for receive modes.	
		0	No Samples Skipping
		1	Skip Alternate Samples
19 (R/W)	DMIRR	Data Mirroring. The `EPPI_CTL.DMIRR` field enables mirroring (bit reversing) of the data coming in or going out on the EPPI data pins.	

```
Pin      PPI Data      PPI Data
Data   (DAT_MRR=0)   (DAT_MRR=1)
------------------------------
 15        15            0
 14        14            1
....      ....          ....
  1         1           14
  0         0           15
```

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	No Data Mirroring
		1	Data Mirroring
18:16 (R/W)	DLEN	Data Length. The `EPPI_CTL.DLEN` bits select the data length for the EPPI. Note that the 20 bits data length selection is valid only for SMPTE modes (`EPPI_CTL.SPLTWRD` set).	

Table 18-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	8 bits
		1	10 bits
		2	12 bits
		3	14 bits
		4	16 bits
		5	18 bits
		6	20 bits
		7	24 bits
15:14 (R/W)	POLS	Frame Sync Polarity. The `EPPI_CTL.POLS` selects whether the frame syncs' polarity is active low versus active high.	
		0	FS1 and FS2 are active high
		1	FS1 is active low. FS2 is active high
		2	FS1 is active high. FS2 is active low
		3	FS1 and FS2 are active low
13:12 (R/W)	POLC	Clock Polarity. The `EPPI_CTL.POLC` selects the rising versus falling edge for sampling data and sampling/driving syncs.	
		0	Clock/Sync Polarity Mode 0. For receive mode: Sample data on falling edge and sample/drive syncs on falling edge. For transmit mode: Drive data on rising edge and sample/drive syncs on rising edge.
		1	Clock/Sync Polarity Mode 1. For receive mode: Sample data on falling edge and sample/drive syncs on rising edge. For transmit mode: Drive data on rising edge and sample/drive syncs on falling edge.
		2	Clock/Sync Polarity Mode 2. For receive mode: Sample data on rising edge and sample/drive syncs on falling edge. For transmit mode: Drive data on falling edge and sample/drive syncs on rising edge.
		3	Clock/Sync Polarity Mode 3. For receive mode: Sample data on rising edge and sample/drive syncs on rising edge. For transmit mode: Drive data on falling edge and sample/drive syncs on falling edge.

Table 18-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	SIGNEXT	Sign Extension. The `EPPI_CTL.SIGNEXT` select whether (for receive modes when `EPPI_CTL.DLEN` selecting 16 bit data length) the data is sign extended or zero filled. Not that `EPPI_CTL.SPLTWRD` is removed from this shared bit.	
		0	Zero Filled
		1	Sign Extended
10 (R/W)	IFSGEN	Internal Frame Sync Generation. The `EPPI_CTL.IFSGEN` bit selects whether the frame syncs are generated internally or are supplied by an external device.	
		0	External Frame Sync
		1	Internal Frame Sync
9 (R/W)	ICLKGEN	Internal Clock Generation. The `EPPI_CTL.ICLKGEN` bit selects whether the `EPPI_CLK` is generated internally or is supplied by an external device.	
		0	External Clock
		1	Internal Clock
8 (R/W)	BLANKGEN	king Generation (ITU Output Mode). The `EPPI_CTL.BLANKGEN` enables ITU output with internal blanking. In GP 8, 10 transmit bit modes (when `EPPI_CTL.SPLTWRD` is cleared) and 16-, 20-, and 24-bit transmit modes (when `EPPI_CTL.SPLTWRD` is set), `EPPI_CTL.BLANKGEN` selects whether or not the EPPI generates blanking and generates preamble and insertion with active data from memory.	
		0	Disable
		1	Enable
7 (R/W)	ITUTYPE	ITU Interlace or Progressive. The `EPPI_CTL.ITUTYPE` selects interlaced or progressive operation for ITU656 mode. This selection is valid for both TX and RX modes.	
		0	Interlaced
		1	Progressive

Table 18-49: EPPI_CTL Register Fields (Continued)

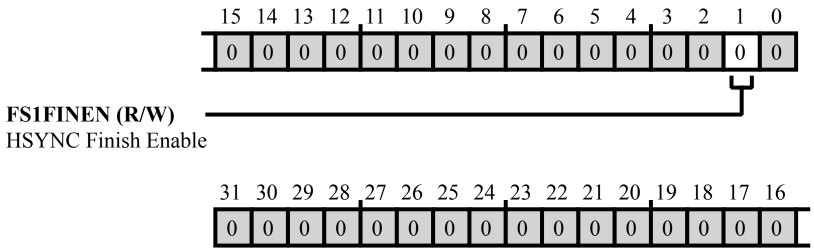
Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	FLDSEL	Field Select/Trigger. The `EPPI_CTL.FLDSEL` bits configure the EPPI field and trigger selection. These are valid for GP modes (`EPPI_CTL.XFRTYPE` =0x3) and ITU656 active video mode (`EPPI_CTL.XFRTYPE` cleared).	
		0	Field Mode 0. Read field 1 (for ITU656 active video mode). Set internal trigger (for GP RX mode). FS3 is toggled on FS2 assertion followed by FS1 assertion (when the `EPPI_CTL.FSCFG` bit selects sync mode 3 and the `EPPI_CTL.IFSGEN` bit selects internal frame sync).
		1	Field Mode 1 Read field 1 and field 2 (ITU656 active video mode). Set external trigger (GP RX mode). FS3 is toggled on FS2 assertion (when the `EPPI_CTL.FSCFG` bit selects sync mode 3 and the `EPPI_CTL.IFSGEN` bit selects internal frame sync).
5:4 (R/W)	FSCFG	Frame Sync Configuration. The `EPPI_CTL.FSCFG` bits configure the EPPI frame syncs. These are valid only for GP modes (`EPPI_CTL.XFRTYPE` =0x3). The output of the frames syncs also depends on whether the EPPI transfer direction is transmit and the EPPI is in ITU output mode (`EPPI_CTL.BLANKGEN` is set).	
		0	Sync Mode 0. FS0 driven in GP mode. FS0 not driven in ITU output mode.
		1	Sync Mode 1. FS1 driven in GP mode. HSYNC driven on FS1 in ITU output mode.
		2	Sync Mode 2. FS2 driven in GP mode. HSYNC driven on FS1 and VSYNC driven on FS1 in ITU output mode.
		3	Sync Mode 3. FS3 driven in GP mode. HSYNC driven on FS1, VSYNC driven on FS2, and FIELD driven on FS3 in ITU output mode.

Table 18-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/W)	XFRTYPE	Transfer Type (Operating Mode). The `EPPI_CTL.XFRTYPE` bits select the EPPI operating mode. In receive mode (`EPPI_CTL.DIR` cleared), the EPPI modes include ITU656 active video only mode, ITU656 entire field mode, ITU656 vertical blanking only mode, and non-ITU656 mode (GP mode). For transmit mode (`EPPI_CTL.DIR` set), the `EPPI_CTL.XFRTYPE` bits have no effect, and the EPPI (in transmit mode) is always in GP mode.	
		0	ITU656 Active Video Only Mode
		1	ITU656 Entire Field Mode
		2	ITU656 Vertical Blanking Only Mode
		3	Non-ITU656 Mode (GP Mode)
1 (R/W)	DIR	PPI Direction. The `EPPI_CTL.DIR` bit selects whether the EPPI is in receive mode (if cleared) or in transmit mode (if set).	
		0	Receive Mode
		1	Transmit Mode
0 (R/W)	EN	PPI Enable. The `EPPI_CTL.EN` bit enables or disables the EPPI.	
		0	Disable
		1	Enable

Control Register 2 Register

The `EPPI_CTL2` register controls HSYNC finish signal generation.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

HSYNC Finish Enable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 18-16: EPPI_CTL2 Register Diagram

Table 18-50: EPPI_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FS1FINEN	HSYNC Finish Enable. The `EPPI_CTL2.FS1FINEN` bit selects whether (if set) the EPPI sends a finish command (010) through the DDE COMMAND line soon after a LINE is received completely or (if cleared) the EPPI sends a finish command (010) through the DDE COMMAND line soon after a FRAME is received completely. Note that the `EPPI_CTL.DMAFINEN` bit must be set for the EPPI to generate either of the finish commands.	
		0	Finish sent after frame RX done. PPI sends a finish command (010) through the DDE COMMAND line soon after a FRAME is received completely
		1	Finish sent after frame/line RX done. PPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.

Clipping Register for EVEN (Luma) Data Register

The `EPPI_EVENCLIP` register selects the clipping threshold for luma data, which provides clipping of individual video components.

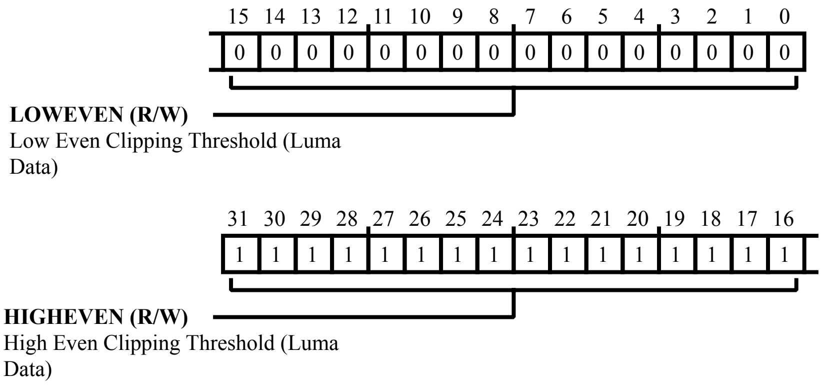
The high even and low even spaces in `EPPI_EVENCLIP` are 16-bits wide and (depending on the `EPPI_CTL.DLEN` bit selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits [25:16] constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with the `EPPI_CTL.SPLTWRD` bit set, the luma data gets the clipping threshold levels of the `EPPI_EVENCLIP` register, and the chroma data gets the clipping threshold levels of the `EPPI_ODDCLIP` register.

Also, note that the `EPPI_EVENCLIP` and `EPPI_ODDCLIP` registers are ignored when the `EPPI_CTL.RGBFMTEN` bit is set.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

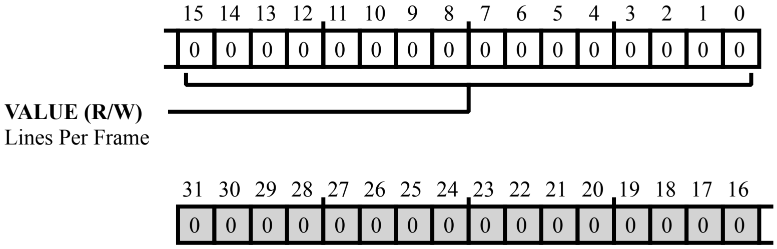
Table 18-51: EPPI_EVENCLIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	HIGHEVEN	High Even Clipping Threshold (Luma Data). The `EPPI_EVENCLIP.HIGHEVEN` bit field selects the clipping threshold for luma data. The high even spaces are 16-bits wide and (depending on the `EPPI_CTL.DLEN` selection) only the corresponding video component bits are considered for clipping.
15:0 (R/W)	LOWEVEN	Low Even Clipping Threshold (Luma Data). The `EPPI_EVENCLIP.LOWEVEN` bit field selects the clipping threshold for luma data. The low even spaces are 16-bits wide and (depending on the `EPPI_CTL.DLEN` selection) only the corresponding video component bits are considered for clipping.

Lines Per Frame Register

The `EPPI_FRAME` register tracks the frame track overflow and underflow errors. This register should be programmed with the number of lines expected per frame. Any write to the `EPPI_FRAME` register will also write the same value to the `EPPI_VCNT` register. But, any write to the `EPPI_VCNT` register does not affect the `EPPI_FRAME` register value. So the `EPPI_FRAME` register should be programmed before the `EPPI_VCNT` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 18-18: EPPI_FRAME Register Diagram

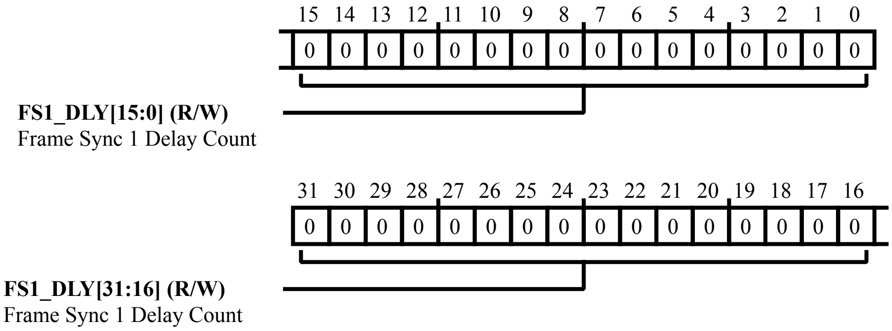
Table 18-52: EPPI_FRAME Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Lines Per Frame. The `EPPI_FRAME.VALUE` holds the number of lines expected per frame of data.

Frame Sync 1 Delay Value Register

The `EPPI_FS1_DLY` register selects the delay count (based on the period of the `EPPI_CLK` clock) between the first rising edge of `EPPI_CLK` after the EPPI is enabled and the first active edge of the associated frame sync when the internal frame sync is used.

Note that if the `EPPI_FS1_DLY` or `EPPI_FS2_DLY` registers are programmed with value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Table 18-53: EPPI_FS1_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	FS1_DLY	Frame Sync 1 Delay Count. The `EPPI_FS1_DLY.FS1_DLY` bit field selects the delay count.

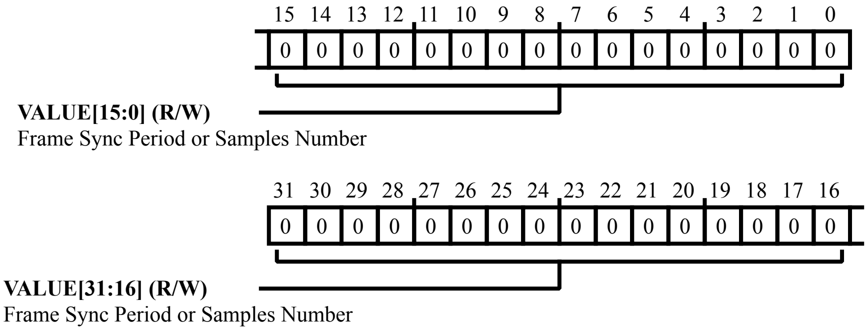
FS1 Period Register / EPPI Active Samples Per Line Register

The `EPPI_FS1_PASPL` register content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2, or 3 FS modes, the `EPPI_FS1_PASPL` register is used for the generation of frame sync 1. The register contains the period required for `EPPI_FS1` based on the `EPPI_CLK` clock.

In GP transmit mode with the `EPPI_CTL.BLANKGEN` bit set, this register contains the number of samples of active video or vertical blanking samples per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for this register is illegal. If programmed as 0, the EPPI regards the `EPPI_FS1_PASPL` register as containing 1.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Frame Sync Period or Samples Number
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Frame Sync Period or Samples Number

Figure 18-20: EPPI_FS1_PASPL Register Diagram

Table 18-54: EPPI_FS1_PASPL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Frame Sync Period or Samples Number. In GP 1, 2, or 3 FS modes, the `EPPI_FS1_PASPL.VALUE` bit field is used for the generation of frame sync 1 and contains the period required for `EPPI_FS1` based on the `EPPI_CLK` clock. In GP transmit mode with the `EPPI_CTL.BLANKGEN` bit set, this bit field contains the number of samples of active video or vertical blanking samples per line.

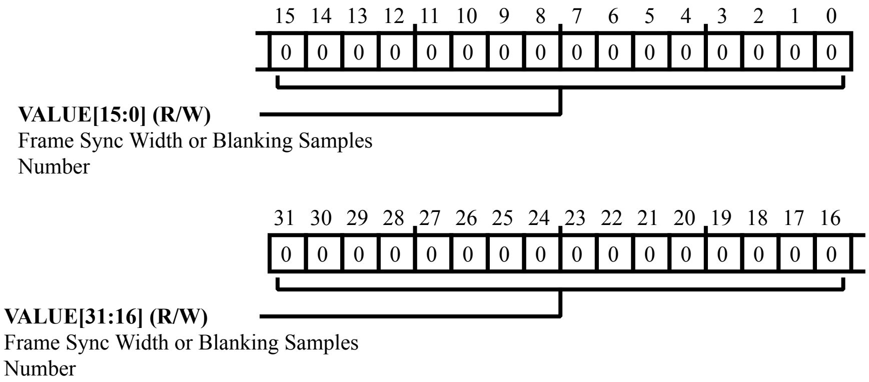
FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register

The `EPPI_FS1_WLHB` register's content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2 or 3 FS modes, `EPPI_FS1_WLHB` is used for the generation of frame sync 1. The register contains the width required for `EPPI_FS1` based on the `EPPI_CLK` clock.

In GP transmit mode with the `EPPI_CTL.BLANKGEN` bit set, this register contains the number of samples of horizontal blanking per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for the `EPPI_FS1_WLHB` register is illegal. If programmed as 0, the EPPI regards the `EPPI_FS1_WLHB` register as containing 1.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Frame Sync Width or Blanking Samples Number
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Frame Sync Width or Blanking Samples Number

Figure 18-21: EPPI_FS1_WLHB Register Diagram

Table 18-55: EPPI_FS1_WLHB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Frame Sync Width or Blanking Samples Number. The `EPPI_FS1_WLHB.VALUE` bit field content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode. In GP 1, 2 or 3 FS modes, the `EPPI_FS1_WLHB.VALUE` bit field is used for the generation of frame sync 1. The register contains the width required for `EPPI_FS1` based on the `EPPI_CLK` clock. In GP transmit mode with `EPPI_CTL.BLANKGEN` set, this bit field contains the number of samples of horizontal blanking per line.

Frame Sync 2 Delay Value Register

The `EPPI_FS2_DLY` register selects the delay count (based on the period of the `EPPI_CLK` clock) between the first rising edge of `EPPI_CLK` after EPPI enabled and the first active edge of the associated frame sync when the internal frame sync is used.

Note that if the `EPPI_FS1_DLY` or `EPPI_FS2_DLY` registers are programmed with the value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

FS2 Period Register / EPPI Active Lines Per Field Register

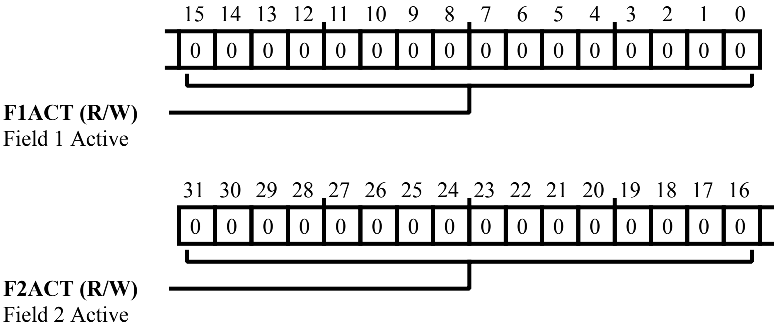
The `EPPI_FS2_PALPF` register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, `EPPI_FS2_PALPF` is used for the generation of frame sync 2. This register contains the period required for `EPPI_FS2` based on the `EPPI_CLK` clock.

In GP transmit mode with the `EPPI_CTL.BLANKGEN` bit set, this register contains the number of lines of active video per field.

Note that a value of 0 for the `EPPI_FS2_PALPF.F1ACT` or `EPPI_FS2_PALPF.F2ACT` bits is illegal. If either is programmed as 0, the EPPI regards the 0 value fields as containing 1.

Also, note that for progressive video, the `EPPI_FS2_PALPF.F2ACT` bit is ignored.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	F2ACT	Field 2 Active. The `EPPI_FS2_PALPF.F2ACT` bit field contains the number of lines of active data in field 2.
15:0 (R/W)	F1ACT	Field 1 Active. The `EPPI_FS2_PALPF.F1ACT` bit field contains the number of lines of active data in field 1.

FS2 Width Register / EPPI Lines Of Vertical Blanking Register

The `EPPI_FS2_WLVB` register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, the `EPPI_FS2_WLVB` register is used for the generation of frame sync 2. The register contains the width required for `EPPI_FS2` based on the `EPPI_CLK` clock.

In GP transmit mode with the `EPPI_CTL.BLANKGEN` bit set, this register contains the number or lines of vertical blanking.

Note that for progressive video, the `EPPI_FS2_WLVB.F2VBBD` and `EPPI_FS2_WLVB.F2VBAD` bits are ignored.

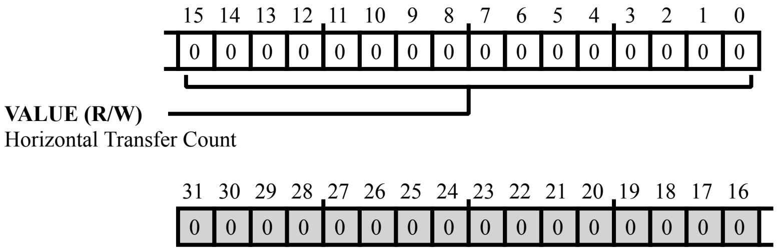
Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	F2VBAD	Field 2 Vertical Blanking After Data. The `EPPI_FS2_WLVB.F2VBAD` bit field contains the number of lines of vertical blanking after field 2.
23:16 (R/W)	F2VBBD	Field 2 Vertical Blanking Before Data. The `EPPI_FS2_WLVB.F2VBBD` bit field contains the number of lines of vertical blanking before field 2.
15:8 (R/W)	F1VBAD	Field 1 Vertical Blanking After Data. The `EPPI_FS2_WLVB.F1VBAD` bit field contains the number of lines of vertical blanking after field 1.
7:0 (R/W)	F1VBBD	Field 1 Vertical Blanking Before Data. The `EPPI_FS2_WLVB.F1VBBD` bit field contains the number of lines of vertical blanking before field 1.

Horizontal Transfer Count Register

The `EPPI_HCNT` register holds the number of samples to read in or write out per line, after `EPPI_HDLY` number of cycles have expired since the assertion of `EPPI_FS1`. Any write to the `EPPI_LINE` register modifies the `EPPI_HCNT` register. But, any write to the `EPPI_HCNT` register does not affect the `EPPI_LINE` register value. So the `EPPI_HCNT` register should be programmed after the `EPPI_LINE` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Horizontal Delay Count. The EPPI_HDLY.VALUE holds the number of EPPI_CLK cycles to delay after assertion of EPPI_FS1 before starting to read or write data.

Interrupt Mask Register

The `EPPI_IMSK` register permits the masking (if associated bit is set) of EPPI error interrupts for YFIFO underflow or overflow, CFIFO underflow or overflow, line track overflow error, line track underflow error, frame track overflow error, frame track underflow error, and ERR_NCOR (ITU preamble error not corrected. These conditions are flagged in the `EPPI_STAT` register and cleared by write-1-to-clear.

Samples Per Line Register

The `EPPI_LINE` register tracks the line track overflow and underflow errors. This register should be programmed with the number of samples expected per line. Any write to the `EPPI_LINE` register will also write the same value to the `EPPI_HCNT` register. However, any write to the `EPPI_HCNT` register does not affect the `EPPI_LINE` register value. So the `EPPI_LINE` register should be programmed before the `EPPI_HCNT` register.

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Samples Per Line. The `EPPI_LINE.VALUE` holds the number of samples expected per line.

Clipping Register for ODD (Chroma) Data Register

The `EPPI_ODDCLIP` register selects the clipping threshold for chroma data, which provides clipping of individual video components.

The high odd and low odd spaces in `EPPI_ODDCLIP` are 16-bits wide and (depending on the `EPPI_CTL.DLEN` bit selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits [25:16] constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with the `EPPI_CTL.SPLTWRD` bit set, the luma data gets the clipping threshold levels of the `EPPI_EVENCLIP` register, and the chroma data gets the clipping threshold levels of the `EPPI_ODDCLIP` register.

Also, note that the `EPPI_EVENCLIP` and `EPPI_ODDCLIP` registers are ignored when the `EPPI_CTL.RGBFMTEN` bit is set.

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	HIGHODD	High Odd Clipping Threshold (Chroma Data). The `EPPI_ODDCLIP.HIGHODD` bit field selects the clipping threshold for luma data. The high odd spaces are 16-bits wide and (depending on the `EPPI_CTL.DLEN` selection) only the corresponding video component bits are considered for clipping.
15:0 (R/W)	LOWODD	Low Odd Clipping Threshold (Chroma Data). The `EPPI_ODDCLIP.LOWODD` bit field selects the clipping threshold for luma data. The low add spaces are 16-bits wide and (depending on the `EPPI_CTL.DLEN` selection) only the corresponding video component bits are considered for clipping.

Status Register

The EPPI_STAT register contains bits that provide information about the current operating state of the EPPI.

Table 18-64: EPPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	FLD	Current Field Received by EPPI. The `EPPI_STAT.FLD` bit indicates whether the current field being received by the PPI is field 1 (if clear) or field 2 (if set).	
		0	Field 1
		1	Field 2
14 (R/W1C)	ERRDET	Preamble Error Detected. The `EPPI_STAT.ERRDET` bit is useful only in ITU receive modes and indicates if an error has been detected in the status word of EAV or SAV sequences (if set) or not (if clear).	
		0	No Preamble Error Detected
		1	Preamble Error Detected
7 (R/W1C)	PXPERR	PxP Ready Error. The `EPPI_STAT.PXPERR` bit is valid only in the RX mode. This bit indicates whether the incoming PPI data overflows the PxP interface (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	

Table 18-64: EPPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	ERRNCOR	Preamble Error Not Corrected. The `EPPI_STAT.ERRNCOR` bit is useful only in the ITU receive modes and indicates if an error in the status word of EAV or SAV sequences can not be cleared (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No uncorrected preamble error has occurred
		1	Preamble error detected but not corrected
5 (R/W1C)	FTERRUNDR	Frame Track Underflow. The `EPPI_STAT.FTERRUNDR` bit indicates whether a frame track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
4 (R/W1C)	FTERROVR	Frame Track Overflow. The `EPPI_STAT.FTERROVR` bit indicates whether a frame track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
3 (R/W1C)	LTERRUNDR	Line Track Underflow. The `EPPI_STAT.LTERRUNDR` bit indicates whether a line track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
2 (R/W1C)	LTERROVR	Line Track Overflow. The `EPPI_STAT.LTERROVR` bit indicates whether a line track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred

Table 18-64: EPPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	YFIFOERR	Luma FIFO Error. For RX modes, the `EPPI_STAT.YFIFOERR` bit indicates whether the Luma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the Luma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
0 (R/W1C)	CFIFOERR	Chroma FIFO Error. For RX modes, the `EPPI_STAT.CFIFOERR` bit indicates whether the chroma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the chroma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred

Vertical Transfer Count Register

The `EPPI_VCNT` register holds the number of lines to read in or write out, after `EPPI_VDLY` number of lines from the start of frame. Any write to the `EPPI_FRAME` register modifies the `EPPI_VCNT` register. However, any write to the `EPPI_VCNT` register does not affect the `EPPI_FRAME` register value. So the `EPPI_VCNT` register should be programmed after the `EPPI_FRAME` register.

19 Pulse-Width Modulator (PWM)

The pulse-width modulator (PWM) module is a flexible and programmable waveform generator. With minimal CPU intervention, the PWM peripheral can generate complex waveforms for:

- Motor control
- Pulse-coded modulation (PCM)
- Digital-to-analog conversion (DAC)
- Power switching
- Power conversion

The PWM module has four PWM pairs capable of three-phase PWM generation for source inverters for AC induction and DC brushless motors.

PWM Features

Each PWM generation unit features:

- 16-bit center-based PWM generation unit
- Programmable PWM pulse width
- Single or double update modes
- Programmable dead time and switching frequency
- Twos-complement implementation which permits smooth transition to full-on and full-off states
- Dedicated asynchronous PWM shutdown signal
- Debounce filter option on trip inputs that allow the system programmer to filter out short transients

Functional Description

The following sections provide details on the functionality of the PWM.

- Architectural Concepts

- Timer Units
- Channel Timing Control Unit
- Output Disable and Cross-Over Modes
- Sync Operation Modes

ADSP-SC58x PWM Register List

The Pulse-Width Modulator unit (PWM) includes multiple timers (providing period flexibility) and channels (providing mode, interrupt, and pulse shape flexibility), permitting a wide variety of PWM output options for motor control and other applications. A set of registers governs PWM operations. For more information on PWM functionality, see the PWM register descriptions.

PWM Definitions

The following definitions are helpful when using the PWM module.

Chopping

Used to simplify the design of isolated gate drive circuits for PWM inverters. If using a transformer coupled power device gate drive amplifier, then the active PWM signal must be chopped at a high frequency.

Dead-Time

A short delay introduced between turning off one PWM signal (for example, AH) and turning on the complementary signal (for example, AL). This short time delay permits turning off a power switch (AH in this case) to completely recover its blocking capability before the complementary switch is turned on. This time delay prevents a potentially destructive short-circuit condition from developing across the dc link capacitor of a typical voltage source inverter.

Duty Cycle

The proportion of on time to the regular interval or period of time (expressed in percent, 100% being fully on). A low duty cycle corresponds to low power, because the power is off for most of the time.

Switching Frequency

The average value of voltage (and current) fed to the load is controlled by turning the switch between supply and load on and off at a fast rate. The longer the switch is on compared to the off periods, the higher the total power supplied to the load.

Architectural Concepts

A clock, whose period is t_{SCLK0_0}, drives the PWM controller. The PWM generator produces four pairs (four high-side and four low-side) of PWM signals on the eight PWM output pins. Each high and low pair signal constitutes a channel. For example, the `PWM_AL` and `PWM_AH` signals make up channel A, and the `PWM_BL` and `PWM_BH` signals make up channel B, and so on.

Each pair of channel outputs references either a main timer or an independent timer. These timers operate on a switching frequency determined by the `PWM_TM0` through `PWM_TM4` registers. There are two duty registers for every PWM output. The registers enable generation of symmetrical or asymmetrical waveforms. The waveforms produce lower harmonic distortion in three-phase PWM inverters, with minimal CPU intervention.

Figure 19-1: PWM Block Diagram

The following list describes the primary blocks.

- Each pair of PWM signals references either the main timer or the independent timer.
- PWMTMR0 is the main timer and can trigger the delayed start of the other timers.
- Timing control units, one for each channel, together form the core of the PWM. The unit generates the required complex waveforms on the high-side and low-side outputs for the respective channel.
- Dead-time insertion occurs after the ideal PWM output pair is generated.
- The gate drive unit generates the high-frequency chopping signal and then mixes it with the requisite PWM output signals.
- The PWM shutdown and interrupt controller manage the various PWM shutdown modes for the timing unit and generate the requisite interrupt signals.
- The PWM sync pulse control unit generates the internal `PWM_SYNC` pulse and also controls whether the external `PWM_SYNC` input pulse is used.

Timer Units

Five timers make up the time base for the PWM module. The main timer, PWMTMR0 operates at a switching frequency determined by the period register `PWM_TM0`. The four remaining timers (PWMTMR1 through PWMTMR4) can operate at independent switching frequencies determined by their respective registers.

The respective time registers (`PWM_TM1` through `PWM_TM4`) can be programmed to work at a multiple of the main timer frequency. In this case, the `PWM_DLYA` through `PWM_DLYD` registers control the lead-lag phase of a given timer based on the main timer PWMTMR0.

NOTE: The delayed operation of a timer requires one of the following:

- The register value of the timer must be equal to the `PWM_TM0` register value.
- The `PWM_TM0` value must be an integer multiple of each register of the timer. Non-integer multiples are not allowed.

PWM Timer Period (PWM_TM) Registers

The 16-bit read/write PWM period registers (`PWM_TM0` through `PWM_TM4`) control the PWM switching frequency. The fundamental timing unit of the PWM controller is t_{SCLK0_0}. Therefore, the time increment (t_{SCLK0_0}) is 10 ns for a 100-MHz system clock (SCLK0_0) frequency, f_{SCLK0_0}. The value written to the register of a timer is effectively the number of t_{SCLK0_0} clock increments in one half of a PWM period. The following equation describes the required timer register value as a function of the desired PWM switching frequency (f_{PWM}):

$$PWM\_TM = f_{SCLK0\_0}/2 \times f_{PWM}$$

Therefore, the PWM switching period (T_s) is:

$$T_s = 2 \times PWM\_TM \times t_{SCLK0\_0}$$

For example, for an f_{SCLK0_0} of 100 MHz and a desired PWM switching frequency (f_{PWM}) of 10 kHz ($T_s = 100$ ms), the correct value to load into the timer register is:

$$PWM\_TM = 100 \times 10^6 \div 2 \times 10 \times 10^3 = 5000$$

The largest value that can be written to the 16-bit timer register is 0xFFFF = 65,535. For an f_{SCLK0_0} of 100 MHz, this value corresponds to a minimum PWM switching frequency of:

$$f_{PWM(min)} = 100 \times 10^6 \div 2 \text{ x } 65535 = 762 \text{ Hz}$$

NOTE: Timer register values of 0 and 1 are not defined. Do not use these values when the PWM outputs or PWM is enabled.

Timer Unit Operation

The PWM timers are up-down counters, and they operate on the peripheral clock with a period of t_{CK}. The period of the PWM timer is divided into two halves. In the first half, the timer roughly counts down from PWM_TMx/2 to –PWM_TMx/2. During this half, the `PWM_STAT.TMR0PHASE` through `PWM_STAT.TMR4PHASE` bits are held at 0. In the second half of the period, the timer roughly counts up from –PWM_TMx/2 to PWM_TMx/2. The `PWM_STAT.TMR0PHASE` through `PWM_STAT.TMR4PHASE` bits indicates a 1 during this half.

The actual partition of the periods varies slightly between odd and even values of the half-period, in the `PWM_TM[n]` registers.

If a timer register value is odd, for example 11, then that timer loads +5 at the beginning of the period. The timer counts down from +5 to –5 in the first half, reloads –5 at the midpoint and counts up from –5 to +5 in the second half. The reload values at the period and mid-period boundaries are the same as the previous count. The timer counts 2 × 11 half-periods = 22 total counts in the entire period as shown in the ***Operation of Timer for Odd Value of PWM_TM*** figure.

Figure 19-3: Operation of Timer for Even Value of PWM_TM

NOTE: In the operation discussed in this section, double-buffering of all channel registers and the timer registers takes place at the period boundary of the respective timers.

Phase Offset Control

The PWM timers (PWMTMR1 through PWMTMR4) can operate with a programmable phase lag relative to the main timer, PWMTMR0. To implement phase offset for a channel, use the counter-registers for channel delay (`PWM_DLYA` - `PWM_DLYD`) with the PWMTMR0 and set the `PWM_CTL.DLYAEN` bit to l.

Phase offset works as follows.

1. If phase lag is used for channel A (and channel A uses PWMTMR1 to generate a duty cycle), when PWMTMR0 reaches its period boundary, it triggers the `PWM_DLYA` register. The register counts out the number SCLK0_0 cycles that are equal to the value programmed in the `PWM_DLYA` register.
2. At the end of this count, the `PWM_DLYA` register sends out a trigger to PWMTMR1. It receives a synchronization pulse in every period of PWMTMR0 at a point delayed from its period boundary by the value in the `PWM_DLYA` register.

For more information on how channels can reference different timers for their outputs, see Channel Timing Control Unit.

NOTE: Satisfy the following conditions when using this feature on timer y for channel Y relative to PWMTMRx.

- Program the `PWM_DLY[n]` register to a value less than 2 × `PWM_TM[n]`.
- `PWM_TM0` = N × `PWM_TM[n]`, where N is an integer.

The function of `PWM_TM[n]` (PWMTMR1 in the example) differs in cases where `PWM_TM0` = `PWM_TM1` (Case 1) to cases where `PWM_TM0` = N × `PWM_TM1` (Case 2). The following examples describe both cases.

Case 1: PWM_TM0 = PWM_TMy

When `PWM_TM0` = `PWM_TMy`, PWMTMRy restarts its period after receiving the synchronization pulse from the channel delay register (`PWM_DLY[n]`). If the trigger from the `PWM_DLY[n]` register is late, PWMTMRy holds its count until the trigger occurs. If the trigger is a bit early, PWMTMRy reloads without regard to whether it has completed its current period. As a result, PWMTMRy resyncs with PWMTMR0 with the phase lag programmed in the `PWM_DLYA` register in every one of its periods.

In this case, the expiration of the delay registers (`PWM_DLY[n]`) is the period boundary of PWMTMRy. Now, all the double buffered registers related to the given channel update (except the delay registers which are double buffered at the period boundary of PWMTMR0).

The ***Phase Offset Control Using DELAY*** figure shows an example where:

- `PWM_TM0`, `PWM_TM1`, and `PWM_TM2` are programmed with the same value.
- `PWM_DLYA` and `PWM_DLYB` are programmed with values DELAY1 and DELAY2 respectively, such that DELAY2 > DELAY1.

- The outputs of Channel A are referenced to PWMTMR1. The outputs of channel B are referenced to PWMTMR2.

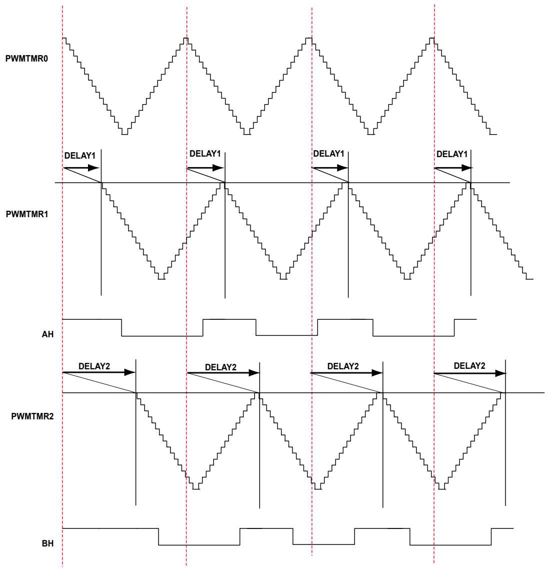

Figure 19-4: Phase Offset Control Using DELAY

The delay registers are double buffered and the new value of DELAY reloads at the period boundary of PWMTMR0. The two options exist when the new value is different from the older one. The behavior of PWMTMRy in both these cases is discussed. The ***Impact of New DELAY Value on Timer Count for Equal Timer Periods*** figure shows the behavior in the two cases. It is assumed that channel B references its outputs to PWMTMR0 and channel A references its outputs to PWMTMR1.

1. The new delay value is higher than the previous value. Here the corresponding PWMTMRy allows more than one time period between consecutive triggers from the channel delay (`PWM_DLYA` - `PWM_DLYD`) registers. In this case, after reaching its period boundary, PWMTMRy holds its count at the period boundary and waits for the trigger from the channel delay register. The ***Impact of New DELAY Value on Timer Count for Equal Timer Periods*** figure shows case A functionality.
2. The next delay value programmed is smaller than the previous value. Here, the corresponding PWMTMRy allows only less than one time period between consecutive triggers from the channel delay register. Though the trigger comes earlier in this case, before PWMTMRy has counted out one full period, it reloads and starts its period again. The ***Impact of New DELAY Value on Timer Count for Equal Timer Periods*** figure shows case B functionality.

Therefore, PWMTMR1 waits and obeys a synchronization pulse from the `PWM_DLYA` register in every one of its periods.

TMR1 waits
PWMTMR1
PWM_AH

Figure 19-5: Impact of New DELAY Value on Timer Count for Equal Timer Periods

Case 2: PWM_TM0 = N x PWM_TMy

In this case, within a single period of PWMTMR0 a program can fit multiple periods (N) of PWMTMRy. Additionally, the channel delay register is triggered only once every N periods of PWMTMRy.

The operation is as follows: Every Nth period of PWMTMRy, PWMTMRy expects a synchronization pulse from the `PWM_DLY[n]` register. When this register counts out that period and the trigger has not yet arrived, PWMTMRy waits at the end of the period for the trigger. PWMTMRy starts counting down once the trigger arrives. If the trigger comes earlier, PWMTMRy restarts immediately without waiting to complete the period count.

In the intervening periods, PWMTMRy operates independently. As the period ends, PWMTMRy reloads and starts the next period without intervention from the channel delay register.

The ***Impact of DELAY Value Change for the Multiple Timer Periods*** shows an example with N = 2. PWMTMRy syncs up with PWMTMR0 every second period, and is free running across every odd period boundary.

Channel Timing Control Unit

The channel timing control unit is the core of the PWM. There are four separate channels, each channel controlling a pair of output signals – the high-side output and the low-side output.

Channel Control

The `PWM_CHANCFG` register controls the static configuration of all the channels and is initialized once before the beginning of a PWM operation.

NOTE: The `PWM_CHANCFG` register is not double buffered. Do not change the contents of the register once the PWM is enabled.

Each channel works with a reference timer base. The time base can be either the main timer PWMTMR0 or the appropriate PWMTMRx. Configure the time base with the `PWM_CHANCFG.REFTMRA` bit field as follows.

- Channel A works with PWMTMR0 or PWMTMR1
- Channel B works with PWMTMR0 or PWMTMR2
- Channel C works with PWMTMR0 or PWMTMR3
- Channel D works with PWMTMR0 or PWMTMR4

The double-buffered channel control registers (`PWM_ACTL` through `PWM_DCTL`) contain bits that control the dynamic pulse behavior of the channel outputs. These registers have bits that enable or disable outputs and select the pulse position of outputs (explained in the following section).

Pulse Positioning and Duty Cycle Registers

The PWM uses the PULSEMODEHI and PULSEMODELO bit fields of the `PWM_[n]CTL` registers to define the region within the timer period where the output pulses are positioned.

- When the `PWM_CHANCFG.MODELSC` bit is 0, the PWM uses the PULSEMODEHI field to specify the pulse positioning for both the high-side and low-side outputs of the channel.
- When the bit is 1, the PWM uses `PWM_ACTL.PULSEMODELO` to define the pulse positioning for the low-side output of the channel. It uses the `PWM_ACTL.PULSEMODEHI` to define the pulse positioning for the high-side output of the channel.

Each channel output has two duty-cycle registers: `PWM_AH0` and `PWM_AH1` for the high-side output, and `PWM_AL0` and `PWM_AL1` for the low-side output. These registers determine the width of the output pulses. When the `PWM_CHANCFG.MODELSC` bit is 0, the high-side duty-cycle registers are used to determine the width of the output pulse for the low side. The duty cycle range that can be programmed into these registers is between –`PWM_TM[n]`/2 and +`PWM_TM[n]`/2 , when ignoring dead time.

When including dead time for channel A, for PULSEMODEs 00 and 01, the programmed duty cycle is modified. The range is limited between the values [–`PWM_TM[n]`/2 + `PWM_CHA_DT`] and [+`PWM_TM[n]`/2 + `PWM_CHA_DT`] considering the high-side output. For PULSEMODEs 10 and 11, the high-side duty cycle registers range is limited between values [`PWM_TM[n]`/2 + `PWM_CHA_DT`] and [–`PWM_TM[n]`/2 – `PWM_CHA_DT`].

The following section explains dead time in detail.

- Switching Dead Time (PWM_DT) Register

NOTE: Values programmed into these registers that fall outside these limits result in over or under modulation.

Duty Cycle and Pulse Positioning Control

The `PWM_ACTL.PULSEMODEHI` and `PWM_ACTL.PULSEMODELO` fields control how the duty cycle registers modify the waveform of the high and low-side outputs. (The `PWM_ACTL.PULSEMODEHI` and `PWM_ACTL.PULSEMODELO` fields are referred to as *pulse mode* in the subsequent discussion.)

- Pulse mode = 00 – Produce a symmetrical pulse waveform around the center of the PWM period. In this mode, PWM uses only one of the duty cycle registers for an output. For example, for the AH output, PWM uses only the `PWM_AH0` register. In this mode, the values in the duty cycle registers are scaled such that a value of 0 produces a 50% duty cycle.
- Pulse mode = 01 – Produce an asymmetrical pulse waveform around the center of the PWM period. In this mode, PWM uses both duty cycle registers. For example, for the PWM_AH output, PWM uses the `PWM_AH0` and `PWM_AH1` registers. In this mode, if the `PWM_AH1` register is programmed with the same value as the `PWM_AH0` register, the output is identical to the output when pulse mode =00.
- Pulse mode = 10 or 11 – Produce pulse waveforms either on the first half or the second half of the PWM period respectively. PWM uses both `PWM_AH0` and `PWM_AH1` registers.

  Pulse mode = 10. If the low side works from the low-side duty-cycle registers, strictly adhere to the condition `PWM_AL0`> `PWM_AL1`.

  In pulse mode = 11. If the low side works from the low-side duty-cycle registers, strictly adhere to the condition `PWM_AL0`< `PWM_AL1`.

The ***Pulse Positioning Modes*** figure shows the pulse positioning modes as previously described for PWM_AH. In the figure, DUTY0 is the value in the `PWM_AL0` register and DUTY1 is the value in the `PWM_AH1` register. The step signal, count, indicates the output of the timer for channel A. In the example, the signal is configured as active high and dead time is zero.

Figure 19-7: Pulse Positioning Modes

Channel Low Side Output Dependent Operation Mode and Dead Time

The low-side output waveform can be programmed to depend on the waveform of the high-side output or to be independent. The PWM uses the `PWM_CHANCFG.MODELSC` bit to control this functionality.

For example, channel A produces the high-side output PWM_AH and the low-side output PWM_AL. When the `PWM_CHANCFG.MODELSC` bit =0, the low-side output is also generated using the high-side duty-cycle registers for pulse width, the `PWM_ACTL.PULSEMODEHI` bits for pulse positioning and the `PWM_CHANCFG.POLAH` bit for polarity. If the `PWM_CH[x]_DT` register is 0, the low-side output is an inverted version of the high-side output.

When the `PWM_CH[x]_DT` register is programmed with a non-zero value, both the high-side and low-side outputs are scaled symmetrically about the points of transition in the zero dead time case. The PWM scales the output by the value programmed in the `PWM_CH[x]_DT` register.

The *Channel Outputs in Dependent Mode for Pulse Mode* figures show the high and low-side outputs for the case with zero and non-zero dead time for `PWM_ACTL.PULSEMODEHI` =00 and 01. DUTY0 is the value programmed into the `PWM_AH0` register. DUTY1 is the value programmed into the `PWM_AH1` register. The `PWM_CHANCFG.POLAH` bit =1, indicates that both signals are active high. The `PWM_CHA_DT` register holds the value DT.

Channel High Side and Low Side Outputs, Independent Operation Mode

Independent control of the `PWM_AH0` and `PWM_AL0` channel outputs is possible by setting the `PWM_CHANCFG.MODELSA` bit to 1. In this case, the PWM module:

- Generates PWM_AH using the `PWM_AH0` register
- Uses the `PWM_AH1` register to configure pulse width

- Uses the `PWM_ACTL.PULSEMODEHI` bit to configure pulse position
- Uses the `PWM_CHANCFG.POLAH` bit to configure polarity
- Generates PWM_AL using `PWM_AL0`
- Uses the `PWM_AL1` register to configure pulse width
- Uses the `PWM_ACTL.PULSEMODELO` bit to configure pulse position
- Uses the `PWM_CHANCFG.POLAL` bit to configure polarity

NOTE: In independent mode, the dead-time insertion is not applicable. The hardware forces dead time to zero.

The ***PWM_AH and PWM_AL in Independent Operation Mode*** figure shows an example of the independent mode of operation where PWM_AH and PWM_AL work from different register bits.

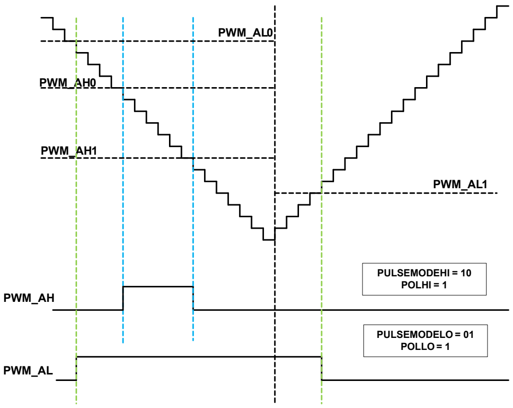

Figure 19-12: PWM_AH and PWM_AL in Independent Operation Mode

PWM_AH and PWM_AL can be positioned in the timer period with a given phase difference between them. Program the `PWM_ACTL.PULSEMODEHI` and `PWM_ACTL.PULSEMODELO` bits to different values to achieve this positioning as shown in the ***Channel Outputs Controlled Independently*** figure.

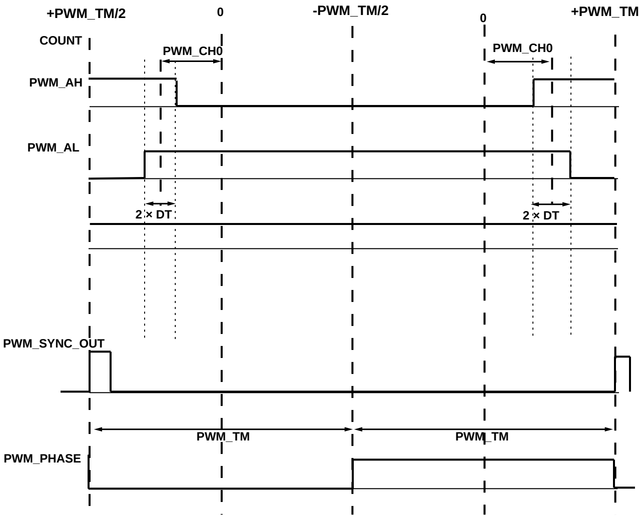

Figure 19-13: Channel Outputs Controlled Independently

Switched Reluctance Motors Application

In typical power converter configurations for switched or variable reluctance motors, motor winding is connected between the two power switches of a given inverter leg. To allow for a complete circuit in the motor winding, turn on both switches at the same time.

PWM uses switched reluctance motors in the following configurations: hard chop, alternate chop, soft chop—bottom on, and soft chop— top on.

The ***Four SR Mode Types, Active High PWM Output Signals*** figure shows the four SR mode types as active high PWM output signals.

Hard chop mode contains independently programmed rising edges of the high and low signals of a channel in the same PWM half cycle. Both signals contain independently programmed falling edges in the next PWM half cycle. The `PWM_CHANCFG.POLAH` and `PWM_CHANCFG.POLAL` bits are programmed to same values.

Alternate chop mode is similar to normal PWM operation except that the PWM channel high and low signal edges are always opposite and are independently programmed. The `PWM_CHANCFG.POLAH` and `PWM_CHANCFG.POLAL` bits are programmed to opposite values. The low-side invert is the only difference between hard chop mode and alternate chop mode.

Soft chop - bottom on uses a 100% duty on the low side of the channel. Soft chop - top on uses a 100% duty on the high side of the channel. Similar to hard chop mode, PWM uses the `PWM_AH0` duty register for the high channel and the `PWM_AL0` duty register for the low channel.

Figure 19-14: Four SR Mode Types, Active High PWM Output Signals

Switching Dead Time (PWM_DT) Register

The second important parameter that must be set up in the initial configuration of the PWM controller is the switching dead time. Dead time is a short delay introduced between turning off one PWM signal (for example, AH) and turning on the complementary signal (for example, AL). This short time delay permits turning off a power switch (AH in this case) to completely recover its blocking capability before the complementary switch is turned on. This time delay prevents a potentially destructive short-circuit condition from developing across the DC link capacitor of a typical voltage source inverter.

The 10-bit, read/write channel A through channel D dead-time registers (`PWM_CHA_DT` through `PWM_CHD_DT`) control the dead time for channel-x. If the value carried by any dead-time register is PWMDT, the dead time, Td, for that channel is:

$$T_d = \texttt{PWM\_CH[x]\_DT} \times 2 \times t_{SCLK0\_0}$$

Therefore, a dead-time value of 0x00A introduces a 200-ns delay (for an SCLK0_0 of 100 MHz). The delay occurs between turning off any PWM signal (for example, AH) and then turning on its complementary signal (for example, AL). The length of dead time can be programmed in increments of $2 \times t_{SCLK0\_0}$ (or 20 ns for an SCLK0_0 of 100 MHz). The channel A through channel D dead-time registers have a maximum value of 0x3FF (1023 decimal) and correspond to a maximum programmed dead time of:

$T_{d(max)} = 1023 \times 2 \times t_{SCLK0\_0} = 1023 \times 2 \times 10 \times 10^{-9} = 20.5$ µs for an f_{SCLK0_0} rate of 100 MHz.

Write 0 to the `PWM_CHA_DT` through `PWM_CHD_DT` registers to program the dead time.

Duty Cycle with Dead Time Control: Calculations for PULSEMODE 00

The duty cycle registers are scaled so that a value of 0 represents a 50% PWM duty cycle. The switching signals produced are also adjusted to incorporate the programmed dead-time value using the channel dead-time registers

(`PWM_CHA_DT` through `PWM_CHD_DT`). The unit in this case produces active low signals so that a low level corresponds to a command to turn-on the associated power device.

The ***Dead Time Between Outputs in Dependent Mode*** figure shows a typical pair of PWM outputs, PWM_AH and PWM_AL. The time values in the figure indicate the integer value in the associated register and can be converted to time by multiplying by the fundamental time increment, t_{CK}. In the example, channel A is working from `PWM_TM0`.

In the example, the pulse mode is set to 00 so that the switching patterns are perfectly symmetrical about the midpoint of the switching period. The dead time is incorporated by moving the switching instants of both PWM signals away from the instant set by the `PWM_AH0` register. Both switching edges are moved by an equal amount (DT × t_{CK}) to preserve the symmetrical output patterns. Also shown is the `PWM_SYNC` output pulse whose rising edge denotes the beginning of the switching period, and the `PWM_STAT.TMR0PHASE` bit.

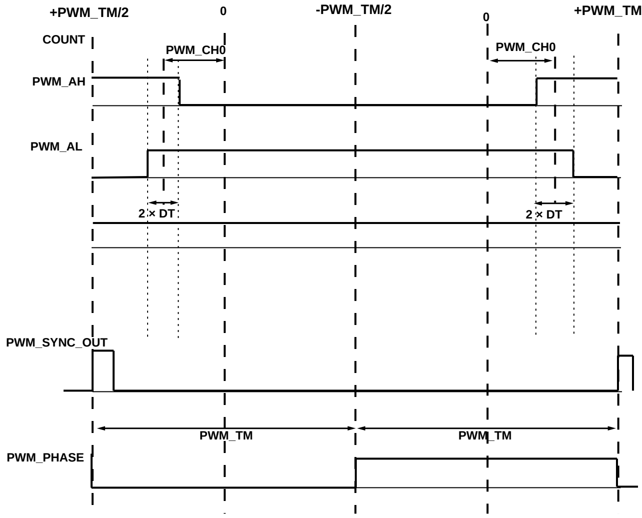

Figure 19-15: Dead Time Between Outputs in Dependent Mode

The PWM timing unit produces the resulting on-times (active low) of the PWM signals over the full PWM period (two half-periods). The figure illustrates this timing. The timing can be written per the following equation.

T_{AH} = (`PWM_TM0` + 2 × (`PWM_AH0` – `PWM_CH[x]_DT`)) × $t_{CK;}$

Range of T_{AH} is [0:2 × `PWM_TM0` × t_{CK}]

T_{AL} = (`PWM_TM0` – 2 × (`PWM_AH0` + `PWM_CH[x]_DT`)) × $t_{CK;}$

Range of T_{AL} is [0:2 × `PWM_TM0` × t_{CK}]

$$d_{AH} = \frac{T_{AH}}{Ts} = \frac{1}{2} + \frac{PWM\_AH0 - DT}{PWM\_TM}$$

$$d_{AL} = \frac{T_{AL}}{Ts} = \frac{1}{2} - \frac{PWM\_AH0 + DT}{PWM\_TM0}$$

The negative values of T_{AH} and T_{AL} are not permitted and the minimum permissible value is zero, corresponding to a 0% duty cycle. In a similar fashion, the maximum value is T_s, the PWM switching period, corresponding to a 100% duty cycle. Calculation of duty for other pulse modes can be similarly executed.

Special Consideration for PWM Operation in Over-Modulation

The PWM timing unit can produce PWM signals with variable duty cycle values at the PWM output pins. In pulse modes 00 and 01, at the extremities of the modulation process, duty cycles of 0% and 100% occur. In pulse modes 01 and 10, at the extremities of the modulation process, duty cycles of 0% and 50% occur. The modulation is called *full off* when the lower extremity of modulation is set for any PWM timer period for the corresponding channel. The modulation is called *full on* when the higher extremity of modulation is set for any PWM timer period for the corresponding channel. In between, for other duty cycle values, the operation is termed *normal modulation*.

Full On Modulation

In pulse modes 00 and 01, a PWM channel is in full on modulation if the high-side output of that channel is asserted. The output is asserted for the whole duration of the period of the PWM timer that channel is referencing. The conditions for full on modulation are:

- PWM_xH0 DT > PWM_TMy/2 for pulse mode 00
- PWM_xH1 DT > PWM_TMy/2 for pulse modes 00 and 01

In pulse mode 10, a PWM channel is in full on modulation if the high-side output of that channel is asserted. The output is asserted for the whole duration of the first half period of the PWM timer that the channel is referencing. The conditions for full on modulation are:

- PWM_xH0 DT > PWM_TMy/2 for pulse mode 10
- PWM_xH1 + DT < PWM_TMy/2 for pulse mode 10

In pulse mode 11, a PWM channel is in full on modulation if the high-side output of that channel is asserted. The output is asserted for the whole duration of the second half period of the PWM timer that the channel is referencing. The conditions for full on modulation are:

- PWM_xH0 + DT < PWM_TMy/2 for pulse mode 11
- PWM_xH1 DT > PWM_TMy/2 for pulse mode 11

Full Off Modulation

In pulse modes 00 and 01, a PWM channel is in full off modulation if the high-side output of that channel is deasserted. The output is deasserted for the whole duration of the period of the PWM timer that channel is referencing. The conditions for full off modulation are:

- PWM_xH0 DT < PWM_TMy/2 for pulse mode 00
- PWM_xH1 DT < PWM_TMy/2 for pulse modes 00 and 01

In pulse mode 10, a PWM channel is in full off modulation if the high-side output of that channel is deasserted. The output is deasserted for the whole duration of the first half period of the PWM timer that the channel is referencing. In the second half-period, it is deasserted anyway. The conditions for full off modulation are:

- PWM_xH0 DT < PWM_TMy/2 for pulse mode 10
- PWM_xH1 + DT < PWM_xH0 DT for pulse mode 10

In pulse mode 11, a PWM channel is in full off modulation if the high-side output of that channel is deasserted. The output is deasserted for the whole duration of the second half period of the PWM timer that the channel is referencing. In the first half of the period, it is deasserted anyway. The conditions for full off modulation are:

- PWM_xH0 + DT > PWM_TMy/2 for pulse mode 11
- PWM_xH1 DT > PWM_xH0 + DT for pulse mode 11

Normal Modulation

All other cases of modulation fall under this category.

Emergency Dead-Time Delays

Sometimes, during modulation transition, it is necessary to insert more emergency dead-time delays to prevent potential shoot through conditions in the inverter. (For example, when the PWM transitions into or out of full on or full off modulation.) Disabling and enabling usage (related to the `PWM_ACTL.DISHI` and `PWM_ACTL.DISLO` bits) also can potentially cause outputs to violate shoot-through condition criteria. Another case is when large values vary the phase delay of a PWM timer. These transitions are detected automatically. If appropriate for safety, an emergency dead-time is inserted to prevent shoot through conditions.

There is another atypical case for the insertion of the additional emergency dead time. It occurs when both PWM signals do not toggle within a dead time of each other. In this case, insert more emergency dead time into one of the PWM signals of a given pair during these transitions. The dead-time delay is inserted into the PWM signal that is toggling into the on-state. In effect, an amount (2 × DT × t_{CK}) from the rising edge of the opposite output delays the turn-on of this signal. After this delay, the PWM signal is allowed to turn-on provided the desired output is still scheduled to be in the on-state after the emergency dead-time delay.

The ***Over Modulation Transition Example*** figure illustrates two examples of such a transition. In the figure, `PWM_ACTL.PULSEMODEHI` is kept at 1. The `PWM_AH` signal has been in full on modulation for some time and, during the current period, its pulse mode is changed to 10, keeping the full on condition. At the half-period boundary, `PWM_AH` is forced to transition to a deasserted state because pulse mode is 10. An emergency dead-time is inserted on the low-side output.

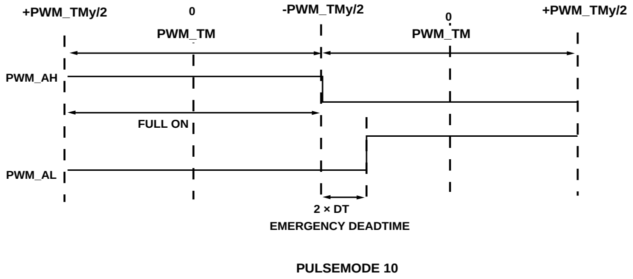

Figure 19-16: Over Modulation Transition Example

Gate Drive Unit

The gate drive unit of the PWM adds features that simplify the design of isolated gate drive circuits for PWM inverters. When using a transformer coupled power device gate drive amplifier, the active PWM signal must be chopped at a high frequency. The `PWM_CHOPCFG` register allows the programming of this chopping mode for high frequency. The chopped active PWM signals can be required for the high-side drivers only, for the low-side drivers only, or for both the high-side and low-side switches. Therefore, independent control of this mode for both high and low-side switches is included with two separate control bits in the `PWM_CHANCFG` register.

The ***High-Side and Low-Side Outputs With Gate Chop Enabled*** figure shows the typical PWM output signals with high-frequency chopping enabled on both high-side and low-side signals. Chopping of the PWM outputs is enabled by setting bits in `PWM_CHANCFG` register. The 8-bit `PWM_CHOPCFG.VALUE` value controls the high frequency chopping. The following equation gives the period of this high frequency carrier.

$T_{chop} = [4 \times (\text{CHOPDIV} + 1)] \times t_{CK}$

and the chopping frequency is therefore an integral subdivision of the peripheral clock frequency:

$f_{chop} = f_{CK}/[4 \times (\text{CHOPDIV} + 1)]$

The `PWM_CHOPCFG.VALUE` value can range from 0 to 255, corresponding to a programmable chopping frequency rate from 122 kHz to 31.25 MHz for a 125 MHz, f_{CK} rate. Program the gate drive features before enabling the PWM controller. Do not change the gate drive features during normal operation of the controller. Following a reset, clear all bits of the `PWM_CHANCFG` register so that high frequency chopping is disabled, by default.

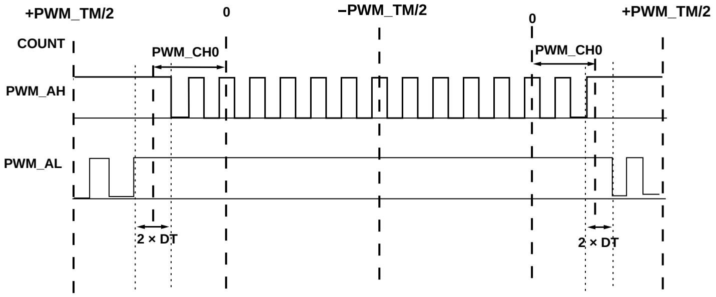

Figure 19-17: High-Side and Low-Side Outputs With Gate Chop Enabled

Output Control Feature Precedence

The order of applying output control features to the PWM signal is important and significant. Use the following order for applying the signal features to the PWM output signal.

1. Duty generation
2. Cross-over
3. High-side or low-side disable
4. Emergency dead-time insertion
5. HPPWM correction for wrong programming
6. Gate-drive chopping
7. Polarity
8. Heightened-Precision PWM (HPPWM) edge placement

NOTE: When HPPWM operation is enabled, the ***cross-over*** feature and the ***gate-drive chopping*** feature must be disabled.

Operating Modes

The PWM generator is capable of operating in the following modes:

- Sync Operation Modes
- Output Disable and Cross-Over Modes
- Heightened-Precision Edge Placement
- Emulation Mode

Sync Operation Modes

The `PWMx_SYNC` pins can operate as internally generated or externally generated. If its internally generated, PWMs can drive the signal to synchronize other PWMs and other devices. If externally generated, the PWMs can be synchronized externally.

External (Triggered) PWM Sync Generation

By setting the `PWM_CTL.EXTSYNC` bit, the PWM is set up in a mode to expect an external `PWM_SYNC` signal on the `PWM_SYNC_IN` pin through the TRU. The trigger source can be any TRU1 trigger master. Multiple PWM units can be precisely synchronized by selecting the same trigger master as the sources for each PWM sync trigger slave. Examples of useful trigger masters include:

- A `PWM_SYNC` GPIO master. This option allows synchronizing the PWMs to an off-chip timing source. (The `PWM_CTL.EXTSYNC` bit must be programmed to 1 to enable the GPIO input.) The `PWM_SYNC` GPIO pads are connected through the pin mux to configurable trigger masters using PWM master IDs TRGM_SYS_PWMn_SYNC_IN. Using the TRU, these masters can be connected to the `PWM_SYNC` trigger slaves in any desired combination.

- A TTU trigger output. This option can include a member of a TTU trigger group, which can also control the timing of other devices such as ADCs, SINC filter inputs, or GP timers. The TTU supports relative trigger delays so that timing offsets can be applied to manage system latencies with precision.
- A general-purpose timer trigger master
- A software trigger master. This option allows starting one or more PWM units simultaneously by an MMR write.

The external `PWM_SYNC` signal only determines the operation of the main timer PWMTMR0.

Synchronize the external sync by setting the `PWM_CTL.EXTSYNCSEL` bit to 0 (assumes the external `PWM_SYNC` selected is asynchronous).

The external `PWM_SYNC` period is expected to be an integer multiple of the value of the `PWM_TM0` period register. When the rising edge of the external `PWM_SYNC` is detected, the PWMTMR0 timer is restarted at the beginning of its period. If the external `PWM_SYNC` period is not exactly an integer multiple of the internal `PWM_SYNC`, the behavior of the PWM channel outputs which are referenced to PWMTMR0 are clipped.

The effect latency from `PWM_SYNC_IN` to the PWM outputs is about three clock cycles in synchronous mode, and five clock cycles in asynchronous mode.

CAUTION: Do not change the value of the `PWM_CTL.EXTSYNC` bit while the PWM is enabled (`PWM_CTL.GLOBEN` =1).

Output Disable and Cross-Over Modes

Each `PWM_ACTL` channel control register contains separate enable bits for the high and low-side signals. The PWM module uses the `PWM_ACTL.DISHI` and `PWM_ACTL.DISLO` bits in the channel A control register to enable or disable the `PWM_AH` and `PWM_AL` outputs respectively. If the disable bit is set (=1), then the corresponding PWM output is disabled, irrespective of the value of the corresponding duty cycle register. This PWM output signal remains in the OFF state as long as the corresponding enable or disable bit is set.

The cross-over bit (`PWM_ACTL.XOVR`) allows programs to send the low-side output through the high-side output pin and the high-side output through the low-side output pin.

One example uses the following configuration:

- The `PWM_AH0` register =0
- The `PWM_CHANCFG.MODELSC` bit =0
- The `PWM_ACTL.DISLO` bit =1
- The `PWM_ACTL.XOVR` bit =1

The low-side output remains off, as in the case without crossover. The difference in cross-over is that the high-side output changes character and becomes like the low-side. What actually occurs is that the low-side duty cycle is sent to the high-side output pins, and the high-side duty cycle is sent to the low side pins. Because the `PWM_ACTL.DISLO` bit =1, the low-side pin remains off (see Output Control Feature Precedence).

The ***XOVR and DISHI/DISLO Functionality*** figure shows this example. In case 1, `PWM_ACTL.XOVR` =0; and in case 2, `PWM_ACTL.XOVR` =1.

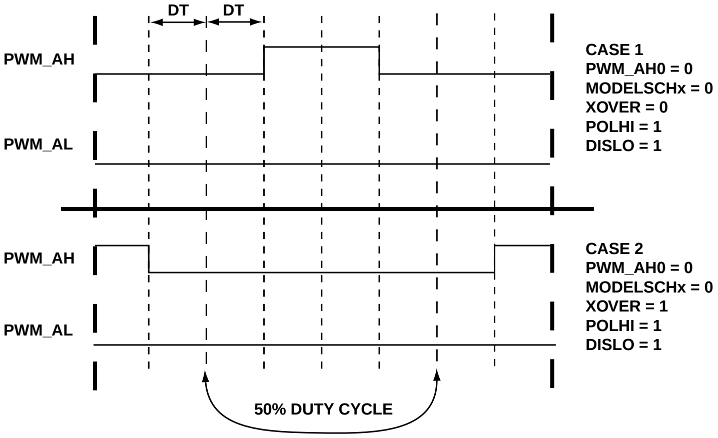

Figure 19-18: XOVR and DISHI/DISLO Functionality

Brushless DC Motor (Electronically Commutated Motor) Control

In the control of an electronically commutated motor (ECM), only two inverter legs are switched at any time. Often, the high-side device in one leg must be switched on at the same time as the low-side driver in a second leg. It is possible to turn on the high-side switch of phase A and the low-side switch of phase B at the same time by:

- Programming identical values for the duty cycles for two PWM channels (for example, `PWM_CH0` = `PWM_CH1`), and
- Setting the `PWM_BCTL.XOVR` bit to crossover the BH and BL pair of PWM signals

To control ECM, normally the third inverter leg (phase C in this example) is disabled for a number of PWM cycles. To implement this function, both the `PWM_CH` and `PWM_CL` outputs are disabled by setting the `PWM_CCTL.DISHI` and `PWM_CCTL.DISLO` bits.

In normal ECM operation, each inverter leg is disabled for certain time periods so that the PWM channel registers change based on the position of the rotor shaft (motor commutation).

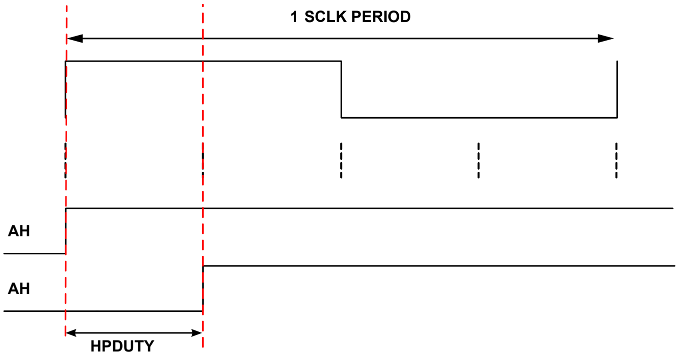
Heightened-Precision Edge Placement

Heightened-precision edge placement allows a fine-grained edge placement within the system clock period. The ***Heightened-Precision Steps in a Single SCLK Period*** figure shows how the SCLK0_0 aligned edge is moved to finer resolution.



1 SCLK PERIOD
AH
AH
HPDUTY

Figure 19-20: Heightened-Precision Steps in a Single SCLK0_0 Period

The heightened-precision mode is enabled by setting bits that correspond to the high or low side output option for the channel in the `PWM_CHANCFG` register. bit. The `PWM_AH0_HP` and `PWM_AH1_HP` registers work alongside the `PWM_AH0` and `PWM_AH1` registers to provide the overall resolution. The following example explains how signed decimal programming is implied for the heightened-precision duty values.

For the `PWM_AH` output, the duty-cycle register-pair `PWM_AH0` and `PWM_AH0_HP` work together in a Q15.8 signed two's complement fixed-point format as shown in the ***Duty Cycle Notation for Heightened-Precision Edge Placement*** figure. The weight of bit position at k is 2k.

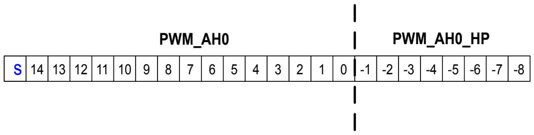


Figure 19-21: Duty Cycle Notation for Heightened-Precision Edge Placement

In the normal modes of operation (not involving heightened-precision edge placement), only the `PWM_AH0` register value is programmed. The duty value programmed is a two's complement integer value. If a value of -1 is desired, the `PWM_AH0` register is programmed with the number 0xFFFF (which is the two's complement of 1 in 16 bits).

In the heightened-precision mode, if a duty value corresponding to 0.75 is required, the equivalent two's complement value of 0.75 in the Q15.8 format is computed: 1111_1111_1111_1111.0100_0000 = 0xFFFF.40. In this case, the `PWM_AH0` register is programmed to 0xFFFF and the `PWM_AH0_HP` register is programmed to 0x40.

Heightened-Precision Edge Placement Example

The following is an example of heightened precision edge placement.

On the *positive side* of the fractional of the duty cycle, at 2 t_{CK} + 0.25 t_{CK}, the values for the `PWM_AH0` and `PWM_AH0_HP` registers are calculated as follows.

The `PWM_AH0` =0x0002 and `PWM_AH0_HP` =0x40 (bits 7:6).

The `PWM_AH_DUTY0` register contains the bit fields from both the `PWM_AH0` and `PWM_AH0_HP` registers. Bits [15:14] represent the decimal part or heightened-precision value and bits [31:16] represent the coarse duty cycle. The value for the combined registers is `PWM_AH_DUTY0` =0x00024000.

On the *negative side* of the fractional of the duty cycle, at –2 t_{CK} – 0.25 t_{CK}, the values for the `PWM_AH0` and `PWM_AH0_HP` registers are calculated as follows:

The coarse register represents the next count of the coarse value for negative values so that –2 becomes –3. These values are the two's complement of the positive offset (value = 3) `PWM_AH0` = 0xFFFD and `PWM_AH0_HP` =0xC0 (bits 7:6).

To derive the correct format for a negative duty-cycle value, for example, –2.25, use: coarse value + 1 =3 for the coarse value and 1 for 0.25. Write out the absolute value as a 32-bit number first:

0000 0000 0000 0011 (.) 0100 0000 0000 0000

Then take the two's complement of the entire 32-bit number:

1111 1111 1111 1101 (.) 1100 0000 0000 0000

NOTE: This value is also written into the full duty register (`PWM_AH_DUTY0`). The correct value for the combined registers written in the `PWM_AH_DUTY0` register is 0xFFFDC000.

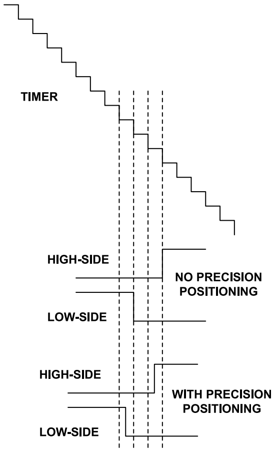
NOTE: The above examples only consider 2 bits of precision, while the ADSP-CM41xF supports up to 4 bits. That means bits [7:4] of the `PWM_AH_DUTY0` register can be used to define the higher precision. Bits

[15:12] of represent the decimal part or heightened-precision value and bits [31:16] represent the coarse duty cycle.

Sample Waveforms for High- and Low-Side with Precision Placement

When the PWM module uses heightened-precision in the dependent mode of operation, both high and low-side outputs shift in the same direction. This operation can result in pulse-expansion of the high-side and pulse-contraction of the low-side or conversely.

The ***Output Shift in The Same Direction*** figure shows an example of a case with DT =1, and pulse expansion occurs on the high-side and pulse-contraction on the low-side. It juxtaposes a case where the PWM module does not use heightened-precision and a case where PWM does use it.



NOTE: BOTH CHANNEL OUTPUTS SHIFT IN THE SAME DIRECTION

Figure 19-22: Output Shift in The Same Direction

The following ***Precision Placement: PULSEMODE*** figures illustrate the cases for pulse modes 1, 2, and 3 (pulse mode 00 is a trivial case of pulse mode 01). The pulse modes are configured in the `PWM_ACTL` and `PWM_BCTL` channel control registers. The figures show what happens to the edges as a decimal part is added to a programmed positive duty. In each case, assume that the original `PWM_AH0.DUTY` register value, which is the coarse duty value, changes to the `PWM_AH1.DUTY` value after programming the enhanced-resolution (`PWM_AH0_HP`, `PWM_AH1_HP`) registers. For example, changing 14 to 14.25 and 10 to 10.75. The figures are not drawn to these numbers. For negative duty values, the shifts are in the opposite direction.

Emulation Mode

Depending upon system configuration, a debug halt may be presented to the PWM unit. The PWM has local control of its response to an emulator halt based on the `PWM_CTL.EMURUN` bit setting.

- `PWM_CTL.EMURUN` =1. When the processor is halted in emulation mode, the outputs continue to toggle and be driven out of the PWM block. The counters and status register bits are set or reset according to the PWM timer count or period settings.
- `PWM_CTL.EMURUN` =0. When the processor is halted in emulation mode, the outputs are shut down (enter their inactive state based on polarity), and all counters that affect status register bits are paused.
- At restart, the PWM counters resume from their paused value. The outputs are still held in their inactive state.

Event Control

The PWM uses bits in the `PWM_IMSK` and `PWM_ILAT` registers for event control. These registers allow masking and show masked interrupt request status bits, respectively. The interrupt status bits are latched and held on the interrupt event. The software must write a 1 to clear the interrupt status bit, usually during the interrupt service routine.

The timer period (TMRxPER) interrupt requests are configured using the `PWM_ILAT.TMR0PER` - `PWM_ILAT.TMR4PER` bits. The PWM uses the interrupts to execute an interrupt service routine (ISR) periodically. The ISR updates the PWM channel control and duty registers (according to a control algorithm based on expected operation and sampled existing operation). The TMRxPER interrupts also can trigger an ADC to sample data for use during the ISR.

The PWM uses the `PWM_CTL.INTSYNCREF` bit field to control the PWM_SYNC interrupt request. The PWM uses the bit field to assign the interrupt request to a system user interrupt of the core. The PWM_SYNC can be configured to be either internal or externally driven using the `PWM_CTL.EXTSYNC` bit. When configured as an external sync, the signal can be further configured as synchronous or asynchronous using the `PWM_CTL.EXTSYNCSEL` bit.

As an example, when the PWM_SYNC interrupt is serviced:

- The ADC samples data
- The data is algorithmically interpreted
- New PWM channel duties are calculated and written to the PWM

More sophisticated implementations include different startup, run time, and shutdown algorithms to determine PWM channel duties based on expected behavior and further features.

During the PWM_SYNC interrupt driven control loop, only the channel delay registers, the duty registers, and the channel C high pulse duty register values are typically updated. To see programming limitations on the PWM registers, see the "Register Descriptions".

Status information about the PWM is available in the `PWM_STAT` register, which stores all status bits, including raw interrupt status bits. In particular, the period boundary of each timer is available, as well as status bits. The PWM uses the status bits to indicate whether the operation is in the first half or the second half of the timer. Additionally, the TRIP status is also available. For more information on TRIP interrupts, see Trip Control Unit .

Trip Control Unit

The PWM output signals can be shut-off in a number of different ways. The trip inputs (`PWM_TRIP[n]`) can be mapped to provide either a temporary or permanent shutdown on any channel outputs (hi/lo/pair). This shutdown mechanism is asynchronous so that the associated PWM output disable circuitry does not go through any clocked logic. This functionality ensures correct PWM shutdown even in the event of a loss of the processor clock. In addition to the hardware shutdown features, the PWM system can be shut down in software with the `PWM_CTL.SWTRIP` bit.

The external trip signal `PWM_TRIP0`, that comes from GPIO generates the TRIP0 input whereas the trigger slaves PWM0_TRIP_TRIGn, PWM1_TRIP_TRIGn and PWM2_TRIP_TRIGn generate TRIP1 input.

During any external trip event (if not disabled), the PWM outputs are turned off. When a PWM output is turned off, it means that the output level is held at a polarity opposite that given in the `PWM_CHANCFG.POLAH` through `PWM_CHANCFG.POLDH` (channel high side polarity) bits. The PWM sync pulse continues to operate, when it is already enabled. A PWMTRIP interrupt occurs if unmasked, to notify the software of this event. In dependent mode of operation, both high and low-side outputs refer to the channel high side polarity bits.

Even if the clock to the PWM is damaged, an external trip event turns off the PWM outputs. In this case, the PWMTRIP interrupt request may not occur.

The PWM trip unit processes hardware or software fault conditions and shuts down the PWM channel outputs immediately on the occurrence of these conditions. The PWM can enable the shutdown mechanism separately for each channel. The design also allows for a self-restart mechanism to be enabled on a channel. Self-restart reenables the channel outputs following the fault condition (allowed only on hardware trips) when the PWMTMRy that the channel is using reaches its period boundary.

These sources are active low inputs where a falling edge on either of these pins indicates a fault condition.

The trip unit can shut down an output of a particular channel in response to the fault event from the `PWM_TRIP0` pin. To enable this functionality, program the `PWM_TRIPCFG.EN0A` bit corresponding to the channel.

Program the `PWM_TRIPCFG.MODE0A` bits to specify the restart mechanism for a channel that has been tripped.

1. If the `PWM_TRIPCFG.MODE0A` bit =0, once tripped, a trip condition is registered on this channel in the `PWM_STAT.FLTTRIPA` bit and the outputs of that channel are immediately shut down. This condition is called a *fault trip* condition. To resume channel output when a fault trip occurs, write a 1 to clear the `PWM_STAT.FLTTRIPA` bit. A processor write cannot clear the bit when the trip condition is still active. The raw trip status is available for both pins in the `PWM_STAT.RAWTRIP0` register bits.
2. If the `PWM_TRIPCFG.MODE0A` bit =1, once tripped, a trip condition is registered on this channel in the `PWM_STAT.SRTRIPA` bit and the outputs of that channel are immediately shut down. This condition is

called a *self-restart trip* condition. If the trip condition is not active at the next period boundary of the PWMTMRy that the channel is using, the status register bit is cleared. The outputs are restored.

The trip input pins have an external pull-down resistor on the chip pin. If the pin becomes disconnected, the processor disables the PWM.

In addition to the hardware trip conditions, a global software trip bit in the `PWM_CTL` register allows for a software-forced fault trip condition. When the global software trip bit is set to 1, irrespective of the values in the `PWM_TRIPCFG` register, it sets all the `PWM_STAT.FLTTRIPA` bits and also gates the channel outputs. To remove the trip condition from the channel, perform a W1C on the `PWM_STAT.FLTTRIPA` bit of the particular channel.

If the `PWM_TRIPCFG.EN0A` bit is set to 1 to, for any channel, then the occurrence of a fault condition on the `PWMTRIPy` bit is logged in the `PWM_STAT.FLTTRIPA` register bit. If the corresponding `PWM_IMSK.TRIP0` bit = 1, then an interrupt request is generated. Tripping a channel output does not interfere with `PWM_SYNC` generation.

The ***Operation Under Hardware Fault Conditions*** figure shows an example where PWMTRIP0 is enabled on channel A as self-restart trip. Channel A works with the `PWM_CHANCFG.POLAH` bit =1. In period 2, the `PWM_AH` signal is full on modulated, and tries to rise at the period boundary where the self-restart occurs for the channel. However, since the low-side output of the channel was only recently removed due to a trip, the rise edge on `PWM_AH` is delayed until the emergency dead-time period is over. PWMTRIP1 is enabled on channel B as a fault trip. Channel B works with the `PWM_CHANCFG.POLAH` bit =0. PWMTRIP1 stays low for an extended time period. The first processor write to reenable the channel output fails. The second processor write passes since the fault condition has gone away.

NOTE: Dead time is ensured on re-enabling the channel outputs after trip.

NOTE: Programs must not allow changes in the configuration or enable bits of `PWM_TRIPCFG` register within ± 10 clock cycles of when the external trip pulse toggles. (The configuration or enable bits of `PWM_TRIPCFG` register select between trip enable and disable). If this time frame is not followed, then unexpected behavior occurs.

Programming Model

The following sections provide general (and some application-specific) programming steps for configuring and using the PWM module.

- Programming Model for Three-Phase AC Motor Control

Programming Model for Three-Phase AC Motor Control

The ***PWM Module and Interaction with System*** figure shows how the PWM unit (green) interfaces to both software (blue) and hardware (yellow). The software configures the unit, calculates duty cycles (Duty A, Duty B, Duty C), and services the interrupts generated by the module (PWM SYNC IRQ, TRIP IRQ). The hardware applies the gate signals (AH, AL, BH, BL, CH, CL) to the inverter and provides an over-current trip signal back to the unit (TRIP0).

The typical three-phase AC motor configuration shown in the ***PWM Module and Interaction with System*** figure applies for both permanent magnet and induction motor types.

Figure 19-26: PWM Module and Interaction with System

System Parameters

The following system parameters (characteristics) influence the module configuration for this application. This example system features:

- One three-phase AC machine
- B6 inverter
- SVPWM, including both linear- and over-modulation
- Switching frequency of 20 kHz
- Dead time of 1us
- Trip signal generated by hardware
- Active high-level gate drive
- Core frequency of 200 MHz
- Peripheral clock of 100 MHz

System State Sequencing

Managing the system state and sequence of states is critically important when programming the PWM module. The ***PWM System States*** figure provides an overview of these states.

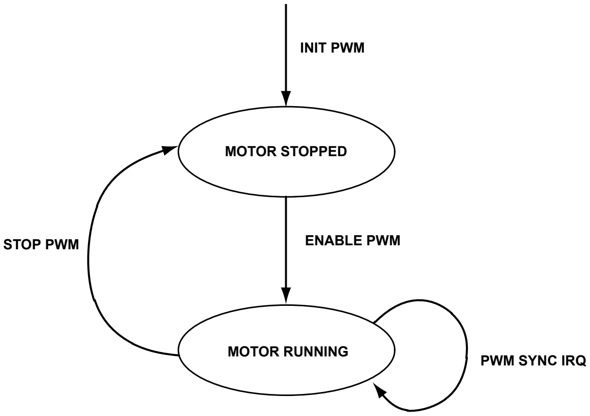

Figure 19-27: PWM System States

As shown in the state diagram, the module configuration is updated on state transitions (indicated by the arrows). The transitions are initialization, motor start, PWM sync interrupt request (on each), and motor stop. The following sections discuss the transitions in detail.

- PWM Initialization for Motor Control
- PWM Enable for Motor Control
- PWM Response to Sync Interrupt for Motor Control
- PWM Disable (and Stop the Motor) for Motor Control

PWM Initialization for Motor Control

The processor must program the PWM at power-up as follows and repeat this programming to bring the PWM and the system into a known (safe) state.

1. Place the PWM module in a safe state and set up synchronization of the module using the following bitwise operations on the `PWM_CTL` and `PWM_CHANCFG` registers:

   ```
   PWM_CTL &= 0xFFE0FF08
   PWM_CTL |= 0x20000
   PWM_CHANCFG &= 0x80808080
   PWM_CHANCFG |= 0x24242424
   ```

   These operations result in the following bit settings:

   - Disable PWM (`PWM_CTL.GLOBEN` =0)
   - Disable delay for channels A, B, C, D (`PWM_CTL.DLYAEN` through `PWM_CTL.DLYDEN` =0). All phases must run with same phase.
   - Use internal synchronization by timer TMR0 (`PWM_CTL.EXTSYNC` =0, `PWM_CTL.EXTSYNCSEL` =1)
   - The same timer, TMR0 (`PWM_CTL.INTSYNCREF` = b#000) synchronizes all phases.

- Low-side is always the inverse of high-side (`PWM_CHANCFG.POLAL` through `PWM_CHANCFG.POLDL` = 1).
- System uses active high gate driver (`PWM_CHANCFG.ENCHOPAH` through `PWM_CHANCFG.ENCHOPDH` =1).
- Disable gate chopping (`PWM_CHANCFG.ENCHOPAL` through `PWM_CHANCFG.ENCHOPDL` =0). PWM does not use the pulse transformer.

2. Set up the trip and associated interrupt requests using the following bitwise operations on the `PWM_TRIPCFG` and `PWM_ILAT` registers:

```
PWM_TRIPCFG &= 0xF0F0F0F0
PWM_TRIPCFG |= 0x1010101
PWM_ILAT &= 0xFFE0FFFC
PWM_ILAT |= 0x1
```

These operations result in the following bit settings:

- All phases must shut down simultaneously in case of fault: (`PWM_TRIPCFG.EN0A` through `PWM_TRIPCFG.EN0D` =0, `PWM_TRIPCFG.MODE0A` through `PWM_TRIPCFG.MODE0D` =0, `PWM_TRIPCFG.EN1A` through `PWM_TRIPCFG.EN1D` =0, `PWM_TRIPCFG.MODE1A` through `PWM_TRIPCFG.MODE1D` =0)
- Enable TRIP0 as fault trigger for all channels (`PWM_TRIPCFG.EN0A` through `PWM_TRIPCFG.MODE1D` =1).
- For thermal control and synchronization, SW intervention is needed at trip. Do not use automatic restart of any channels.
- Generate an interrupt at trip on TRIP0 (`PWM_ILAT.TMR0PER` = 1).

3. Configure the PWM channels using the following bitwise operations on the `PWM_TRIPCFG` and `PWM_ILAT` registers:

```

PWM_CHA_DT=0x32 PWM_CHB_DT=0x32 PWM_CHC_DT=0x32
PWM_TM0 = 0x9C4
PWM_ACTL = 0xFFFFF0000
PWM_BCTL = 0xFFFFF0000
PWM_CCTL = 0xFFFFF0000
PWM_AH0 = 0x0
PWM_BH0 = 0x0
PWM_CH0 = 0x0
```

These operations result in the following bit settings:

- Configure a dead time of 1 μs (DT =0x32 =0x32)
- Configure a PWM frequency of 20 kHz (assuming a system clock frequency of 100Mhz, so a clock divisor of 5000:1) (`PWM_TM0` =0x9C4)

- Disable all outputs (`PWM_ACTL.DISHI` through `PWM_CCTL.DISHI` =0, `PWM_ACTL.DISLO` through `PWM_CCTL.DISLO` =0)
- Use conventional PWM, disable crossover (`PWM_ACTL.XOVR` through `PWM_CCTL.XOVR` =0)
- Use symmetrical pulse position on all outputs (`PWM_ACTL.PULSEMODEHI` through `PWM_CCTL.PULSEMODEHI` =0, `PWM_ACTL.PULSEMODELO` through `PWM_CCTL.PULSEMODELO` =0)
- Set an initial duty-cycle of 50% (`PWM_AH0` through`PWM_CH0` =0x0)

PWM Enable for Motor Control

The processor must do the following programming to enable the PWM before starting the motor.

1. Start the PWM timer TMR0 using the `PWM_CTL |=0x1` bitwise operation on the `PWM_CTL` register.

   ADDITIONAL INFORMATION: This operation has the same effect as setting the `PWM_CTL.GLOBEN` bit =1.

2. Enable six PWM outputs using the following bitwise operations on the `PWM_ACTL` through `PWM_CCTL` registers.

   ```
   PWM_ACTL|=0x3
   PWM_BCTL|=0x3
   PWM_CCTL|=0x3
   ```

   ADDITIONAL INFORMATION: These operations have the same effect as enabling high and low-side channel outputs by setting the `PWM_ACTL.DISHI` through `PWM_CCTL.DISHI` bits =1 and the `PWM_ACTL.DISLO` through `PWM_CCTL.DISLO` bits =1.

3. Enable the PWM TRIP0 interrupt using the `PWM_ILAT |= 0x1` bitwise operation on the `PWM_ILAT` register.

   ADDITIONAL INFORMATION: This operation has the same effect as setting the `PWM_ILAT.TRIP0` bit =1

PWM Response to Sync Interrupt for Motor Control

When the PWM sync interrupt occurs, the processor could need to update to the PWM duty cycle with a value calculated by the motor control algorithm. This application uses symmetric pulses position and uses dependent high and low-side output. So, the PWM updates only one register for each phase.

1. Write the new duty cycle value (calculated by motor control algorithm) to the timer when the sync interrupt occurs.

   The following bitwise operations on the `PWM_AH0` through `PWM_CH0` registers accomplish this task:

```
PWM_AH0 = Duty_A_mc_algorithm_current_value
PWM_BH0 = Duty_B_mc_algorithm_current_value
PWM_CH0 = Duty_C_mc_algorithm_current_value
```

PWM Disable (and Stop the Motor) for Motor Control

The processor must program the PWM as follows to stop the motor, disable the PWM, and disable PWM interrupts. These actions place the PWM and system in a safe, passive state.

1. Disable the PWM timer using the `PWM_CTL &= 0xFFFFFFFE` bitwise operation on the `PWM_CTL` register.

   ADDITIONAL INFORMATION: This operation has the same effect as clearing the `PWM_CTL.GLOBEN` bit =0.

2. Disable all PWM outputs using the following bitwise operations on the `PWM_ACTL` through `PWM_CCTL` registers.

   ```
   PWM_ACTL &= 0xFFFFFFFFC
   PWM_BCTL &= 0xFFFFFFFFC
   PWM_CCTL &= 0xFFFFFFFFC
   ```

   These operations disable PWM outputs where the `PWM_ACTL.DISHI` through `PWM_CCTL.DISHI` bits =1 and the `PWM_ACTL.DISLO` through `PWM_CCTL.DISLO` bits =0)

3. Set the PWM duty-cycle to 50% using the following bitwise operations on the `PWM_AH0` through `PWM_CH0` registers.

   ```
   PWM_AH0 =0x0
   PWM_BH0 =0x0
   PWM_CH0 =0x0
   ```

   These operations have the same effect as clearing the `PWM_AH0.DUTY` through `PWM_CH0.DUTY` bit =0.

4. Disable the PWM TRIP0 interrupt request using the `PWM_ILAT &= 0xFFFFFFFE` bitwise operation on the `PWM_ILAT` register.

   ADDITIONAL INFORMATION: This operation has the same effect as clearing the PWM TRIP0 interrupt request `PWM_ILAT.TRIP0` =0.

ADSP-SC58x PWM Register Descriptions

Pulse-Width Modulator (PWM) contains the following registers.

Table 19-5: ADSP-SC58x PWM Register List

Name	Description
`PWM_ACTL`	Channel A Control Register

Table 19-6: PWM_ACTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	PULSEMODELO	Low Side Output Pulse Position. The PWM_ACTL.PULSEMODELO bits select the pulse position for Channel A low side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_AL0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (PWM_AL0 and PWM_AL1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (PWM_AL0 and PWM_AL1).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half

9:8 (R/W)	PULSEMODEHI	High Side Output Pulse Position. The `PWM_ACTL.PULSEMODEHI` bits select the pulse position for Channel A high side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the `PWM_AH0` register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (`PWM_AH0` and `PWM_AH1`). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (`PWM_AH0` and `PWM_AH1`).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half
2 (R/W)	XOVR	high-low Crossover Enable. The `PWM_ACTL.XOVR` bit enables crossover between the channels high and low side outputs. When enabled, this bit directs the PWM to send the low-side output through the high-side output pin and the high-side output through the low side output pin.	
		0	Disable Crossover
		1	Enable Crossover
1 (R/W)	DISLO	Channel Low Side Output Disable. The `PWM_ACTL.DISLO` bit enables the channels low side output.	
		0	Enable Low Side Output
		1	Disable Low Side Output
0 (R/W)	DISHI	Channel High Side Output Disable. The `PWM_ACTL.DISHI` bit enables the channels high side output.	
		0	Enable High Side Output
		1	Disable High Side Output

Channel A-High Duty-0 Register

The PWM_AH0 and PWM_AH1 registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the high side output pulses for the channel A duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the `PWM_ACTL.PULSEMODEHI` bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM_AH0 register to determine the assertion and deassertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel A high pulse output for a count less than PWM_AH0 and deasserts this output for a count greater than PWM_AH1.

The value range for the PWM_AH0 and PWM_AH1 registers depends on the period of the timer being used by the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 (two's complement) and +PWM_TM0/2, when dead time (PWM_CHA_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM_AH0 and PWM_AH1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 + PWM_CHA_DT (two's complement) and +PWM_TM0/2 + PWM_CHA_DT.

When dead time is considered for left half or right half pulse modes, if PWM_TM0 is used, the duty cycle values may be between PWM_TM0/2 + PWM_CHA_DT (two's complement) and -PWM_TM0/2 - PWM_CHA_DT .

Note that using values in the PWM_AH0 or PWM_AH1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

DUTY (R/W)
Coarse Duty Value

Figure 19-34: PWM_AH_DUTY1 Register Diagram

Table 19-12: PWM_AH_DUTY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DUTY	Coarse Duty Value. The `PWM_AH_DUTY1.DUTY` bits determine the output pulse-widths in the normal PWM operation. When heightened-precision edge placement is enabled, the `PWM_AH_DUTY1.DUTY` bit field forms the integer part of a non-integer, fixed-point duty cycle value in Q15.8 format.
15:14 (R/W)	ENHDIV	Enhanced Precision Divider Bits. The `PWM_AH_DUTY1.ENHDIV` bits form the decimal part of a non-integer, fixed-point duty cycle value when heightened-precision edge placement is enabled in Q15.8 format.

Channel A-Low Duty-0 Register

The `PWM_AL0` and `PWM_AL1` registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the low side output pulses for the channel A duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the `PWM_ACTL.PULSEMODELO` bits. When the pulse mode is symmetrical, the PWM uses the value in the `PWM_AL0` register to determine the assertion and deassertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel A low pulse output for count less than `PWM_AL0` and deasserts this output for count greater than `PWM_AL1`.

The value range for the `PWM_AL0` and `PWM_AL1` registers depends on the period of the timer being used by the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 (two's complement) and +`PWM_TM0`/2, when dead time (`PWM_CHA_DT`) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for `PWM_AL0` and `PWM_AL1` depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 + `PWM_CHA_DT` (two's complement) and +`PWM_TM0`/2 + `PWM_CHA_DT`.

When dead time is considered for left half or right half pulse modes, if `PWM_TM0` is used, the duty cycle values may be between `PWM_TM0`/2 + `PWM_CHA_DT` (two's complement) and -`PWM_TM0`/2 - `PWM_CHA_DT`.

Note that using values in the `PWM_AL0` or `PWM_AL1` registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

		1	Asymmetrical
		2	Left Half
		3	Right Half

Table 19-19: PWM_BCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9:8 (R/W)	PULSEMODEHI	High Side Output Pulse Position. The `PWM_BCTL.PULSEMODEHI` bits select the pulse position for Channel B high side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the `PWM_BH0` register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (`PWM_BH0` and `PWM_BH1`). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (`PWM_BH0` and `PWM_BH1`). 0 Symmetrical 1 Asymmetrical 2 Left Half 3 Right Half
2 (R/W)	XOVR	high-low Crossover Enable. The `PWM_BCTL.XOVR` bit enables crossover between the channels high and low side outputs. When enabled, this bit directs the PWM to send the low-side output through the high-side output pin and the high-side output through the low side output pin. 0 Disable Crossover 1 Enable Crossover
1 (R/W)	DISLO	Channel Low Side Output Disable. The `PWM_BCTL.DISLO` bit enables the channels low side output. 0 Enable Low Side Output 1 Disable Low Side Output
0 (R/W)	DISHI	Channel High Side Output Disable. The `PWM_BCTL.DISHI` bit enables the channels high side output. 0 Enable High Side Output 1 Disable High Side Output

Channel B-High Duty-0 Register

The `PWM_BH0` and `PWM_BH1` registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the high side output pulses for the channel B duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the `PWM_BCTL.PULSEMODEHI` bits. When the pulse mode is symmetrical, the PWM uses the value in the `PWM_BH0` register to determine the assertion and deassertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel B high pulse output for count less than `PWM_BH0` and deasserts this output for count greater than `PWM_BH1`.

The value range for the `PWM_BH0` and `PWM_BH1` registers depends on the period of the timer being used by the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 (two's complement) and +`PWM_TM0`/2, when dead time (`PWM_CHB_DT`) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for `PWM_BH0` and `PWM_BH1` depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 + `PWM_CHB_DT` (two's complement) and +`PWM_TM0`/2 + `PWM_CHB_DT`.

When dead time is considered for left half or right half pulse modes, if `PWM_TM0` is used, the duty cycle values may be between `PWM_TM0`/2 + `PWM_CHB_DT` (two's complement) and -`PWM_TM0`/2 - `PWM_CHB_DT`.

Note that using values in the `PWM_BH0` or `PWM_BH1` registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

When heightened-precision edge placement is enabled, the `PWM_BH_DUTY1.DUTY` bit field forms the integer part of a non-integer, fixed-point duty cycle value in Q15.8 format.
15:14 (R/W)	ENHDIV	Enhanced Precision Divider Bits. The `PWM_BH_DUTY1.ENHDIV` bits form the decimal part of a non-integer, fixed-point duty cycle value when heightened-precision edge placement is enabled in Q15.8 format.

Channel B-Low Duty-0 Register

The `PWM_BL0` and `PWM_BL1` registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the low side output pulses for the channel B duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the `PWM_BCTL.PULSEMODELO` bits. When the pulse mode is symmetrical, the PWM uses the value in the `PWM_BL0` register to determine the assertion and deassertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel B low pulse output for count less than `PWM_BL0` and deasserts this output for count greater than `PWM_BL1`.

The value range for the `PWM_BL0` and `PWM_BL1` registers depends on the period of the timer being used by the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 (two's complement) and +`PWM_TM0`/2, when dead time (`PWM_CHB_DT`) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for `PWM_BL0` and `PWM_BL1` depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 + `PWM_CHB_DT` (two's complement) and +`PWM_TM0`/2 + `PWM_CHB_DT`.

When dead time is considered for left half or right half pulse modes, if `PWM_TM0` is used, the duty cycle values may be between `PWM_TM0`/2 + `PWM_CHB_DT` (two's complement) and -`PWM_TM0`/2 - `PWM_CHB_DT`.

Note that using values in the `PWM_BL0` or `PWM_BL1` registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

Channel B-Low Heightened-Precision Duty-1 Register

The `PWM_BL1_HP` register provides a fine-grained edge placement within the system clock period. This register, in conjunction with the `PWM_BL1` register, allows programs to specify fractional duty cycles. The `PWM_BL1_HP` register and the `PWM_BL1` register work together in a Q15.8 signed two's complement fixed-point format.

Note that the bit fields in the `PWM_BL1_HP` and the `PWM_BL1` registers are also present in the single full duty register (if available).

Channel B-Low Full Duty0 Register

The full duty registers can be used instead of the combined duty and heightened-precision duty registers.The `PWM_BL_DUTY0` register contains the `PWM_BL_DUTY0.DUTY` bit field from the `PWM_BL0` register and the `PWM_BL_DUTY0.ENHDIV` bit field from the `PWM_BL0_HP` register.

Note that the `PWM_BL_DUTY0` register reads the `PWM_BL0` and the `PWM_BL0_HP` register values and visa-versa.

When heightened-precision edge placement is enabled, bits [15:8] of these registers form the decimal part of a non-integer, fixed-point duty cycle value in Q15.8 format. The lowest bits are ignored.

Figure 19-54: PWM_CCTL Register Diagram

Table 19-32: PWM_CCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	PULSEMODELO	Low Side Output Pulse Position. The PWM_CCTL.PULSEMODELO bits select the pulse position for Channel C low side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_CL0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (PWM_CL0 and PWM_CL1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (PWM_CL0 and PWM_CL1).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half

Table 19-32: PWM_CCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	PULSEMODEHI	High Side Output Pulse Position. The `PWM_CCTL.PULSEMODEHI` bits select the pulse position for Channel C high side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the `PWM_CH0` register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (`PWM_CH0` and `PWM_CH1`). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (`PWM_CH0` and `PWM_CH1`).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half
2 (R/W)	XOVR	high-low Crossover Enable. The `PWM_CCTL.XOVR` bit enables crossover between the channels high and low side outputs. When enabled, this bit directs the PWM to send the low-side output through the high-side output pin and the high-side output through the low side output pin.	
		0	Disable Crossover
		1	Enable Crossover
1 (R/W)	DISLO	Channel Low Side Output Disable. The `PWM_CCTL.DISLO` bit enables the channels low side output.	
		0	Enable Low Side Output
		1	Disable Low Side Output
0 (R/W)	DISHI	Channel High Side Output Disable. The `PWM_CCTL.DISHI` bit enables the channels high side output.	
		0	Enable High Side Output
		1	Disable High Side Output

Channel C-High Pulse Duty Register 0

The `PWM_CH0` and `PWM_CH1` registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the high side output pulses for the channel C duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the `PWM_CCTL.PULSEMODEHI` bits. When the pulse mode is symmetrical, the PWM uses the value in the `PWM_CH0` register to determine the assertion and deassertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel C high pulse output for count less than `PWM_CH0` and deasserts this output for count greater than `PWM_CH1`.

The value range for the `PWM_CH0` and `PWM_CH1` registers depends on the period of the timer being used by the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 (two's complement) and +`PWM_TM0`/2, when dead time (`PWM_CHC_DT`) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for `PWM_CH0` and `PWM_CH1` depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 + `PWM_CHC_DT` (two's complement) and +`PWM_TM0`/2 + `PWM_CHC_DT`.

When dead time is considered for left half or right half pulse modes, if `PWM_TM0` is used, the duty cycle values may be between `PWM_TM0`/2 + `PWM_CHC_DT` (two's complement) and -`PWM_TM0`/2 - `PWM_CHC_DT`.

Note that using values in the `PWM_CH0` or `PWM_CH1` registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

Table 19-37: PWM_CHANCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
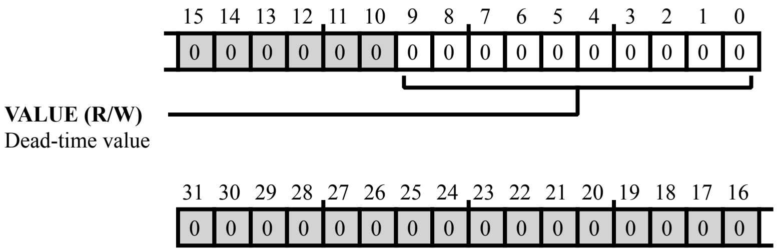
1 (R/W)	MODELSA	Channel A Mode of low Side Output. The `PWM_CHANCFG.MODELSA` bit selects whether the low side output waveform is based on independent controls or whether the low side output depends on the high side output controls. When `PWM_CHANCFG.MODELSA` =0, the low side output is an inverted form of the high side output, which is generated using the `PWM_AH0` and `PWM_AH1` registers for pulse width, using the `PWM_ACTL.PULSEMODEHI` bits for pulse positioning, and `PWM_CHANCFG.POLAH` bits for polarity.	
		0	Invert of high output
		1	Independent control
0 (R/W)	REFTMRA	Channel A Timer Reference. The `PWM_CHANCFG.REFTMRA` bit selects whether the PWM uses PWMTMR1 or PWMTMR0 as the reference timer for Channel A operation.	
		0	PWMTMR0 is Channel A reference
		1	PWMTMR1 is Channel A reference

Channel A Dead-time Register

The `PWM_CHA_DT` register controls the value of dead-time for channel A independently.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

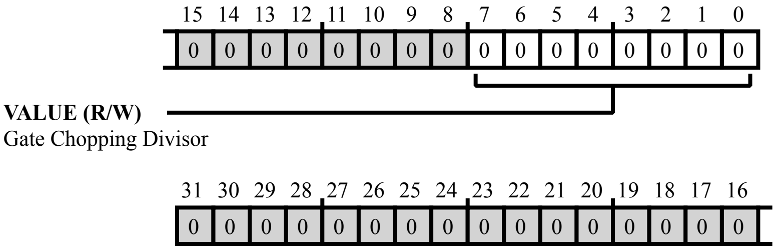
Table 19-41: PWM_CHD_DT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	VALUE	Dead-time value. The `PWM_CHD_DT.VALUE` bit field contains the dead-time value.

Chop Configuration Register

The `PWM_CHOPCFG` register holds a divisor value that controls the chopping frequency. The PWM permits a mixing of the output signals with a high-frequency chopping signal to aid with interfacing to pulse transformers. Also note that high-frequency chopping may be independently enabled for each channel's high-side and the low-side outputs using channel control bits. (For example, control chopping for Channel A with the `PWM_CHANCFG.ENCHOPAH` and `PWM_CHANCFG.ENCHOPAH` bits.)



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R/W)
Gate Chopping Divisor

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 19-64: PWM_CHOPCFG Register Diagram

Table 19-42: PWM_CHOPCFG Register Fields

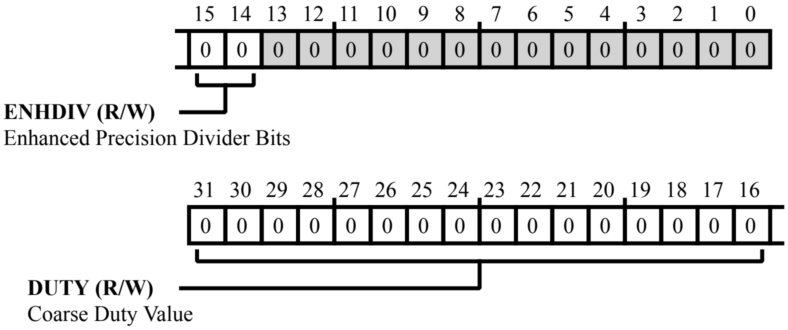
Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Gate Chopping Divisor. The `PWM_CHOPCFG.VALUE` bits provide the high frequency chopping divisor. When the divisor value is changed, the new period takes effect from the next edge of the chopping signal. The `PWM_CHOPCFG.VALUE` value may be calculated using either of the following formulas: CHOPDIV = $[(T_{CHOP}/T_{CK}) / 4] - 1$ CHOPDIV = $[(f_{CK} / f_{CHOP}) / 4] - 1$

Channel C-High Full Duty0 Register

The full duty registers can be used instead of the combined duty and heightened-precision duty registers.The `PWM_CH_DUTY0` register contains the `PWM_CH_DUTY0.DUTY` bit field from the `PWM_CH0` register and the `PWM_CH_DUTY0.ENHDIV` bit field from the `PWM_CH0_HP` register.

Note that the `PWM_CH_DUTY0` register reads the `PWM_CH0` and the `PWM_CH0_HP` register values and visa-versa.

When heightened-precision edge placement is enabled, bits [15:8] of these registers form the decimal part of a non-integer, fixed-point duty cycle value in Q15.8 format. The lowest bits are ignored.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

DUTY (R/W)
Coarse Duty Value

Figure 19-66: PWM_CH_DUTY1 Register Diagram

Table 19-44: PWM_CH_DUTY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DUTY	Coarse Duty Value. The PWM_CH_DUTY1.DUTY bits determine the output pulse-widths in the normal PWM operation. When heightened-precision edge placement is enabled, the PWM_CH_DUTY1.DUTY bit field forms the integer part of a non-integer, fixed-point duty cycle value in Q15.8 format.
15:14 (R/W)	ENHDIV	Enhanced Precision Divider Bits. The PWM_CH_DUTY1.ENHDIV bits form the decimal part of a non-integer, fixed-point duty cycle value when heightened-precision edge placement is enabled in Q15.8 format.

Channel C-Low Pulse Duty Register 0

The PWM_CL0 and PWM_CL1 registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the low side output pulses for the channel C duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM_CCTL.PULSEMODELO bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM_CL0 register to determine the assertion and deassertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel C low pulse output for count less than PWM_CL0 and deasserts this output for count greater than PWM_CL1.

The value range for the PWM_CL0 and PWM_CL1 registers depends on the period of the timer being used by the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 (two's complement) and +PWM_TM0/2, when dead time (PWM_CHC_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM_CL0 and PWM_CL1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 + PWM_CHC_DT (two's complement) and +PWM_TM0/2 + PWM_CHC_DT.

When dead time is considered for left half or right half pulse modes, if PWM_TM0 is used, the duty cycle values may be between PWM_TM0/2 + PWM_CHC_DT (two's complement) to -PWM_TM0/2 - PWM_CHC_DT.

Note that using values in the PWM_CL0 or PWM_CL1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

Table 19-45: PWM_CL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	DUTY	Duty Cycle Asserted Count. The PWM_CL0.DUTY bits select the duty cycle asserted count for Channel C low side output.

Channel C-Low Pulse Duty Register 1

The `PWM_CL0_HP` register provides a fine-grained edge placement within the system clock period. This register, in conjunction with the `PWM_CL0` register, allows programs to specify fractional duty cycles. The `PWM_CL0_HP` register and the `PWM_CL0` register work together in a Q15.8 signed two's complement fixed-point format.

Note that the bit fields in the `PWM_CL0_HP` and the `PWM_CL0` registers are also present in the single full duty register (if available).

Timer reference for Internal Sync
EXTSYNCSEL (R/W)
External Sync Select
EXTSYNC (R/W)
External Sync

Figure 19-73: PWM_CTL Register Diagram

Table 19-51: PWM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:18 (R/W)	INTSYNCREF	Timer reference for Internal Sync. The `PWM_CTL.INTSYNCREF` bits select the timer reference for the internal sync. Note that all other combinations reserved.	
		0	PWMTMR0 provides sync reference
		1	PWMTMR1 provides sync reference
		2	PWMTMR2 provides sync reference
		3	PWMTMR3 provides sync reference
		4	PWMTMR4 provides sync reference

Table 19-51: PWM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	EXTSYNCSEL	External Sync Select. The `PWM_CTL.EXTSYNCSEL` bit selects whether the external sync signal is synchronous or asynchronous. Note that latency in PWM sync response differs between asynchronous and synchronous external sync modes. For more information, see the PWM functional description.	
		0	Asynchronous External Sync
		1	Synchronous External Sync
16 (R/W)	EXTSYNC	External Sync. The `PWM_CTL.EXTSYNC` bit selects whether the PWM uses an external or internal sync signal for the main timer (PWMTMR0). Do not change the value of the `PWM_CTL.EXTSYNC` bit while the PWM is enabled (`PWM_CTL.GLOBEN` =1).	
		0	Internal sync used
		1	External sync used
8 (R/W)	ADEN	Asymmetric Dead-time Enable. When symmetric dead-time is enabled (`PWM_CTL.ADEN` = 0), in the dependent mode, both the high-side and low-side outputs are reduced by DT cycles on both the assertion and de-assertion edges. When symmetric dead-time is disabled (`PWM_CTL.ADEN` = 1), the falling edges of both high and low-side outputs occur at the programmed duty value, but their rise-times are delayed by 2 x DT.	
		0	Dead-time is symmetric
		1	Dead-time is asymmetric
7 (R/W)	DLYDEN	Enable Delay Counter for Channel D. The `PWM_CTL.DLYDEN` bit enables the Channel D delay counter, supporting phase-offset control. Do not change the value of the `PWM_CTL.DLYDEN` bit while the PWM is enabled (`PWM_CTL.GLOBEN` =1).	
		0	Disable
		1	Enable
6 (R/W)	DLYCEN	Enable Delay Counter for Channel C. The `PWM_CTL.DLYCEN` bit enables the Channel C delay counter, supporting phase-offset control. Do not change the value of the `PWM_CTL.DLYCEN` bit while the PWM is enabled (`PWM_CTL.GLOBEN` =1).	
		0	Disable
		1	Enable

Table 19-51: PWM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	DLYBEN	Enable Delay Counter for Channel B. The `PWM_CTL.DLYBEN` bit enables the Channel B delay counter, supporting phase-offset control. Do not change the value of the `PWM_CTL.DLYBEN` bit while the PWM is enabled (`PWM_CTL.GLOBEN` =1).	
		0	Disable
		1	Enable
4 (R/W)	DLYAEN	Enable Delay Counter for Channel A. The `PWM_CTL.DLYAEN` bit enables the Channel A delay counter, supporting phase-offset control. Do not change the value of the `PWM_CTL.DLYAEN` bit while the PWM is enabled (`PWM_CTL.GLOBEN` =1).	
		0	Disable
		1	Enable
3 (R/W)	DUEN	Double Update Mode Enable. In Single Update Mode, double buffering of all registers happens at the period boundary of the PWM timer. In Double Update Mode, double buffering of all registers (except delay counter registers) happens at the middle of the period as well as the beginning of the period.	
		0	Single Update Mode
		1	Double Update Mode
2 (R0/W)	SWTRIP	Software Trip. The `PWM_CTL.SWTRIP` bit permits tripping a fault condition through software, shutting down PWM output. This bit always read as 0. If the `PWM_CTL.SWTRIP` bit and `PWM_CTL.GLOBEN` bit are set in the same write, the write does not trip the fault condition.	
		0	Don't force fault
		1	Force a Fault Trip Condition
1 (R/W)	EMURUN	Output Behavior During Emulation Mode. The `PWM_CTL.EMURUN` bit selects PWM output behavior during emulation mode.	
		0	Disable Outputs
		1	Enable Outputs

Table 19-51: PWM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	GLOBEN	Module Enable. The `PWM_CTL.GLOBEN` bit enables the PWM, enabling all timers and outputs. While this bit is enabled, processor code should not change the value of the `PWM_CTL.DLYAEN` bit, `PWM_CTL.DLYBEN` bit, `PWM_CTL.DLYCEN` bit, `PWM_CTL.DLYDEN` bit, `PWM_CTL.EXTSYNCSEL` bit, or any bits in the `PWM_CHANCFG` register. Note that there is a latency between PWM disable and the cessation of output waveforms. There is also a latency between PWM enable and start of output waveforms. For the latency description, see the PWM functional description.	
		0	Disable
		1	Enable

Channel D Control Register

The PWM_DCTL register selects the low and high side output pulse mode, enables low and high side output, and enables low/high side output crossover.

Table 19-52: PWM_DCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	PULSEMODELO	Low Side Output Pulse Position. The PWM_DCTL.PULSEMODELO bits select the pulse position for Channel D low side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_DL0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (PWM_DL0 and PWM_DL1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (PWM_DL0 and PWM_DL1).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half

Table 19-52: PWM_DCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	PULSEMODEHI	High Side Output Pulse Position. The `PWM_DCTL.PULSEMODEHI` bits select the pulse position for Channel D high side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the `PWM_DH0` register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (`PWM_DH0` and `PWM_DH1`). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (`PWM_DH0` and `PWM_DH1`).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half
2 (R/W)	XOVR	high-low Crossover Enable. The `PWM_DCTL.XOVR` bit enables crossover between the channels high and low side outputs. When enabled, this bit directs the PWM to send the low-side output through the high-side output pin and the high-side output through the low side output pin.	
		0	Disable Crossover
		1	Enable Crossover
1 (R/W)	DISLO	Channel Low Side Output Disable. The `PWM_DCTL.DISLO` bit enables the channels low side output.	
		0	Enable Low Side Output
		1	Disable Low Side Output
0 (R/W)	DISHI	Channel High Side Output Disable. The `PWM_DCTL.DISHI` bit enables the channels high side output.	
		0	Enable High Side Output
		1	Disable High Side Output

Channel D-High Duty-0 Register

The `PWM_DH0` and `PWM_DH1` registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the high side output pulses for the channel D duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the `PWM_DCTL.PULSEMODEHI` bits. When the pulse mode is symmetrical, the PWM uses the value in the `PWM_DH0` register to determine the assertion and deassertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel D high pulse output for count less than `PWM_DH0` and deasserts this output for count greater than `PWM_DH1`.

The value range for the `PWM_DH0` and `PWM_DH1` registers depends on the period of the timer being used by the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 (two's complement) and +`PWM_TM0`/2, when dead time (`PWM_CHD_DT`) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for `PWM_DH0` and `PWM_DH1` depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 + `PWM_CHD_DT` (two's complement) to +`PWM_TM0`/2 + `PWM_CHD_DT`.

When dead time is considered for left half or right half pulse modes, if `PWM_TM0` is used, the duty cycle values may be between `PWM_TM0`/2 + `PWM_CHD_DT` (two's complement) to -`PWM_TM0`/2 - `PWM_CHD_DT`.

Note that using values in the `PWM_DH0` or `PWM_DH1` registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

Channel D-High Pulse Heightened-Precision Duty Register 0

The `PWM_DH0_HP` register provides a fine-grained edge placement within the system clock period. This register, in conjunction with the `PWM_DH0` register, allows programs to specify fractional duty cycles. The `PWM_DH0_HP` register and the `PWM_DH0` register work together in a Q15.8 signed two's complement fixed-point format.

Note that the bit fields in the `PWM_DH0_HP` and the `PWM_DH0` registers are also present in the single full duty register (if available).

Channel D-High Full Duty0 Register

The full duty registers can be used instead of the combined duty and heightened-precision duty registers.The `PWM_DH_DUTY0` register contains the `PWM_DH_DUTY0.DUTY` bit field from the `PWM_DH0` register and the `PWM_DH_DUTY0.ENHDIV` bit field from the `PWM_DH0_HP` register.

Note that the `PWM_DH_DUTY0` register reads the `PWM_DH0` and the `PWM_DH0_HP` register values and visa-versa.

When heightened-precision edge placement is enabled, bits [15:8] of these registers form the decimal part of a non-integer, fixed-point duty cycle value in Q15.8 format. The lowest bits are ignored.

When heightened-precision edge placement is enabled, the `PWM_DH_DUTY1.DUTY` bit field forms the integer part of a non-integer, fixed-point duty cycle value in Q15.8 format.
15:14 (R/W)	ENHDIV	Enhanced Precision Divider Bits. The `PWM_DH_DUTY1.ENHDIV` bits form the decimal part of a non-integer, fixed-point duty cycle value when heightened-precision edge placement is enabled in Q15.8 format.

Channel D-Low Pulse Duty Register 0

The `PWM_DL0` and `PWM_DL1` registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the low side output pulses for the channel D duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the `PWM_DCTL.PULSEMODELO` bits. When the pulse mode is symmetrical, the PWM uses the value in the `PWM_DL0` register to determine the assertion and deassertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel D low pulse output for count less than `PWM_DL0` and deasserts this output for count greater than `PWM_DL1`.

The value range for the `PWM_DL0` and `PWM_DL1` registers depends on the period of the timer being used by the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 (two's complement) and +`PWM_TM0`/2, when dead time (`PWM_CHD_DT`) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for `PWM_DL0` and `PWM_DL1` depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if `PWM_TM0` is used, the duty cycle values may be between -`PWM_TM0`/2 + `PWM_CHD_DT` (two's complement) and +`PWM_TM0`/2 + `PWM_CHD_DT`.

When dead time is considered for left half or right half pulse modes, if `PWM_TM0` is used, the duty cycle values may be between `PWM_TM0`/2 + `PWM_CHD_DT` (two's complement) and -`PWM_TM0`/2 - `PWM_CHD_DT`.

Note that using values in the `PWM_DL0` or `PWM_DL1` registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

Channel A Delay Register

The `PWM_DLYA` register controls a delay for the Channel A timer (only PWMTMR1, PWMTMR2, PWMTMR3 or PWMTMR4) with reference to the main timer (PWMTMR0). To use apply this delay, the delay must be enabled (`PWM_CTL.DLYAEN` =1). For more information about applying the delay, see the PWM Functional Description section. Note that the `PWM_DLYA` delay value must be less that less that twice the period value of the timer being used for the channel (for example, if PWMTMR1 is used, `PWM_DLYA` must be less than 2xPWMTMR1). Also, note that the period of the main timer must be an integer multiple of the timer being used for the channel (for example, if PWMTMR1 is used, PWMTMR0 = NxPWMTMR1, where N is an integer).

15:14 (R/W)	ENHDIV	Enhanced Precision Divider Bits. The `PWM_DL_DUTY0.ENHDIV` bits form the decimal part of a non-integer, fixed-point duty cycle value when heightened-precision edge placement is enabled in Q15.8 format.

Channel D-Low Full Duty1 Register

The full duty registers can be used instead of the combined duty and heightened-precision duty registers.The `PWM_DL_DUTY1` register contains the `PWM_DL_DUTY1.DUTY` bit field from the `PWM_DL1` register and the `PWM_DL_DUTY1.ENHDIV` bit field from the `PWM_DL1_HP` register.

Note that the `PWM_DL_DUTY1` register reads the `PWM_DL1` and the `PWM_DL1_HP` register values and visa-versa.

When heightened-precision edge placement is enabled, bits [15:8] of these registers form the decimal part of a non-integer, fixed-point duty cycle value in Q15.8 format. The lowest bits are ignored.

Table 19-68: PWM_DL_DUTY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DUTY	Coarse Duty Value. The `PWM_DL_DUTY1.DUTY` bits determine the output pulse-widths in the normal PWM operation. When heightened-precision edge placement is enabled, the `PWM_DL_DUTY1.DUTY` bit field forms the integer part of a non-integer, fixed-point duty cycle value in Q15.8 format.
15:14 (R/W)	ENHDIV	Enhanced Precision Divider Bits. The `PWM_DL_DUTY1.ENHDIV` bits form the decimal part of a non-integer, fixed-point duty cycle value when heightened-precision edge placement is enabled in Q15.8 format.

Interrupt Latch Register

The `PWM_ILAT` register latches the occurrence of unmasked (enabled) PWM interrupt requests. These interrupt requests are unmasked or masked with the `PWM_IMSK` register.

		1	Interrupt Latched
16 (R/W1C)	TMR0PER	PWMTMR0 Period Boundary Interrupt Latched Status. The `PWM_ILAT.TMR0PER` bit indicates the latched status of the PWMTMR0 period boundary interrupt request.	
		0	No Interrupt Latched
		1	Interrupt Latched
1 (R/W1C)	TRIP1	TRIP1 Interrupt Latched Status. The `PWM_ILAT.TRIP1` bit indicates the latched status of the TRIP1 interrupt request.	
		0	No Interrupt Latched
		1	Interrupt Latched
0 (R/W1C)	TRIP0	TRIP0 Interrupt Latched Status. The `PWM_ILAT.TRIP0` bit indicates the latched status of the TRIP0 interrupt request.	
		0	No Interrupt Latched
		1	Interrupt Latched

Interrupt Mask Register

The `PWM_IMSK` register masks (disables) or unmasks (enables) PWM interrupt requests. When an unmasked interrupt occurs, the PWM latches the interrupt status in the `PWM_ILAT` register.

20 (R/W1C)	TMR4PER	PWMTMR4 Period Boundary Status. The `PWM_STAT.TMR4PER` bit indicates whether or not the PWMTMR4 period boundary has been reached.	
		0	PWMTMR4 period boundary not reached
		1	PWMTMR4 period boundary reached
19 (R/W1C)	TMR3PER	PWMTMR3 Period Boundary Status. The `PWM_STAT.TMR3PER` bit indicates whether or not the PWMTMR3 period boundary has been reached.	
		0	PWMTMR3 period boundary not reached
		1	PWMTMR3 period boundary reached
18 (R/W1C)	TMR2PER	PWMTMR2 Period Boundary Status. The `PWM_STAT.TMR2PER` bit indicates whether or not the PWMTMR2 period boundary has been reached.	
		0	PWMTMR2 period boundary not reached
		1	PWMTMR2 period boundary reached
17 (R/W1C)	TMR1PER	PWMTMR1 Period Boundary Status. The `PWM_STAT.TMR1PER` bit indicates whether or not the PWMTMR1 period boundary has been reached.	
		0	PWMTMR1 period boundary not reached
		1	PWMTMR1 period boundary reached
16 (R/W1C)	TMR0PER	PWMTMR0 Period Boundary Status. The `PWM_STAT.TMR0PER` bit indicates whether or not the PWMTMR0 period boundary has been reached.	
		0	PWMTMR0 period boundary not reached
		1	PWMTMR0 period boundary reached
11 (R/NW)	SRTRIPD	Self-Restart Trip Status for Channel D. The `PWM_STAT.SRTRIPD` bit indicates whether the PWM Channel D self-restart has been tripped. For more information, see the `PWM_TRIPCFG.MODE0A` bit description.	
		0	Channel D Self-Restart Trip Status is "not tripped"
		1	Channel D Self-Restart Trip Status is "tripped"

Table 19-71: PWM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W1C)	FLTTRIPD	Fault Trip Status for Channel D. The `PWM_STAT.FLTTRIPD` bit indicates whether the PWM Channel D fault has been tripped. For more information, see the `PWM_TRIPCFG.MODE0A` bit description.	
		0	Channel D Fault Trip Status is "not tripped"
		1	Channel D Fault Trip Status is "tripped"
9 (R/NW)	SRTRIPC	Self-Restart Trip Status for Channel C. The `PWM_STAT.SRTRIPC` bit indicates whether the PWM Channel C self-restart has been tripped. For more information, see the `PWM_TRIPCFG.MODE0A` bit description.	
		0	Channel C Self-Restart Trip Status is "not tripped"
		1	Channel C Self-Restart Trip Status is "tripped"
8 (R/W1C)	FLTTRIPC	Fault Trip Status for Channel C. The `PWM_STAT.FLTTRIPC` bit indicates whether the PWM Channel C fault has been tripped. For more information, see the `PWM_TRIPCFG.MODE0A` bit description.	
		0	Channel C Fault Trip Status is "not tripped"
		1	Channel C Fault Trip Status is "tripped"
7 (R/NW)	SRTRIPB	Self-Restart Trip Status for Channel B. The `PWM_STAT.SRTRIPB` bit indicates whether the PWM Channel B self-restart has been tripped. For more information, see the `PWM_TRIPCFG.MODE0A` bit description.	
		0	Channel B Self-Restart Trip Status is "not tripped"
		1	Channel B Self-Restart Trip Status is "tripped"
6 (R/W1C)	FLTTRIPB	Fault Trip Status for Channel B. The `PWM_STAT.FLTTRIPB` bit indicates whether the PWM Channel B fault has been tripped. For more information, see the `PWM_TRIPCFG.MODE0A` bit description.	
		0	Channel B Fault Trip Status is "not tripped"
		1	Channel A Fault Trip Status is "tripped"

Table 19-71: PWM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	SRTRIPA	Self-Restart Trip Status for Channel A. The `PWM_STAT.SRTRIPA` bit indicates whether the PWM Channel A self-restart has been tripped. For more information, see the `PWM_TRIPCFG.MODE0A` bit description.	
		0	Channel A Self-Restart Trip Status is "not tripped"
		1	Channel A Self-Restart Trip Status is "tripped"
4 (R/W1C)	FLTTRIPA	Fault Trip Status for Channel A. The `PWM_STAT.FLTTRIPA` bit indicates whether the PWM Channel A fault has been tripped. For more information, see the `PWM_TRIPCFG.MODE0A` bit description.	
		0	Channel A Fault Trip Status is "not tripped"
		1	Channel A Fault Trip Status is "tripped"
3 (R/NW)	RAWTRIP1	Raw Trip 1 Status. The `PWM_STAT.RAWTRIP1` bit indicates the raw input level for the PWM TRIP1 input.	
		0	TRIP1 Level is Low
		1	TRIP1 Level is High
2 (R/NW)	RAWTRIP0	Raw Trip 0 Status. The `PWM_STAT.RAWTRIP0` bit indicates the raw input level for the PWM TRIP0 input.	
		0	TRIP0 Level is Low
		1	TRIP0 Level is High
1 (R/W1C)	TRIP1	Status bit set when TRIP1 is active low. The `PWM_STAT.TRIP1` bit indicates whether the PWM TRIP1 fault has been tripped with an active-low input.	
		0	TRIP1 status is "not tripped"
		1	TRIP1 status is "tripped" (active low)
0 (R/W1C)	TRIP0	Status bit set when TRIP0 is active low. The `PWM_STAT.TRIP0` bit indicates whether the PWM TRIP0 fault has been tripped with an active-low input.	
		0	TRIP0 status is "not tripped"
		1	TRIP0 status is "tripped" (active low)

Sync Pulse Width Register

The `PWM_SYNC_WID` register selects the pulse width for the external sync pulse available on the `PWM_SYNC` pin. The relation between the `PWM_SYNC_WID` register value and the pulse width (T_{PWM_SYNC}) is give by the formula:

$$PWM\_SYNC\_WID = (T_{PWM\_SYNC} / t_{CK}) - 1$$

For more information about applying the sync pulse width, see the PWM Functional Description section. Note that if the pulse width is changed in between sync pulses, the PWM applies the changed width on the next internal sync pulse. If, while the sync pulse is active, the chosen timer reaches its period boundary, the changed pulse width takes effect on that period boundary.

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	VALUE	Sync Pulse Width. The `PWM_SYNC_WID.VALUE` bits select the pulse width for the external sync pulse available on the `PWM_SYNC` pin.

Timer 0 Period Register

The `PWM_TM0` register controls the switch period T_{SP} of the PWMTMR0 timer. The `PWM_TM0` value is in units of t_{CK} (the period of the peripheral clock) and the and is given by the formula:

PWM_TM0= $(T_{SP}) / 2 \times t_{CK}$

The value written to the register is effectively the number of t_{CK} clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that `PWM_TM0` values of 0 and 1 are not defined and must not be used when the PWM is enabled.

Timer 1 Period Register

The `PWM_TM1` register controls the switch period (T_{SP} of the PWMTMR1 timer. The `PWM_TM1` value is in units of t_{CK} (the period of the peripheral clock) and the and is given by the formula:

PWM_TM1= (T_{SP}) / 2 x t_{CK}

The value written to the register is effectively the number of t_{CK} clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that `PWM_TM1` values of 0 and 1 are not defined and must not be used when the PWM is enabled.

Timer 2 Period Register

The PWM_TM2 register controls the switch period (T_{SP} of the PWMTMR2 timer. The PWM_TM2 value is in units of t_{CK} (the period of the peripheral clock) and the and is given by the formula:

PWM_TM1= (T_{SP}) / 2 x t_{CK}

The value written to the register is effectively the number of t_{CK} clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that PWM_TM2 values of 0 and 1 are not defined and must not be used when the PWM is enabled.

Timer 3 Period Register

The PWM_TM3 register controls the switch period (T_{SP} of the PWMTMR3 timer. The PWM_TM3 value is in units of t_{CK} (the period of the peripheral clock) and the and is given by the formula:

PWM_TM3= (T_{SP}) / 2 x t_{CK}

The value written to the register is effectively the number of t_{CK} clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that PWM_TM3 values of 0 and 1 are not defined and must not be used when the PWM is enabled.

Timer 4 Period Register

The `PWM_TM4` register controls the switch period (T_{SP} of the PWMTMR4 timer. The `PWM_TM4` value is in units of t_{CK} (the period of the peripheral clock) and the and is given by the formula:

PWM_TM4= (T_{SP}) / 2 x t_{CK}

The value written to the register is effectively the number of t_{CK} clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that `PWM_TM4` values of 0 and 1 are not defined and must not be used when the PWM is enabled.

Table 19-78: PWM_TRIPCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	MODE0A	Mode of TRIP0 for Channel A. The `PWM_TRIPCFG.MODE0A` bit selects the trip mode of TRIP0 for Channel A. In fault-trip mode (`PWM_TRIPCFG.MODE0A` =0), after the input is tripped, the trip status appears in the corresponding channels fault-trip status bit (for example, `PWM_STAT.FLTTRIPA`), and the PWM immediately shuts down outputs of that channel. After a fault trip occurs, when the trip condition is no longer active, the processor may cause channel outputs to resume by completing a write-1-to-clear the corresponding fault-trip status bit. The raw (input level) trip input state is available from the `PWM_STAT.RAWTRIP0` and `PWM_STAT.RAWTRIP0` bits. In self-restart mode (`PWM_TRIPCFG.MODE0A` =1), after the input is tripped, the trip status appears in the corresponding channels self-restart status bit (for example, `PWM_STAT.SRTRIPA`), and the PWM immediately shuts down outputs of that channel. On the next timer period boundary (of the PWMTMRx used by that channel), if the trip condition is not active, the PWM clears the status and restarts the channels output.	
		0	Fault Trip on TRIP0 Input
		1	Self Restart on TRIP0 Input
0 (R/W)	EN0A	Enable TRIP0 as a trip source for Channel A. The `PWM_TRIPCFG.EN0A` bit enables TRIP0 as a trip source for Channel A.	
		0	Disable TRIP0 for Channel A
		1	Enable TRIP0 for Channel A

20 General-Purpose Timer (TIMER)

The general-purpose timer (GP Timer) module serves as a collection of system timers that support various system-level functions. These functions include:

- Synchronized PWM waveform output capability
- External signal capture
- External event count
- General time-base functionality

Additionally, interrupt requests can be generated upon completion of timer events. Moreover, GP timers can act both as trigger masters and trigger slaves.

GP Timer Features

Each timer can be individually configured in any of these modes:

- Pin interrupt capture mode
- Windowed watchdog mode
- Pulse-width count and capture (WDTH_CAP) mode
- External Event (EXT_CLK) mode
- Pulse-width modulation (PWM_OUT) mode

Other features include:

- Synchronous operation
- Consistent management of period and pulse width values
- Autobaud detection for UART module (where available)
- Graceful bit pattern termination when stopping
- Support for center-aligned PWM patterns
- Error detection on implausible pattern values

- All read and write accesses to 32-bit registers are atomic
- Every timer has its dedicated interrupt request output

ADSP-SC58x TIMER Register List

The General-Purpose Timer block (TIMER) provides timers that may be used for external event capture and measurement, system timing, and PWM waveform generation. A set of registers governs TIMER operations. For more information on TIMER functionality, see the TIMER register descriptions.

Table 20-1: ADSP-SC58x TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register
TIMER_BCAST_WID	Broadcast Width Register

Figure 20-1: Timer Block Diagram

Internal Interface

The processor core always accesses the timer registers through the MMR access bus. Hardware ensures that all read and write operations from and to 32-bit timer registers are atomic. Every timer has a dedicated data interrupt request. There is also one common timer status and error interrupt request output that connects to the system event controller. Whenever a data interrupt request is generated, a data trigger master pulse is also driven out, if enabled. Each timer has an individual trigger input line, and each timer can be either started or stopped as a trigger slave.

In total, the GP timer module can have up to (N + 1) interrupt request output lines and N data trigger lines.

Internal Timer Connections

The Timers support alternate inputs for the clock/capture (see External Interface). Some signals have internal default alternate connections according to the ***Timer Signal Routing*** table.

Table 20-5: Timer Signal Routing

Timer Signal	Connection
TM0_ACLK0	SYS_CLKIN1

Table 20-5: Timer Signal Routing (Continued)

Timer Signal	Connection
TM0_ACI5	DAI0_CRS_PB04

TM0_ACI6	DAI1_CRS_PB04
TM0_ACLK6	DAI1_CRS_PB03
TM0_ACI07	CNT0_TO signal
TM0_ACLK7	SYS_CLKIN0

External Interface

Each GP timer module can support up to 16 individual timers. However, most processors have less than this number. The exact number of timers available on a given processor is available in the data sheet for the processor.

Every timer has one main input/output signal (`TIMER_TMR[n]`) and, usually, one auxiliary input pin, used as an alternate capture input (`TIMER_ACI[n]`). Each timer can either run with a time base of SCLK0_0 or can reference an external clock on one of two `TIMER_ACLK[n]` pins. The TMR_ALT_CLK0 signal maps to individual alternate clock (`TIMER_ACLK[n]`) pins for one or more timers. For instance, a TM_ACLK3 pin would provide an alternate site to supply an external signal that would serve as reference clock for TMR3. Likewise, the TMR_ALT_CLK1 signal from each timer unit connects together internally to provide a single global timer clock pin (`TIMER_CLK`) for the GP timer module. It is used as an additional time base.

GP Timer Operating Modes

The following sections provide information on the various operating modes of the GP timer.

General Operation

The core of every timer is a 32-bit counter that can be interrogated through the read-only `TIMER_TMR[n]_CNT` register. Once the module enables a timer, it loads the timer `TIMER_TMR[n]_CNT` register with a starting value.

A timer can operate in one of several different modes, configured through the `TIMER_TMR[n]_CFG` register for that timer. These modes are: PWMOUT, EXTCLK, WIDCAP, WATCHDOG, PININT, and IDLE. The ***Timer Mode Descriptions*** table summarizes the modes.

Table 20-6: Timer Mode Descriptions

Timer Mode	Description
PWMOUT	Generates single or continuous PWM waveforms with programmable pulse width, period, and delay
EXTCLK	Counts edges of an externally applied waveform
WIDCAP	Captures pulse width or period of an externally applied waveform

Table 20-6: Timer Mode Descriptions (Continued)

Timer Mode	Description
WATCHDOG	Monitors pulse width or period of an external signal and compares against a window of acceptable values, optionally generating an interrupt when it falls inside or outside of that window
PININT	Can generate an interrupt request on an active edge applied to a timer pin
IDLE	Idle; no activity

Period, Width and Delay Register Interaction

When the timer is started, writes to the buffer registers are immediately copied through to the double-buffered period, pulse width, and delay registers. These values are then ready for use in the first timer period. When a timer is already running, software can write new values to the `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` registers. The written values are buffered and do not update into the registers until the end of the current period. (The update occurs when the value in the `TIMER_TMR[n]_CNT` register equals the value in the `TIMER_TMR[n]_PER` register.)

If new values are not written to these registers, the value from the previous period is reused. Writes to these registers are atomic; it is not possible for the high word to be written without the low word also being written. Values written to the period, pulse width, and delay registers are always stored in the buffer registers. Reads from the same register always return the current, active value of period, pulse width, or delay value. Written values are not readback until they become active.

The usage of the `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` registers varies, depending on the mode of the timer specified by the `TIMER_TMR[n]_CFG.TMODE` bits. See the ***Usage of the Period, Width, and Delay Registers in Different Timer Modes*** table for more information.

Table 20-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes

Timer Mode	**`TIMER_TMR[n]_PER`**	**`TIMER_TMR[n]_WID`**	**`TIMER_TMR[n]_DLY`**
IDLE	Not writable	Not writable	Not writable
WATCHDOG	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.	Read-only. Retains value of last measured width or period of the input signal.	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.
WIDCAP	Read-only. Period value captured at the appropriate time and updated from its buffer register simultaneously with the Width register.	Read-only. Width value captured at the appropriate time and updated from its buffer register simultaneously with the Period register.	Not used
PWMOUT	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.
EXTCLK	Can be updated on-the-fly.	Not used	Not used

Table 20-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes (Continued)

Timer Mode	TIMER_TMR[n]_PER	TIMER_TMR[n]_WID	TIMER_TMR[n]_DLY
PININT	Not used	Not used	Not used

If any of the period, pulse width, and delay registers are not used, then programs cannot write into that register. For example, in WIDCAP mode, the delay registers are not used. So, the program is not allowed to write any value to the TIMER_TMR[n]_DLY register. To prevent undesired operation, program the TIMER_TMR[n]_CFG.TMODE bits before programming the period, width, or delay registers.

If a program changes the TIMER_TMR[n]_CFG.TMODE bits from a status register to writable register (for example in PWMOUT mode), hardware does not clear these registers. These values are automatically overwritten by new values specified by software.

In PWMOUT mode with small periods, there may not be enough time between updates from the buffer registers to write these registers. The next period can use one old value and one new value. To prevent (width + pulse delay) > period errors, write the width and delay registers before the period register when decreasing the values. Write the period register before the width and delay registers when increasing the value.

Single-Pulse PWMOUT Mode

In single-pulse PWMOUT mode, the timer generates a single pulse on the TIMER_TMR[n] pin. This mode is frequently used to implement a precise delay, often with generating an output trigger. The timer module uses the value in the TIMER_TMR[n]_DLY register to control the assertion of a pulse. The value in the TIMER_TMR[n]_WID register defines the pulse width. The TIMER_TMR[n]_PER is not used and cannot be written in this mode. After completion of the pulse, the timer is automatically stopped, and optionally generates an interrupt. The timer uses the TIMER_TMR[n]_CFG.PULSEHI bit to control pulse polarity.

The timer can be configured to generate a data interrupt request after satisfying various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is not necessary to clear the relevant TIMER_RUN bit to stop the timer cleanly. At the end of the pulse, the timer stops automatically and the corresponding TIMER_RUN bit is cleared. To generate multiple discrete pulses (as opposed to a continuous PWM waveform), write a 1 to the appropriate TIMER_RUN bit, and wait for the timer to stop. Then, write another 1 to the same TIMER_RUN bit.

Continuous PWMOUT Mode

In continuous PWMOUT mode, the timer generates a repetitive pulse with a well-defined period, duty cycle, and pulse position. The TIMER_TMR[n]_DLY, TIMER_TMR[n]_PER, and TIMER_TMR[n]_WID registers are programmed with the values of the required PWM pulse. After the timer is started, the counter counts towards the value programmed in the TIMER_TMR[n]_PER register. Initially, the TIMER_TMR[n] pin remains in a deasserted state. The pin toggles to an asserted state when the value in the TIMER_TMR[n]_CNT register equals the value in the TIMER_TMR[n]_DLY register.

The timer can control the assertion sense of the TIMER_TMR[n] pin with the TIMER_TMR[n]_CFG.PULSEHI bit. The TIMER_TMR[n] pin holds this value for the number of clock cycles specified in the TIMER_TMR[n]_WID register. Then, the pin deasserts and holds this value until the completion of the programmed period. The same waveform is generated repeatedly until the timer is disabled.

The timer can be configured to generate a data interrupt request after satisfying any of various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is important to guarantee that the programmed period is greater than or equal to the sum of width and delay. Similarly, delay must be less than period. Violating either of these criteria results in an unpredictable waveform on the TIMER_TMR[n] pin until the situation is rectified by writing proper values to these registers.

The maximum frequency possible to generate on the TIMER_TMR[n] pin is achieved by setting TIMER_TMR[n]_PER to 2 and TIMER_TMR[n]_WID to 1. This operation makes the TIMER_TMR[n] pin toggle each SCLK0_0 clock cycle (assuming the timer is configured to clock internally), producing a duty cycle of 50%.

When the TIMER_STOP_CFG.TMR[nn] bit of a timer is 0, the timer treats a stop operation as a stop-is-pending condition. When terminated with this setting, the timer automatically completes the current waveform and then stops cleanly, remaining in a deasserted state. This funtionality prevents truncation of the current pulse and unwanted PWM patterns at the TIMER_TMR[n] pin. The processor can determine when the timer stops running by polling the corresponding TIMER_RUN.TMR[nn] bit until it reads 0 or by waiting for the last interrupt (if enabled).

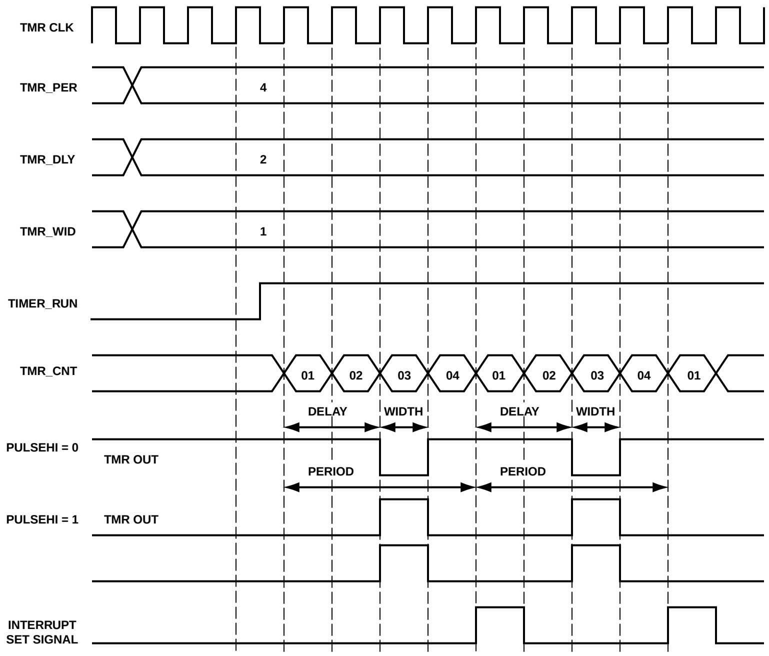

Figure 20-2: Signal Generation in Continuous PWMOUT Mode

The TIMER_TMR[n]_CFG register cannot be reconfigured until after the timer stops and the TIMER_RUN register reads 0.

Programs can force a timer to stop immediately in PWMOUT mode by writing a 1 to the `TIMER_STOP_CFG` register followed by writing a 1 to the `TIMER_RUN_CLR` register. (Or, a program can stop a timer by writing a 0 to the appropriate `TIMER_RUN.TMR[nn]` bit.) This operation stops the timer whether the pending stop is waiting for the end of the current period or the end of the current pulse width. The timer can use this feature to regain immediate control of a timer during an error recovery sequence.

Use this feature carefully, as it can corrupt the PWM pattern generated at the `TIMER_TMR[n]` pin, though after such a stop the pin deasserts automatically. Each timer samples its `TIMER_RUN.TMR[nn]` bit at the end of each period. It stops cleanly at the end of the first period after the `TIMER_RUN.TMR[nn]` bit is low. A timer that is disabled and then restarted (before the end of the current period), continues to run as if nothing happened. Typically, the program disables a PWMOUT timer and then waits for it to stop itself.

Width Capture (WIDCAP) Mode

The timer uses WIDCAP mode, often called capture mode, to measure pulse widths on the `TIMER_TMR[n]` or `TIMER_ACI[n]` inputs. The polarity (active high or low) of the input signal can be selected with the `TIMER_TMR[n]_CFG.PULSEHI` bit. The ***Timer Signal Flow in Width Capture Mode*** figure shows the control signal flow for WIDCAP_CAP mode.

Figure 20-3: Timer Signal Flow in Width Capture Mode

NOTE: SCLK in the ***Timer Signal Flow in Width Capture Mode*** figure is SCLK0_0.

In this mode, the timer uses the `TIMER_TMR[n]_CFG.TINSEL` bit to select between the `TIMER_TMR[n]` or `TIMER_ACI[n]` input. The internally clocked timer is used to determine the period and pulse width of the externally applied rectangular waveforms.

When a timer is enabled in this mode, the timer resets the count in its `TIMER_TMR[n]_CNT` register to 0x0000 0001. It does not start counting until it detects a leading edge on the selected input pin.

When the timer detects the first leading edge, it starts incrementing. When it detects a trailing edge of a waveform, it captures the current 32-bit value of its `TIMER_TMR[n]_CNT` register into its width buffer register. At the next leading edge, the timer transfers the current 32-bit value of its `TIMER_TMR[n]_CNT` register into its period buffer register. The `TIMER_TMR[n]_CNT` register is reset to 0x0000 0001 again, and the timer continues counting and capturing until it is disabled.

In this mode, programs can measure both the pulse width and the pulse period of a waveform. The timer does not use the `TIMER_TMR[n]_DLY` register in this mode. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to control the definition of leading edge and trailing edge of the `TIMER_TMR[n]/TIMER_ACI[n]` pin.

In WIDCAP mode, the following events always occur at the same time as one unit:

1. The `TIMER_TMR[n]_PER` register is updated from the period buffer register.
2. The `TIMER_TMR[n]_WID` register is updated from the width buffer register.
3. The `TIMER_DATA_ILAT.TMR[nn]` bit is set (if enabled).
4. A timer data trigger pulse is generated (if enabled).

The `TIMER_TMR[n]_CFG.TMODE` bit 0 controls the point in time at which this set of events is executed. Taken together, these four events are called a measurement report. The `TIMER_STAT_ILAT` register is not set at a measurement report. A measurement report occurs, at most, once per input signal period. The current `TIMER_TMR[n]_CNT` value is always copied to the width buffer and period buffer registers at the trailing and leading edges of the input signal, respectively. But, these values are not visible to software. A measurement report event samples the captured values into visible registers and sets the timer interrupt request to signal that the `TIMER_TMR[n]_PER` and the `TIMER_TMR[n]_WID` registers are ready to be read.

When the `TIMER_TMR[n]_CFG.TMODE` bit =b#1011, the measurement report occurs just after the width buffer register captures its value at a falling edge. Then, the `TIMER_TMR[n]_WID` register reports the pulse width measured in the pulse that has ended, but the `TIMER_TMR[n]_PER` register reports the pulse period measured at the end of the previous period. If only the first trailing edge has occurred, then the first period value has not yet been measured at the first measurement report. So, the period value is not valid. A read of the `TIMER_TMR[n]_PER` value in this case returns 0. See the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure for more information.

Figure 20-5: Example of Width Capture Asserted Mode (TMODE=b#1010)

NOTE: SCLK in the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure is SCLK0_0.

To measure the pulse width of a waveform that has only one leading edge and one trailing edge, set `TIMER_TMR[n]_CFG.TMODE` = b#1011. If `TIMER_TMR[n]_CFG.TMODE` = b#1010 for this case, no period value is captured in the period buffer register. Instead, the timer genererates an error report interrupt request (if enabled) when the `TIMER_TMR[n]_CNT` range is exceeded and the counter wraps around. In this case, both the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers read 0 (because no measurement report occurred to copy the value captured in the width buffer register to the `TIMER_TMR[n]_WID` register).

If using the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010 mode to measure the width of a single pulse, programs can disable the timer after taking the interrupt that ends the measurement interval. If desired, restart the timer as appropriate in preparation for another measurement. This procedure prevents the timer from free-running after the width measurement and logging errors generated by the timer count overflowing.

Width Capture Mode Overflow

A timer status interrupt request (when enabled) is generated when the `TIMER_TMR[n]_CNT` register wraps around from 0xFFFF FFFF to 0 in the absence of a leading edge. At that point, the `TIMER_STAT_ILAT` bit is set and the `TIMER_ERR_TYPE` bits change to indicate a count overflow due to a period greater than the range of the counter. This indication is referred to as an error report. A data interrupt request in WIDCAP mode indicates that a new measurement is ready to be read (a measurement report). Similarly, an interrupt request on the timer status interrupt line (shared interrupt request for all timers) indicates an overflow error when generated in this mode.

The `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are never updated at the time an overflow error is signaled. If the timer overflows and the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010, the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are not updated. If the timer overflows and the

`TIMER_TMR[n]_CFG.TMODE` bit =b#1011, the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are updated only if a trailing edge is detected at a previous measurement report.

Software can count the number of error reports between measurement report interrupt requests to measure input signal periods longer than 0xFFFF FFFF. Each error report interrupt request adds a full 2^{32}SCLK0_0 counts to the total for the period, but the width is ambiguous. Ensure that if software monitors only the status interrupt request, then status interrupt requests from all other timers are masked.

Refer to the ***Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)*** figure. The period is 0x1 0000 0004, but the pulse width could be either 0x0 0000 0002 or 0x1 0000 0002.

Figure 20-6: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK0_0.

The waveform applied to the `TIMER_TMR[n]` (or `TIMER_ACI[n]`) pin is not required to have a 50% duty cycle. The minimum input low time is little more than one SCLK0_0 period. The minimum input high time is a little more than one SCLK0_0 period. (Refer to the product data sheet for details.) The maximum `TIMER_TMR[n]` input frequency is less than SCLK0_0/2, with a 50% duty cycle. Under these conditions, the WIDCAP mode timer measures: period =2 and pulse width =1.

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK0_0.

Windowed Watchdog (WATCHDOG) Modes

In windowed watchdog (WATCHDOG) modes, a timer can take inputs from either the `TIMER_TMR[n]` pin or the `TIMER_ACI[n]` pin. With this mode, the timer can monitor pulse width (width watchdog mode) or pulse period (period watchdog mode) on the input line. It also compares the measured value against a minimum required value and maximum allowed value and generates an interrupt request appropriately. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to select polarity of the input signal.

The waveform applied to the input pin in watchdog mode is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet.

Windowed Watchdog Width Mode

In windowed watchdog width mode, the timer counter monitors the pulse width of an input signal on either the `TIMER_TMR[n]` pin or one of the alternate clock pins (`TIMER_ACLK[n]`). Program the minimum pulse width (p_{MIN}) in the `TIMER_TMR[n]_DLY` register and the maximum pulse width (p_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK0_0 or alternate clock). The timer can generate an interrupt if the deasserting pulse edge occurs:

- Inside the window (p_{MIN} < pulse width ≤ p_{MAX}), or
- Outside the window (pulse width ≤ p_{MIN} or pulse width > p_{MAX})

After enabling the timer in this mode, it always starts counting at the asserting edge of the input signal. Any pulse that is already active when the timer is enabled is ignored.

With the `TIMER_TMR[n]_CFG.IRQMODE` bit =b#11, the timer generates an interrupt if the timed pulse width exceeds p_{MAX}, or if the pulse width is less than p_{MIN}. After attaining p_{MAX}, the pulse stays at an active level, and the counter keeps on counting until it sees a deasserting edge. When the input pulse is not active, the counter holds its current value until it again sees an asserting edge, or it restarts. An interrupt can also be generated for when the pulse occurs within the specified window condition, by setting `TIMER_TMR[n]_CFG.IRQMODE` =b#10.

In this mode, a trailing edge on the input pin triggers capturing of pulse width into the `TIMER_TMR[n]_WID` register. During the inactive portion of the input signal, the internal counter does not increment. The ***Watchdog Width Mode Timing*** figure shows the signal flow in this mode.

Figure 20-8: Watchdog Width Mode Timing

NOTE: SCLK in the ***Watchdog Width Mode Timing*** figure is SCLK0_0.

To check only the upper limit on pulse width (p_{MAX} but not p_{MIN}), then program p_{MIN} as 0 or 1. In such a case, it is better to use `TIMER_TMR[n]_CFG.IRQMODE` =b#11. With `TIMER_TMR[n]_CFG.IRQMODE` = b#10, a pulse width of 1 clock cycle results in an interrupt. For details, see the ***Windowed Watchdog Width Mode Interpretation*** table.

Table 20-8: Windowed Watchdog Width Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE= b#10	IRQMODE= b#11	Error Interrupt?
0 or 1	Anything ≥ 1	PW = 1	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
> 1 but ≤ (Period -1)	Anything > 1	PW ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < PW≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt

	-	PW > TMR_PER	Undefined	Undefined	b#11 Error Type
-	0	-	Undefined	Undefined	b#10 Error Type

Windowed Watchdog Period Mode

In this mode, the timer monitors the number of clock cycles between two consecutive rising or falling edges of an input signal on either the `TIMER_TMR[n]` or `TIMER_ACI[n]` pin. Program the required minimum number of clock cycles (t_{MIN}) in the `TIMER_TMR[n]_DLY` register and the required maximum allowed number of clock cycles (t_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK0_0) or alternate time clock (`TIMER_ACLK[n]`). The timer can generate an interrupt when two consecutive occurrences of an active edge are:

- Within a specified window (t_{MIN} < Pulse Period ≤ t_{MAX}), or
- Outside a specified window (pulse width ≤ (t_{MIN} or t_{MAX} < pulse width)

When the `TIMER_TMR[n]_CFG.IRQMODE` bit =b#11 and the pulse period > t_{MAX} or is ≤ t_{MIN}, the timer generates an interrupt (if unmasked). After attaining the t_{MAX} value, the counter keeps on counting until it sees an active edge on the input line. An interrupt can also be generated for when the pulse occurs within the specified window condition, by setting `TIMER_TMR[n]_CFG.IRQMODE` =b#10. Refer to the ***Watchdog Period Mode Timing*** figure for timer functionality in period watchdog mode.

Pin Interrupt (PININT) Mode

In PININT mode, any active edges on either the `TIMER_TMR[n]` pin or the `TIMER_ACI[n]` pin can cause an edge-based interrupt, if enabled. (The timer uses the `TIMER_TMR[n]_CFG.TINSEL` register to select the pin). The event on the input pin can set the `TIMER_DATA_ILAT.TMR[nn]` bit and issue a system interrupt request. Program the `TIMER_TMR[n]_CFG.PULSEHI` bit to change active edge polarity.

Since the interrupt request is generated in the SCLK0_0 clock domain, the width of the input signal must be more than one SCLK0_0 period. Along with generating the interrupt request, the timer also generates a trigger pulse (configured using the `TIMER_TRG_MSK` register). Due to the configuration of polarity, glitches can cause the generation of an undesired interrupt request at the input. To avoid this problem, programs must ensure that interrupt requests are unmasked only after configuring the desired polarity.

External Clock (EXTCLK) Mode

The timer uses EXTCLK mode, sometimes referred to as the counter mode, to count external events (signal edges), on either the `TIMER_TMR[n]` or `TIMER_ACI[n]` input pin. The timer works as a counter clocked by an external source (the signal at the pin), which can be asynchronous to SCLK0_0. The current count in the `TIMER_TMR[n]_CNT` register represents the number of leading-edge events detected. The `TIMER_TMR[n]_PER` register is programmed with the value of the maximum timer external count before stopping or issuing an interrupt request or trigger.

The `TIMER_TMR[n]_CFG.PULSEHI` bit determines the polarity of the leading edge on the input pin. The timer uses the `TIMER_TMR[n]_CFG.TINSEL` bit to select whether the event is counted on the `TIMER_TMR[n]` or on the `TIMER_ACI[n]` pin. The `TIMER_STAT_ILAT.TMR[nn]` and `TIMER_ERR_TYPE` bits are set if *one* of these conditions is met:

- `TIMER_TMR[n]_CNT` wraps around from 0xFFFF FFFF to 0
- The period = 0 at startup
- `TIMER_TMR[n]_CNT` register rolls over (from count = period to count = 0x1)

The `TIMER_TMR[n]_WID` and `TIMER_TMR[n]_DLY` registers are unused in this mode and must not be written.

The ***EXTCLK Mode Control Flow*** figure shows a flow diagram for EXTCLK mode.

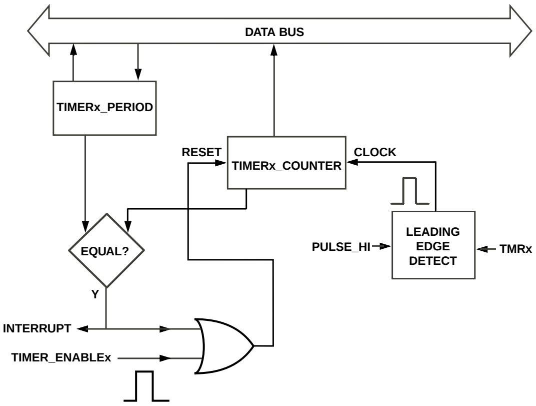

Figure 20-10: EXTCLK Mode Control Flow

The waveform applied to the input pin is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet. Program the period to any value from 1 to (2^{32} – 1), inclusive.

After the timer has started, it resets the `TIMER_TMR[n]_CNT` register to 0x0 and then waits for the first leading edge on the input pin. This edge causes `TIMER_TMR[n]_CNT` to be incremented to the value 0x1, and every subsequent leading edge increments it by one. After the `TIMER_TMR[n]_CNT` register reaches the value programmed in the `TIMER_TMR[n]_PER` register, the corresponding `TIMER_DATA_ILAT` bit is set, and an interrupt and trigger are both generated (if enabled). The next leading-edge reloads the `TIMER_TMR[n]_CNT` register with 0x1, and the timer continues counting until it is disabled.

GP Timer Programming Concepts

Using the features, operating modes, and event control for the GP timer to their greatest potential requires an understanding of some GP timer-related concepts.

Setting Up Constantly Changing Timer Conditions

This task shows how to use different period, pulse width, and delay settings for each of the first three timer periods after the timer starts.

1. Program the first set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.
2. Enable the timer using the `TIMER_RUN` register.
3. Immediately program the second set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values, as needed.
4. Wait for the first timer interrupt request.
5. Program the third set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.

Each new setting is then programmed when the preceding timer interrupt request is received.

Configuring, Enabling, and Disabling One or More Timers

1. Configure the relevant timers for the operating mode and other properties using the `TIMER_TMR[n]_CFG` register.
2. Write a 1 to the representative `TIMER_RUN.TMR[nn]` bit. Or, use the `TIMER_RUN_SET` register to avoid disturbing the settings of other timers that are not going through configuration.

   The timer is enabled and operating.
3. To stop one or more timers, first program the `TIMER_STOP_CFG` register to determine whether to stop immediately or gracefully upon receiving a stop command.

   ADDITIONAL INFORMATION: PWMOUT modes are the only modes where a timer can be configured for graceful termination.
4. Write a 0 to the representative `TIMER_RUN.TMR[nn]` bits to stop the timer according to their `TIMER_STOP_CFG` settings. Alternately, write a 1 to the appropriate `TIMER_RUN_CLR.TMR[nn]` bits to avoid disturbing the settings of other timers that are not terminating.

   The timers stop.

Configuring Timer Data and Status Interrupts

1. Configure the `TIMER_TMR[n]_CFG.IRQMODE` bit field with the desired interrupt properties.
2. Unmask the interrupt source at the system event controller.
3. Set the `TIMER_TMR[n]_CFG.IRQMODE` field but leave the interrupt masked at the system level to poll the `TIMER_DATA_ILAT.TMR[nn]` bit of the timer without generating an interrupt.
4. Use the `TIMER_STAT_IMSK` register to generate interrupt requests by overflow or error conditions (incorrect programming values). The timer uses the `TIMER_STAT_ILAT.TMR[nn]` bits to report interrupt errors, when the timer status interrupt source is unmasked at the system event controller.
5. To poll the `TIMER_STAT_ILAT.TMR[nn]` bit of the timer without generating an interrupt, unmask the corresponding bit in the `TIMER_STAT_IMSK` register, but leave the interrupt masked at the system level.

Using the Timer Broadcast Feature

The broadcast feature provides a means to update period, width, and delay registers simultaneously across more than one timer.

1. Enable the appropriate broadcast bits (`TIMER_TMR[n]_CFG.BPEREN`, `TIMER_TMR[n]_CFG.BWIDEN are TIMER_TMR[n]_CFG.BDLYEN`) for the timers involved in the broadcast. The use of these bits depends on which broadcast registers the timer uses (`TIMER_BCAST_PER`, `TIMER_BCAST_WID`, or `TIMER_BCAST_DLY`).

2. Program the `TIMER_BCAST_PER` register (for example), to broadcast the period setting across the multiple timers enabled.

   The enabled timers load their `TIMER_TMR[n]_PER` registers with the value specified in the `TIMER_BCAST_PER` register.

3. Repeat Step 2 as needed for the `TIMER_BCAST_WID` and `TIMER_BCAST_DLY` register settings.

Timer Illegal States

The following sections use these definitions:

- Startup. The first clock period during which the timer counter is running after the timer is started by writing the `TIMER_RUN` register.
- Rollover. The time when the current count in `TIMER_TMR[n]_CNT` matches the value in `TIMER_TMR[n]_PER` and the counter is reloaded with the value 1.
- Overflow. The timer counter was incremented instead of doing a rollover when it was holding the maximum count value of 0xFFFF FFFF. The counter does not have a large enough range to express the next greater value and so it erroneously loads a new value of 0x0000 0000.
- Unchanged. No new error.

When the `TIMER_ERR_TYPE` register is designated unchanged, it displays the previously reported error code orb# 00 when there has been no error since this timer was enabled.

When the `TIMER_STAT_ILAT` register is unchanged, it reads 0 when there has been no error or overflow since this timer was enabled. Or, it reads 0 if software has performed a W1C to clear any previous error. If software has not acknowledged a previous error, the `TIMER_STAT_ILAT` register reads 1. Software can read the `TIMER_STAT_ILAT` register to check for errors. If a particular bit of a timer is set in this register, software can then read the `TIMER_ERR_TYPE` register for more information. Once detected, software can W1C the appropriate `TIMER_STAT_ILAT` bit to acknowledge the error.

Read the following tables as:

- In mode __ at event __,
- if `TIMER_TMR[n]_PER` is __ and `TIMER_TMR[n]_WID` is __ and `TIMER_TMR[n]_DLY` is __,
- then `TIMER_ERR_TYPE` is __ and `TIMER_STAT_ILAT` is __.

Startup error conditions do not prevent the timer from starting. Similarly, overflow and rollover error conditions do not stop the timer. Illegal cases can cause unwanted behavior of the `TIMER_TMR[n]` pin.

NOTE: For PININT mode, the timer does not use error functionality.

Continuous PWMOUT Mode

Table 20-10: Startup Event

ADSP-SC58x TIMER Register Descriptions

General-Purpose Timer Block (TIMER) contains the following registers.

Table 20-22: ADSP-SC58x TIMER Register List

Name	Description
`TIMER_BCAST_DLY`	Broadcast Delay Register
`TIMER_BCAST_PER`	Broadcast Period Register
`TIMER_BCAST_WID`	Broadcast Width Register
`TIMER_DATA_ILAT`	Data Interrupt Latch Register
`TIMER_DATA_IMSK`	Data Interrupt Mask Register
`TIMER_ERR_TYPE`	Error Type Status Register
`TIMER_RUN`	Run Register
`TIMER_RUN_CLR`	Run Clear Register
`TIMER_RUN_SET`	Run Set Register
`TIMER_STAT_ILAT`	Status Interrupt Latch Register
`TIMER_STAT_IMSK`	Status Interrupt Mask Register
`TIMER_STOP_CFG`	Stop Configuration Register
`TIMER_STOP_CFG_CLR`	Stop Configuration Clear Register
`TIMER_STOP_CFG_SET`	Stop Configuration Set Register
`TIMER_TMR[n]_CFG`	Timer n Configuration Register
`TIMER_TMR[n]_CNT`	Timer n Counter Register
`TIMER_TMR[n]_DLY`	Timer n Delay Register
`TIMER_TMR[n]_PER`	Timer n Period Register
`TIMER_TMR[n]_WID`	Timer n Width Register
`TIMER_TRG_IE`	Trigger Slave Enable Register
`TIMER_TRG_MSK`	Trigger Master Mask Register

Broadcast Delay Register

For timers with `TIMER_TMR[n]_CFG.BDLYEN` enabled, a write to the `TIMER_BCAST_DLY` register concurrently updates the delay (`TIMER_TMR[n]_DLY`) registers of only those timers. A read of the `TIMER_BCAST_DLY` register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's `TIMER_TMR[n]_DLY` register.

Table 20-23: TIMER_BCAST_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Delay Value. A write to the `TIMER_BCAST_DLY.VALUE` bit field concurrently updates the delay (`TIMER_TMR[n]_DLY`) registers of only those timers. A read of the `TIMER_BCAST_DLY.VALUE` bit field returns 0x0000 0000, and no bus error is generated.

Broadcast Period Register

For timers with `TIMER_TMR[n]_CFG.BPEREN` enabled, a write to the `TIMER_BCAST_PER` register concurrently updates the period (`TIMER_TMR[n]_PER`) registers of only those timers. A read of `TIMER_BCAST_PER` returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's `TIMER_TMR[n]_PER` register.

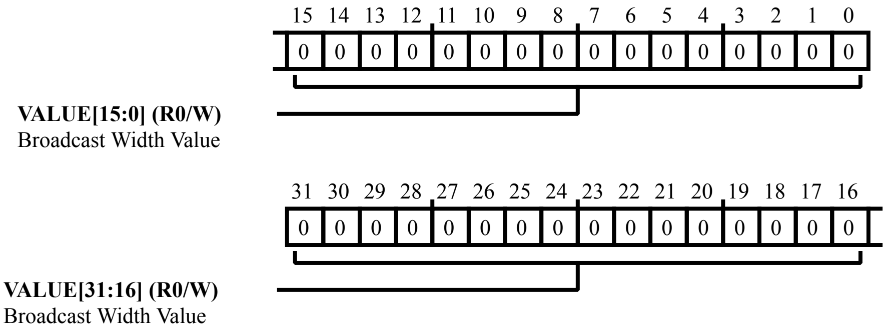
Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Period Value. A write to the `TIMER_BCAST_PER.VALUE` bit field concurrently updates the period (`TIMER_TMR[n]_PER`) registers of only those timers. A read of the `TIMER_BCAST_PER.VALUE` bit fields returns 0x0000 0000, and no bus error is generated.

Broadcast Width Register

For timers with `TIMER_TMR[n]_CFG.BWIDEN` enabled, a write to the `TIMER_BCAST_WID` register concurrently updates the width (`TIMER_TMR[n]_WID`) registers of only those timers. A read of the `TIMER_BCAST_WID` register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's `TIMER_TMR[n]_WID` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Broadcast Width Value

Figure 20-13: TIMER_BCAST_WID Register Diagram

Table 20-25: TIMER_BCAST_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Width Value. A write to the `TIMER_BCAST_WID.VALUE` bit field concurrently updates the width (`TIMER_TMR[n]_WID`) registers of only those timers. A read of the `TIMER_BCAST_WID.VALUE` bit field returns 0x0000 0000, and no bus error is generated.

Data Interrupt Latch Register

The TIMER_DATA_ILAT holds the latched interrupt status for interrupt requests that have been unmasked (enabled) by the TIMER_DATA_IMSK register and generated according to the conditions selected by the `TIMER_TMR[n]_CFG.IRQMODE` bits. If a bit in TIMER_DATA_ILAT is already set and the corresponding interrupt is masked in TIMER_DATA_IMSK, the latch holds its old value, leaving the interrupt request asserted until it is reset by software with a W1C operation.

Note that interrupt service routines (ISRs) should clear the appropriate bits in TIMER_DATA_ILAT before returning from the ISR, to ensure that the interrupt is not re-issued. To make sure that no timer event is missed, the latch should be reset at the very beginning of the ISR when in EXTCLK mode.

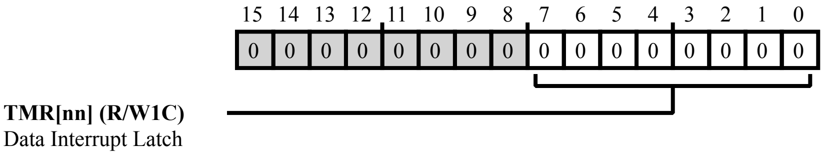

Figure 20-14: TIMER_DATA_ILAT Register Diagram

Table 20-26: TIMER_DATA_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W1C)	TMR[nn]	Data Interrupt Latch. For all `TIMER_DATA_ILAT.TMR[nn]` bits, status of =0 indicates no interrupt is latched, and status of =1 indicates a latched interrupt (indicating an unmasked interrupt request from a timer with a condition matching the one selected with corresponding `TIMER_TMR[n]_CFG.IRQMODE` bit has occurred).

Data Interrupt Mask Register

Each timer may generate a unique processor data interrupt request signal. The `TIMER_DATA_IMSK` register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the `TIMER_DATA_IMSK` register is 0xFFFF, masking these interrupts after reset.

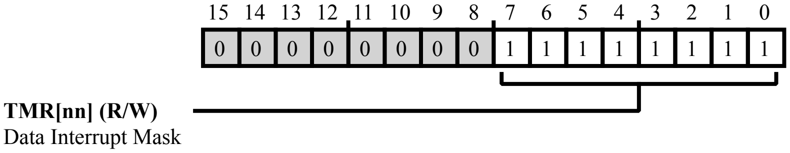

Figure 20-15: TIMER_DATA_IMSK Register Diagram

Table 20-27: TIMER_DATA_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Data Interrupt Mask. For all `TIMER_DATA_IMSK.TMR[nn]` bits, write =0 unmasks (enables) the corresponding data interrupt request, and write =1 masks (disables) the corresponding data interrupt request.

Error Type Status Register

The TIMER_ERR_TYPE register contains error type status bits for each timer. These bits indicate the type of error (if any) in a running timer. This register is read-only. These status bits are cleared at reset and when a particular timer is enabled.

Each time an error request interrupt is latched in the TIMER_STAT_ILAT register, the corresponding TERRx bits in the TIMER_ERR_TYPE register are loaded with a code that identifies the type of error that was detected. This status value is held until the next error or until a particular timer is restarted. No bus error is generated if a write is performed on the TIMER_ERR_TYPE register.

Run Register

The `TIMER_RUN` allows all timers to be enabled simultaneously, permitting them to run synchronously. For each timer, there is a single start/stop control bit. Writing a 1 to this bit starts the corresponding timer; writing a 0 stops the timer with mechanism specified in the timer stop configuration `TIMER_STOP_CFG` register.

The start/stop control bits can be set/reset individually or in any combination. While starting or stopping one particular timer directly with this register, software must perform a read-modify write, so the bits corresponding to other timers remain unchanged. To avoid this need, software can use the `TIMER_RUN_CLR` register.

Reading the `TIMER_RUN` register shows the start status for the corresponding timer. A 1 indicates that the timer is running.

If a timer is in run state (corresponding run bit is =1), a software write of 1 in this bit does not have any effect on the timer state. The write does not result in restarting the timer.

Note that the `TIMER_RUN` register is not used in PININT mode. PININT mode starts as soon as the `TIMER_TMR[n]_CFG.TMODE` bits are set to 111.

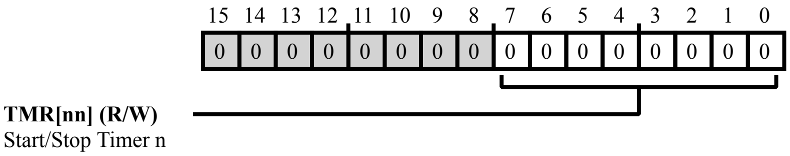

Figure 20-17: TIMER_RUN Register Diagram

Table 20-29: TIMER_RUN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Start/Stop Timer n. For all `TIMER_RUN.TMR[nn]` bits, write =0 for stop, and write =1 for start. Read =1 when timer is running.

Run Clear Register

The `TIMER_RUN_CLR` register is an alias register, providing a mechanism to clear a specific start/stop bit in the `TIMER_RUN` register without affecting other bits in `TIMER_RUN`. To stop a particular timer, software must write a 1 into the corresponding `TIMER_RUN_CLR` bit. Writing a 0 has no effect. Because `TIMER_RUN_CLR` is a write-only register, the result of any write to this register must be checked by reading the `TIMER_RUN` register. A read of the `TIMER_RUN_CLR` returns 0x0000.

Note that the stopping mechanism of a timer may be abrupt or graceful (after completion of current waveform period) depending on the selection in the `TIMER_STOP_CFG` register.

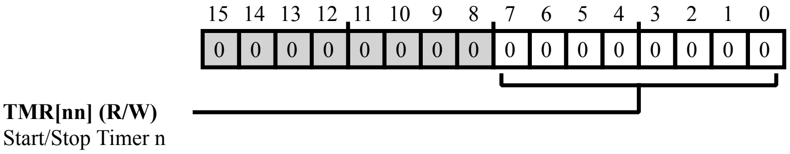

Figure 20-18: TIMER_RUN_CLR Register Diagram

Table 20-30: TIMER_RUN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W1C)	TMR[nn]	RUN Clear Alias. For all `TIMER_RUN_CLR.TMR[nn]` bits, write =0 has no effect, and write =1 for stop (clearing the corresponding in start/stop bit in the `TIMER_RUN` register). Using `TIMER_RUN_CLR` to clear start/stop bits permits stopping specific timers without influencing run status of other timers.

Run Set Register

The TIMER_RUN_SET register is an alias register, providing a mechanism to set a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To start a particular timer, software must write a 1 into the corresponding TIMER_RUN_SET bit. Writing a zero has no effect. For an example, to start timer 3 without affecting any other timer, write 0x0008 into TIMER_RUN_SET. Because TIMER_RUN_SET is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_SET returns 0x0000.

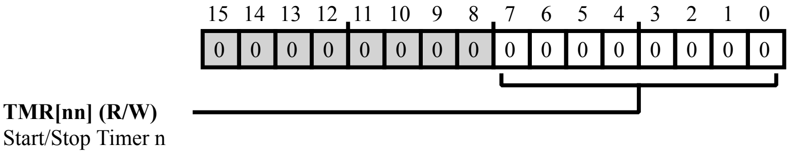

Figure 20-19: TIMER_RUN_SET Register Diagram

Table 20-31: TIMER_RUN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W1S)	TMR[nn]	RUN Set Alias. For all `TIMER_RUN_SET.TMR[nn]` bits, write =0 has no effect, and write =1 for start (setting the corresponding start/stop bit in the TIMER_RUN register). Using TIMER_RUN_SET to set start/stop bits permits starting specific timers without influencing the run status of other timers.

Status Interrupt Latch Register

The `TIMER_STAT_ILAT` holds the latched interrupt status for error interrupt requests, indicating a timer overflow condition or indicating that prohibited programming has occurred for a timer. These interrupt status bits are sticky and are W1C. The bits in the `TIMER_STAT_ILAT` register provide information regarding each timer interrupt request source.

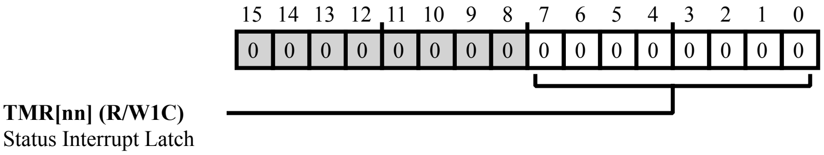

Figure 20-20: TIMER_STAT_ILAT Register Diagram

Table 20-32: TIMER_STAT_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W1C)	TMR[nn]	Status Interrupt Latch. For all `TIMER_STAT_ILAT.TMR[nn]` bits, status of 0 indicates no error interrupt request is latched, and status of 1 indicates a timer counter overflow or programming error interrupt request is latched.

Status Interrupt Mask Register

While each timer may generate a status interrupt request, these requests are OR'ed to generate a single status interrupt signal to the system event controller. The `TIMER_STAT_IMSK` register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the `TIMER_STAT_IMSK` register is 0xFFFF, masking these interrupts after reset.

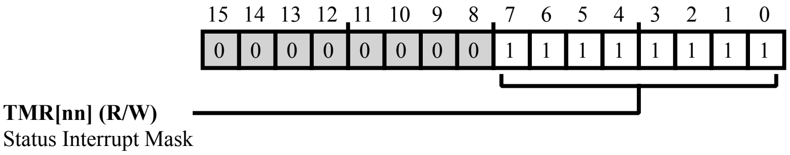

Figure 20-21: TIMER_STAT_IMSK Register Diagram

Table 20-33: TIMER_STAT_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Status Interrupt Mask. For all `TIMER_STAT_IMSK.TMR[nn]` bits, write =0 unmasks (enables) the corresponding status interrupt request, and write =1 masks (disables) the corresponding status interrupt request.

Stop Configuration Register

The `TIMER_STOP_CFG` register selects the stop mode for each timer. Timers may be stopped abruptly (immediate halt - all modes) or gracefully in PWMOUT modes (single pulse and continuous). The halt is achieved through either a write =0 to the corresponding bit in `TIMER_RUN` or a write =1 to the corresponding bit in `TIMER_RUN_CLR`. A read of `TIMER_STOP_CFG` returns the last value written.

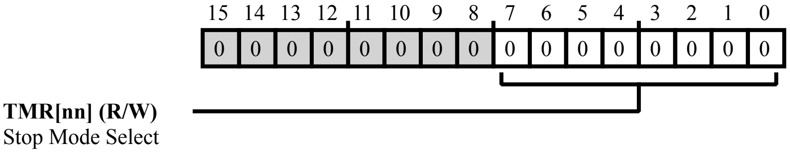

Figure 20-22: TIMER_STOP_CFG Register Diagram

Table 20-34: TIMER_STOP_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Stop Mode Select. For all `TIMER_STOP_CFG.TMR[nn]` bits, write =0 for graceful termination (PWMOUT modes only), and write =1 for abrupt (immediate halt) on stop.

Stop Configuration Clear Register

This is an alias register, providing a mechanism to clear a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To clear a bit in TIMER_STOP_CFG, software must write a 1 to the corresponding bit of TIMER_STOP_CFG_CLR register. Writing a zero has no effect. Because the TIMER_STOP_CFG_CLR register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_CLR register returns 0x0000.

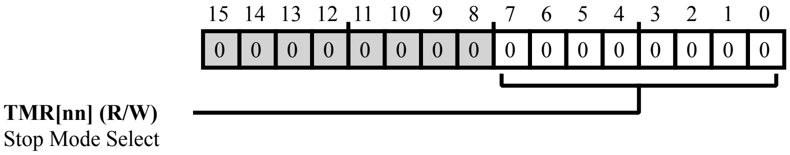

Figure 20-23: TIMER_STOP_CFG_CLR Register Diagram

Table 20-35: TIMER_STOP_CFG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W1C)	TMR[nn]	STOP_CFG Clear Alias. For all `TIMER_STOP_CFG_CLR.TMR[nn]` bits, write =0 has no effect, and write =1 for graceful stop in PWMOUT modes (clearing the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_CLR to clear stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Stop Configuration Set Register

This is an alias register, providing a mechanism to set a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To set a bit in the TIMER_STOP_CFG register, software must write a 1 to the corresponding bit of the TIMER_STOP_CFG_SET register. Writing a zero has no effect. Because the TIMER_STOP_CFG_SET register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_SET register returns 0x0000.

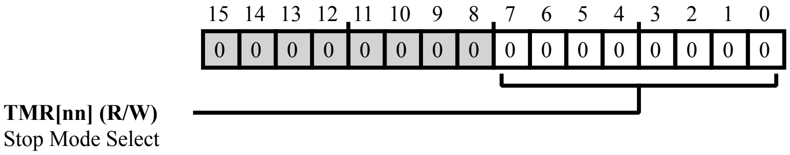

Figure 20-24: TIMER_STOP_CFG_SET Register Diagram

Table 20-36: TIMER_STOP_CFG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W1S)	TMR[nn]	STOP_CFG Set Alias. For all `TIMER_STOP_CFG_SET.TMR[nn]` bits, write =0 has no effect, and write =1 for abrupt stop (setting the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_SET to set stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Timer n Configuration Register

Each timer has a `TIMER_TMR[n]_CFG` register that specifies its operating mode. Only write to a `TIMER_TMR[n]_CFG` register when the corresponding timer is not running.

After disabling a timer operating in PWMOUT mode, verify that the timer has stopped running by checking the start/stop status of the timer in the `TIMER_RUN` register before writing to the timer's `TIMER_TMR[n]_CFG` register.

Note that a timer's `TIMER_TMR[n]_CFG` register may be read at any time.

Table 20-37: TIMER_TMR[n]_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EMURUN	Emulation Run. The `TIMER_TMR[n]_CFG.EMURUN` bit causes the timer to run (count) during emulation.	
		0	Stop Timer During Emulation
		1	Run Timer During Emulation
14 (R/W)	BPEREN	Broadcast Period Enable. The `TIMER_TMR[n]_CFG.BPEREN` bit enables updates to the `TIMER_TMR[n]_PER` register simultaneously across more than one timer.	
		0	Disable Broadcast to PER Register
		1	Enable Broadcast to PER Register

Table 20-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	BWIDEN	Broadcast Width Enable. The `TIMER_TMR[n]_CFG.BWIDEN` bit enables updates to the `TIMER_TMR[n]_WID` register simultaneously across more than one timer.	
		0	Disable Broadcast to WID Register
		1	Enable Broadcast to WID Register
12 (R/W)	BDLYEN	Broadcast Delay Enable. The `TIMER_TMR[n]_CFG.BDLYEN` bit enables updates to the `TIMER_TMR[n]_DLY` register simultaneously across more than one timer.	
		0	Disable Broadcast to DLY Register
		1	Enable Broadcast to DLY Register
11 (R/W)	OUTDIS	Output Disable. The `TIMER_TMR[n]_CFG.OUTDIS` bit enables or disables the timer pin output buffer.	
		0	Enable TMR Pin Output Buffer
		1	Disable TMR Pin Output Buffer
10 (R/W)	TINSEL	Timer Input Select (for WIDCAP, WATCHDOG, PININT modes).	
		0	Use TMR Pin Input
		1	Use TMR Alternate Capture Input
9:8 (R/W)	CLKSEL	Clock Select. The `TIMER_TMR[n]_CFG.CLKSEL` bit field selects the TIMER clock to use.	
		0	Use SCLK0_0
		1	Use TMR_ALT_CLK0 as TMR Clock
		3	Use TMR_ALT_CLK1 as TMR Clock
7 (R/W)	PULSEHI	Polarity Response Select. The `TIMER_TMR[n]_CFG.PULSEHI` bit defines specific behaviors of the timer based on the operating mode. For more information, see the specific operating mode in the Programming Concepts section.	
		0	Negative Response or Pulse. A Negative Edge Response or Negative Action Pulse on the TMR pin.
		1	Positive Response or Pulse. A Positive Edge Response or Positive Action Pulse on the TMR pin.

Table 20-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SLAVETRIG	Slave Trigger Response.. The TIMER_TMR[n]_CFG.SLAVETRIG bit controls the trigger response. The trigger pulse has no effect (to stop or start the timer) if the timer is already in the requested state.	
		0	Pulse Stops Timer if it is Running
		1	Pulse Starts Timer if it is Stopped
5:4 (R/W)	IRQMODE	Interrupt Modes. The TIMER_TMR[n]_CFG.IRQMODE bit field selects the interrupt request mode. Note that any mismatched combination of the TIMER_TMR[n]_CFG.IRQMODE and the TIMER_TMR[n]_CFG.TMODE bits results in no interrupt being generated. In WIDCAP modes, the position of the interrupt is controlled with the TIMER_TMR[n]_CFG.TMODE bit, and the TIMER_TMR[n]_CFG.IRQMODE bit is ignored. Whenever an interrupt is generated, a trigger master pulse is also generated, if enabled in the TIMER_TRG_MSK register.	
		0	Active Edge Mode. The timer generates an interrupt at every active edge. The active edge polarity depends on the state of the TIMER_TMR[n]_CFG.PULSEHI bit. Valid for PININT mode only.
		1	Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_DLY register. This mode is valid for all PWMOUT modes.
		2	Width Plus Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_WID register plus the value in the TIMER_TMR[n]_DLY register. (PWMOUT modes only) The timer generates an interrupt if the deasserting edge is within the specified window. (WATCHDOG modes only)
		3	Period Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_PER register. (Continuous PWMOUT and EXTCLK modes only) The timer generates an interrupt if the deasserting edge is outside the specified window.(WATCHDOG modes only)

Table 20-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W)	TMODE	Timer Mode Select. The `TIMER_TMR[n]_CFG.TMODE` bit field selects the operating mode of each timer.	
		0-7	Idle Mode
		8	Period Watchdog Mode
		9	Width Watchdog Mode
		10	Measurement Report at Asserting Edge of Waveform
		11	Measurement Report at Deasserting Edge of Waveform
		12	Continuous PWMOUT Mode
		13	Single Pulse PWMOUT Mode
		14	EXTCLK Mode
		15	PININT (pin interrupt) Mode

Timer n Counter Register

The `TIMER_TMR[n]_CNT` register holds the current timer count. After enabling, the count is re-initialized to either 0x0 or 0x1, depending on the configuration and mode. The `TIMER_TMR[n]_CNT` register is read-only and may be read at any time (whether the timer is running or stopped). Reading the `TIMER_TMR[n]_CNT` register returns an atomic 32-bit value.

Depending on the timer operation mode, the counter increment can be clocked by a number of sources, including SCLK0_0, the TMR or alternate capture input pins, `TIMER_ACLK[n]`. The counter retains its value after the timer is disabled.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Width Value. The `TIMER_TMR[n]_WID.VALUE` bit field holds the width value for the corresponding timer.

Trigger Slave Enable Register

As a trigger slave, each timer can generate a unique data trigger pulse signal. The `TIMER_TRG_IE` contains trigger input enable bits for these signals, disabling or enabling the triggers as programmed. The reset value of the `TIMER_TRG_IE` register is 0xFFFF, masking these triggers after reset.

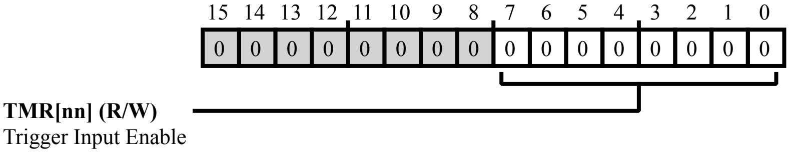

Figure 20-30: TIMER_TRG_IE Register Diagram

Table 20-42: TIMER_TRG_IE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Trigger Input Enable. For all `TIMER_TRG_IE.TMR[nn]` bits, write =0 disables the corresponding trigger input, and write =1 enables the corresponding trigger input.

Trigger Master Mask Register

As a trigger master, each timer can generate a unique data trigger pulse signal. The `TIMER_TRG_MSK` register contains a trigger mask for these outputs, masking (disabling) or unmasking (enabling) the triggers as programmed. The reset value of the `TIMER_TRG_MSK` register is 0xFFFF, masking these triggers after reset.

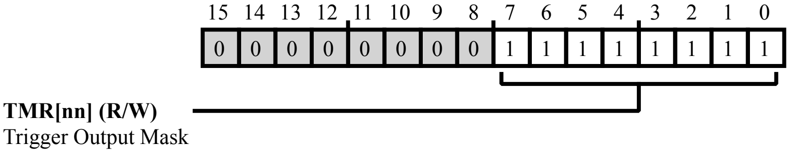

Figure 20-31: TIMER_TRG_MSK Register Diagram

Table 20-43: TIMER_TRG_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TMR[nn]	Trigger Output Mask. For all `TIMER_TRG_MSK.TMR[nn]` bits, write =0 unmasks (enables) the corresponding data trigger output, and write =1 masks (disables) the corresponding data trigger output.

21 Watchdog Timer (WDOG)

The processor has a 32-bit watchdog timer that can be used to verify system reliability by generating an event to the processor core when the watchdog expires before software updates it.

For the ADSP-SC58x processors, a system typically assigns WDG0 to Core ID=0 and WDG1 to Cores ID=1 and ID=2. The system clock (SCLK0_0) clocks the watchdog timers.

WDOG Features

The watchdog timer has the following features:

- Programmable 32-bit watchdog count value
- 8-bit disable bit pattern
- General-purpose core event generation

The watchdog timer can supervise system software stability by periodically reloading it to prevent expiration of the downward-counting timer (such that the count never becomes 0). When used in this fashion, an expiring timer can indicate the system software is not running normally.

Expiration of the WDOG counter generates a general-purpose interrupt, which can be used in a variety of ways:

- as an interrupt vector sent through the System Event Controller (SEC) to the core to be serviced by a handler function, providing full software control of device resources (for example, GPIO management and reset control).
- as a fault condition through the SEC to provide hardware-automated:
  - signalling of the fault condition on external pins to the system,
  - system reset requests to the Reset Control Unit (RCU), and/or
  - trigger outputs (SEC0_FAULT trigger master) through the Trigger Routing Unit (TRU) to initiate activities in a variety of potential trigger slaves (for example, GPIO control).

To facilitate debugging, the watchdog timer does not decrement (even if enabled) when the processor is in emulation mode.

WDOG Functional Description

When enabled, the 32-bit watchdog timer counts downward every SCLK0_0 cycle. If it reaches zero, the watchdog expiration event is generated, which can be used in many ways.

To start the watchdog timer:

1. Program the watchdog timeout period (in SCLK0_0 cycles) in the `WDOG_CNT` register. With the watchdog disabled, this write also preloads the `WDOG_STAT` register.
2. Enable the watchdog timer by writing any value other than 0xAD to the `WDOG_CTL.WDEN` field.

Once the watchdog is enabled, writes to the `WDOG_CNT` register are ignored. The counter begins decrementing, and the current counter value can be read from the 32-bit `WDOG_STAT` register at any time.

To prevent the counter from expiring, software must "kick" the watchdog by writing any value to the `WDOG_STAT` register while the current count is non-zero. While the value written is irrelevant and ignored, this action resets the current counter in the `WDOG_STAT` register to the programmed `WDOG_CNT` value, and decrementing continues. The internal counter continues decrementing until it reaches zero, at which point the expiration event is generated, and the `WDOG_CTL.WDRO` rollover bit is set.

Watchdog operation continues in this manner unless disabled by explicitly writing 0xAD to the `WDOG_CTL.WDEN` field.

The watchdog expiration event can be used in a variety of ways, as listed below.

- The watchdog expiration event itself is one of numerous interrupt sources that is managed by the System Event Controller. Like other peripheral sources, this event can be used to cause a vector to a handler function that executes based on interrupt priority.
- The watchdog expiration event can be used to initiate automated hardware response through the SEC Fault Interface (SFI).

For this, the WDOG expiry has to be configured as the fault source in the SEC. Then the response to the WDOG expiry can be set to any of the below:

- Signalling through the external fault pin.
- System reset
- Trigger outputs to numerous potential trigger slaves.

For further details on how watchdog expiration event can be used with the SFI, see Configuring the WDOG Expiry Event to Issue a System Reset.

ADSP-SC58x WDOG Register List

The Watchdog Timer unit (WDOG) provides a software-based watchdog timer that can improve system reliability by generating an event to the processor core if the watchdog expires before being updated by software. A set of registers governs WDOG operations. For more information on WDOG functionality, see the WDOG register descriptions.

Table 21-1: ADSP-SC58x WDOG Register List

WDOG Block Diagram

The *Watchdog Timer Block Diagram* figure shows the detailed block diagram for the watchdog timer.

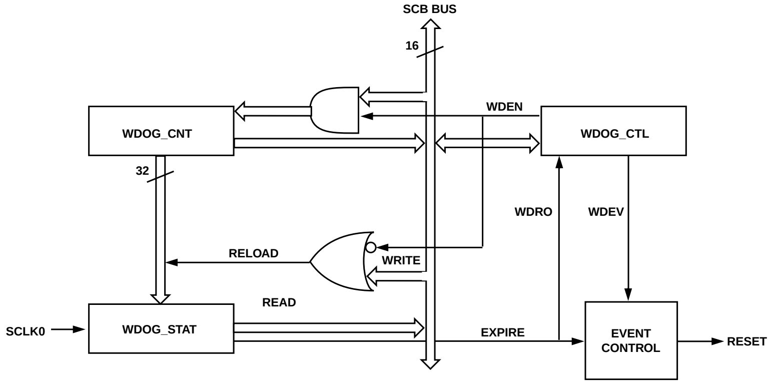

Figure 21-1: Watchdog Timer Block Diagram

Internal Interface

The system clock (SCLK0_0) clocks the watchdog timer. The registers are accessed through the 16-bit peripheral MMR access bus. 32-bit read/write operations always access the 32-bit `WDOG_CNT` and `WDOG_STAT` registers. Hardware ensures that those accesses are atomic. When the counter expires, the WDOG expiration event is generated.

External Interface

The watchdog timer does not directly interact with any external pins.

ADSP-SC58x WDOG Register Descriptions

Watchdog Timer Unit (WDOG) contains the following registers.

Table 21-3: ADSP-SC58x WDOG Register List

Name	Description
`WDOG_CNT`	Count Register
`WDOG_CTL`	Control Register
`WDOG_STAT`	Watchdog Timer Status Register

Count Register

The `WDOG_CNT` register holds the programmable, unsigned count value. A valid write to this register also pre-loads the WDOG counter. For added safety, the `WDOG_CNT` register can be updated only when the WDOG timer is disabled. A write to the `WDOG_CNT` register while the timer is enabled does not modify the contents of this register. This register must be accessed with 32-bit read/writes only.

Table 21-5: WDOG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	WDRO	Watch Dog Rollover. Software can determine whether the timer has rolled over by interrogating the `WDOG_CTL.WDRO` status bit. This is a sticky bit that is set whenever the watch dog timer count reaches 0 and cleared only by disabling the watch dog timer and then writing a 1 to the bit.	
		0	WDT Has Not Expired
		1	WDT Has Expired
11:4 (R/W)	WDEN	Watch Dog Enable. The `WDOG_CTL.WDEN` field is used to enable and disable the watchdog timer. Writing any value other than the disable value into this field enables the watchdog timer. This multi-bit disable key minimizes the chance of inadvertently disabling the watchdog timer.	
		173	Counter Disabled. All other values mean that the counter is enabled.

Watchdog Timer Status Register

The `WDOG_STAT` register contains the current count value of the watchdog timer. Reads of this register return the current count value. When the watchdog timer is enabled, the `WDOG_STAT` register is decremented by 1 on each SCLK0_0 cycle. When the count value reaches 0, the watchdog timer stops counting, and the expiry event is generated. The `WDOG_STAT` register is a 32-bit unsigned system MMR that must be accessed with 32-bit reads and writes.

Values cannot be stored directly in this register but are instead copied from the `WDOG_CNT` register. This copy process can happen in two ways:

- While the watchdog timer is disabled, writing the `WDOG_CNT` register pre-loads the `WDOG_STAT` register.
- While the watchdog timer is enabled, writing the `WDOG_STAT` register loads it with the value in the `WDOG_CNT` register.
- While the watchdog timer is disabled, writing to the `WDOG_STAT` register also reloads it with the value in the `WDOG_CNT` register.

When the processor executes a write (of an arbitrary value) to the `WDOG_STAT` register, the value in the `WDOG_CNT` register is copied into the `WDOG_STAT` register. Typically, software sets the value of `WDOG_CNT` at initialization, then periodically writes to the `WDOG_STAT` register before the watchdog timer expires. This reloads the watchdog timer with the value from `WDOG_CNT` and prevents generation of the expiry event.

If the program does not reload the counter before SCLK0_0 x count register cycles, an expiry event is generated, and the `WDOG_CTL.WDRO` bit is set. When this happens, the counter stops decrementing and remains at zero. If the counter is enabled with a zero loaded to the counter, the `WDOG_CTL.WDRO` bit is set immediately and the counter remains at zero and does not decrement.

Table 21-6: WDOG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Current Count Value (Status). The `WDOG_STAT.VALUE` bit field contains the current count value of the watchdog timer.

22 Real Time Clock (RTC)

The processor contains a Real Time Clock (RTC) which provides a set of digital watch features, including time of day, alarm, and stopwatch countdown. It is typically used to implement either a real-time watch or a life counter which counts the elapsed time since the last system reset. The RTC uses dedicated power supply pins and is independent of any reset, which enables it to maintain functionality even when the rest of the processor is powered down.

RTC Features

The RTC interface has the following features.

- Provides a 1 Hz clock with a second, minute, hour, and day counter (0–32767 days)
- Alarm with a time-of-day interrupt
- Operates on a dedicated supply from an external 3.3 V battery
- Stopwatch function
- Interrupt generation for different events
- Standard two-pin interface with an external 32.768 kHz crystal, 6 pF capacitor on each pin, and a 100 MΩ resistor between the pins
- RTC power switches to the I/O supply when the processor is powered on, saving battery life
- Calibration corrects time once a day; application can use the RTCXTALIN pin to determine calibration settings
- Power down and bus disable

RTC Functional Description

The RTC provides a set of digital watch features to the processor. The RTC external interface consists of two clock pins, which together with the external components form the reference clock circuit for the RTC. It uses an external 32.768 kHz crystal with external capacitor and operates on a dedicated external 3.3 V Lithium coin cell which is never powered off.

The following are functional characteristics of the RTC.

Power supply partitioning

The RTC logic is partitioned between the processor core supply voltage and RTC supply voltage. The core of RTC unit functions on a RTC power supply.

Battery life

To increase the battery life of the external 3.3V cell, most functions reside in the RTC core voltage domain which runs off the processor supply. Only basic clock circuitry resides in the RTC IO voltage.

Reads/writes to 1Hz registers

There is no latency when reading 1 Hz registers, as the values come from the shadow registers.

Writes to the RTC 1 Hz registers are synchronized to the 1 Hz RTC clock.

ADSP-SC58x RTC Register List

The Real-Time Clock (RTC) provides clock-related services, including a set of processor events that can be counted during program execution. A set of registers governs RTC operations. For more information on RTC functionality, see the RTC register descriptions.

Table 22-1: ADSP-SC58x RTC Register List

Name	Description
`RTC_ALM`	RTC Alarm Register

RTC Definitions

The following definitions are helpful when using the RTC module.

RTC HV

The RTC HV is the portion of the RTC which runs on 3.3 V domain and contains the logic for RTC counting/ clock functionality

RTC LV

The RTC LV operates on the core voltage supply and provides the control/access functionality and user interface to the application

Oscillator

The oscillator is the heart of the RTC. It works with the dedicated external crystal to generate a 32768 Hz signal which is divided down to a 1Hz clock used to operate the rest of the RTC

RTC Signal Descriptions

The RTC signals are listed in the following table.

Table 22-5: RTC Signal Descriptions

Signal Name	Signal Description
XTALIN	Pin of the dedicated 32.768KHz external crystal
XTALOUT	Pin of the dedicated 32.768KHz external crystal
VDDRTC	Power supply pin (from Lithium Coin Cell) for RTC module

RTC Architectural Concepts

The key use of the RTC is to provide the time keeping function and maintain the time and date in an accurate and reliable manner with minimal power consumption. In addition to time keeping it also provides the stopwatch and alarm features. The RTC uses the internal counters to keep the time of the day in terms of seconds, minutes, hours and days. This data is enough for the user application to extract the date and time information from the RTC.

Interrupts can be issued periodically, either every second, every minute, every hour, or every day. Each of these interrupts can be independently controlled. It is the responsibility of the program to set the correct time by a software write into the `RTC_CLK` register. Once set, the counters maintain time as long as the RTC supply is valid. The RTC provides two alarm features, programmed with the RTC alarm register (`RTC_ALM`). The first is a time of day alarm (hour, minute, and second). When the alarm interrupt is enabled, the RTC generates an interrupt each day at the time specified. The second alarm feature allows the application to specify a day as well as a time.

The RTC also provides a stopwatch function that acts as a countdown timer. The application can program a second count into the RTC stopwatch count register (`RTC_STPWTCH`). When the stopwatch interrupt is enabled and the specified number of seconds has elapsed, the RTC generates an interrupt.

RTC Block Diagram

The RTC block diagram provides a top level block diagram of the elements used. The main blocks of the RTC are the individual counters, the alarm register, and the event control.

Power Supply Partitioning

The RTC logic is partitioned between the processor core supply voltage and RTC supply voltage. The core of RTC unit functions on a RTC power supply so that the RTC can maintain the time even if the processor power is off. When the core supply voltage is absent, interrupts are ignored.

When the processor's I/O supply is above a certain threshold, the RTC switches to the I/O supply to conserve battery power.

NOTE: Battery power supply can operate the RTC when the I/O voltage is turned off.

The RTC is partitioned into two blocks. The counting and clock function is provided in the I/O voltage domain (VDD_EXT), while the control and access function and the user interface are provided in the core voltage domain. The RTC I/O operates on a dedicated power supply provided by the external 3.3 V (nominal) lithium coin cell. The RTC also has the ability to switch to the I/O supply (VDD_EXT). The RTC LV operates on the nominal core voltage supply (VDD_INT). The interface between both blocks is provided by a set of level shifters. The partitioning at chip level is shown in the ***Power Supply Partition*** figure.

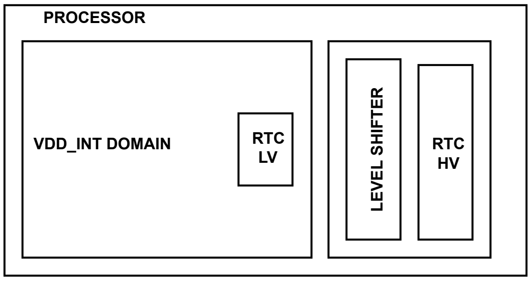

Figure 22-2: Power Supply Partition

Battery Life

To increase the battery life of the external 3.3V cell, most functions reside in the RTC core voltage domain which runs off the processor supply. Only basic clock circuitry resides in the RTC IO voltage. The RTC module provides the following features to extend battery life.

- The seconds, minutes, hours and days counters reside inside the RTC IO voltage.
- The alarm register and comparators reside inside the RTC IO voltage. This allows programs to power down the rest of the chip without the alarm being reset.
- The programmable interface registers, through which the application reads or writes the current time and alarm settings, are part of the RTC core voltage. In order to set the current time and/or alarm, software writes into the shadow registers in the RTC core voltage. The data is then transferred into the corresponding register in the RTC IO voltage by hardware.
- The RTC core voltage runs primarily on the processor's peripheral clock while the RTC IO voltage runs primarily on a self generated 1 Hz clock. The synchronization circuitry sits inside the RTC core voltage.
- The stopwatch circuitry is inside the RTC core voltage and operates on a 1 Hz clock, level shifted from the RTC IO voltage.

Writes to the 1 Hz Registers

Writes to the RTC 1 Hz registers are synchronized to the 1 Hz RTC clock. When setting the time of day, do not factor in the delay when writing to the RTC 1 Hz registers. The most accurate method of setting the RTC is to monitor the seconds (1 Hz) event flag or to program an interrupt for this event and then write the current time to the RTC status register (RTC_STAT) in the interrupt service routine (ISR). The new value is inserted ahead of the incremented value. Hardware adds one second to the written value (with appropriate carries into minutes, hours and days) and loads the incremented value at the next 1 Hz tick, when it represents the then-current time.

Writes posted at any time are properly synchronized to the 1 Hz clock. Writes complete at the rising edge of the 1 Hz clock. A write posted just before the 1 Hz tick may not be completed until the 1 Hz tick one second later.

Reads From the 1 Hz Registers

There is no latency when reading 1 Hz registers, as the values come from the shadow registers. The shadows are updated and ready for reading by the time any RTC interrupts or event flags for that second are asserted. Once the internal core logic completes its initialization sequence after SCLK0_0 starts, there is no point in time when it is unsafe to read the 1 Hz registers (for synchronization reasons). The registers always return coherent values, although the values may be unknown.

RTC Operating Modes

The following sections provide information on the operating modes available to the real-time clock.

Alarm

The RTC provides two alarm features, programmed with the RTC alarm register (RTC_ALM). The first is a time of day alarm (hour, minute, and second). When the alarm interrupt is enabled, the RTC generates an interrupt each day at the time specified.

Day Alarm

The second alarm feature allows the application to specify a day as well as a time. When the day alarm interrupt is enabled, the RTC generates an interrupt on the day and time specified. The alarm interrupt and day alarm interrupt can be enabled or disabled independently.

Stopwatch

The RTC stopwatch count register (RTC_STPWTCH) contains the countdown value for the stopwatch. The stopwatch counts down seconds from the programmed value and generates an interrupt (if enabled) when the count reaches 0. The counter stops counting at this point and does not resume counting until a new value is written to the RTC_STPWTCH register. Once running, the counter may be overwritten with a new value. This allows the stopwatch to be used as a watchdog timer with a precision of one second.

The stopwatch can be programmed to any value between 0 and (2^{16} – 1) seconds, which is a range of 18 hours, 12 minutes, and 15 seconds. Typically, software should wait for a 1 Hz tick, then write the RTC_STPWTCH register. One second later, the RTC_STPWTCH value changes to the new value and begins decrementing. Because the register write occupies nearly one second, the time from writing a value of N until the stopwatch interrupt is nearly N + 1 seconds. To produce an exact delay, software can compensate by writing N – 1 to get a delay of nearly N seconds. This implies that a delay of 1 second with the stopwatch cannot be achieved. Writing a value of 1 immediately after a 1 Hz tick results in a stopwatch interrupt nearly two seconds later. To wait one second, software should just wait for the next 1 Hz tick

Digital Watch Mode

The primary function of the RTC is to maintain an accurate day count and time of day. The RTC accomplishes this by means of four counters:

- 60-second counter
- 60-minute counter
- 24-hour counter
- 32768-day counter

The RTC provides a set of digital watch features. The internal oscillator generates a 32768 Hz signal using the crystal which is scaled down to 1 Hz and used to clock the second, minute, hour and day counters. The 32768 day counter increments each day at midnight (during the change from 23:59:59). The counter operates on the RTC supply (either the external battery or I/O supply) and is active irrespective of the status of the processor core supply (VDD_INT). When the processor core and I/O supply are valid then the following occurs.

- The current time is updated every second into the RTC clock register (`RTC_CLK`)
- Interrupts can be issued periodically every second, every minute, every hour or every day

Each of the interrupts can be independently controlled, and are described in the RTC Event Control section.

It is the responsibility of the program to set the correct time by a software write into the `RTC_CLK` register. Once set, the counters maintain time as long as the RTC supply is valid.

Calibration for Accuracy

To guard against the possibility of long term (> 1 day) errors, the RTC provides a calibration feature using 4 bits of the `RTC_INIT` register (not available for the stopwatch function).

This is a simple a time correction at the end of every day (when the clock register changes from a Day:Hour:Min:Sec value of XXX:23:59:59 to YYY:00:00:00). It functions by adding or subtracting an integer number of seconds (to a maximum of 7) from the start of the next day, to correct accumulated time error over the course of the previous day. The number of seconds that are added or subtracted is defined in the `RTC_INIT.CAL` bit field.

As an example, if there is a –50 ppm error in the 1 Hz frequency, this translates into a 86400 ´ 50 ppm seconds (+4.32 seconds) error. That is at time 00:00:00, RTC time is 4.32 seconds ahead of actual time. The RTC can correct this by adding 4 seconds (if 4 is the value written into the calibration register) to the time at 00:00:00. Therefore, from 23:59:59, the timer counter jumps directly to 00:00:04, (there is no 00:00:00 to 00:00:03 time occurrences). At the instant it jumps to 00:00:04, the error reduces to +0.32 seconds over the course of the day, which is only 3.7 ppm.

As a second example, if there is a +50 ppm error in the 1 Hz frequency, this also translates into 86400 ´ 50 ppm seconds (–4.32 seconds) error. In this case the time must be subtracted. This is corrected in the RTC by counting

00:00:00 to 00:00:03 twice, so that the time is effectively subtracted. As soon as the RTC reaches 00:00:04, the error reduces to –0.32 seconds over the course of the previous day and accumulated error is minimized.

When the RTC is powered up for the first time, the calibration values are written once to ensure proper function (if they are not to be used, write 0000). These register bits are sticky, which means that once set, they retain their value irrespective of the status of the core power supply.

The addition or subtraction of time can only be in integer multiples of seconds. Zero to seven seconds can be added or subtracted using 4 bits. The MSB indicates addition (0) or subtraction (1). The three LSBs indicate number of seconds (0 – 7 represented by their binary 3 bit equivalents). Because the clock runs at a time period of one second (@ 1 Hz frequency) 0.25 or 0.5 second resolution is not possible.

The calibration technique introduces a guard band for alarm by definition. In case the alarm is set within the duration of the time (Day:00:00:00 to Day:00:00:06) corrected by the calibration register, then it occurs at the nearest corrected time. This is shown in the following two examples.

If the `RTC_INIT.CAL` is 0101, the RTC clock jumps from 23:59:59 to 00:00:05 due to calibration. If the alarm is set to 00:00:01, it occurs at the RTC time 00:00:05.

If the `RTC_INIT.CAL` is 1101, then the RTC clock counts from 00:00:00 to 00:00:04 twice and then moves to 00:00:05. If the alarm is set to 00:00:01, it occurs at the RTC time 00:00:05.

Accuracy

In order to perform calibration on the bench, use the RTXI pin and check the ppm deviation from 32.768 kHz. This ppm error is the same as in the internal 1Hz clock and the calibration register should be updated with the corresponding values as explained in Calibration for Accuracy above.

Note that total accuracy is ≤ ±35 ppm, < ±1.5 minutes per month of error, inclusive of any inaccuracies of the RTC input crystal at room temperature. This is achieved with a crystal of ±10 ppm error at 25°C. A crystal error of ±20 ppm translates into a maximum inaccuracy of ±45 ppm.

RTC Event Control

The RTC generates multiple events depending on the value on `RTC_CLK`, `RTC_ALM` and `RTC_STPWTCH` registers. It generates an event on each second, minute, hour, day. It also generates an event when an alarm or day alarm or stopwatch expiry occurs.

RTC Events

The RTC can provide interrupts at several programmable intervals

- Per Second
- Per minute (clock counter x:y:z:59)
- Per hour (clock counter x:y:59:59)
- Per day (clock counter x:23:59:59)

- Everyday at a particular time (day alarm)
- On a particular day and time (time of the day alarm)
- Expiry of Stop Watch counter
- When the 1 Hz clock from RTC HV fails

The RTC can also be programmed to provide an interrupt at the completion of all pending writes to any of the RTC 1Hz registers (`RTC_ALM`, `RTC_CLK`, `RTC_INIT` and `RTC_STPWTCH`). Any of these interrupts can be individually enabled/disabled through the bits in `RTC_IEN` register.

Programs can disable all the RTC interrupts when the processor enters emulation space by setting the `RTC_IEN.EMUDIS` bit. Interrupts are not generated even if the individual interrupt enable bits in the `RTC_IEN` register are set.

In the service routine, the `RTC_STAT` register should be read to identify the cause of the interrupt. While reading the status register the RTC automatically clears the respective status bit, ensuring that the cause has been cleared before ending the routine. Note that the pending RTC interrupt is cleared whenever all enabled and set (=1) bits in the `RTC_STAT` register are read, or when all bits in the `RTC_IEN` register corresponding to pending events are cleared (=0).

RTC Status and Error Signals

The RTC contains a status register (`RTC_STAT`) that provides the status on the errors and other events generated by the module. The module captures the 1 Hz clock failures in this register as well. The `RTC_STAT` register contains the RTC event flags and RTC interrupt status. Once set by the event, each bit remains set until cleared by a software read of this register. These sticky bits are independent of the interrupt enable bits in the `RTC_IEN` register. Values are cleared by reading `RTC_STAT` register, except for the `RTC_STAT.WRPEND`, `RTC_STAT.ALM` and `RTC_STAT.DAYALM` bits. Writes to the `RTC_STAT` register have no effect.

RTC Programming Model

The following sections provide basic programming steps for the RTC interface.

Power-Up, Power-Down and Reset

The `RTC_INIT.PWDN` programmable bit is provided to power down the RTC. Power-down is interpreted as a crystal oscillator disable, which reduces power dissipation to only leakage current. Once set or reset, this bit retains its value unless changed, irrespective of the status of core supply.

The inclusion of the power-down bit (`RTC_INIT.PWDN`) as well as the possibility that the RTC may not be used in certain applications introduces specific constraints on the power-up and reset behavior of the RTC. These are described below.

1. When the RTC is powered-up for the first time, it remains in an undefined state until the core powers-up and the corresponding `RTC_INIT.PWDN` bit is written by software. Programs should clear (=0) the `RTC_INIT.PWDN` bit if the RTC function is desired and set it (=1) if it is not.
2. After clearing the `RTC_INIT.PWDN` bit the application must wait at least until the first seconds' event before it writes the timer and alarm registers. This is because the oscillator has a startup time before the clock is generated.

   This sequence applies only to the first time the RTC supply (battery or I/O) is connected. Once the `RTC_INIT.PWDN` bit is set or reset, its value is retained as long as RTC supply (battery or I/O) is valid.
3. After the RTC supply is connected for the first time and the `RTC_INIT.PWDN` bit =0, the application is free to power-up and power-down the core supply any number of times without loss of RTC function (provided the RTC supply, battery or I/O, is valid). Conversely, if the `RTC_INIT.PWDN` bit =1, then the RTC oscillator remains disabled irrespective of the status of the core supply.
4. The current status of the RTC power-down is updated by hardware into the initialization status register (`RTC_INITSTAT.PWDN`). This is useful when the rest of the processor wakes up from power-down and needs to know the status of the RTC.
5. Whenever the processor core wakes up from power-down, the values of the `RTC_CLK`, `RTC_ALM` and `RTC_STPWTCH` registers is zero until the first seconds' event after power-up. At the first seconds' event, an arbitrary value is uploaded into these registers. To put them in a defined state software must write the desired value into these registers. If the `RTC_CLK` and `RTC_ALM` registers have been set before core power-down and subsequent power-up, their values are valid throughout, but can be read by the program only after the first seconds' event after power-up.

Register Access

The interface to the RTC is through a set of memory-mapped registers. The RTC is configured through software and the current state of the RTC is also determined through reads and writes to these registers. Writes of the alarm, clock, stopwatch and initialization registers is performed in a two step sequence.

1. The desired values are programmed into a shadow register in the processor's core VDD_INT domain and operating on the processor's peripheral clock.
2. The contents of the shadow register are synchronized onto the contents of the RTC's internal clock register which operates on the 1 Hz clock in the RTC power domain.

To ensure that writes between the core voltage and RTC voltage domain are properly synchronized, all write commands should be issued immediately after a seconds' event in the RTC status register (`RTC_STAT`). This two step sequence results in a write latency of up to 1 second.

While the write sequence is ongoing, the write pending (`RTC_STAT.WRPEND`) bit is set and is cleared by hardware when the process is complete. Resetting or powering down the peripherals while a write is in progress, (that is when this bit is set) is forbidden. Subsequent writes to the same register before completion of the previous write are ignored.

- Do not attempt write to any of `RTC_CLK`, `RTC_ALM` or `RTC_STPWTCH` registers when the RTC oscillator is powered down or when the `RTC_INIT.RDEN` bit is set.
- During initialization, after a write of the `RTC_INIT` register, make sure that the `RTC_STAT.WRPEND` bit is cleared before attempting writes to other registers.

The `RTC_INIT` register can be written any time. However, programs must ensure that the interrupt enable bits corresponding to Clock, Alarm and Stopwatch features are set only after initializing the `RTC_CLK`, `RTC_ALM` and `RTC_STPWTCH` registers. The `RTC_STAT` and `RTC_INITSTAT` registers can be read any time.

ADSP-SC58x RTC Register Descriptions

Real Time Clock (RTC) contains the following registers.

Table 22-6: ADSP-SC58x RTC Register List

Name	Description
`RTC_ALM`	RTC Alarm Register
`RTC_CLK`	RTC Clock Register
`RTC_IEN`	Interrupt Enable Register
`RTC_INIT`	RTC Initialization Register
`RTC_INITSTAT`	RTC Initialization Status Register
`RTC_STAT`	RTC Status Register
`RTC_STPWTCH`	RTC Stop Watch Register

RTC Alarm Register

The `RTC_ALM` register is programmed by software for the time (in hours, minutes, and seconds) the alarm interrupt occurs. Reads and writes can occur at any time. The alarm interrupt occurs whenever the hour, minute, and second fields first match those of the `RTC_CLK` register. The day interrupt occurs whenever the day, hour, minute, and second fields first match those of the `RTC_CLK` status register.

Bit No. (Access)	Bit Name	Description/Enumeration
31:17 (R/W)	DAY	Alarm Day. The `RTC_ALM.DAY` bit provides the alarm day from 0 to 32767. The day interrupt occurs whenever the day, hour, minute, and second fields first match those of the RTC status register.
16:12 (R/W)	HOUR	Alarm Hour. The `RTC_ALM.HOUR` bit field configures the alarm to occur whenever the alarm hour (0 to 23) first matches that of the RTC status register.
11:6 (R/W)	MIN	Alarm Minute. The `RTC_ALM.MIN` bit field configures the alarm to occur whenever the alarm minute (0 to 59) first matches that of the RTC status register.
5:0 (R/W)	SEC	Alarm Second. The `RTC_ALM.SEC` bit field configures the alarm to occur whenever the seconds (0 to 59) first match those of the RTC status register.

RTC Clock Register

The `RTC_CLK` register is used to read or write the current time. It has no reset and an undefined value when the RTC VDD is first powered up. Writing invalid time values is forbidden (for example, an hour value more than 23 and a minute value more than 59). The `RTC_CLK` register is updated every second. If the RTC is already running when the core starts up, the values read from `RTC_CLK` are zero until the first second event comes. In this case, programs must wait for the second event and then read this register.

		0	Oscillator is powered down
		1	Oscillator is running
1 (R/NW)	DAYALMPND	Day Alarm Pending. The RTC_INITSTAT.DAYALMPND bit indicates that an alarm has occurred. This indication is useful when the core has powered down or reset in the middle of operation. This bit is cleared when the RTC_INITSTAT register is read.	
		0	Alarm occurred
		1	No alarm occurred
0 (R/NW)	ALMPND	Alarm Pending. The RTC_INITSTAT.ALMPND bit indicates that an alarm has occurred. This indication is useful when the core has powered down or reset in the middle of operation. This bit is cleared when the RTC_INITSTAT register is read.	
		0	No alarm occurred
		1	Alarm occurred

RTC Status Register

The RTC_STAT register contains the RTC event flags and RTC interrupt status. These bits are sticky. Once set by the event, each bit remains set until cleared by a software read. These sticky bits are independent of the interrupt enable bits in the RTC_IEN register. Values are cleared by reading the RTC_STAT register, except for the RTC_STAT.WRPEND bit, which is read-only. Writes of 0 or 1 to any bit of this register has no effect. This register is cleared at reset.

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	WRDONE	Write Done. The `RTC_STAT.WRDONE` bit shows that the register write is complete. The `RTC_STAT.WRDONE` bit is applicable only for the alarm, clock and stopwatch registers.	
		0	Write is done
		1	Write is not done
0 (R/NW)	WRPEND	Write Pending. The `RTC_STAT.WRPEND` bit shows that a write to the `RTC_CLK`, `RTC_ALM`, `RTC_STPWTCH`, or `RTC_INIT` register is pending. This bit is automatically cleared and set by the hardware.	
		0	No write pending
		1	Write pending

RTC Stop Watch Register

The RTC_STPWTCH register contains the countdown value for the stop watch. The stopwatch counts down seconds from the programmed value and generates an interrupt (if SW_INTEN=1) when the count reaches 0. The counter stops counting at this point and does not resume counting until a new nonzero value is written to the RTC_STPWTCH register. Writing a value of 0 to the running stopwatch forces it to stop; no interrupt is generated in this case. The register can be programmed to any value between 0 and (2^{16-1}) seconds (that is, a range of 18 hours, 12 minutes and 15 seconds).

23 General-Purpose Counter (CNT)

The GP counter converts pulses from incremental position encoders into data that is representative of the actual position of the pulse. This conversion is done by integrating (counting) pulses on one or two inputs. Since integration provides relative position, some devices also feature a zero-position input (zero marker). The GP counter can use the zero position input feature to establish a reference point for verifying that the acquired position does not drift over time. In addition, the GP counter can use the incremental position information to determine speed, if the time intervals are measured.

The GP counter provides flexible ways to establish position information. When used with the GP timer block, the GP counter can allow for the acquisition of coherent position or time stamp information that enables speed calculation.

GP Counter Features

The GP counter includes the following features:

- 32-bit up or down counter
- Quadrature encode mode (Gray code)
- Binary encoder mode
- Alternative frequency-direction mode
- Timed direction and up or down counting modes
- Zero marker or push-button support
- Capture event timing in association with GP Timer
- Boundary comparison and boundary setting features
- M/N frequency scaling of the inputs CUD/CDG

GP Counter Functional Description

The *GP Counter Block Diagram* shows a block diagram of the GP counter. The `CNT_UD` and `CNT_DG` pins accept various forms of incremental inputs. The 32-bit counter processes the inputs. The GP counter uses the `CNT_ZM` pin to sense the pressing of a push button.

NOTE: When enabled, the GP counter requires 3 SCLK0_0 cycles of initialization before recognizing valid toggles on its input pins.

The three input pins can be filtered (debounced) before the GP counter evaluates them.

The GP counter also features a flexible boundary comparison. In all of the operating modes, the counter can be compared to an upper and lower limit. It takes various actions when reaching these limits.

The module can optionally generate an interrupt request to the system through its IRQ line. On many processors, a GP timer module can use an output to generate time stamps on certain events.

ADSP-SC58x CNT Register List

The GP Counter (CNT) provides support for manually controlled rotary controllers, such as the volume wheel on a radio device. This unit also supports industrial encoders.

The CNT converts pulses from incremental position encoders into data that is representative of the actual position. To complete this task, the CNT integrates (counts) pulses on one or two inputs. Because integration provides relative position, a zero position input (zero marker) is usually provided that establishes a reference point, verifying that the acquired position does not drift over time. The incremental position information may also be used to determine speed, if the relevant time intervals are measured. The CNT provides flexible ways to establish position information. When used in conjunction with the General-purpose Timer (TIMER), the CNT allows acquisition of coherent position/time stamp information, enabling speed calculation.

A set of registers govern CNT operations. For more information on CNT functionality, see the CNT register descriptions.

GP Counter Operating Modes

The GP counter has the following five modes of operation.

1. Quadrature Encoder
2. Binary Encoder
3. Up/Down Counter
4. Direction Counter

5. Timed Direction

With the exception of the timed direction mode, the GP counter can operate with the GP timer block to capture additional timing information (time stamps) associated with events detected by this block.

Quadrature Encoder Mode

In this mode, the `CNT_UD` and `CNT_DG` inputs expect a quadrature-encoded signal that is interpreted as a two-bit Gray code. The order of transitions of the `CNT_UD` and `CNT_DG` inputs determines whether the counter increments or decrements. The `CNT_CNTR` register contains the number of transitions that have occurred as shown in the ***Quadrature Events and Counting Mechanism*** table. Optionally, an interrupt is generated when both inputs change within one SCLK0_0 cycle. Gray coding prohibits such transitions. Therefore, the `CNT_CNTR` register remains unchanged, and an error condition is signaled.

Table 23-5: Quadrature Events and Counting Mechanism

CNT_COUNTER Register Value	-4	-3	-2	-1	0	+1	+2	+3	+4
CDG, CUD Inputs	00	01	11	10	00	01	11	10	00

It is possible to reverse the count direction of the Gray-coded signal by enabling the polarity inverter of either the `CNT_UD` pin or the `CNT_DG` pin. Inverting both pins does not alter the behavior. The GP counter can enable this feature with the `CNT_CFG.CDGINV` and `CNT_CFG.CUDINV` bits.

As an example, the `CNT_DG` and `CNT_UD` inputs are 00 and the next transition is to 01. These inputs normally change the counter in increments as shown in the table. If the `CNT_UD` polarity is inverted, this condition generates a received input of 01 followed by 00. The results is a decrement of the counter, altering the behavior of the connected hardware.

Binary Encoder Mode

This mode is almost identical to quadrature encoder mode, with the exception that the `CNT_UD`: `CNT_DG` inputs expect a binary-encoded signal. The order of transitions of the `CNT_UD` and `CNT_DG` inputs determines whether the counter increments or decrements. The `CNT_CNTR` register contains the number of transitions that have occurred as shown in the ***Binary Events and Counting Mechanism*** table. Optionally, an interrupt is generated when the detected code steps by more than 1 (in binary arithmetic) within one SCLK0_0 cycle. Such transitions are erroneous. Therefore, the `CNT_CNTR` register remains unchanged, and an error condition is signaled.

Table 23-6: Binary Events and Counting Mechanism

CNT_COUNTER Register Value	-4	-3	-2	-1	0	+1	+2	+3	+4
CDG:CUD Inputs	00	01	10	11	00	01	10	11	00

Reversing the `CNT_UD` and `CNT_DG` pin polarity has a different effect in binary encoder mode than for the quadrature encoder mode. Inverting the polarity of the `CNT_UD` pin only, or inverting both the `CNT_UD` and `CNT_DG` pins, results in reversing the count direction.

Up/Down Counter Mode

In this mode, the counter increments or decrements at every active edge of the input pins. The GP counter uses the `CNT_CFG.CUDINV` bit to select an active edge and has the following results.

- If the GP counter module detects an active edge at the `CNT_UD` input, the counter increments.
- If the GP counter module detects an active edge at the `CNT_DG` input, the counter decrements.
- If simultaneous edges occur on the `CNT_DG` and `CNT_UD` pins, the counter remains unchanged, and both up-count and down-count events are signaled in the `CNT_STAT` register.

Direction Counter Mode

In this mode, the counter is incremented or decremented at every active edge of the `CNT_DG` input pin. The state of the `CNT_UD` input determines whether the counter increments or decrements. The GP counter uses the `CNT_CFG.CUDINV` bit to select the polarity.

If the GP counter detects an active edge at the `CNT_DG` input, the counter value changes by one in the selected direction.

Timed Direction Mode

In this mode, the counter is incremented or decremented at each SCLK0_0 cycle. The state of the `CNT_UD` input determines whether the counter increments or decrements. The GP counter uses the `CNT_CFG.CUDINV` bit to select the polarity. The `CNT_DG` pin can be used to gate the clock. The GP counter uses the `CNT_CFG.CDGINV` bit to select the polarity.

GP Counter Programming Model

The following sections provide information for programming the interface.

GP Counter General Programming Flow

The following are general guidelines for configuring and enabling the GP counter.

1. Initialize (but do not enable) the GP counter for the desired mode and settings through the `CNT_CFG` register.
2. Usually, events of interest are processed using interrupts rather than by polling status bits. In this case, clear all status bits and activate the interrupt generation requests with the `CNT_IMSK` register.
3. Configure interrupts at the system level to insure desired interrupt signaling to the system.
4. If timing information is required, set up the relevant GP Timer in width capture mode.
5. Finally, enable interrupt requests and the GP Counter itself using the `CNT_IMSK` and `CNT_CFG` registers, respectively.

GP Counter Mode Configuration

The GP counter can use the `CNT_ZM` input pin to sense the zero marker output of a rotary device or to detect the pressing of a push button. There are four programming schemes, which are functional in all counter modes:

- Push-button mode
- Zero-marker-zeros-counter mode
- Zero-marker-error mode
- Zero-once mode

Configuring GP Counter Push-Button Operation

Use the following procedure to configure push-button operation:

1. Set `CNT_IMSK.CZM` to enable (unmask) the zero marker interrupt.
2. Select the active edge polarity through the `CNT_CFG.CZMINV` bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

An active edge at the `CNT_ZM` input sets the `CNT_IMSK.CZM` bit.

Configuring Zero-Marker-Zeros-Counter Mode

The following provides information on configuring zero-marker-zeros-counter mode for the GP counter.

1. Set `CNT_IMSK.CZMZ` to enable `CNT_CNTR`. The zero marker interrupt zeroes the counter.
2. Set `CNT_CFG.ZMZC` to enable ZMZC mode.
3. Select the active edge polarity through the `CNT_CFG.CZMINV` bit.
4. Proceed with any other desired configuration steps and enable the peripheral.

This configuration causes an active level at the `CNT_ZM` pin to clear the `CNT_CNTR` register and keep it cleared until the `CNT_ZM` pin is deactivated. In addition, the `CNT_STAT.CZMZ` bit is set.

Configuring Zero-Marker-Error Mode

The GP counter uses this mode to detect discrepancies between counter-value and the zero marker output of certain rotary encoder devices.

1. Set the `CNT_STAT.CZME` bit to enable this mode.
2. Select the active edge of the `CNT_ZM` pin through the `CNT_CFG.CZMINV` bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

When the GP counter detects an active edge at the `CNT_ZM` input pin, it compares the four LSBs of the `CNT_CNTR` register to zero. If they are not zero, the GP counter uses `CNT_STAT.CZME` bit to signal a mismatch.

Configuring Zero-Once Mode

The GP counter uses this mode to perform an initial reset of the counter-value when it detects an active zero marker. After that, the zero marker is ignored (the counter is no longer reset).

1. Set the `CNT_CMD.W1ZMONCE` bit to enable this mode.
2. Select the active edge of the `CNT_ZM` pin through the `CNT_CFG.CZMINV` bit.
3. Ensure that at least one of the following bits is enabled: `CNT_IMSK.CZM`, `CNT_IMSK.CZME`, `CNT_IMSK.CZMZ`.
4. Proceed with any other desired configuration steps and enable the peripheral.

The `CNT_CNTR` register and the `CNT_CMD.W1ZMONCE` bit are cleared on the next active edge of the `CNT_ZM` pin. Now the `CNT_CMD.W1ZMONCE` bit can be read to check whether the event has already occurred.

Configuring Boundary Auto-Extend Mode

In this mode, hardware modifies the boundary registers (`CNT_MIN` and `CNT_MAX`) whenever the `CNT_CNTR` value reaches either of them. The GP counter uses this mode to monitor the widest angle a thumb wheel even if the software did not generate interrupts.

1. Initialize `CNT_CNTR` with the desired value.
2. Set both `CNT_MIN` and `CNT_MAX` to this same value.
3. Configure the `CNT_CFG.BNDMODE` field for auto extend mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

The `CNT_MAX` register is loaded with the current `CNT_CNTR` value when the latter increments beyond the `CNT_MAX` value. Similarly, the `CNT_MIN` register is loaded with the `CNT_CNTR` value when the latter decrements below the `CNT_MIN` value. The `CNT_STAT.MAXC` and `CNT_STAT.MINC` status bits are set when the `CNT_CNTR` value matches the respective boundary register value.

Configuring Boundary Capture Mode

In this mode, the `CNT_CNTR` value is latched into the `CNT_MIN` register at one detected edge of the `CNT_ZM` input pin, and latched into the `CNT_MAX` boundary register at the opposite edge.

1. To capture the `CNT_ZM` pin rising edge into `CNT_MIN` and the falling edge into `CNT_MAX`, program `CNT_CFG.CZMINV` for active high polarity. Conversely, to capture the `CNT_ZM` pin falling edge into `CNT_MIN` and the rising edge into `CNT_MAX`, program `CNT_CFG.CZMINV` for active low polarity.
2. Program the `CNT_IMSK.MAXC` and `CNT_IMSK.MINC` interrupt mask bits according to interrupt generation requirements.
3. Configure the `CNT_CFG.BNDMODE` field for boundary capture mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

The `CNT_STAT.MAXC` and `CNT_STAT.MINC` status bits report the capture event, depending on how interrupt masks are configured.

Configuring Boundary Compare and Boundary Zero Modes

In these modes, the two boundary registers (`CNT_MAX` and `CNT_MIN`) are compared to the value in the `CNT_CNTR` register.

1. Program `CNT_MAX` and `CNT_MIN` registers with appropriate upper and lower range values.
2. Program the `CNT_IMSK.MAXC` and `CNT_IMSK.MINC` interrupt mask bits according to interrupt generation requirements.
3. Configure the `CNT_CFG.BNDMODE` field for boundary compare mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

If after incrementing, `CNT_CNTR` = `CNT_MAX`, then the `CNT_STAT.MAXC` bit is set. Similarly if after decrementing, `CNT_CNTR` = `CNT_MIN`, then the `CNT_STAT.MINC` bit is set.

Additionally, for boundary zero mode, the counter-value in `CNT_CNTR` is set to zero. The `CNT_STAT.MAXC` and `CNT_STAT.MINC` bits are not set when software updates the `CNT_MAX` or `CNT_MIN` registers.

Configuring GP Counter Push-Button Operation

Use the following procedure to configure push-button operation:

1. Set `CNT_IMSK.CZM` to enable (unmask) the zero marker interrupt.
2. Select the active edge polarity through the `CNT_CFG.CZMINV` bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

An active edge at the `CNT_ZM` input sets the `CNT_IMSK.CZM` bit.

GP Counter Programming Concepts

Using the features, operating modes, and event control for the GP counter to their greatest potential requires an understanding of some GP counter-related concepts. Some key aspects to consider are input noise filtering and capturing timing information.

CNT Input Noise Filtering

In all modes, the three input pins can be filtered to present clean signals to the GP counter logic. The GP counter uses the `CNT_CFG.DEBEN` bit to enable or disable this filtering. The ***Programmable Noise Filtering*** figure shows the filtering operation for the `CNT_UD` pin.

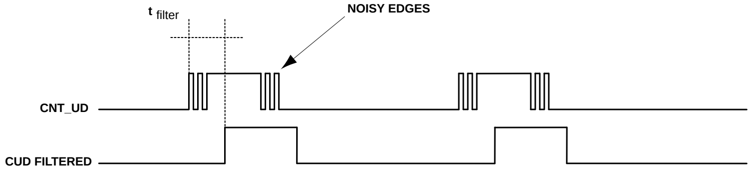

Figure 23-2: Programmable Noise Filtering

The CNT module implements the filtering mechanism using counters for each GP counter pin, where each counter is initialized from the `CNT_DEBNCE.DPRESCALE` field. When a transition is detected on a pin, the corresponding counter starts counting up to the programmed number of SCLK0_0 cycles. The state of the pin is latched after time t_{filter} and passed on to the GP counter logic.

The following formula determines the time t_{filter}, given SCLK0_0 and the `CNT_DEBNCE.DPRESCALE` value, where lower values of `CNT_DEBNCE.DPRESCALE` result in shorter debounce delays:

$t_{filter} = 128 \times (2^{DPRESCALE} \times SCLK0\_0)$

Capturing Counter Interval and CNT_CNTR Read Timing

When the count speed is low, it is often useful to capture the time elapsed since the last count event. Program the `TIMER_TMR[n]_CFG` register of the associated GP timer in a width capture mode with the following bit settings.

- `TIMER_TMR[n]_CFG.PULSEHI` = 0
- `TIMER_TMR[n]_CFG.TMODE` = b#1011
- `TIMER_TMR[n]_CFG.TINSEL` = 1

The *Capture Intervals* figure shows and the following list describe the operation of the GP counter and the GP timer in this mode.

Figure 23-3: Capture Intervals

NOTE: SCLK in the ***Capture Intervals*** figure is SCLK0_0.

1. The CNT_TO signal generates a pulse every time a count event occurs. In addition, when the processor reads the CNT_CNTR register, the CNT_TO signal presents a pulse which is extended (high) until the next count event.
2. The GP timer updates its TIMER_TMR[n]_PER register with the period (measured from falling edge to falling edge, because TIMER_TMR[n]_CFG.PULSEHI = 0) of the CNT_TO signal.
3. The TIMER_TMR[n]_WID register is updated with the pulse width (the portion where CNT_TO is low, again because TIMER_TMR[n]_CFG.PULSEHI = 0).
4. Both registers are updated at every rising edge of the CNT_TO signal (because TIMER_TMR[n]_CFG.TMODE= b#011).

The TIMER_TMR[n]_PER register contains the period between the last two count events. The TIMER_TMR[n]_WID register contains the time since the last count event and the read of the CNT_CNTR register, both measured in SCLK0_0 cycles.

Read the CNT_CNTR register to latch the two time measurements, providing a coherent triplet of information to calculate speed and position.

NOTE: Speed restrictions apply to the use of the CNT_TO signal. Therefore, programs must not operate at count event rates that are high. For instance, if CNT_CNTR is incremented or decremented every SCLK0_0 cycle (timed direction mode), the CNT_TO signal is not valid.

Capturing Time Interval Between Successive Counter Events

When the required timing information is the interval between successive count events, program the associated timer in a width capture mode. Set the TIMER_TMR[n]_CFG bit of TIMER_TMR[n]_CFG.PULSEHI = 1, TIMER_TMR[n]_CFG.TMODE = b#1010 and TIMER_TMR[n]_CFG.TINSEL = 1. Typically, this information is sufficient if the speed of GP counter events does not to reach low values.

The ***Period Register Timing*** figure shows the operation of the GP counter and the GP timer in this mode.

Figure 23-4: Period Register Timing

The CNT_TO signal generates a pulse every time a count event occurs. The GP timer updates its TIMER_TMR[n]_PER register with the period (measured from rising edge to rising edge) of the CNT_TO signal. The TIMER_TMR[n]_PER register is updated at every rising edge of the CNT_TO signal and contains the number of SCLK0_0 cycles that have elapsed since the previous rising edge.

Incidentally, the TIMER_TMR[n]_WID register is also updated at the same time, but is generally of no interest in this mode of operation. If no reads of the CNT_CNTR register occur between counter events, the TIMER_TMR[n]_WID register only contains the width of the CNT_TO pulse. If a read of CNT_CNTR has occurred between events, the TIMER_TMR[n]_WID register contains the time between the read of CNT_CNTR and the next event.

This mode can also be used with TIMER_TMR[n]_CFG.PULSEHI = 0. In this case, the period of CNT_TO is measured between falling edges. It results in the same values as in the previous case, only the latching occurs one SCLK0_0 cycle later.

GP Counter Event Control

Eleven events can be signaled to the processor using status information and optional interrupt requests. The GP counter uses the respective bits in the CNT_IMSK register to enable the interrupt requests. It uses dedicated bits in the CNT_STAT register to report events. When an interrupt request from the GP counter is serviced, the application software is responsible for correct interpretation of the events. It is recommended to logically AND the content of the CNT_IMSK and CNT_STAT registers to identify pending interrupt requests.

Perform a write-one-to-clear (W1C) operation to the CNT_STAT register to clear the interrupt requests. Hardware does not clear the status bits automatically, unless the counter module is disabled.

The following sections describe the events associated with the GP counter.

Illegal Gray and Binary Code Events

When illegal transitions occur in quadrature encoder or binary encoder modes, the CNT_STAT.IC bit is set. If enabled by the CNT_STAT.IC bit, the counter module generates an interrupt request. Set the CNT_STAT.IC bit only in the quadrature encoder or binary encoder modes.

Up/Down Count Events

The GP counter uses the CNT_STAT.UC bit to indicate whether the counter has been incremented. Similarly, the CNT_STAT.DC bit reports decrements. The two events are independent. For instance, if the counter increments by one and then decrements by two, both bits remain set, even though the resulting counter-value shows a decrement by one.

In up/down counter mode, hardware can detect simultaneous active edges on the CNT_UD and CNT_DG inputs. In that case, the CNT_CNTR remains unchanged, but both the CNT_STAT.UC and CNT_STAT.DC bits are set. Interrupt requests for these events can be enabled through the CNT_IMSK.UC and CNT_IMSK.DC bits. Use this feature carefully when the counter is clocked at high rates. This suggestion is especially critical when the counter operates in DIR_TMR mode, as interrupts are generated every SCLK0_0 cycle.

These events can also be used for more push buttons, when GP counter features are unnecessary. When up/down counter mode is enabled, the GP counter can use these count events to report interrupts from push buttons that connect to the CNT_UD and CNT_DG inputs.

Zero-Count Events

The CNT_STAT.CZERO status bit indicates that the CNT_CNTR has reached a value equal to 0x0000 0000 after an increment or decrement. This bit is not set when the counter value is set to zero by a write to CNT_CNTR or by setting the CNT_CMD.W1LCNTZERO bit. If enabled by the CNT_IMSK.CZERO bit, the GP counter module generates an interrupt request.

Overflow Events

There are two status bits that indicate whether the signed counter-register has overflowed from a positive to a negative value or conversely. The CNT_STAT.COV31 bit reports that the 32-bit CNT_CNTR register has either incremented from 0x7FFF FFFF to 0x8000 0000, or decremented from 0x8000 0000 to 0x7FFF FFFF.

If enabled by the CNT_IMSK.COV31 bit, an interrupt request is generated. Similarly, in applications where only the lower 16 bits of the counter are of interest, the CNT_STAT.COV15 status bit reports counter transitions from

0xXXXX 7FFF to 0xXXXX 8000, or from 0xXXXX 8000 to 0xXXXX 7FFF. If enabled by the `CNT_IMSK.COV15` bit, an interrupt request is generated.

Boundary Match Events

The `CNT_STAT.MINC` and `CNT_STAT.MAXC` status bits report boundary events as described in Configuring Boundary Capture Mode. These bits are not set if the software updates the `CNT_CNTR`, `CNT_MAX`, or `CNT_MIN` registers or writes to the `CNT_CMD` register. The `CNT_IMSK.MINC` and `CNT_IMSK.MAXC` bits enable interrupt request generation on boundary events.

Zero Marker Events

The `CNT_STAT.CZM`, `CNT_STAT.CZME`, and `CNT_STAT.CZMZ` bits are associated with zero marker events, as described in Configuring GP Counter Push-Button Operation. Each of these events can optionally generate an interrupt request, when enabled by the corresponding `CNT_IMSK.CZM`, `CNT_IMSK.CZME` and `CNT_IMSK.CZMZ` bits.

ADSP-SC58x CNT Register Descriptions

CNT (CNT) contains the following registers.

Table 23-7: ADSP-SC58x CNT Register List

Name	Description
`CNT_CFG`	Configuration Register
`CNT_CMD`	Command Register
`CNT_CNTR`	Counter Register
`CNT_DEBNCE`	Debounce Register
`CNT_IMSK`	Interrupt Mask Register
`CNT_MAX`	Maximum Count Register
`CNT_MIN`	Minimum Count Register
`CNT_STAT`	Status Register

Configuration Register

The CNT_CFG register configures counter modes, configures input pins, and enables the CNT.

Command Register

The `CNT_CMD` register configures the CNT, enabling operations such as zeroing a counter register and copying or swapping boundary registers. These actions are taken by setting the appropriate bit.

Read operations from this register do not return meaningful values, with the exception of the `CNT_CMD.W1ZMONCE` bit, where a set bit indicates that the bit has been set by software before, but a zero marker event has not yet been detected on the `CNT_ZM` pin yet. For more information, see the CNT functional description.

The `CNT_CNTR`, `CNT_MIN`, and `CNT_MAX` registers can be initialized to zero by setting the `CNT_CMD.W1LCNTZERO`, `CNT_CMD.W1LMINZERO`, and `CNT_CMD.W1LMAXZERO` bits. In addition to clearing registers, the `CNT_CMD` register permits modifying the `CNT_MIN` and `CNT_MAX` boundary registers in a number of ways. The current counter value in the `CNT_CNTR` register can be captured and loaded into either of the two boundary registers to create new boundary limits. This operation is performed by setting the `CNT_CMD.W1LMAXCNT` and `CNT_CMD.W1LMINCNT` bits. Alternatively, the counter can be loaded from `CNT_MAX` or `CNT_MIN` using the `CNT_CMD.W1LCNTMAX` and `CNT_CMD.W1LCNTMIN` bits. It is also possible to transfer the current `CNT_MAX` value into `CNT_MIN` (or conversely) through the `CNT_CMD.W1LMINMAX` and `CNT_CMD.W1LMAXMIN` bits.

Another counter operation is the ability to only have the zero marker clear the `CNT_CNTR` register once. For more information, see the CNT functional description.

It is possible for multiple actions to be performed simultaneously by setting multiple bits in the `CNT_CMD` register. However, there are restrictions. The bits associated with each command have been grouped together such that all bits that involve a write to the `CNT_CNTR`, `CNT_MAX`, or `CNT_MIN` registers are located within bits 4-bit groups of the `CNT_CMD` register.

Note that a maximum of three commands can be issued at any one time, excluding the `CNT_CMD.W1ZMONCE` command. Also, note that `CNT_CMD.W1LCNTMIN`, `CNT_CMD.W1LCNTMAX`, and `CNT_CMD.W1LCNTZERO` bits have to be used exclusively. Never set more than one of them at the same time.

Figure 23-6: CNT_CMD Register Diagram

Table 23-9: CNT_CMD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W)	W1ZMONCE	Write 1 Zero Marker Clear Once Enable. The `CNT_CMD.W1ZMONCE` enables a single zero marker clear of the `CNT_CNTR` register. Reading a 1 in this bit indicates that the bit has been set by software before, but no zero marker event has been detected on the `CNT_ZM` pin yet.
10 (R0/W)	W1LMAXMIN	Write 1 MAX Copy from MIN. The `CNT_CMD.W1LMAXMIN` bit transfers the current `CNT_MIN` register value into `CNT_MAX` register.
9 (R0/W)	W1LMAXCNT	Write 1 MAX Capture from CNTR. The `CNT_CMD.W1LMAXCNT` bit loads the current value in the `CNT_CNTR` register into the `CNT_MAX` register to create a new boundary limit.
8 (R0/W)	W1LMAXZERO	Write 1 MAX to Zero. Writing a 1 to the `CNT_CMD.W1LMAXZERO` bit clears the `CNT_MAX` register.
7 (R0/W)	W1LMINMAX	Write 1 MIN Copy from MAX. The `CNT_CMD.W1LMINMAX` bit transfers the current `CNT_MAX` register value into `CNT_MIN` register.
5 (R0/W)	W1LMINCNT	Write 1 MIN Capture from CNTR. The `CNT_CMD.W1LMINCNT` bit loads the current value in the `CNT_CNTR` register into the `CNT_MIN` register to create a new boundary limit.
4 (R0/W)	W1LMINZERO	Write 1 MIN to Zero. Writing a 1 to the `CNT_CMD.W1LMINZERO` bit clears the `CNT_MIN` register.

Table 23-9: CNT_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R0/W)	W1LCNTMAX	Write 1 CNTR Load from MAX. The `CNT_CMD.W1LCNTMAX` bit loads the current value in the `CNT_MAX` register into the `CNT_CNTR` register to create a new boundary limit.
2 (R0/W)	W1LCNTMIN	Write 1 CNTR Load from MIN. The `CNT_CMD.W1LCNTMIN` bit loads the current value in the `CNT_MIN` register into the `CNT_CNTR` register to create a new boundary limit.
0 (R0/W)	W1LCNTZERO	Write 1 CNTR to Zero. Writing a 1 to the `CNT_CMD.W1LCNTZERO` bit clears the `CNT_CNTR` register.

Counter Register

The CNT_CNTR register holds the 32-bit, two's-complement count value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows use of the CNT as a 16-bit counter if sufficient for the application.

Interrupt Mask Register

The `CNT_IMSK` register supports enabling (unmasking) interrupt request generation from each of the CNT events.

All bits in `CNT_IMSK` either disable/mask an interrupt request (if bit cleared) or enable/unmask an interrupt request (if bit set).

Maximum Count Register

The `CNT_MAX` register holds the 32-bit, two's-complement, higher boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

Minimum Count Register

The `CNT_MIN` register holds the 32-bit, two's-complement, lower boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

Status Register

The CNT_STAT register provides status information for each of the CNT events as configured in the CNT_IMSK register. When a CNT event is detected, the corresponding bit in this register is set. It remains set until either software writes a 1 to the bit (write-1-to-clear) or the CNT is disabled.

All bits in the CNT_STAT register indicate either no interrupt request pending (if bit cleared) or an interrupt request pending (if bit set).

Table 23-15: CNT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W1C)	CZMZ	Counter Zeroed By Zero Marker Interrupt. The CNT_STAT.CZMZ bit indicates a zero marker error. If the CNT_CFG.ZMZC bit =1, this interrupt request is generated when the CZMII latch reports a significant edge on the CZM input. Once cleared by software the CNT_STAT.CZM bit is not set again when the CZM input remains active without pulsing.	
		0	No error
		1	Error occurred

Table 23-15: CNT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	CZME	Zero Marker Error Interrupt. The `CNT_STAT.CZME` bit behaves similarly to the `CNT_STAT.CZM` bit, with the exception that `CNT_STAT.CZME` is not set on the CZM edge when the lower four bits of the `CNT_CNTR` are not zero. In many applications this indicates an error condition, as the zero marker might be out of sync with the counter.	
		0	No error
		1	Error occurred
8 (R/W1C)	CZM	CZM Pin/Pushbutton Interrupt. The `CNT_STAT.CZM` bit indicates a CZM pin/pushbutton error. This interrupt request is generated when a significant edge is seen on the CZM pin, regardless what mode the counter is operating in. This is often used to sense push buttons (especially with the debouncing circuit enabled).	
		0	No error
		1	Error occurred
7 (R/W1C)	CZERO	CNT_CNTR Counts To Zero Interrupt. The `CNT_STAT.CZERO` bit indicates a counts to zero error. This error is generated when the `CNT_CNTR` register has incremented or decremented toward 0x0000.0000. The latch is not set when software writes to the `CNT_CNTR` register directly or when the counter is zeroed by writes to the `CNT_CMD` register.	
		0	No error
		1	Error occurred
6 (R/W1C)	COV15	Bit 15 Overflow Interrupt. The `CNT_STAT.COV15` bit indicates a bit 15 overflow error. This error is generated when the 16-bit twos-complement `CNT_CNTR` register has incremented from 0xxxxx.7FFF to 0xxxxx.8000 or decremented from 0xxxxx.8000 to 0xxxxx.7FFF.	
		0	No error
		1	Error occurred
5 (R/W1C)	COV31	Bit 31 Overflow Interrupt. The `CNT_STAT.COV31` bit indicates a bit 31 overflow error. This error is generated when the 32-bit twos-complement `CNT_CNTR` register has incremented from 0x7FFF.FFFF to 0x8000.0000 or decremented from 0x8000.0000 to 0x7FFF.FFFF.	
		0	No error
		1	Error occurred

Table 23-15: CNT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W1C)	MAXC	Max Count Interrupt. The `CNT_STAT.MAXC` bit indicates a max count error. This interrupt is used in boundary compare (BND_COMP) mode. If after incrementing the `CNT_CNTR` register equals `CNT_MAX`, the `CNT_STAT.MAXC` bit is set.	
		0	No error
		1	Error occurred
3 (R/W1C)	MINC	Min Count Interrupt. The `CNT_STAT.MINC` bit indicates a minimum count error. This interrupt is used in boundary compare (BND_COMP) mode. If, after decrementing, the `CNT_CNTR` register equals `CNT_MIN`, the `CNT_STAT.MINC` bit is set.	
		0	No error
		1	Error occurred
2 (R/W1C)	DC	Down Count Interrupt. The `CNT_STAT.DC` bit indicates a down count error. This interrupt is generated when the `CNT_CNTR` register decrements.	
		0	No error
		1	Error occurred
1 (R/W1C)	UC	Up Count Interrupt. The `CNT_STAT.UC` bit indicates an up count interrupt. This interrupt is generated when the `CNT_CNTR` register increments.	
0 (R/W1C)	IC	Illegal Gray/Binary Code Interrupt. The `CNT_STAT.IC` bit indicates a illegal Gray/Binary Code interrupt and should only be used in these modes. In normal operation those codes can increment or decrement the `CNT_CNTR` register by one at a time. If the sensed inputs instruct the counter to increment or decrement by two, the `CNT_STAT.IC` bit is set. Hardware sets the `CNT_STAT.IC` bit in QUAD_ENC and BIN_ENC encoder modes only.	
		0	No error
		1	Error occurred

24 ADC Control Module (ACM)

The processor includes an ADC control module (ACM) that provides an interface that synchronizes the controls between the processor and an analog-to-digital converter (ADC). The processor initiates analog-to-digital conversions, based on either external or internal events.

Traditionally, ADC sampling uses processor interrupts and the interrupt service routine programming of the appropriate peripheral for initiating the ADC conversion process. Events initiate the interrupts. The interrupt service routine usually programs the SPORT or SPI peripherals. This traditional approach has some limiting factors:

- The ADC sampling instances are not precisely controlled due to interrupt latencies (which can vary) or due to variable instruction execution cycles
- Consumption of processor instruction cycles can be prohibitive, especially for high frequency of conversion-related events.
- If the ADC requires control signals with specific set-up, hold, or zero time for sampling time, it is difficult to provide the signals with GP flags in the application. For example, channel select pins, ADC mode select, ADC range pin.

The ADC control module (ACM) provides dedicated hardware to work around these limitations. The module samples the events and provides sampling signals and timing to the ADC in real time. The ADC permits flexible scheduling of sampling instants and provides precise sampling signals to the ADC. The ACM saves processor bandwidth and provides precise control for ADC sampling time. Furthermore, the processor can be interfaced directly to multiple ADCs without any glue logic required.

The ACM synchronizes the ADC conversion process (by providing the ADC clock, the ADC conversion start signal, and related ADC controls). However, other peripherals such as SPORT acquire the actual data from the ADC. The processor does not support ACM operation with the SPI. The ***ADC/SPORT Interface*** figure shows how an external ADC can be interfaced using the ACM and SPORT0 peripherals of the processor.

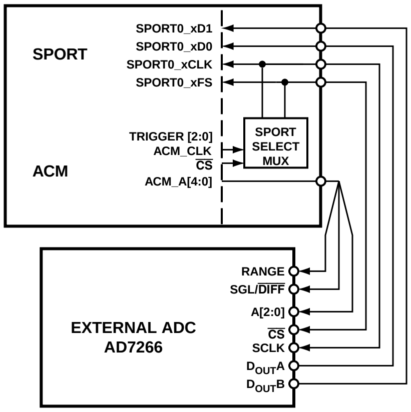

Figure 24-1: ADC/SPORT Interface

NOTE: The processor does not include an on-chip, internal ADC.

ACM Features

The ADC control module (ACM) offers the following features and capabilities:

- The ACM on the ADSP-SC58x/ADSP-2158x processors operate on the SCLK0_0 domain.
- The ACM can interface to the ADC at a maximum clock frequency of 30 MHz.
- It provides serial clock, chip select, and five general-purpose control lines capable of controlling the ADC operations. Internally routes serial clock and frame sync (chip select) signals to serial port 0.

  Only SPORT0 performs actual data acquisition from the ADC (no other SPORT instance). The `ACM_CLK` and `ACM_FS` signals are multiplexed with the SP0_CLK and SP0_FS signals. These signals are driven through the DAI0 and not through the GPIO port. The SPORT uses the `ACM_CTL.EN` bit to control the connection between SPORT0 and the ACM. By setting the `ACM_CTL.EN` bit, the ACM clock and FS are internally multiplexed to the SPORT0 SPORT0_CLK_O/SPORT0_FS_O outputs of the DAI0.
- The ACM can accept three trigger inputs (one from external on `ACM_T0` and two from the TRU) based on which it can precisely initiate the ADC sampling events. The trigger inputs can be internally generated or externally supplied. The polarity of trigger inputs is configurable.
- The ACM can handle 16 ADC sampling events per valid trigger received. Each event can be independently programmed to specify when to initiate ADC sampling for a trigger input.
- Two independent 32-bit ACM timers that can be used to divide 16 events into two groups of 8 events.
- Automatically stops the ACM timer after completion of associated events, saving power.
- Four-deep pending FIFO to queue the active events when the ACM is busy.
- The ACM can internally generate serial clock up to SCLK ÷ 2 rate. Improved granularity for internal clock generation, allowing both odd and even SCLK:ACLK ratios.

- The ACM clock can be gated (active only during enabled events) to interface it with SPI-compatible ADCs.
- When initiating an ADC sampling cycle, the width of chip select signal can be configured from 1 ACLK to 256 ACLKs. ADC can also use the width of chip select signal as start of conversion. Further the polarity of this signal can be configured as active-high or active-low signal.
- Auto ACLK adjustment at the time of $\overline{\text{CS}}$ assertion. After assertion of the $\overline{\text{CS}}$ signal, the first edge of ACLK can be configured to be either rising edge or falling edge.
- The ACM provides the five general-purpose control lines that can be programmed for required set-up and hold time based on the ADC sampling cycle. Additionally, zero time can be inserted between two successive sampling cycles.
- The ACM provides 16 event order registers (one per each event) which indicate the order in which events are handled. Optionally, the trigger input of the ACM can clear these registers automatically.
- The ACM hardware flags the appropriate event completion status bit on completion of an event. If an event is missed, the appropriate event missed status bit is flagged. Each event has separate bits. Optionally, the event completion interrupt and event missed interrupt can be triggered on these respective conditions.
- Predictable latency between the internal occurrence of an event and the assertion of a sampling event.
- The ACM can operate as trigger master to provide signal to TRU upon completion of events.

ACM Functional Description

The ADC control module uses internal ACM timers and the event time register to create events. Enable one of the timers (or both timers) for the ACM operation. Program the appropriate event control register and event time register values. After receiving a valid trigger on the selected trigger input, the timer starts counting. When the timer count matches the time specified in the event time register (`ACM_EVTIME[n]`), the comparators generate an active event signal to the timing generation unit. The signal starts the ADC access. The event must be enabled and the event must be associated with the timer. The counter continues counting, and for each match with enabled event time, the ACM gives an event signal to the timing generation unit.

ADSP-SC58x ACM Register List

The ADC control module (ACM) provides an interface that synchronizes the controls between the processor and an analog-to-digital converter (ADC). The analog-to-digital conversions are initiated by the processor, based on external or internal events. A set of registers govern ACM operations. For more information on ACM functionality, see the ACM register descriptions.

ACM Event Handling Latency

The ACM ensures a predictable latency between the internal occurrence of an event and the assertion of a sampling event by the timing generation unit (for example, the assertion of $\overline{\text{CS}}$ and other ACM signals). The internal occurrence of an event is when the event time value matches the ACM timer count value.

Latency between occurrence of an event to $\overline{\text{CS}}$ assertion = (t_S + t_{ED}) *SCLK* cycles, where:

- t_S= ADC control setup cycles programmed in the `ACM_TC0` register
- t_{ED} = 1 SCLK0_0 cycle latency

This predictable latency is applicable only when events are generated when the timing generation unit is idle. If this unit was processing a prior sampling event, the new event is held in the pending event FIFO. The duration that the new event is held in the pending event FIFO increases the latency.

If an external trigger input is selected as a trigger input, then synchronization to this signal leads to a 3 SCLK0_0 cycle fixed delay and 1 SCLK0_0 cycle variability. This result is due to delays in latching asynchronous external triggers. When the external trigger is synchronous to SCLK0_0, the 1 SCLK0_0 cycle variability is eliminated. The latency from the external trigger to the start of the count of an ACM timer becomes fixed at 3 SCLK0_0 cycles. This latency is denoted as t_{TRIG}.

As a result, the total latency between an external trigger and the assertion of an ADC sampling event is:

Total latency = t_{TRIG} + t_{ED} + t_{PD} + t_S

The latency calculation assumes that the sampling event is not queued in the pending event FIFO. The ***Latency of External Triggers to Assertion of ADC Sampling Events*** figure shows latency details from the occurrence of external triggers to the assertion of ADC sampling events.

Observe the following timing definitions:

- t_{TRIG} = trigger to timer start delay (3–4 SCLK0_0 cycles)
- t_{PD} = event time (programmed in the `ACM_EVTIME[n]` register of the event)
- t_{ED} = internal event delay (1 SCLK0_0 cycle)
- t_S = setup time (programmed in the `ACM_TC0` register)
- t_{CSW} = $\overline{\text{CS}}$ width (programmed in the `ACM_TC1.CSW` bit field)
- t_H = hold time (programmed in the `ACM_TC1` register)

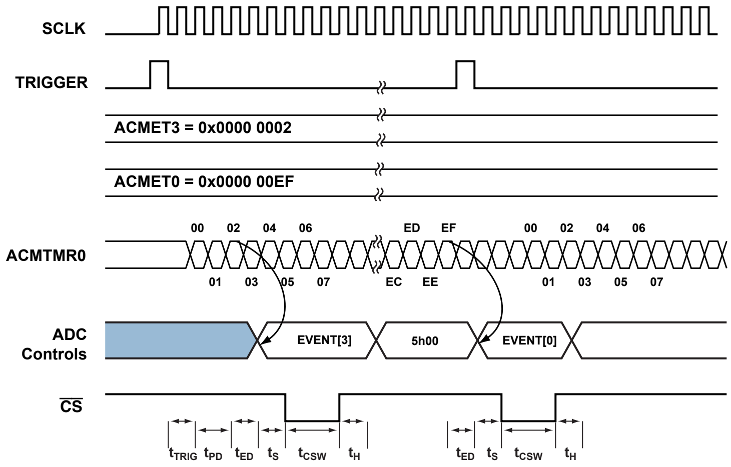

Figure 24-2: Latency of External Triggers to Assertion of ADC Sampling Events

ACM Timing Specifications

The AC timing of the ACM signals is specified in the product-specific data sheet. When trigger sources external to the processor are used for triggering the ACM, the minimum pulse width for the sources must be greater than one SCLK0_0 period. This pulse width is the minimum needed for the ACM trigger logic to detect the source as a valid trigger (for example, external signals on the GPIO, timer, or PWM sync pins).

- When the processor uses the ACM with the SPORTs, the requirements for the SPORT data signals vary. The setup and hold time requirements for the SPORT data signals for the `SPORT_ACLK` signal differ from those requirements for an internally-generated or externally-supplied SPORT clock. Consult the product-specific data sheet for information on these timing requirements.

When using gated clock mode (`ACM_CTL.CLKMOD` =1), configure the interfaced serial mode in gated clock mode (`SPORT_CTL_A.GCLKEN`, `SPORT_CTL_B.GCLKEN` =1). In this case, some conditions must be satisfied to set up the serial port in gated clock mode. These conditions are:

- The serial port needs at least 7 serial clock cycles between enabling the SPORT and first frame sync. If this requirement is not met, the SPORT may drop the first data. (For subsequent data, this requirement is not applicable.)
- Set the frame sync to the inactive (deasserted) state when the SPORT is enabled. Otherwise, one extra cycle (in addition to the cycle mentioned) is needed before the frame sync can be applied. If this requirement is not met, the SPORT may drop the first data.

ACM External Pin Timing

The ACM clock (`ACM_CLK`) is derived internally from SCLK0_0 using the `ACM_TC0.CKDIV` divider. The other output signals, such as the ADC control pins (`ACM_A0` through `ACM_A4`) and the chip select are driven on the rising edge of SCLK0_0. As a result, these signals cannot be synchronous to the `ACM_CLK` signal.

The ACM uses timing configuration registers (`ACM_TC0` and `ACM_TC1`) to configure setup, hold, and other timing parameters of the ADC control signals, the width of the chip select signal, and the frequency of `ACM_CLK`. The polarity of $\overline{\text{CS}}$ and the `ACM_CLK` signals can be configured in the ACM control register (`ACM_CTL`). The timing parameters of the ADC control pins cannot be individually specified.

The ***Timing Reference*** figure shows the inactive period of $\overline{\text{CS}}$ as t_{CSIW}. The inactive period of $\overline{\text{CS}}$ is the sum of the three timing parameters; Setup time (t_s), Zero time (t_z) and the Hold time (t_H):

$t_{CSIW} = t_S + t_Z + t_H$.

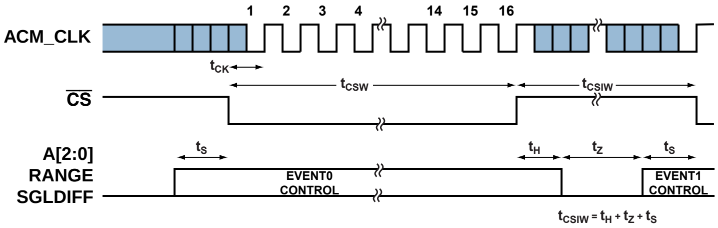

Figure 24-3: Timing Reference

Proper specification of the values of these three parameters yields the desired inactive period of $\overline{\text{CS}}$.

The ADC provides a predictable latency from the occurrence of an internal event to the assertion of an external ADC sampling event. The ADC controls and drives the $\overline{\text{CS}}$ signal on the rising edge of SCLK0_0. Therefore, the setup time (T_s) of these signals is specified in terms of SCLK0_0. However, the hold-time and zero-time are specified in terms of `ACM_CLK` cycles.

To achieve an accurate timing relationship between the $\overline{\text{CS}}$ and `ACM_CLK` (which is normally a free running clock) signals, the `ACM_CLK` signal is realigned with the active edge of $\overline{\text{CS}}$. This realignment of the `ACM_CLK` signal ensures that the setup time of the first active edge of `ACM_CLK`, relative to the active edge of $\overline{\text{CS}}$, is at least 1 `ACM_CLK` cycle.

The following set of figures in the cases show various scenarios of `ACM_CLK` realignment. All of these figures assume an *ACM_CLK:SCLK* ratio of 1:4.

- Case 1—Chip select asserted during the high phase of `ACM_CLK`
- Case 2—Chip select asserted during the low phase of `ACM_CLK`
- Case 3—Chip select asserted right before the falling edge of `ACM_CLK`
- Case 4—Chip select asserted right before the rising edge of `ACM_CLK`
- Case 5—`ACM_CLK` polarity set to 1 (`ACM_CTL.CLKPOL` =1)

Realignment of the ACM clock causes the suppression or extention of clock edges, leading to duty cycle variation. Ensure that systems interfacing with the ACM can tolerate such duty cycle variation.

The set of figures shows both the ACM-generated $\overline{\text{CS}}$ signal, which is output externally onto the appropriate `ACM_FS` pin, and the serial port receive frame sync signal. This internal signal is routed to the frame sync input of the appropriate SPORT.

The ACM clock polarity can be configured using the `ACM_CTL.CLKPOL` bit. After the $\overline{\text{CS}}$ signal is asserted, the first edge of `ACM_CLK` can be configured to be either rising edge or falling edge. Also, by default the clock is free running; it is possible to gate the ACM clock during an inactive $\overline{\text{CS}}$ period using the `ACM_CTL.CLKMOD` bit.

Case 1—Chip Select Asserted During the High Phase of `ACM_CLK` (`ACM_CTL.CLKPOL` =0)

The ***Chip Select Asserted During the High Phase of*** `ACM_CLK` figure shows the realignment of `ACM_CLK` when $\overline{\text{CS}}$ is asserted during the high phase of `ACM_CLK`. The first edge of `ACM_CLK`, after the assertion of $\overline{\text{CS}}$, is the falling edge.

The two reference clock signals (REF ACLK1 and REF ACLK2) illustrate how the `ACM_CLK` signal can be generated from a free running clock (REF ACLK1). This setup meets the timing requirements between the `ACM_CLK` and $\overline{\text{CS}}$ signals. The REF ACLK2 signal is based on the free running clock REF ACLK1. However, the REF ACLK2 signal is adjusted such that its period is immediately reset upon the assertion of $\overline{\text{CS}}$. In the resulting `ACM_CLK` signal, the time from the active edge of $\overline{\text{CS}}$ to the falling edge of `ACM_CLK` is constant at a period of 1 `ACM_CLK` cycle. See `ACM_CLK` in the ***Chip Select Asserted During the High Phase of*** `ACM_CLK` figure.

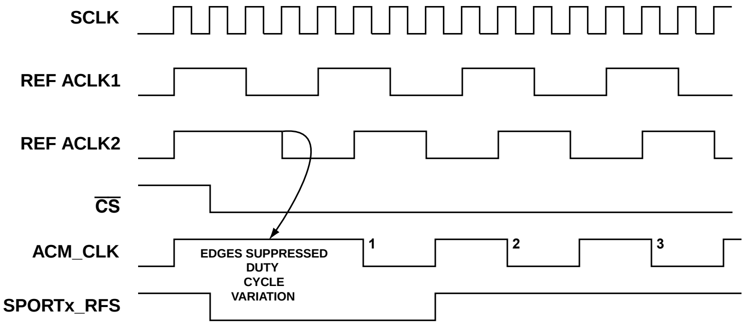

Figure 24-4: Chip Select Asserted During the High Phase of `ACM_CLK`

Case 2—Chip Select Asserted During the Low Phase of `ACM_CLK` (`ACM_CTL.CLKPOL` =0)

Refer to the ***Chip Select Asserted During the Low Phase of*** `ACM_CLK` figure. When the $\overline{\text{CS}}$ signal is asserted during the low phase of `ACM_CLK`, `ACM_CLK` is immediately pulled high which causes a duty cycle variation. In this case, (similar to Case 1), the time from the active edge of $\overline{\text{CS}}$ to the falling edge of `ACM_CLK` is 1 `ACM_CLK` period.

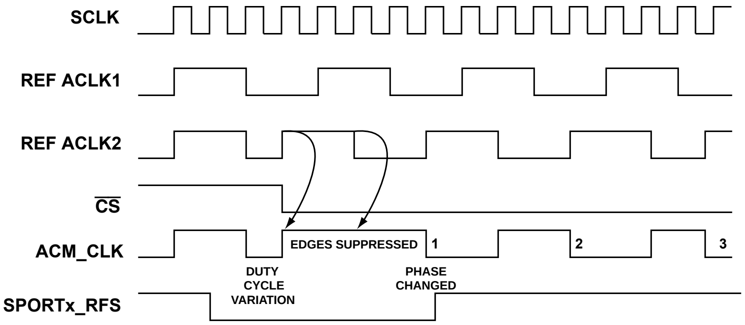

Figure 24-5: Chip Select Asserted During the Low Phase of `ACM_CLK`

Case 3—Chip Select Asserted Right Before the Falling Edge of `ACM_CLK` (`ACM_CTL.CLKPOL` =1)

Refer to the ***Chip Select Asserted Right Before the Falling Edge of*** `ACM_CLK` figure. When $\overline{\text{CS}}$ is asserted right before the falling edge of `ACM_CLK`, the falling edge of `ACM_CLK` is suppressed. This functionality ensures that the time from the active edge of $\overline{\text{CS}}$ to the falling edge of `ACM_CLK` is constant at a period of 1 `ACM_CLK` cycle.

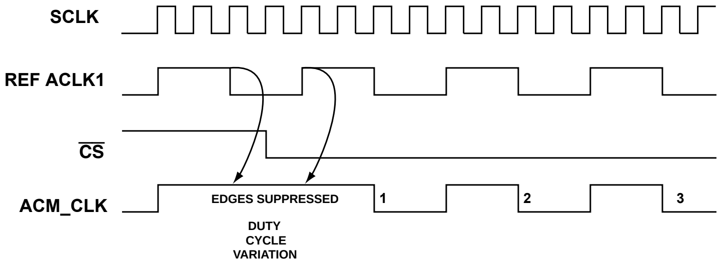

Figure 24-6: Chip Select Asserted Right Before the Falling Edge of `ACM_CLK`

Case 4—Chip Select Asserted Right Before the Rising Edge of `ACM_CLK` (`ACM_CTL.CLKPOL` =0)

Refer to the ***Chip Select Asserted Right Before the Rising Edge of*** `ACM_CLK` figure. When $\overline{\text{CS}}$ is asserted right before the rising edge of `ACM_CLK`, the high phase of `ACM_CLK` is extended. This extension ensures that the time from the active edge of $\overline{\text{CS}}$ to the falling edge of `ACM_CLK` is constant at a period of 1 `ACM_CLK` cycle.

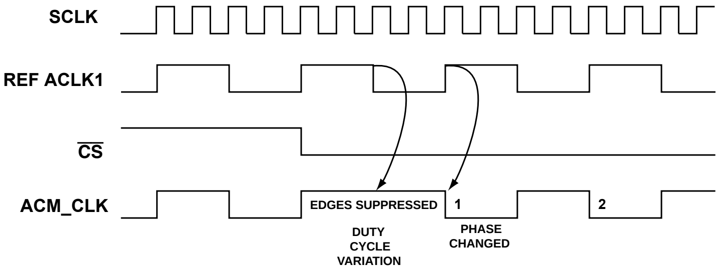

Figure 24-7: Chip Select Asserted Right Before the Rising Edge of `ACM_CLK`

Case 5— `ACM_CLK` Polarity Set to 1 (`ACM_CTL.CLKPOL` =1)

When the `ACM_CLK` polarity is set to 1 (the `ACM_CTL.CLKPOL` bit is set to 1), the first `ACM_CLK` edge after the assertion of $\overline{\text{CS}}$ is the rising edge. The ACM ensures that the time from the active edge of $\overline{\text{CS}}$ to the rising edge of `ACM_CLK` has a constant duration of 1 `ACM_CLK` cycle. The ***Polarity Set to 1*** figure shows an example diagram of the case where `ACM_CTL.CLKPOL` =1.

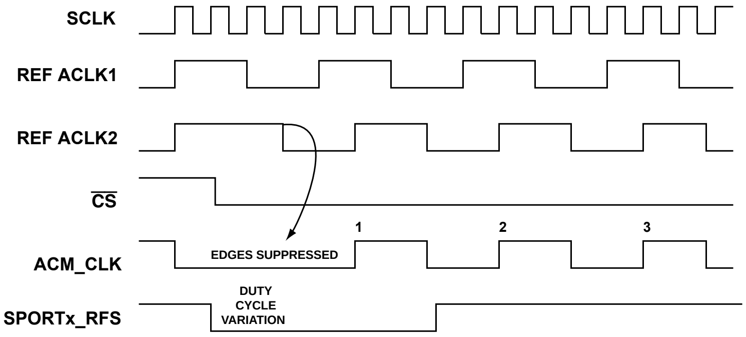

Figure 24-8: Polarity Set to 1

ACM Architectural Concepts

The following sections provide information on the architecture of the ACM module.

Clocking

The ACM on the ADSP-SC58x/ADSP-2158x processors operate on the SCLK0_0 domain. The term SCLK in this chapter is a generic reference to SCLK0_0. For more details on SCLK0_0 programming refer to CDU Functional Description.

Block Diagram

The ADC Control Module (ACM) consists of two independent 32-bit ACM timers, 16 event register pairs, 16 event comparators and a timing generation unit.

The ACM can accept four trigger inputs (internal as well as external signals). On receiving a valid trigger on selected trigger input, the ACM timer/s start counting (based on the mode of the ACM). The trigger input can be independently selected for each timer.

Two sets of eight event register pairs (a total of 16 event register pairs) determine the ADC controls for each ADC sample. The registers also determine when the sample occurs. The event register pair consists of the event control register (`ACM_EVCTL[n]`) and the event time register (`ACM_EVTIME[n]`). The event comparators unit compares the timer of the ACM count with the event time of associated enabled events. When the count matches, the event comparators unit signals to the timing generation unit. The unit starts handling the events by driving the $\overline{CS}$ and `ACM_A4` to `ACM_A0` signals accordingly.

The ***ACM Block Diagram*** shows the structure of the ACM. The following sections discuss these blocks in detail.

Trigger Inputs

The ACM can accept four trigger inputs, based on which the ACM timers start running at the SCLK0_0 rate. The ACM contains three 32-bit internal timers (timer 0, timer 2, and timer 3). Each timer can be independently configured to use one of these trigger inputs. The ACM uses `ACM_CTL.TRGSEL0` and `ACM_CTL.TRGSEL1` bit fields to select the trigger input for Timer0 and Timer1 respectively.

Out of the 4 trigger inputs to the ACM design:

- `ACM_T0` is driven from the chip I/O
- `ACM_T2` and `ACM_T3` are driven from the TRU

The ACM uses two trigger inputs when both ACM timers are enabled for different trigger inputs. However, it uses only one trigger if both ACM timers are enabled for same trigger input or if a single ACM timer is enabled. The non-selected trigger inputs are *do-not-care* for the ACM. At most two, and at least one selected trigger input must be active in the system for the ACM to start operation.

The following list briefly describes the possible trigger inputs:

- Trigger input 0 (`ACM_T0`) – PE8:

Trigger input 0 is sourced from the PE8 pin of the GPIO port E (sometimes also referred as GPIO[72]). When the ACM is enabled, the input tap on the PE8 pin is enabled. The ACM trigger input can be from any source (internal or external) depending on the PE8 pin configuration.

When the PE8 pin is configured in GPIO mode (`PORT_FER` =0), the source of the GPIO signal can be either internal or external. The source depends on the GPIO direction, configured in the E `PORT_DIR` register. When the PE8 pin is configured in function mode (`PORT_FER` =1), the trigger 0 input is sourced in from peripheral signals. The source is based on the `PORT_MUX` register setting for the PE8 pin. For example, the ACM can source this trigger input from the `PWM_SYNC` signal if the multiplex bits for the PE8 pin are set to b#00. The PWM unit internally generates the `PWM_SYNC` signal or it can be provided externally. If the multiplex bits for PE8 are configured to b#01, the trigger input is sourced from the `EPPI_FS1` signal. The EPPI0 unit internally generates this signal or it can be generated externally.

Consider the source of the trigger input when programming the `PORT_FER.PX8` and `PORT_MUX.MUX8` bits for the PE8 pin. Enabling the input tap ensures that the ACM operation does not interfere with the module driving the PE8 pin.

- Trigger input 2 (`ACM_T2`) – (PG5) – ACM Slave TriggerID 135:

  The trigger routing unit (TRU) of the processor provides system-level sequence control without core intervention. When this trigger input mode is selected, the ACM acts as a trigger slave and accepts a trigger through the trigger slave ID-135. The slave-select (`TRU_SSR[n].SSR`) field of the SSR 135 register can be configured to receive triggers from a specific trigger master. In this way, `ACM_T2` trigger input can accept triggers asserted by that particular trigger master or through software. The software writes the ID of that trigger master to one of the four fields in the `TRU_MTR` register. The trigger response from selected master is internally routed to ACM trigger input. This way, ACM slave trigger ID 135 can receive any one of the 86 internal triggers available.

- Trigger input 3 (`ACM_T3`) – ACM Slave TriggerID 136:

  Similar to the `ACM_T2` input, the TRU of the processor provides the ACM trigger input 3 (`ACM_T3`) internally. When this trigger input mode is selected, the ACM acts as trigger slave and accepts a trigger through trigger slave ID 136. The slave-select (`TRU_SSR[n].SSR`) field of the SSR 136 register can be configured to receive triggers from a specific trigger master. In this way, the ACM slave trigger ID 136 can accept triggers asserted by that particular trigger master or through software. The software writes the ID of that trigger master to one of the four fields in the `TRU_MTR` register. The trigger response from selected master is internally routed to the ACM trigger input. This way, ACM slave trigger ID 136 can receive any one of the 86 internal triggers available.

  See the Trigger Routing Unit (TRU) chapter for more details about trigger slaves and trigger masters.

For all trigger input signals, the active edge of the trigger is programmable in the ACM control register as either rising edge or falling edge trigger.

The ***Detailed ACM Trigger Generation Logic*** figure shows the detailed ACM trigger generation logic.

Figure 24-10: Detailed ACM Trigger Generation Logic

When the processor uses external trigger sources external for triggering the ACM timers, the minimum pulse width for these sources must be greater than one SCLK0_0 period. (For example, `ACM_T1`:`ACM_T0`).

NOTE: A latency of no more than four SCLK0_0 cycles exists between external trigger and ACM timer starts counting. Refer to the ACM Event Handling Latency section for further details.

Timers

The ACM module has two independent 32-bit timers (ACMTMR0 and ACMTMR1) which start counting at the system clock (SCLK0_0) rate when a valid trigger is detected on a selected trigger input. The timers are independently enabled using the timer enable bits (`ACM_CTL.TMR0EN`, `ACM_CTL.TMR1EN`). The timers can be independently configured for one of the four trigger inputs with configurable polarity of the signal. Enable at least one ACM timer for proper ACM operation.

By default, each ACM timer has 8 events associated with it. If both timers are enabled, Event[7:0] are associated with ACMTMR0 while Event[15:8] are associated with ACMTMR1. However, if only one timer is enabled, all of the event registers are associated with that particular timer. For example, if only ACMTMR1 is enabled (if `ACM_CTL.TMR0EN` =0 and `ACM_CTL.TMR1EN` =1), ACMTMR1 handles all 16 events, Event[15:0].

The timers start counting when a trigger input occurs that is selected for that particular timer. The timer only stops counting under one of the following conditions:

1. A timer rollover occurs.
2. All the events associated with the trigger have completed.

A timer rollover cannot occur unless the event time register of an event is programmed at some point after the trigger occurs. This practice is contrary to ACM programming guidelines.

In the second case, the exact time at which the timer stops counting depends on the FIFO state when the last event occurred internally.

If a trigger occurs while the timer is counting, the time resets and starts counting again. In this case, some of the events can miss which results in flagging the appropriate status bit and optionally an event missed interrupt.

When an ACM timer is disabled or the ACM itself is disabled, the timer resets to zero.

Event Register Pairs

An event for the ACM is a point in time where ADC sampling occurs on a particular channel of the ADC with the specified control settings of the ADC.

The ACM can handle a total of 16 events which are grouped into two sets of 8 events. The 8 events can be assigned to each of the timers (if both timers are enabled) or all 16 events can be assigned to one particular timer. (Assignment happens when only one timer is enabled). See the Timers sections for details.

All events can be independently configured and enabled. The enabled events determine the ADC controls and timing for each ADC sampling interval. Each event consists of a register pair with an event control register (`ACM_EVCTL[n]`) and an event time register (`ACM_EVTIME[n]`). The `ACM_EVCTL[n]` register enables a particular event and determines settings for the ADC control lines (`ACM_A[4:0]`) for that particular ADC conversion. The ACM uses the `ACM_EVTIME[n]` register to determine the time offset from the corresponding ACM timer trigger input to the start of that particular event. (The time offset is when the event occurs based on trigger input.) This time offset can be specified in terms of the system clock of the processor.

Enable at least one event associated with an enabled ACM timer, for ACM to execute ADC sampling.

Event Comparators Unit

The event comparators block consists of 16 event time comparators which determine when an enabled event could happen. After detecting valid trigger on selected trigger input, ACM timer starts running at *SCLK* rate. The comparators compare the ACM timer count with the event time specified in the `ACM_EVTIME[n]` register of the enabled event. If the time value matches, the comparators indicate an active event signal to the timing generation unit.

If an event happens when another event is ongoing, the occurred event is stored in the pending event FIFO of timing generation unit. If more than one event associated with an ACM timer is active during the same SCLK0_0 cycle, only the highest priority event is processed. All other events are missed (even if there was space in the pending event FIFO). However, if both timers are enabled and if multiple events associated with both ACM timers are active at the same SCLK0_0 cycle, then two events are signaled. One highest priority active event for each timer is signaled.

The priority of events is fixed; the event with the lowest event ID has higher priority compared to other events.

When both ACM timers are enabled, Event0 has the highest priority and Event7 has the lowest priority in the Event[0:7] group associated with ACMTIMER0. Similarly, Event8 has the highest priority and Event15 has the lowest priority in the Event[8:15] group associated with ACMTIMER1. So if Event1 and Event5 occur simultaneously, then Event5 is missed, even if space exists in the pending FIFO. But between the Event[0:7] and Event[8:15] group, simultaneous events can be written into the FIFO.

For example, if Event0 and Event9 occur together, then both are written into the FIFO. The Event[0:7] group has higher priority. Therefore, the order of events in the FIFO is Event0 first and then Event9. If Event1, Event5, Event9, Event15 occurred together, then Event5, and Event15 are missed. Event1 and Event9 are put into the FIFO (Event1 first followed by Event9). When both timers trigger events simultaneously, the event triggered by ACMTMR0 is given higher priority.

When only a single ACM timer is enabled, then all 16 events, Event[0:15], are assigned to that timer. Event0 has highest priority; while Event15 has lowest priority. In this case, if Event1, Event5, Event9, Event15 happened together, then only Event1 is placed in forwarded. Event5, Event9, and Event15 are missed, even if space exists in the pending FIFO.

If an event is missed, the `ACM_STAT.EMISS` bit and the corresponding bit in the ACM event missed status register (`ACM_MEVSTAT`) are set.

Timing Generation Unit

After event signaling from event comparators, the timing generation unit initiates an ADC sampling interval as per settings of that particular event. It generates ADC control signals based on the `ACM_EVCTL[n].EPF` bit field setting. The ACM uses timing registers (`ACM_TC0`, `ACM_TC1`) to determine the timing of output signals (`ACM_CLK`, $\overline{\text{CS}}$, `A[4:0]`). These registers contains the fields for set-up time, hold time and zero time for the output signals and ACM clock divider.

The pending FIFO is part of the timing generation unit. If an event occurs when the ACM is busy with another event, the occurred event is stored in the pending event FIFO. This pending event is serviced (for example, the ACM starts an ADC conversion for the event that occurred), after completion of an ongoing event.

The pending event FIFO has a depth of 4, so it can hold up to four pending events. If an event occurs when the pending event FIFO is full, that event is missed. If an event is missed, the `ACM_STAT.EMISS` bit is set and the corresponding bit in the `ACM_MEVSTAT` register also is set.

When the ACM is disabled, all pending entries in the pending FIFO are flushed.

Status Flags and Interrupts

The ACM provides a read-only status register (`ACM_STAT`) to check the module activities. Activities include identifying which event is being serviced, whether any event has been missed, or whether all the events have been serviced for the current trigger.

In addition to this register, the ACM also provides two general-purpose status registers, the ACM event completion status register (`ACM_EVSTAT`) and the ACM missed event status register (`ACM_MEVSTAT`). The `ACM_EVSTAT` register specifies how to service a completed enabled event for a particular trigger cycle. The `ACM_MEVSTAT` register specifies which enabled event has been missed for that particular trigger cycle. This information is provided for all 16 events through individual bits.

Based on these status bits, the ACM can generate two interrupts, event-completed or event-missed, for each event. These interrupts can be selectively enabled for particular ACM events through the ACM completed event interrupt mask register (`ACM_EVMSK`) and the ACM missed event interrupt mask register (`ACM_MEVMSK`).

The event completion interrupt is generated only after the entire event completes externally. (For example, when the $\overline{\text{CS}}$ signal goes inactive, and the hold time (`TH`) and zero time (`TZ`) periods are completed for that particular event). The ACM uses the `ACM_EVSTAT` register to provide the status of each event indicating which event has caused the interrupt. It is also possible to generate this interrupt when all the events associated with an ACM timer are completed for an ACM trigger cycle. Write the relevant W1C (write 1 to clear) bit in the `ACM_EVSTAT` register to clear this interrupt.

The event missed interrupt is generated when an enabled event is missed for a trigger cycle and the corresponding mask bit in the `ACM_MEVMSK` register is set. The event comparators unit can miss the event when more than one event, related to the same timer, are active during the same SCLK0_0 cycle. The timing generation unit can miss when an event occurred and the event pending FIFO was full. The ACM uses the `ACM_MEVSTAT` register to provide the status of each missed event indicating which event-miss caused the interrupt. Write the relevant W1C bit in the `ACM_MEVSTAT` register to clear this interrupt.

NOTE: A status bit set either in the `ACM_EVSTAT` or `ACM_MEVSTAT` registers triggers an interrupt only if the corresponding bit in the `ACM_EVMSK` or `ACM_MEVMSK` registers is enabled.

The ACM provides an event completion interrupt upon completion of particular event or all events. The ACM can also provide a trigger output to the trigger routing unit (TRU) of the processor. Trigger slaves can use this trigger output for their operations without requiring core intervention.

Event Order Registers

For debugging purpose, ACM hardware includes 16 event order registers, one per each event. These registers indicate the order in which the events complete externally.

These registers are denoted as `ACM_EVORD[n]`, where n stands for event ID, 0–15. The ACM module uses the 8-bit `ACM_EVORD[n].ORD` field of this register to indicate the order the ADC data has been captured for the event. This field accumulates the order count every trigger cycle, unless it is cleared in the software. At each trigger cycle, the values of the register are updated. The ACM must read the register at the end of each trigger cycle (as it writes the new order value of the event in the next trigger cycle). Thus, the 8-bit field can store the order of 256 data captures at a stretch, after which it starts the order count from zero again.

All the event registers can be reset in software by setting the `ACM_CTL.ORST` bit. When set, it clears all the register values to zero. This bit is auto-cleared to 0 after all `ACM_EVORD[n]` registers are cleared. The ACM can select trigger inputs of the timers to automatically clear these registers, when the `ACM_CTL.AOREN` bit is set. The ACM uses the `ACM_CTL.OTSEL` bit to determine which trigger input to select for this auto-clearing.

The event order functionality is demonstrated with an example where the ACM has only three events enabled (Event1, Event7, and Event13). The ***Event Order Timing*** figure shows the event order register value of these events at different stages.

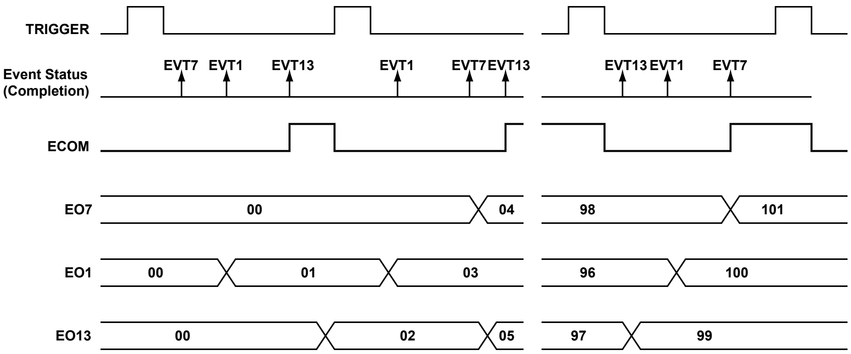

Figure 24-11: Event Order Timing

ACM Operation

The ***ACM Operation, Two Events*** figure shows the ACM operation where only two events (Event0 and Event3) are enabled. The line labeled "ADC Controls" depicts the timing of the ADC control signals: `ACM_A4` through `ACM_A0`.

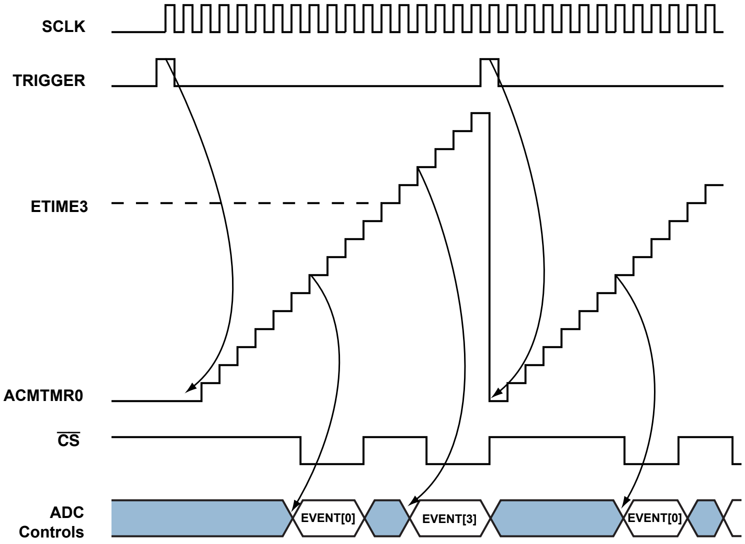

Figure 24-12: ACM Operation, Two Events

The ***ACM Operation, Two Events*** figure depicts a usage case. The `ACM_EVTIME[n]` 3 time register is programmed with a count value that is greater than the value programmed in Event0. So, Event3 occurs after Event0. There are, however, no restrictions on the order of the different events. Event0 time can be greater than, less than or equal to Event3 time.

If the value in Event0 time register is less than the value in Event3 time, Event3 occurs after Event0. If the value in Event0 is greater than the value in Event3, then Event3 occurs before Event0. If Event0 time is equal to the Event3 time, the events are processed according to their priorities. Only the highest priority event is processed. Other lower-priority events are missed (even if there is a space in pending event FIFO), as the same ACM timer handles both events. Event0 has the highest priority. So in this case, the timing generation unit processes Event0, while Event3 is missed. In this case, the Event3 missed status bit (`ACM_MEVSTAT.EV3`) is set and the event missed bit (`ACM_STAT.EMISS`) is set, indicating that an event has been missed.

If event times are not sufficiently spaced apart, an event could occur while a previous event is underway (while the chip select of the previous event is asserted). In this situation, the second event is queued in the pending event FIFO. If the pending event FIFO is full, the event is not queued and is missed. This situation happens most commonly when enabling both ACM timers with different trigger inputs and the sources of these triggers are not synchronized together. In this case, it is possible that the events controlled by the two timers overlap. It is therefore important to consider the possibility of events occurring either simultaneously or being missed when enabling events on two asynchronously triggered timers. It is the programs responsibility to ensure that the values in the event time registers do not lead to event misses. The bits corresponding to the missed event in the `ACM_MEVSTAT` and `ACM_STAT` registers are flagged on a missed event.

When both ACM timers are enabled and they triggered the events simultaneously, the event triggered by `ACM_TMR0` has the higher priority. For example, when an `ACM_TMR0` event (one of events 0 through 7) and `ACM_TMR1` event (one of events 8 through 15) occur simultaneously:

- The timing generation unit processes the `ACM_TMR0` event, or
- The `ACM_TMR0` event is queued in the pending event FIFO before the processing or the queuing of the `ACM_TMR1` event.

When all the events enabled for a given ACM timer are processed, the ACM timer stops incrementing. (This timer action is not reflected in the ***ACM Operation, Two Events*** figure). Also, the corresponding event completion bit (`ACM_STAT.ECOM1`, `ACM_STAT.ECOM0`) is flagged. The same bit is also reflected in the status register for event compilation (`ACM_EVSTAT`). This register can optionally generate the event completion interrupt when the corresponding bit in the event completion interrupt mask register (`ACM_EVMSK`) is set. Two separate bits are available, one for each ACM timer.

The processor can use the ACM to generate various sequences of ADC sampling events through appropriate programming of event time registers, event control registers, and triggers. For more information, see the use cases described in Emulation Mode Use Case.

ACM Programming Concepts

Since the ACM module is used with the SPORT, PWM, GP timer, and GPIO, the programming must comply with the following guidelines for reliable operation of the ACM.

- The ACM is a control module and provides clock and chip select and control signals with required timing. But for capturing the data from ADC, the ACM uses one of the halves of SPORT1.
- Enable the ACM before enabling the SPORT. The SPORT can be configured before enabling the ACM. Configure the SPORT in slave mode [external clock (`SPORT_CTL_A.ICLK` =0), external frame sync (`SPORT_CTL_A.IFS` =0)] as receiver.

  The timings of external ADC decide the settings of `SPORT_CTL_A.LFS`, `SPORT_CTL_A.LAFS`, `SPORT_CTL_A.CKRE` bits. Generally, the SPORT is configured in DSP serial mode to receive the ADC samples, but other operating modes (such as multichannel) are possible.

  If the ACM is programmed in gated clock mode (`ACM_CTL.CLKMOD` =1), set the serial port also in gated clock mode (`SPORT_CTL_A.GCLKEN` =1).
- DMA mode of SPORT operation is preferred, as it saves the processor MIPS when receiving chunks of data. However, receiving ADC samples in core mode is also possible. When using DMA mode, configure the DMA registers of the selected SPORT appropriately and enable DMA before enabling the SPORT. When using the primary and secondary channels of a SPORT to receive data from two ADC channels, use the 2D feature of DMA to de-interleave the data from two channels. When using core mode of SPORT operation, register the core handler to handle the data read requests from the SPORT receiver.

- In addition to SPORT register settings, first set the DAI registers to enable: SPORT data pins, the ACM clock, the $\overline{\text{CS}}$, and the data pins. Then, configure the PORT registers for the trigger and control pins. When using either of the `ACM_T1`/`ACM_T0` trigger inputs for ACM timers, configure the `PORT_FER` and `PORT_MUX` bits of the corresponding pins (PE8 or PG5) according to source of trigger input.
- When using ACM_T[2:3] trigger inputs for ACM timers, the ACM can configure and enable the trigger routing unit (TRU) at this step. Program the corresponding slave trigger ID using the `TRU_SSR[n]` register to select the required master trigger. When using these trigger inputs, do not configure the `TRU_SSR[n]` register when the ACM is enabled. The default value of this register is zero and the master trigger ID 0 is system reserved.
- Before enabling the ACM (by setting the `ACM_CTL.EN` bit), program all the control bits of ACM control register. These control bits include ACM trigger selects (`ACM_CTL.TRGSEL1`/`ACM_CTL.TRGSEL0`), trigger input polarities (`ACM_CTL.TRGPOL1`/`ACM_CTL.TRGPOL0`), $\overline{\text{CS}}$ signal polarity (`ACM_CTL.CSPOL`), ACM clock polarity (`ACM_CTL.CLKPOL`), ACM clock mode (`ACM_CTL.CLKMOD`), and serial port unit selection and the `ACM_EVORD[n]` register settings.
- Configure the ACM timing control registers to define the ACM clock frequency and the setup, hold, and zero time of the ACM control signals.
- Program the timer enabled bits (`ACM_CTL.TMR0EN`/`ACM_CTL.TMR1EN`) together only after the ACM is enabled. Once the bits are programmed, do not change them. Modifying these enable bits in the ACM control register is not recommended while the ACM is in operation. Doing so can cause events to change dependency from one timer to the other and can cause the values in the ACM status registers (`ACM_EVSTAT` and `ACM_STAT`) to be inaccurate. If both timers are required for use, enable them together after the ACM is enabled. If one timer is already enabled, disable and then reenable the ACM and then program both timer enable bits together. Similarly, when both timers are running, disable them together.
- Once the peripherals have been configured, enable the ACM first and then the SPORT DMA and finally the SPORT module itself. Ideally, a trigger should not be active when enabling the ACM.
- After enabling the ACM, configure and enable the event register pairs (event control and event time registers) to create the required events.
- ACLK is an external clock relative to the SPORT peripheral. Observe any SPORT requirements around a minimum number of stable external clock cycles before the assertion of the first SPORT frame sync. The SPORT requires a minimum of 3 clock cycles before it is able to recognize a frame sync. When the SPORT is configured in gated clock mode, this requirement becomes a minimum of 7 SPORT clock cycles. The required number of ACLK cycles should elapse before first assertion of $\overline{\text{CS}}$. Use any of the following methods:
    - Ensure that ACM triggers are generated at least 3 ACLK cycles after the ACM is enabled.
    - Ensure that the event time value (`ACM_EVTIME[n]`) of the first active event is such that 3 ACLK cycles elapse before the event is processed.

- When the minimum number of ACLK cycles before the assertion of $\overline{\text{CS}}$ is not observed, the SPORT can miss the data of the first ADC sampling event. There is a software workaround for fulfilling this requirement. Program the `ACM_TC0.CKDIV` value after enabling the SPORT (subsequently after enabling the ACM) but before the trigger is applied. Since the default value of `ACM_TC0.CKDIV` is 1, the ACLK frequency is higher. Therefore, the SPORT can receive the required clock cycles within a short period (before the frame sync arrives).
- When using the `ACM_T2`/`ACM_T3` trigger inputs, the master can be enabled as a last step (if it is configured only to provide triggers to the ACM) to generate the triggers.
- While disabling the ACM system, disable the SPORT first, then the DMA. Finally, disable the ACM.

Emulation Mode Use Case

This section describes the usage modes of the ACM by illustrating how to implement various sequencing ADC sampling modes.

Single-Shot Sequencing Mode Emulation

In single-shot sequencing mode, all enabled events are sequentially issued one after the other on the occurrence of an ACM trigger. The sequence of events is fixed, starting with Event0 and ending with Event15.

The ***Single Shot Sequencing*** figure shows an example of single-shot sequencing mode where only Event0 and Event1 are enabled. The value ETIME0 is written into the ACM_ET0 register, and ACMTMR0 is enabled in this mode.

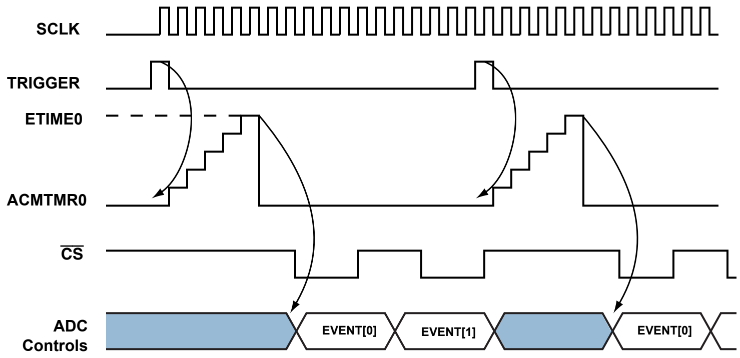

Figure 24-13: Single Shot Sequencing

To emulate this mode of operation using the ACM:

- Configure the appropriate trigger source for initiating ACM activity. Refer to ADC Control Module (ACM) for information on signals that can trigger the ACM counters.
- Enable only one ACM timer (ACMTMR0)
- Enable events and program the event time values as: Event0 time = X, Event1 time = X + Y, Event2 time = X + 2Y where:

  X = `ETIME0`, the initial time offset from trigger (if needed)

$Y = t_H + t_{CSW} + t_S + t_Z$, where t_H is the hold time, t_Z is the zero time, and t_S is the setup time for ACM control lines, as specified in ACM timing registers.

For more information, refer to the ACM External Pin Timing section.

NOTE: Y has to be slightly less than the calculated value to ensure that the next event occurs before the first event completes. Then, the next event is in the pending FIFO and enables the transitions between events without a break.

Continuous Sequencing Mode Emulation

Continuous sequencing mode is similar to single-shot sequencing mode, except in continuous sequencing the event sequencing continuously repeats. As in single-shot mode, the time offset is programmable in continuous mode. The trigger in continuous mode is relevant only for the first time. Therefore, any subsequent triggers after the first active edge of the trigger are neglected.

The ***Continuous Sequencing*** figure shows an example of continuous sequencing mode with only two events – Event0, Event1 enabled. To emulate continuous sequencing mode using ACM:

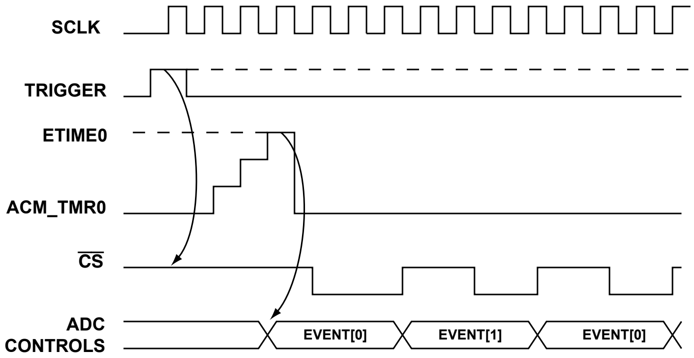

Figure 24-14: Continuous Sequencing

- Enable only one ACM timer (for example ACMTIMER0). Select a timer trigger input from the TRU (either of the `ACM_T[n]`[3:2].

  If `ACM_T2` is selected, program ACM slave trigger ID 33 to select ACM event completion (whose master trigger ID is 19) as trigger input. If `ACM_T3` is selected as trigger input, configure ACM slave trigger ID 34.

- Configure rest of the settings required by programming ACM control and timing registers.
- Enable ACM events with required ACM control lines settings.

  Program the event time registers as: Event0 time = X, Event1 time = X + Y, Event 2 time = X + 2Y where:

  X and Y values, in terms of SCLK, are as described in the single-shot case. (Y must be slightly less than $t_H + t_{CSW} + t_S + t_Z$ to avoid any break between events.)

- Configure and enable system event controller (SEC).

Also configure, map, and enable the ACM event completion interrupt. This interrupt occurs on the completion of all enabled ACM events for the current trigger. That means that programs must only set the `ACM_EVMSK.IECOM0` bit (or the `ACM_EVMSK.IECOM1` bit, if using ACMTIMER1) register.

- Enable ACM, SPORT, and SPORT DMA as per the guidelines in the ACM Programming Concepts section.
- Since the ACM trigger input is configured as ACM event completion trigger output, the first trigger is necessary to start the ACM operation. We can provide this dummy trigger by writing master trigger ID into master trigger register (`TRU_MTR`).

  Write the ACM event completion trigger ID (19) into the `TRU_MTR` register. This action triggers the ACM timers and the ACM starts handling the events.
- After completing all events, the ACM provides an event completion trigger and the corresponding interrupt is generated. The ACM trigger output is provided to the ACM timers. The timers reset their counter and start running from zero. The ACM rehandles all the enabled ACM events. This sequence continues.

  However, in order to provide the trigger outputs properly, clear the interrupt latch in the ISR by clearing the `ACM_EVSTAT.ECOM0S` (or `ACM_EVSTAT.ECOM1S`, if using ACMTIMER1) bit.

ADSP-SC58x ACM Register Descriptions

ADC Control Module (ACM) contains the following registers.

Table 24-5: ADSP-SC58x ACM Register List

Name	Description
`ACM_CTL`	Control Register
`ACM_EVCTL[n]`	Event N Control Register
`ACM_EVMSK`	Event Complete Interrupt Mask Register
`ACM_EVORD[n]`	Event N Order Register
`ACM_EVSTAT`	Event Complete Status Register
`ACM_EVTIME[n]`	Event N Time Register
`ACM_MEVMSK`	Missed Event Interrupt Mask Register
`ACM_MEVSTAT`	Missed Event Status Register
`ACM_STAT`	Status Register
`ACM_TC0`	Timing Configuration 0 Register
`ACM_TC1`	Timing Configuration 1 Register
`ACM_TMR0`	Timer 0 Register
`ACM_TMR1`	Timer 1 Register

Control Register

The `ACM_CTL` register enables and selects the various modes of operation of the ACM.

Figure 24-15: ACM_CTL Register Diagram

Table 24-6: ACM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EPS	External Peripheral Select. The `ACM_CTL.EPS` bit selects whether the ACM interfaces to half SPORT A or half SPORT B.	
		0	Half SPORT A Interfaces to ACM
		1	Half SPORT B Interfaces to ACM
14 (R/W)	OTSEL	Order Trigger Select. The `ACM_CTL.OTSEL` bit selects whether TMR0 or TMR1 triggers a reset of the event order (`ACM_EVORD[n]`) registers. This bit is applicable only if the `ACM_CTL.AOREN` bit is set.	
		0	ACM TMR0 Triggers Reset of Order Registers
		1	ACM TMR1 Triggers Reset of Order Registers

Table 24-6: ACM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	AOREN	Automatic Order Reset Enable. The `ACM_CTL.AOREN` bit enables automatic reset of the event order (`ACM_EVORD[n]`) registers, based on the selected timer trigger. The `ACM_CTL.OTSEL` bit selects the trigger.	
		0	Disable Automatic Order Reset
		1	Enable Automatic Order Reset
12 (R/W)	ORST	Order Register Reset. The `ACM_CTL.ORST` bit resets the event order (`ACM_EVORD[n]`) register value to 0. This bit auto-clears to 0 after the `ACM_EVORD[n]` registers clear.	
11 (R/W)	CLKMOD	ADC Clock Mode. The `ACM_CTL.CLKMOD` bit selects gated clock mode (`ACM_CLK` is gated when the ADC CS is inactive) or continuous (ACM generates continuous `ACM_CLK`).	
		0	Continuous Clock Mode
		1	Gated Clock Mode
10 (R/W)	CLKPOL	Clock Polarity. The `ACM_CTL.CLKPOL` bit selects whether the rising or falling edge of `ACM_CLK` comes after ADC CS becomes active.	
		0	Falling Edge of Clock After CS
		1	Rising Edge of Clock After CS
9 (R/W)	CSPOL	Chip Select Polarity. The `ACM_CTL.CSPOL` bit selects whether ADC CS is active high or low.	
		0	Active Low CS
		1	Active High CS
8 (R/W)	TRGPOL1	Trigger Polarity TMR1. The `ACM_CTL.TRGPOL1` bit selects whether the trigger polarity for ACM TMR1 occurs on the falling or rising edge.	
		0	Rising Edge Trigger
		1	Falling Edge Trigger
7 (R/W)	TRGPOL0	Trigger Polarity TMR0. The `ACM_CTL.TRGPOL0` bit selects whether the trigger polarity for ACM TMR0 occurs on the falling or rising edge.	
		0	Rising Edge Trigger
		1	Falling Edge Trigger

Table 24-6: ACM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:5 (R/W)	TRGSEL1	Trigger Select TMR1. The `ACM_CTL.TRGSEL1` bits select the external trigger for ACM TMR1.	
		0	Trigger 0 (ACM_T0 Pin)
		1	Trigger 1 (ACM_T1 Pin)
		2	Trigger 2 (Trigger Input 2 - TRU Slave)
		3	Trigger 3 (Trigger Input 3 - TRU Slave)
4:3 (R/W)	TRGSEL0	Trigger Select TMR0. The `ACM_CTL.TRGSEL0` bits select the external trigger for ACM TMR0.	
		0	Trigger 0 (ACM_T0 Pin)
		1	Trigger 1 (ACM_T1 Pin)
		2	Trigger 2 (Trigger Input 2 - TRU Slave)
		3	Trigger 3 (Trigger Input 3 - TRU Slave)
2 (R/W)	TMR1EN	TMR1 Enable. The `ACM_CTL.TMR1EN` bit enables ACM TMR1.	
		0	Disable ACM TMR1
		1	Enable ACM TMR1
1 (R/W)	TMR0EN	TMR0 Enable. The `ACM_CTL.TMR0EN` bit enables ACM TMR0.	
		0	Disable ACM TMR0
		1	Enable ACM TMR0
0 (R/W)	EN	ACM Enable. The `ACM_CTL.EN` bit enables ACM operation.	
		0	Disable ACM
		1	Enable ACM

Event N Control Register

The `ACM_EVCTL[n]` registers each hold the ADC control value corresponding to the event related to the register. These control registers each have an event enable bit, that permits a selective enable of a particular event.

Do not program the `ACM_EVCTL[n]` register when an event is active. Program this register before setting trigger and re-program this register after all the events are complete (`ACM_STAT.ECOM1` or `ACM_STAT.ECOM0` bit is set). If no events are enabled in this register (for example, all `ACM_EVCTL[n].ENAEV` bits =0, and the `ACM_STAT.ECOM0` or `ACM_STAT.ECOM1` bits are set) and an interrupt generates (if unmasked) a trigger is applied with the Timer enabled.

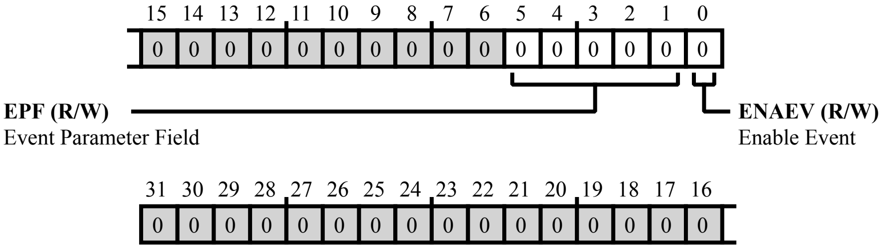

Figure 24-16: ACM_EVCTL[n] Register Diagram

Table 24-7: ACM_EVCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5:1 (R/W)	EPF	Event Parameter Field. The `ACM_EVCTL[n].EPF` bits select values for the ADC control pins (`ACM_A[n]`. These values are output when the enabled event occurs. Selection of `ACM_EVCTL[n].EPF` values are based on the type of ADC, usage mode, and other items. For more information, see the operating modes section. All `ACM_EVCTL[n].EPF` bits have the same external pin timing.	
0 (R/W)	ENAEV	Enable Event. The `ACM_EVCTL[n].ENAEV` bit causes a sampling event to occur based on the controls selected by the `ACM_EVCTL[n].EPF` bit field when an event (time comparison match or other external trigger) occurs. If disabled, the corresponding event has no significance, and the control values are not used.	
		0	Disable Event
		1	Enable Event

Event Complete Interrupt Mask Register

The ACM_EVMSK register enables interrupts corresponding to status bits in the ACM_EVSTAT register. When a bit in the ACM_EVMSK register is set (=1), an interrupt generates when the corresponding event complete bit in the ACM_EVSTAT register is set.

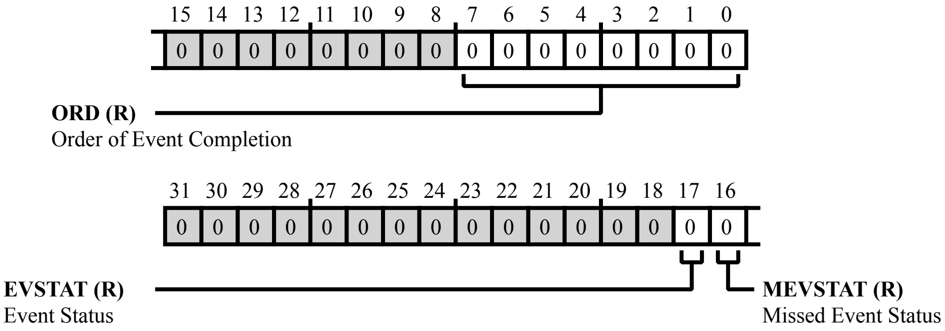
Event N Order Register

The `ACM_EVORD[n]` registers hold the ADC data capture event order. These registers can store the order of 256 data captures at a stretch. The `ACM_EVORD[n]` registers also have status bits indicating whether an event misses or completes in the trigger cycle.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ORD (R)
Order of Event Completion
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
EVSTAT (R)
Event Status
MEVSTAT (R)
Missed Event Status

Figure 24-18: ACM_EVORD[n] Register Diagram

Table 24-9: ACM_EVORD[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	EVSTAT	Event Status. The `ACM_EVORD[n].EVSTAT` bit reflects the state of the corresponding event bit in the `ACM_EVSTAT` register.	
16 (R/NW)	MEVSTAT	Missed Event Status. The `ACM_EVORD[n].MEVSTAT` bit reflects the state of the corresponding event bit in the `ACM_MEVSTAT` register.	
7:0 (R/NW)	ORD	Order of Event Completion. The `ACM_EVORD[n].ORD` bits indicate the order of event completion. Zero indicates the first event completed (after the ACM is enabled or after the `ACM_CTL.ORST` bit is set) and 255 indicates the 256th event completed.	
		0	1st Event Completed
		1	2nd Event Completed
		255	256th Event Completed

Event Complete Status Register

The ACM_EVSTAT register identifies which enabled event has occurred for a particular trigger cycle. When an ACM_EVSTAT bit is cleared (=0), this status indicates that the ACM has not begun or completed conversion for the corresponding event (conversion not done). When an ACM_EVSTAT bit is set (=1), this status indicates that the ACM has completed conversion for the corresponding event (conversion done).

		0	No Event 10 Conversion
		1	Event 10 Conversion Done
9 (R/W1C)	EV9	Event 9 Status. The `ACM_EVSTAT.EV9` bit indicates when the ACM has completed the conversion for event 9. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 9 Conversion
		1	Event 9 Conversion Done
8 (R/W1C)	EV8	Event 8 Status. The `ACM_EVSTAT.EV8` bit indicates that the ACM has completed the conversion for event 8. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 8 Conversion
		1	Event 8 Conversion Done
7 (R/W1C)	EV7	Event 7 Status. The `ACM_EVSTAT.EV7` bit indicates when the ACM has completed the conversion for event 7. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 7 Conversion
		1	Event 7 Conversion Done

Table 24-10: ACM_EVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	EV6	Event 6 Status. The `ACM_EVSTAT.EV6` bit indicates when the ACM has completed the conversion for event 6. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 6 Conversion
		1	Event 6 Conversion Done
5 (R/W1C)	EV5	Event 5 Status. The `ACM_EVSTAT.EV5` bit indicates when the ACM has completed the conversion for event 5. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 5 Conversion
		1	Event 5 Conversion Done
4 (R/W1C)	EV4	Event 4 Status. The `ACM_EVSTAT.EV4` bit indicates when the ACM has completed the conversion for event 4. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 4 Conversion
		1	Event 4 Conversion Done
3 (R/W1C)	EV3	Event 3 Status. The `ACM_EVSTAT.EV3` bit indicates when the ACM has completed the conversion for event 3. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 3 Conversion
		1	Event 3 Conversion Done
2 (R/W1C)	EV2	Event 2 Status. The `ACM_EVSTAT.EV2` bit indicates when the ACM has completed the conversion for event 2. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 2 Conversion
		1	Event 2 Conversion Done

Table 24-10: ACM_EVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	EV1	Event 1 Status. The `ACM_EVSTAT.EV1` bit indicates when the ACM has completed the conversion for event 1. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 1 Conversion
		1	Event 1 Conversion Done
0 (R/W1C)	EV0	Event 0 Status. The `ACM_EVSTAT.EV0` bit indicates when the ACM has completed the conversion for event 0. If set and the corresponding bit in `ACM_EVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 0 Conversion
		1	Event 0 Conversion Done

Event N Time Register

The `ACM_EVTIME[n]` registers each hold a 32-bit event time value. There are 16 event time registers, 8 for each ACM timer (when both timers are enabled). If only one timer is enabled, all 16 of the `ACM_EVTIME[n]` registers are assigned to the enabled timer.

Do not program the `ACM_EVTIME[n]` register when an event is active. Program this register before setting a trigger and re-program the register after all events are complete (`ACM_STAT.ECOM1` or `ACM_STAT.ECOM0` bits are set). If no events are enabled in this register (for example, the `ACM_EVCTL[n].ENAEV` bits =0 and the `ACM_STAT.ECOM0` or `ACM_STAT.ECOM1` bits =1) and an interrupt generates (if unmasked), a trigger is applied with the Timer enabled.

Missed Event Interrupt Mask Register

The ACM_MEVMSK register enables interrupts corresponding to status bits in the ACM_MEVSTAT register. When a bit is set in the ACM_MEVMSK register, an interrupt generates when the corresponding event missed bit in the ACM_MEVSTAT register is set.

Missed Event Status Register

The ACM_MEVSTAT register indicates which enabled event is missed for a particular trigger cycle. When a ACM_MEVSTAT register bit is set (=1), this status indicates a miss of the corresponding event. This status generates an interrupt if the corresponding bit in the ACM_MEVMSK register is set.

14 (R/W1C)	EV14	Event 14 Missed. The `ACM_MEVSTAT.EV14` bit indicates a miss of event 14 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 14 Missed Status
		1	Event 14 Missed
13 (R/W1C)	EV13	Event 13 Missed. The `ACM_MEVSTAT.EV13` bit indicates a miss of event 13 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 13 Missed Status
		1	Event 13 Missed
12 (R/W1C)	EV12	Event 12 Missed. The `ACM_MEVSTAT.EV12` bit indicates a miss of event 12 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 12 Missed Status
		1	Event 12 Missed
11 (R/W1C)	EV11	Event 11 Missed. The `ACM_MEVSTAT.EV11` bit indicates a miss of event 11 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 11 Missed Status
		1	Event 11 Missed
10 (R/W1C)	EV10	Event 10 Missed. The `ACM_MEVSTAT.EV10` bit indicates a miss of event 10 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 10 Missed Status
		1	Event 10 Missed

Table 24-13: ACM_MEVSTAT Register Fields (Continued)

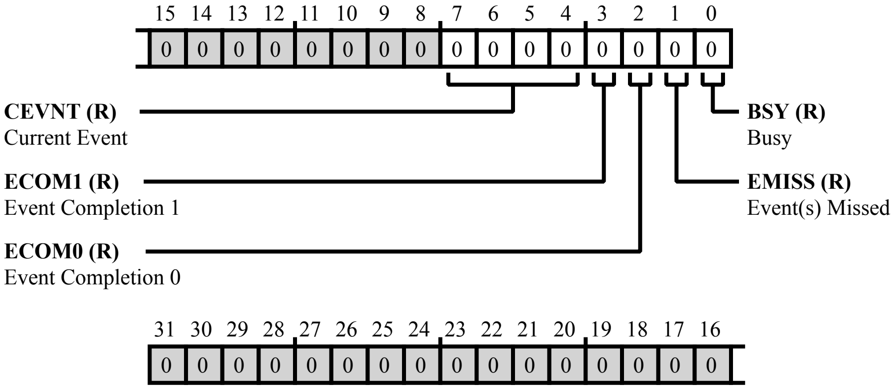
Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	EV9	Event 9 Missed. The `ACM_MEVSTAT.EV9` bit indicates when a miss of event 9 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 9 Missed Status
		1	Event 9 Missed
8 (R/W1C)	EV8	Event 8 Missed. The `ACM_MEVSTAT.EV8` bit indicates a miss instance of event 8 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 8 Missed Status
		1	Event 8 Missed
7 (R/W1C)	EV7	Event 7 Missed. The `ACM_MEVSTAT.EV7` bit indicates a miss of event 7 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 7 Missed Status
		1	Event 7 Missed
6 (R/W1C)	EV6	Event 6 Missed. The `ACM_MEVSTAT.EV6` bit indicates a miss of event 6 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 6 Missed Status
		1	Event 6 Missed
5 (R/W1C)	EV5	Event 5 Missed. The `ACM_MEVSTAT.EV5` bit indicates a miss of event 5 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 5 Missed Status
		1	Event 5 Missed

Table 24-13: ACM_MEVSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W1C)	EV4	Event 4 Missed. The `ACM_MEVSTAT.EV4` bit indicates a miss of event 4 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 4 Missed Status
		1	Event 4 Missed
3 (R/W1C)	EV3	Event 3 Missed. The `ACM_MEVSTAT.EV3` bit indicates a miss of event 3 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 3 Missed Status
		1	Event 3 Missed
2 (R/W1C)	EV2	Event 2 Missed. The `ACM_MEVSTAT.EV2` bit indicates a miss of event 2 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 2 Missed Status
		1	Event 2 Missed
1 (R/W1C)	EV1	Event 1 Missed. The `ACM_MEVSTAT.EV1` bit indicates a miss of event 1 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 1 Missed Status
		1	Event 1 Missed
0 (R/W1C)	EV0	Event 0 Missed. The `ACM_MEVSTAT.EV0` bit indicates a miss of event 0 since the last trigger. If set and the corresponding bit in `ACM_MEVMSK` is set (interrupt enabled), the condition generates an interrupt. This bit is W1C.	
		0	No Event 0 Missed Status
		1	Event 0 Missed

Status Register

The `ACM_STAT` register indicates the ACM event that is currently being serviced, pending events, missed events, and missed triggers.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 24-14: ACM_STAT Register Fields

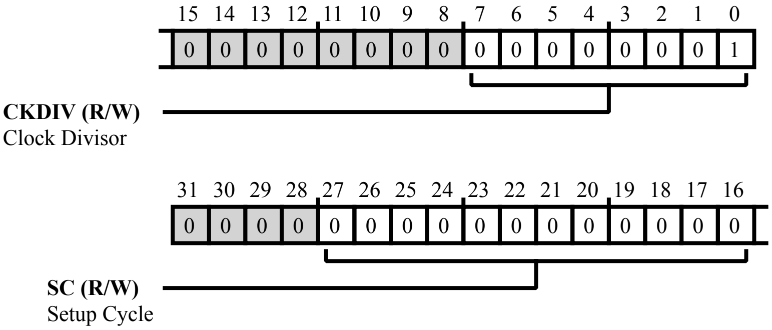
Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/NW)	CEVNT	Current Event. The `ACM_STAT.CEVNT` bits indicate to which event (0 through 15) the ongoing access (current event, if any) corresponds.	
		0	Current Event Correspond to Event 0
		1	Current Event Correspond to Event 1
		15	Current Event Correspond to Event 15
3 (R/NW)	ECOM1	Event Completion 1. The `ACM_STAT.ECOM1` bit indicates TMR1 event completion for all enabled ACM TMR1 events and the current trigger. The ACM clears this bit with each trigger.	
		0	No Status
		1	ACM TMR1 Events Complete
2 (R/NW)	ECOM0	Event Completion 0. The `ACM_STAT.ECOM0` bit indicates TMR0 event completion for all enabled ACM TMR0 events and the current trigger. The ACM clears this bit with each trigger.	
		0	No Status
		1	ACM TMR0 Events Complete

Table 24-14: ACM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	EMISS	Event(s) Missed. The `ACM_STAT.EMISS` bit indicates a missed event time (any bits in `ACM_MEVSTAT` set). This bit is cleared by writing into the `ACM_MEVSTAT` register.	
		0	No Missed Event(s)
		1	Missed Event(s)
0 (R/NW)	BSY	Busy. The `ACM_STAT.BSY` bit indicates when the ACM is busy (an external sampling event in progress; CS is active or about to go active).	
		0	Idle
		1	Busy

Timing Configuration 0 Register

The ACM_TC0 register determines the frequency of ACM_CLK (using the ACM_TC0.CKDIV field) and the setup cycles (using the ACM_TC0.SC field) for the ADC controls. Setup cycles are specified in terms of SCLK0_0.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SC (R/W)
Setup Cycle

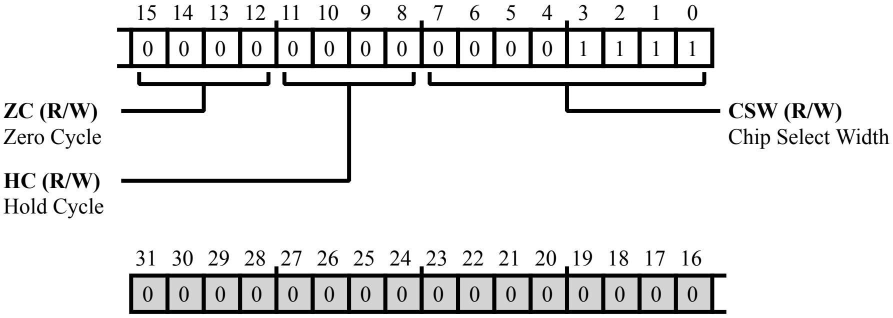
Figure 24-24: ACM_TC0 Register Diagram

Table 24-15: ACM_TC0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27:16 (R/W)	SC	Setup Cycle. The ACM_TC0.SC bits select the ADC control pins and the setup time in SCLK0_0 cycles with respect to the ADC chip select active edge. The setup time may be calculated from: Setup Time = ACM_TC0.SC + 1. The maximum setup cycle time is 4096 * SCLK0_0, and the minimum setup cycle time is 1 SCLK0_0.	
		0	1 SCLK0_0 Cycle Setup Time
		1	2 SCLK0_0 Cycles Setup Time
		4095	4096 SCLK0_0 Cycles Setup Time
7:0 (R/W)	CKDIV	Clock Divisor. The ACM_TC0.CKDIV bits select the frequency of ACM_CLK as a function of the system clock frequency (SCLK0_0) and the value of the CKDIV field according to the formula: ACM_CLK frequency = (SCLK0_0 frequency)/(ACM_TC0.CKDIV + 1) The maximum ACM_CLK frequency is SCLK0_0/2, and the minimum ACM_CLK frequency is SCLK0_0/256. For example, for a 100 MHz SCLK0_0, the ACM_CLK frequency range is from 390 KHz to 50 MHz. The value ACM_TC0.CKDIV =0 is reserved.	

Timing Configuration 1 Register

The ACM_TC1 register provides programmability for the active duration of the following ADC controls: chip select (T_{CSW}), Hold Cycles (T_H), and Zero Cycles (T_Z).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 1

31:0 (R/NW)	TMRCNT	Active TMR1 Count Value. The `ACM_TMR1.TMRCNT` bit field contains the active count value for ACM timer 1.

25 Controller Area Network (CAN)

The processor contains a Controller Area Network (CAN) module based on the CAN 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. The CAN protocol is compatible with the control applications. It can communicate reliably over a network and incorporates CRC checking, message error tracking, and fault node confinement.

NOTE: This document assumes familiarity with the CAN standard. For more information, refer to Version 2.0 of the CAN specification from Robert Bosch GmbH.

CAN Features

Key features of the CAN module include:

- Conformity to the CAN 2.0B (active) standard
- Dedicated acceptance mask for each mailbox
- Support for data rates of up to 1M bit/s
- Support for standard (11-bit) and extended (29-bit) identifiers
- 32 mailboxes (8 transmit, 8 receive, 16 configurable)
- Data filtering (first 2 bytes) for acceptance filtering (DeviceNet^{TM} mode)
- Error status and warning registers
- Universal counter-module
- Readable receive and transmit pin values
- Support for remote frames
- Active or passive network support
- Interrupts, including transmit or receive complete, error, and global
- Clock derived from CDU0_CLKO4 through a programmable divider, eliminating the need for an extra crystal

CAN Functional Description

The following sections provide information on the functional operation of the CAN module. This section also provides listings of the CAN registers and interrupts.

ADSP-SC58x CAN Register List

The controller area network (CAN) module implements the CAN 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. A set of registers govern CAN operations. For more information on CAN functionality, see the CAN register descriptions.

Table 25-1: ADSP-SC58x CAN Register List

ADSP-SC58x CAN Interrupt List

Table 25-2: ADSP-SC58x CAN Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
84	CAN0_RX	CAN0 Receive	Level	
85	CAN0_TX	CAN0 Transmit	Level	
86	CAN0_STAT	CAN0 Status	Level	
87	CAN1_RX	CAN1 Receive	Level	
88	CAN1_TX	CAN1 Transmit	Level	
89	CAN1_STAT	CAN1 Status	Level	

External Interface

The interface to the CAN bus is a simple two-wire line. The ***Representation of CAN Transceiver Interconnection*** shows a symbolic representation of the CAN transceiver interconnection. Typically, the `CAN_TX` output and `CAN_RX` input pins of the processor connect to an external CAN `CAN_TX` and `CAN_RX` pins (respectively) of the tranceiver. The `CAN_TX` and `CAN_RX` pins operate with TTL levels and are appropriate for operation with CAN bus transceivers according to ISO/DIS 11898.

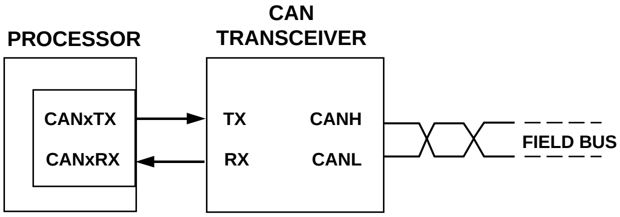

Figure 25-1: Representation of CAN Transceiver Interconnection

CAN data is either dominant (logic 0) or recessive (logic 1). The default state of the `CAN_TX` output is recessive.

Architectural Concepts

The full CAN controller features 32 message buffers called mailboxes. Eight mailboxes are dedicated for message transmission, eight are for reception, and 16 are programmable in direction.

The CAN module architecture is based around a 32-entry mailbox RAM. The CAN serial interface or the processor core accesses the mailbox sequentially. Each mailbox consists of eight 16-bit control and data registers and two optional 16-bit acceptance mask registers. Configure all of these registers before enabling the mailbox.

Since the mailbox area is implemented as RAM, the reset values of these registers are undefined. The ***CAN Mailbox Area*** figure shows the mailbox area. The data is divided into fields, which include a message identifier, a time stamp, a byte count, up to 8 bytes of data, and several control bits.

Figure 25-2: CAN Mailbox Area

The CAN mailbox identification register pair (CAN_MB[nn]_ID0/1) includes:

- The 29-bit identifier (base part CAN_AM[nn]H.BASEID plus the extended part CAN_AM[nn]L.EXTID/ CAN_AM[nn]H.EXTID)
- The acceptance mask enable bit (CAN_MB[nn]_ID1.AME)
- The remote transmission request bit (CAN_MB[nn]_ID1.RTR)
- The identifier extension bit (CAN_MB[nn]_ID1.IDE)

NOTE: Do not write to the identifier of a message object while the mailbox is enabled for the CAN module (the corresponding bit in CAN_MC1 is set).

The other mailbox area registers and bits are:

- The data length code bit (CAN_MB[nn]_LENGTH.DLC). The upper 12 bits of this register for each mailbox are marked as reserved. Always, set these 12 bits to zero.
- The mailbox word registers (CAN_MB[nn]_DATA0/1/2/3) supply up to 8 bytes for the data field. The data is sent MSB first based on the number of bytes defined in the CAN_MB[nn]_LENGTH.DLC bit. For example, if only one byte is transmitted or received (CAN_MB[nn]_LENGTH.DLC=1), then it is stored in the most significant byte of the CAN_MB[nn]_DATA3 register.
- The time stamp value bits (CAN_MB[nn]_TIMESTAMP.TSV)

The final registers in the mailbox area are the acceptance mask registers (CAN_AM[nn]H and CAN_AM[nn]L). The acceptance mask is enabled when the CAN_MB[nn]_ID1.AME bit is set.

Setting the CAN_CTL.DNM and CAN_AM[nn]H.FDF bits enables the *filtering on data field* option. When enabled, the CAN_MB[nn]_ID0.EXTID[15:0] bits are reused as acceptance code (DFC) for the data field filtering.

Mailbox Control

Mailbox control memory-mapped registers (MMRs) function as control and status registers for the 32 mailboxes. Each bit in these registers represents one specific mailbox. Since CAN MMRs are all 16 bits wide, pairs of registers manage certain functionality for all 32 individual mailboxes. Mailboxes 0–15 are configured or monitored in registers with a suffix of 1. Similarly, mailboxes 16–31 use the same named register with a suffix of 2. For example, the CAN mailbox direction registers (`CAN_MD1` / `CAN_MD2`) control mailboxes. See the ***CAN Mailbox Register Pair*** figure. The ***CAN Register List*** table shows the mailbox control registers.

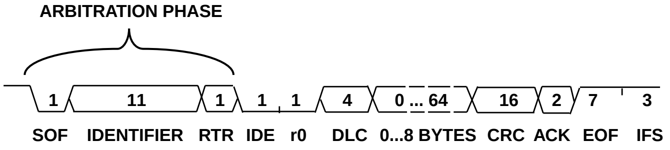
Figure 25-4: CAN Mailbox Register Pair

Mailboxes 24–31 support transmit operation only and mailboxes 0–7 are receive-only mailboxes. Therefore, the lower 8 bits in the 1 registers and the upper 8 bits in the 2 registers are sometimes reserved or are restricted in their use.

Protocol Fundamentals

Although the `CAN_RX` and `CAN_TX` pins are TTL-compliant signals, the CAN signals beyond the transceiver have asymmetric drivers. A low state on the `CAN_TX` pin activates strong drivers while a high state activates weak drivers. So, the active low state is the *dominant* state and the active high state is the *recessive* state. If the CAN module is passive, the `CAN_TX` pin is always high. If two CAN nodes transmit at the same time, dominant bits overwrite recessive bits.

The CAN protocol specifies that all nodes trying to send a message on the CAN bus attempt to send a frame once the bus is available. The ***Standard CAN Frame*** figure shows the frame. The Start of Frame (SOF) indicator signals the beginning of a new frame. Each CAN node then begins transmitting its message starting with the message ID.



SOF - START OF FRAME (SINGLE BIT = 0)
RTR - REMOTE TRANSMISSION REQUEST (REMOTE FRAME = 1)
IDE - IDENTIFIER EXTENSION (EXTENDED ID FRAME = 1)
r0 - RESERVED FOR FUTURE EXPANSION
DLC - DATA LENGTH CONTROL (NUMBER OF DATA BYTES IN FRAME)
CRC - CYCLIC REDUNDANCY CHECK (ERROR BITS IN FRAME)
ACK - ACKNOWLEDGE (RECEIVER DRIVES ONE DOMINANT BIT TO ACK)
EOF - END OF FRAME (SERIES OF 7 RECESSIVE BITS = b#1111111)
IFS - INTERFRAME SPACE (3 RECESSIVE BITS = b#111)

Figure 25-5: Standard CAN Frame

While transmitting, the CAN controller samples the `CAN_RX` pin to verify that the driven logic level is the value it placed on the `CAN_TX` pin. The names for the logic levels apply here. When a transmitting node places a recessive 1 on the `CAN_TX` pin and detects a dominant 0 on the `CAN_RX` pin, another node has placed a dominant bit on the bus. In this case, the dominant bit from from the other node has a higher priority.

Therefore, if the value sensed on the `CAN_RX` pin is the value driven on the `CAN_TX` pin, transmission continues. Otherwise, the CAN controller senses that it has lost arbitration. Module configuration determines the next course of action.

The ***Standard CAN Frame*** figure shows a basic 11-bit identifier frame. The `CAN_MB[nn]_ID1.RTR` bit follows the SOF and identifier. The `CAN_MB[nn]_ID1.RTR` bit indicates whether the frame contains data (data frame) or is a request for data associated with the message identifier in the frame sent (remote frame).

> **NOTE:** In the CAN protocol, a dominant bit in the `CAN_MB[nn]_ID1.RTR` field wins arbitration against a remote frame request (`CAN_MB[nn]_ID1.RTR`=1) for the same message ID. This functionality allows a remote request to be a lower priority than a data frame.

The next field of interest in the frame is the `CAN_MB[nn]_ID1.IDE` bit. When set, it indicates that the message is an extended frame with a 29-bit identifier instead of an 11-bit identifier. In an extended frame, the first part of the message resembles the ***Extended CAN Frame*** figure.

Figure 25-6: Extended CAN Frame

For the `CAN_MB[nn]_ID1.RTR` field, a dominant bit in the `CAN_MB[nn]_ID1.IDE` field wins arbitration against an extended frame with the same lower 11 bits. Standard frames have a higher priority than extended frames.

The internal logic automatically generates the Substitute Remote Request (SRR), the reserved bits r0 and r1, and the checksum (CRC). (The SRR is always sent as recessive; reserved bits r0 and r1 are always sent as dominant).

CAN Operating Modes

The CAN controller is in configuration mode when coming out of processor reset. Hardware behavior can be altered only when CAN is in configuration mode. Before initializing the mailboxes, configure the CAN bit timing to work on the CAN bus. The controller connect to the CAN bus.

Data Transfer Modes

The following sections provide information on the data transfer modes supported by the CAN controller.

Transmit Operations

The ***CAN Transmit Operation Flowchart*** shows the CAN transmit operation. Mailboxes 24–31 are dedicated transmitters. Configure mailboxes 8–23 as transmitters by writing 0 to the corresponding bit in the `CAN_MD1` or `CAN_MD2` registers. Enable mailbox n (`CAN_MC1.MB`=1). After writing the data and the identifier into the mailbox area, the message is sent. Then, the corresponding transmit request bit is set (`CAN_TRS1.MB`=1).

EXIT

Figure 25-7: CAN Transmit Operation Flowchart

When a transmission completes, the corresponding bits in the `CAN_TRS1` or `CAN_TRS2` and `CAN_TRR1` or `CAN_TRR2` registers are cleared. If the transmission is successful, the corresponding bit in the `CAN_TA1`/ `CAN_TA2` register is set. If the transmission aborts due to lost arbitration or a CAN error, the corresponding bit in the CAN_AA1/CAN_AA2 register is set. A requested transmission can also be manually aborted by setting the corresponding bit in the CAN_TRR1/CAN_TRR2 register.

Software sets multiple `CAN_TRS1.MB` bits simultaneously. These bits are reset after either a successful or an aborted transmission.

The CAN hardware sets these bits in the following cases:

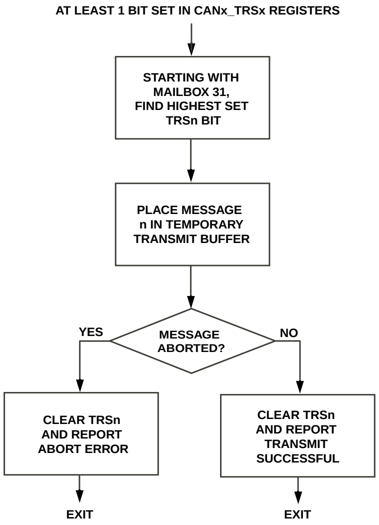
- When using the auto-transmit mode of the universal counter
- When a message loses arbitration and the single-shot `CAN_OPSS1.MB` bit is not set
- When a remote frame request occurs (only possible for receive or transmit mailboxes if the feature for automatic remote frame handling is enabled (`CAN_RFH1.MB`=1)).

NOTE: Manage the mailbox area when a CAN_TRS1 or CAN_TRS2 bit is set. Write access to the mailbox is permissible with a bit set. But, changing data in such a mailbox can lead to unexpected data during transmission.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the CAN_TRS1 or CAN_TRS2 bit associated with a disabled mailbox can result in erroneous behavior. Similarly, disabling a mailbox before the associated CAN_TRS1 or CAN_TRS2 bit is reset by the internal logic can cause unpredictable results.

Retransmission

Normally, the current message object is resent after the loss of arbitration or error frame detection on the CAN bus line. If there is more than one transmit message object pending, the message object with the highest mailbox transmits first. See the ***Transmit Flow*** figure. The currently aborted transmission restarts after any messages with higher priority are sent.



AT LEAST 1 BIT SET IN CANx_TRSx REGISTERS

PLACE MESSAGE n IN TEMPORARY TRANSMIT BUFFER
MESSAGE ABORTED?
YES
NO
CLEAR TRSn AND REPORT ABORT ERROR
CLEAR TRSn AND REPORT TRANSMIT SUCCESSFUL
EXIT
EXIT

Figure 25-8: Transmit Flow

A message written into the mailbox does not replace a message under preparation. The message under preparation is copied into the temporary transmit buffer when the internal transmit request for the CAN core module is set. The message in the buffer is not replaced until:

- The message is sent successfully
- The arbitration on the CAN bus line is lost
- There is an error frame on the CAN bus line

Single-Shot Transmission

When using the single-shot transmission feature (`CAN_OPSS1.MB`=1), the corresponding `CAN_TRS1` bit is cleared after the message is successfully sent. The bit is cleared even if the transmission aborts due to a lost arbitration or an error frame on the CAN bus line. Therefore, there is no further attempt to transmit the message again when the initial try failed, and the abort error is reported (`CAN_AA1.MB`=1).

Auto-Transmission

In auto-transmit mode, the message in mailbox 11 (MB11) can be sent periodically using the universal counter. This mode often broadcasts heartbeats to all CAN nodes. So, messages sent this way usually have a high priority.

The period value is written to the `CAN_UCRC` register. Auto-transmission mode is enabled by setting the `CAN_UCCNF.UCCNF` field to 0x03. When enabled, the counter `CAN_UCCNT` is loaded with the value in the `CAN_UCRC` register. The counter decrements to 0 at the CAN bit clock rate and is then reloaded from `CAN_UCRC`. Each time the counter reaches a value of 0, internal logic automatically sends the `CAN_TRS1.MB` bit. The corresponding message from mailbox 11 transfers.

For proper auto-transmit operation, configure mailbox 11 as a transmit mailbox. The mailbox must contain valid data (identifier, control bits, and data) before the counter expires and after this mode is enabled.

Receive Operation

The CAN hardware autonomously receives messages and discards invalid messages. Once a valid message is successfully received, the receive logic interrogates all enabled receive mailboxes. The logic interrogates sequentially, from mailbox 23 down to mailbox 0, whether the message is of interest to the local node or not.

Each incoming data frame is compared to all identifiers stored in the active receive and transmit mailboxes with the feature for remote frame handling enabled (=1). The active receive mailboxes indices of `CAN_MD1` and `CAN_MC1` registers are set to 1. The message identifier of the received message, along with the identifier extension (`CAN_MB[nn]_ID1.IDE`) and remote transmission request (`CAN_MB[nn]_ID1.RTR`) bits, are compared with the register settings of each mailbox. In standard mode, the message is compared with the content of the `CAN_MB[nn]_ID1` register. In extended mode, the content of the `CAN_MB[nn]_ID0` register must also match.

If the acceptance mask enable `CAN_MB[nn]_ID1.AME` bit is not set, a match is signaled only if `CAN_MB[nn]_ID1.IDE`, `CAN_MB[nn]_ID1.RTR`, and all (11 or 29) identifier bits are exact. If, however, the `CAN_MB[nn]_ID1.AME` bit is set, the acceptance mask registers (`CAN_AM[nn]H`/L) determine which of the `CAN_MB[nn]_ID1.IDE` and `CAN_MB[nn]_ID1.RTR` bits must match.

The following logic applies:

[(Received Message ID) XNOR (`CAN_MB[nn]_ID0`/1)] OR [(`CAN_MB[nn]_ID1.AME`) AND (`CAN_AM[nn]H` /L)].

This logic appears graphically in the *CAN Message Receive Logic* figure.

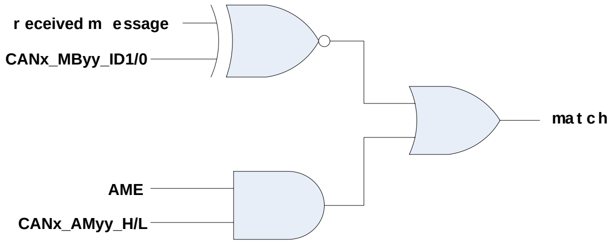

Figure 25-9: CAN Message Receive Logic

A one (1) at the respective bit position in the `CAN_AM[nn]H`/`CAN_AM[nn]L` mask registers means that the bit does not need to match when `CAN_MB[nn]_ID1.AME`=1. This way, a mailbox can accept a group of messages.

Table 25-3: Mailbox Used for Acceptance Filtering

MCn	MDn	RFHn	Mailbox n	Comment
0	X	X	Ignored	Mailbox n disabled
1	0	0	Ignored	Mailbox n enabled; Mailbox n configured for transmit; Remote frame handling disabled
1	0	1	Used	Mailbox n enabled; Mailbox n configured for transmit; Remote frame handling enabled
1	1	X	Used	Mailbox n enabled; Mailbox n configured for receive

If the acceptance filter finds a matching identifier, the content of the received data frame is stored in that mailbox. A received message is stored only once, even if multiple receive mailboxes match its identifier. If the current identifier does not match any mailbox, the message is not stored.

The *CAN Receive Operation Flowchart* illustrates the decision tree of the receive logic when processing the individual mailboxes.

If a message is received for a mailbox and that mailbox still contains unread data (`CAN_RMP1.MB`), then the program decides whether to overwrite the old message. If the `CAN_OPSS1.MB` bit is cleared, the corresponding `CAN_RML1.MB` bit is set, and the stored message is overwritten. The receive message lost interrupt request occurs (`CAN_GIS.RMLIS` is set). If, however, the `CAN_OPSS1.MB` bit is set, the next mailboxes are checked for another matching identifier. If no match is found, the message is discarded, and the next message is checked.

NOTE: If a receive mailbox is disabled, an ongoing receive message for that mailbox is lost even if a second mailbox is configured to receive the same identifier.

Data Acceptance Filtering

If Device Net mode is enabled (`CAN_CTL.DNM` = 1) and the mailbox is set up for filtering on data field, the filtering occurs on the standard ID of the message and data fields. The data field filtering can be programmed for either the first byte only or the first 2 bytes, as shown the ***Data Field Filtering*** table.

If the `CAN_AM[nn]H.FDF` bit is set, the corresponding `CAN_AM[nn]L` register holds the data field mask (DFM bits 15:0]). If the `CAN_AM[nn]H.FDF` bit is cleared, the corresponding `CAN_AM[nn]L` register holds the extended identifier mask (`CAN_AM[nn]H.EXTID` bits 15:0).

Table 25-4: Data Field Filtering

FDF (Filter on Data Field)	FMD (Full Mask Data Field)	Description
0	0	Do not allow filtering on the data field
0	1	Not allowed. FMF must be 0 when FDF is 0
1	0	Filter on first data byte only
1	1	Filter on first two data bytes

Watchdog Mode

Watchdog mode ensures that messages are received periodically. It also observes whether a certain node on the network is alive and functioning properly. Watchdog mode detects and manages the failure cases, as needed.

Enable this mode by programming the universal counter to watchdog mode by setting the `CAN_UCCNF.UCCNF` to 0x2. Once enabled, the `CAN_UCCNT` register is loaded with the predefined value contained in `CAN_UCRC`. This counter decrements at the CAN bit rate.

If the `CAN_UCCNF.UCCT` and `CAN_UCCNF.UCRC` bits are set and a message is received in mailbox 4 before the counter counts down to 0, the counter is reloaded with the `CAN_UCRC` contents. If the counter has counted down to 0 without receiving a message in mailbox 4, then the `CAN_GIS.UCEIS` bit is set. The counter reloads automatically with the contents of the `CAN_UCRC` register. If an interrupt request is desired for this event, set the `CAN_GIM.UCEIM` bit. With the mask bit set, when a watchdog interrupt request occurs, the `CAN_GIF.UCEIF` bit is also set.

Write to the `CAN_UCCNF` register to reload the counter with the contents of `CAN_UCRC` or to disable the register.

The `CAN_UCRC` register controls the time period it takes for the watchdog interrupt request to occur.

Time Stamps

To get an indication of the time of the receive or transmit time for each message, program the CAN universal counter to time stamp mode. Enable this mode by setting the `CAN_UCCNF.UCCNF` field to 0x01.

If enabled, the value of the 16-bit free-running counter (`CAN_UCCNT`) is written into the `CAN_MB[nn]_TIMESTAMP` register of the corresponding mailbox. The operation occurs when a received message is stored or a message is transmitted.

The time stamp value is captured at the sample point of the Start of Frame (SOF) bit of each incoming or outgoing message. Afterwards, this time stamp value is copied to the `CAN_MB[nn]_TIMESTAMP` register of the corresponding mailbox.

If the mailbox is configured for automatic remote frame handling (`CAN_RFH1.MB` = 1), the time stamp value is written for transmission of a data frame or the reception of the requested data frame. The mailbox is configured for transmit or receive.

Clear the counter by setting the `CAN_UCCNF.UCRC` bit to 1. Or, disable the counter by clearing the `CAN_UCCNF.UCE` bit. Write to the `CAN_UCCNT` register to load the counter with a value.

It is also possible to clear the counter (`CAN_UCCNT`) by the reception of a message in mailbox number 4 (synchronization of all time stamp counters in the system). This operation is accomplished by setting the `CAN_UCCNF.UCCT` bit.

The `CAN_GIS.UCEIS` bit is set when the counter overflows. A global CAN interrupt request can optionally occur by unmasking the `CAN_GIM.UCEIM` bit. If the interrupt source is unmasked, the `CAN_GIF.UCEIF` bit is also set.

Remote Frame Handling

Automatic handling of remote frames for a transmit mailbox is enabled by setting the corresponding `CAN_RFH1.MB` bit.

Remote frames are data frames that have no data field and the `CAN_MB[nn]_ID1.RTR` bit is set. The data length code (DLC) of the requesting remote frame overrules the DLC of the responding data frame. A DLC can be programmed with values in the range of 0–15, but DLC values greater than 8 are considered as 8.

A remote frame contains:

- The identifier bits
- The control field `CAN_MB[nn]_LENGTH.DLC` (data length count)
- The remote transmission request (`CAN_MB[nn]_ID1.RTR`) bit

Only configurable mailboxes MB8–MB23 can process remote frames, but all mailboxes can receive and transmit remote frame requests. The `CAN_OPSS1` register has no effect when configured for automatic remote frame handling. All content of a mailbox is always overwritten by an incoming message.

NOTE: If a remote frame is received, the DLC of the corresponding mailbox is overwritten with the received value.

Erroneous behavior can result when the `CAN_RFH1.MB` bit is changed while the corresponding mailbox is processing. To avoid the risk of inconsistent messages, programs must temporarily disable the mailbox while its data registers are updating.

Temporarily Disabling CAN Mailbox

If a mailbox is enabled and configured to transmit, monitor the write accesses to the data field to avoid transmitting inconsistent messages. Be careful if the mailbox is transmitting (or attempting to transmit) repeatedly. Also, if this mailbox is used for automatic remote frame handling, the data field must be updated without losing an incoming remote request frame and without sending inconsistent data. Therefore, the CAN controller allows for temporarily disabling the mailbox using the mailbox temporary disable register (`CAN_MBTD`).

The pointer to the requested mailbox to the `CAN_MBTD.TDPTR` field is written, and the `CAN_MBTD.TDR` bit is set. Internal logic then sets the corresponding `CAN_MBTD.TDA` flag.

If a mailbox is configured as transmit (`CAN_MD1` = 0) and the `CAN_MBTD.TDA` bit is set, the content of the data field of that mailbox can be updated. If there is an incoming remote request frame while the mailbox is temporarily disabled,

- Internal logic sets the corresponding transmit request bit (`CAN_TRS1.MB`), and
- The data length code (DLC) of the incoming message is written to the corresponding mailbox.

However, the requested message is not sent until the `CAN_MBTD.TDR` bit is cleared. Similarly, all transmit requests for temporarily disabled mailboxes are ignored until the `CAN_MBTD.TDR` bit is cleared. Additionally, transmission of a message immediately aborts when the mailbox is temporarily disabled and the corresponding transmission request reset (`CAN_TRR1.MB`) bit for this mailbox is set.

If a mailbox is configured to receive (`CAN_MD1` = 1), then after issuing a temporary disable request, the `CAN_MBTD.TDA` flag is set. The mailbox is not processed. If there is an incoming message for a temporarily disabled mailbox, the internal logic waits until reception is complete or there is an error on the CAN bus before setting `CAN_MBTD.TDA`. Once this flag is set, the mailbox can then be disabled (`CAN_MC1` = 0) without the risk of losing an incoming frame. The `CAN_MBTD.TDR` bit must then be reset as soon as possible.

When the `CAN_MBTD.TDA` flag is set for a given mailbox, only the data field of that mailbox can be updated. Accesses to the control bits and the identifier are denied.

Bit Timing

The CAN controller does not have a dedicated clock. Instead, the CAN clock is derived from the system clock based on a configurable number of time quanta. The time quantum (TQ) is derived from the formula:

TQ = (BRP + 1)/CDU0_CLKO4

where BRP is the 10-bit bit rate prescaler field in the `CAN_CLK` register.

Although the `CAN_CLK.BRP` field can be set to any value, it is recommended that the value be greater than or equal to 4. Restrictions apply to the bit timing configuration when BRP is less than 4.

The `CAN_CLK` register defines the TQ value, and multiple time quanta make up the duration of a CAN bit on the bus. The `CAN_TIMING` register controls the nominal bit time and the sample point of the individual bits in the CAN protocol. The ***Three Phases of a CAN Bit*** figure shows the three phases of a CAN bit: the synchronization segment, the segment before the sample point, and the segment after the sample point.

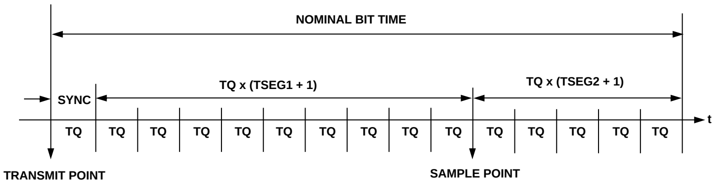

Figure 25-11: Three Phases of a CAN Bit

The synchronization segment is fixed to one TQ. Synchronize the nodes on the bus. All signal edges are expected to occur within this segment.

The `CAN_TIMING.TSEG1` and `CAN_TIMING.TSEG2` fields control how many TQs the CAN bits consist of, resulting in the CAN bit rate. The following formula gives the nominal bit time.

$t_{BIT} = TQ \times [1 + (1 + TSEG1) + (1 + TSEG2)]$

For safe receive operations on given physical networks, the sample point is programmable by the `CAN_TIMING.TSEG1` field. The `CAN_TIMING.TSEG2` field holds the number of TQs to complete the bit time. Often, best sample reliability is achieved with sample points in the high 80% range of the bit time. Never use sample points lower than 50%. Therefore, `CAN_TIMING.TSEG1` must always be greater than or equal to `CAN_TIMING.TSEG2`.

The CAN module does not distinguish between the propagation segment and the phase segment-1 as defined by the standard. The `CAN_TIMING.TSEG1` value is intended to cover both of them. The `CAN_TIMING.TSEG2` value represents the phase segment-2.

If the CAN module detects a recessive-to-dominant edge outside the synchronization segment, it can automatically move the sampling point such that the CAN bit is still handled properly. The synchronization jump width (`CAN_TIMING.SJW`) field specifies the maximum number of TQs, ranging from 1 to 4 (SJW + 1), allowed for such a resynchronization attempt. The SJW value must not exceed `CAN_TIMING.TSEG2` or `CAN_TIMING.TSEG1`. Therefore, the fundamental rule for writing `CAN_TIMING` is:

$SJW \leq TSEG2 \leq TSEG1$

In addition to this fundamental rule, `CAN_TIMING.TSEG2` must also be greater than or equal to the information processing time (IPT). IPT is the time required by the logic to sample the `CAN_RX` input, which is 3 system clock cycles.

Therefore, restrictions apply to the minimal value of `CAN_TIMING.TSEG2` if `CAN_CLK.BRP` is less than 2. If `CAN_CLK.BRP` is set to 0, the `CAN_TIMING.TSEG2` field must be greater than or equal to 2. If `CAN_CLK.BRP` is set to 1, the minimum `CAN_TIMING.TSEG2` value is 1.

NOTE: Use the same nominal bit rate for all nodes on a CAN bus.

With all the timing parameters set, the final consideration is sampling performance. The default behavior of the CAN controller is to sample the CAN bit once. The controller samples at the point described by the `CAN_TIMING` register and controlled by the `CAN_TIMING.SAM` bit. If this bit is set, however, the input signal is oversampled three times at the system clock rate. The resulting value is generated by a majority decision of the three sample values. Always keep the `CAN_TIMING.SAM` bit cleared if the BRP value is less than 4.

Do not modify the `CAN_CLK` and `CAN_TIMING` registers during normal operation. Always enter configuration mode first. Writes to these registers have no effect when CAN is not in configuration or debug mode. If not coming out of processor reset, enter configuration mode by setting the `CAN_CTL.CCR` bit and poll the `CAN_STAT` register until `CAN_STAT.CCA` is set.

NOTE: If the `CAN_TIMING.TSEG1` field is programmed to 0, the module does not leave the configuration mode.

During configuration mode, the module is not active on the CAN bus line. The `CAN_TX` output pin remains recessive and the module does not receive or transmit messages or error frames. After leaving the configuration mode, all CAN internal core registers and the CAN error counters are set to their initial values.

A soft reset does not change the values of `CAN_CLK` and `CAN_TIMING`. Therefore, an ongoing transfer through the CAN bus cannot be corrupted by changing the bit timing parameter or initiating the soft reset (by setting the `CAN_CTL.SRS` bit).

CAN Low Power Features

The CAN module includes built-in sleep and suspend modes to save power.

The following sections describe the behavior of the CAN module in these modes.

Built-In Suspend Mode

The most modest of power savings mode is the suspend mode. This mode is entered by setting the `CAN_CTL.CSR` bit. The module enters the suspend mode after the current operation of the CAN bus finishes. Then, the internal logic sets the `CAN_STAT.CSA` bit. Once CAN enters this mode, the module is no longer active on the CAN bus line, slightly reducing power consumption.

In suspend mode, the `CAN_TX` output pin remains in a recessive state, and the module does not receive or transmit messages or error frames. The content of the `CAN_CEC` register remains unchanged. Clear `CAN_CTL.CSR` to exit suspend mode.

The only difference between suspend mode and configuration mode is that the `CAN_CTL` and `CAN_STAT` registers are not reset when exiting suspend mode.

Built-In Sleep Mode

The next level of power savings can be realized by using the built-in sleep mode for the module. This mode is entered by setting the `CAN_CTL.SMR` bit. The module enters the sleep mode after the current operation of the CAN bus finishes. Once this mode is entered, many of the internal CAN module clocks are shut off, reducing power consumption, and the `CAN_INT.SMACK` bit is set.

When the CAN module is in sleep mode, all register reads return the contents of `CAN_INT` instead of the usual contents. All register writes, except to `CAN_INT`, are ignored in sleep mode. A small part of the module is clocked continuously to allow for waking up out of sleep mode.

A write to the `CAN_INT` register ends sleep mode. If the `CAN_CTL.WBA` bit is set before entering sleep mode, a dominant bit on the `CAN_RX` pin also ends sleep mode. When software sets the `CAN_CTL.SMR` bit, hardware sets the `CAN_CTL.CSR` bit as well, making sleep mode a super set of suspend mode. When the controller wakes up from sleep mode, hardware automatically clears `CAN_CTL.SMR` and `CAN_CTL.CSR`. If, however, the controller never enters sleep mode because the wake-up condition was met before `CAN_INT.SMACK` bit turns to 1, the `CAN_CTL.SMR` and `CAN_CTL.CSR` bits do not always automatically clear. Therefore, clear the two bits using software, when returning from sleep mode.

Soft Reset

The CAN controller features a build-in reset mechanism called soft reset. Soft reset is entered immediately after software has set the `CAN_CTL.SRS` bit. Soft reset brings all control registers to a defined state. Mailbox and error registers remain unaffected. Soft reset does not alter the `CAN_TIMING` and `CAN_CLK` registers and does not disturb the on-going transmission of a currently pending message, acknowledge bit or error frame. However, when recovering from soft reset, software can lose track of transmission or reception reports and interrupt requests.

CAN Event Control

The following is a description of how CAN generates and controls events.

CAN Interrupt Signals

The CAN module provides three independent interrupt requests: two mailbox interrupt requests (mailbox receive interrupt request (MBRIRQ) and mailbox transmit interrupt request (MBTIRQ)) and a global CAN status interrupt request (GIRQ). The values of these three interrupt requests can also be read through the `CAN_GIS` register.

Mailbox Interrupts

Each of the 32 mailboxes in the CAN module can generate a receive or transmit interrupt request, depending on the mailbox configuration. To enable a mailbox to generate an interrupt request, set the corresponding `CAN_MBIM1` bit.

If a mailbox is configured as a receive mailbox, the corresponding `CAN_MBRIF1` bit and `CAN_RMP1` bit are set after a received message is stored in mailbox n. When using the feature for automatic remote frame handling (`CAN_RFH1`=1), the receive interrupt flag is set after the requested data frame is stored in the mailbox.

If any `CAN_MBRIF1` bits are set, the mailbox generates a `CAN_INT.MBRIRQ` interrupt request. To clear the `CAN_INT.MBRIRQ` interrupt request, software must clear all of the set `CAN_MBRIF1` bits by writing a 1 to those bit locations in `CAN_MBRIF1`. Prior to this operation, software must clear the corresponding `CAN_RMP1` bit.

If a mailbox is configured as a transmit mailbox, the corresponding `CAN_MBTIF1` bit in the transmit interrupt flag is set after the message in mailbox n is sent correctly. The corresponding `CAN_TA1` bit is also set. The `CAN_TA1` bits maintain their state even after the corresponding mailbox n is disabled (`CAN_MC1`=0). When using the feature for automatic remote frame handling, the transmit interrupt flag is set after the requested data frame is sent from the mailbox.

If any `CAN_MBTIF1.MB` bits are set, the MBTIRQ interrupt output is raised in the `CAN_INT` register. To clear the MBTIRQ interrupt request, software must clear all of the bits that are set in the `CAN_MBTIF1` register by writing a 1 to those bit locations. Additionally, software must clear the associated `CAN_TA1` bit or set the associated `CAN_TRS1` bit to clear the interrupt source that asserts the `CAN_MBTIF1` bit.

Global Interrupt

The global CAN interrupt logic implements with three registers:

- The `CAN_GIM` register, where each interrupt source can be enabled or disabled separately
- The `CAN_GIS` register
- The `CAN_GIF` register

The interrupt mask bits only affect the content of the `CAN_GIF` register. If the mask bit is not set in the `CAN_GIM` register, the corresponding flag bit is not set when the event occurs. The interrupt status bits in the `CAN_GIS` register, however, are always set when the corresponding interrupt event occurs, independent of the mask bits. Thus, the interrupt status bits can be used to poll interrupt events.

The `CAN_INT.GIRQ` bit is only asserted if a bit in the `CAN_GIF` register is set. The read-only `CAN_INT.GIRQ` bit remains set as long as at least 1 bit in `CAN_GIF` is set. All bits in the interrupt status and interrupt flag registers remain set until cleared by software or a soft reset has occurred.

NOTE: The `CAN_GIF` register is read-only (RO). In the global CAN interrupt ISR, clear the interrupt latch by writing a 1 to the corresponding bit of the `CAN_GIS` register. The operations clear the related bits of the `CAN_GIS` and `CAN_GIF` registers, as well as the `CAN_INT.GIRQ` bit.

There are several interrupt events that can activate this GIRQ interrupt request:

- Access denied event interrupt (`CAN_GIM.ADIM`, `CAN_GIS.ADIS`, `CAN_GIF.ADIF`): At least one access to the mailbox RAM occurred during a data update by internal logic.

- Universal counter exceeded event interrupt (`CAN_GIM.UCEIM`, `CAN_GIS.UCEIS`, `CAN_GIF.UCEIF`): There is an overflow of the universal counter (in time stamp mode or event counter mode) or the counter has reached the value 0x0000 (in watchdog mode).
- Receive message lost event interrupt (`CAN_GIM.RMLIM`, `CAN_GIS.RMLIS`, `CAN_GIF.RMLIF`): A message is received for a mailbox that currently contains unread data. At least 1 bit in the `CAN_RMLn` register is set. If the bit in `CAN_GIS` and `CAN_GIF` registers is cleared and there is at least 1 bit in `CAN_RML1` still set, then the bit in the `CAN_GIS` and `CAN_GIF` registers is not set again. The internal interrupt source signal is only active if a new bit in `CAN_RML1` is set.
- Abort acknowledge event interrupt (`CAN_GIM.AAIM`, `CAN_GIS.AAIS`, `CAN_GIF.AAIF`): At least 1 `CAN_AA1.MB` bit in the `CAN_AA1` registers is set. If the bit in the `CAN_GIS` and `CAN_GIF` registers is cleared and there is at least 1 bit in `CAN_AA1` still set, then the bit in the `CAN_GIS` and `CAN_GIF` registers is not set again. The internal interrupt source signal is only active if a new bit in `CAN_AA1` is set. The `CAN_AA1.MB` bits maintain state even after the corresponding mailbox n is disabled (`CAN_MC1` = 0).
- Access to unimplemented address event interrupt (`CAN_GIM.UIAIM`, `CAN_GIS.UIAIS`, `CAN_GIF.UIAIF`): There was a CPU access to an address which is not implemented in the controller module.
- Wake-up event interrupt (`CAN_GIM.WUIM`, `CAN_GIS.WUIS`, `CAN_GIF.WUIF`): The CAN module has left the sleep mode because of detected activity on the CAN bus line.
- Bus-off event interrupt (`CAN_GIM.BOIM`, `CAN_GIS.BOIS`, `CAN_GIF.BOIF`): The CAN module has entered the bus-off state. This interrupt source is active if the status of the CAN core changes from normal operation mode to the bus-off mode. If the bit in the `CAN_GIS` and `CAN_GIF` registers is cleared and the bus-off mode is still active, then this bit is not set again. If the module leaves the bus-off mode, the bit in the `CAN_GIS` and `CAN_GIF` registers remains set, if not explicitly cleared.
- Error-passive event interrupt (`CAN_GIM.EPIM`, `CAN_GIS.EPIS`, `CAN_GIF.EPIF`): The CAN module has entered the error-passive state. This interrupt source is active if the status of the CAN module changes from the error-active mode to the error-passive mode. If the bit in the `CAN_GIS` and `CAN_GIF` registers is cleared and the error-passive mode is still active, then this bit is not set again. If the module leaves the error-passive mode, the bit in the `CAN_GIS` and `CAN_GIF` registers remains set, if not explicitly cleared.
- Error warning receive event interrupt (`CAN_GIM.EWRIM`, `CAN_GIS.EWRIS`, `CAN_GIF.EWRIF`): The CAN receive error counter (`CAN_CEC.RXECNT`) has reached the warning limit. If the bit in the `CAN_GIS` and `CAN_GIF` registers) is cleared and the error warning mode is still active, this bit is not set again. If the module leaves the error warning mode, the bit in the `CAN_GIS` and `CAN_GIF` registers remains set, if not explicitly cleared.
- Error warning transmit interrupt (`CAN_GIM.EWTIM`, `CAN_GIS.EWTIS`, `CAN_GIF.EWTIF`): The CAN transmit error counter (`CAN_CEC.TXECNT`) has reached the warning limit. If the bit in the `CAN_GIS` and `CAN_GIF` registers is cleared and the error warning mode is still active, this bit is not set again. If the module leaves the error warning mode, the bit in the `CAN_GIS` and `CAN_GIF` registers remains set, if not explicitly cleared.

Event Counter

For diagnostic functions, it is possible to use the universal counter as an event counter. The counter can be programmed in the CAN_UCCNF[3:0] field to increment on one of these conditions:

- 0x6 – CAN error frame. Counter increments if there is an error frame on the CAN bus line.
- 0x7 – CAN overload frame. Counter increments if there is an overload frame on the CAN bus line.
- 0x8 – Lost arbitration. Counter increments every time arbitration on the CAN line is lost during transmission.
- 0x9 – Transmission aborted. Counter increments every time arbitration is lost or a transmit request is canceled (CAN_AA1 is set).
- 0xA – Transmission succeeded. Counter increments every time a message sends without detected errors (CAN_TA1 is set).
- 0xB – Receive message rejected. Counter increments every time a message is received without detected errors but not stored in a mailbox because there is no matching identifier found.
- 0xC – Receive message lost. Counter increments every time a message is received without detected errors but not stored in a mailbox because the mailbox contains unread data (CAN_RML1 is set).
- 0xD – Message received. Counter increments every time a message is received without detected errors, whether the received message is rejected or stored in a mailbox.
- 0xE – Message stored. Counter increments every time a message is received without detected errors, has an identifier that matches an enabled receive mailbox, and is stored in the receive mailbox (CAN_RMP1 is set).
- 0xF – Valid message. Counter increments every time a valid transmit or receive message is detected on the CAN bus line.

CAN Warnings and Errors

The processor controls CAN warnings and errors using the error counter (CAN_CEC) register, the error status (CAN_ESR) register, and the error counter warning level (CAN_EWR) register. The following sections describe error handling.

Programmable Warning Limits

Programs can set the warning level for CAN_GIS.EWTIS and CAN_GIS.EWRIS separately by writing to the CAN_EWR.EWLREC and CAN_EWR.EWLTEC fields. After power-on reset, the CAN_EWR register is set to the default warning level of 96 for both error counters. After a soft reset, the contents of this register remain unchanged.

Error Handling

Error management is a part of the CAN standard. Several different kinds of bus errors can occur during transmissions:

- Bit error – Only the transmitting node detects this error. Whenever a node transmits, it continuously monitors its receive pin (CAN_RX) and compares the received bit with the transmitted bit. During the arbitration phase, the node postpones the transmission if the received and transmitted bits do not match. However, after the arbitration phase, a bit error is signaled any time the value on `CAN_RX` does not equal what is transmitted on the `CAN_TX` pin. (The arbitration phase completes when the `CAN_MB[nn]_ID1.RTR` bit is sent successfully.)

- Form error. Occurs when a fixed-form bit position in the CAN frame contains one or more illegal bits. Occurs when a dominant bit is detected at a delimiter or end of frame bit position.
- Acknowledge error. Occurs whenever a message is sent and no receivers drive an acknowledge bit.
- CRC error. Occurs whenever a receiver calculates the CRC on the data it received and finds it different than the CRC that transmitted on the bus itself.
- Stuff error. The CAN specification requires the transmitter to insert an extra stuff bit of opposite value after 5 bits have transmitted with the same value. The receiver disregards the value of the stuff bits. However, it takes advantage of the signal edge to resynchronize itself. A stuff error occurs on receiving nodes whenever the sixth consecutive bit value is the same as the previous 5 bits.

Once the CAN module detects any of the errors, it updates the `CAN_ESR` and `CAN_CEC` registers. In addition to the standard errors, the `CAN_ESR.SAO` flag signals when the `CAN_RX` pin sticks at dominant level, indicating a possibility of shorted wires.

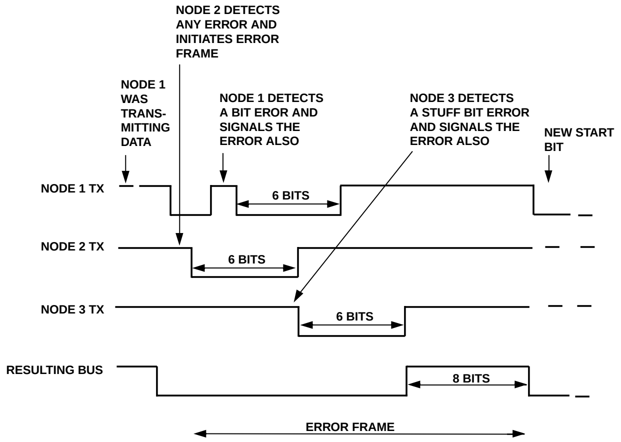
Error Frames

It is important that all nodes on the CAN bus ignore data frames that any single node failed to receive. Every node sends an error frame as soon as it has detected an error as shown in the ***CAN Error Example*** figure.

A device that has detected an error still completes the ongoing bit. It initiates an error frame by sending six dominant and eight recessive bits to the bus. Since this activity is a violation of the bit stuffing rule, all nodes are signaled to discard the ongoing frame. (All receivers that did not detect the transmission error in the first instance now detect a stuff bit error.)

The transmitter can detect a normal bit error sooner. It aborts the transmission of the ongoing frame and tries resending it later.

When all nodes on the bus have detected the error, they also send six dominant and eight recessive bits to the bus. The resulting error frame consists of two different fields. The first field is the superposition of error flags contributed from the different stations, which are a sequence of 6–12 dominant bits. The second field is the error delimiter and consists of eight recessive bits indicating the end of frame.



NODE 2 DETECTS ANY ERROR AND INITIATES ERROR FRAME

NODE 3 DETECTS A STUFF BIT ERROR AND SIGNALS THE ERROR ALSO
NEW START BIT
NODE 1 TX
6 BITS
NODE 2 TX
6 BITS
NODE 3 TX
6 BITS
RESULTING BUS
8 BITS
ERROR FRAME

Figure 25-12: CAN Error Example

For CRC errors, the error frame initiates at the end of the frame, rather than immediately after the failing bit.

After having received eight recessive bits, every node knows that the error condition is resolved and, if messages are pending, starts transmission. The transmitter that had to abort its operation must win the new arbitration again; otherwise its message is delayed as determined by priority.

Because the transmission of an error frame destroys the frame under transmission, a faulty node erroneously detecting an error can block the bus. So, there are two node states which determine a nodes right to signal an error—error-active and error-passive.

- *Error-active* nodes have an error detection rate below a certain limit. These nodes drive an active error flag of six dominant bits.
- *Error-passive* nodes have a higher error detection rate and can have a local problem and therefore have a limited right to signal errors. These nodes drive a passive error flag consisting of six recessive bits. Therefore, an error-passive transmitting node is still able to inform the other nodes about the aborting of a self-transmitted frame. But, it is no longer able to destroy correctly received frames of other nodes.

Error Levels

The CAN specification requires each node in the system to operate at one of three levels. The ***CAN Error Level Description*** table describes the levels. This functionality prevents nodes with high error rates from blocking the entire network, as local hardware can cause the errors. The CAN module provides an error counter for transmit (TEC) and an error counter for receive (REC). The `CAN_CEC` register contains each of these 8-bit counters.

After initialization, both the TEC and the REC counters are 0. Each time a bus error occurs, one of the counters increments by either 1 or 8, depending on the error situation. Refer to version 2.0 of the CAN specification. Successful transmit or receive operations decrement the respective counter by 1.

If either of the error counters exceeds 127, the CAN module goes into an error-passive state and the `CAN_STAT.EP` bit is set. Once this state occurs, the module is not allowed to send any more active error frames. However, the module can still transmit messages and signal passive error frames in case the transmission fails due to bit errors.

If one of the counters exceeds 255 (that is, when an 8-bit counter overflows), the CAN module disconnects from the bus and it goes into bus-off mode. In this mode, the `CAN_STAT.EBO` bit is set. Software intervention is needed for recovery from this state, unless the `CAN_CTL.ABO` bit is enabled. The bit puts the module into active mode after the bus-off recovery sequence.

Table 25-5: CAN Error Level Description

Level	Condition	Description
Error active	Transmit and receive error counters <128	This level is the initial condition level. As long as errors stay below 128, the node drives active error flags during error frames.
Error passive	Transmit or receive error counter-value from 128 through 255, inclusive	Errors have accumulated to a level that requires the node to drive passive error flags during error frames
Bus off	Transmit or receive error counters greater than 255	CAN module goes into bus-off mode

In addition to the three levels in the table, the CAN module also generates separate transmit and receive warnings (CAN specification enhancement). By default, when one of the error counters exceeds 96, it signals and reports a warning in the `CAN_STAT` register. The CAN receive warning flag (`CAN_STAT.WR`) bit is set when `CAN_CEC.RXECNT` exceeds 96. The CAN transmit warning flag (`CAN_STAT.WT`) bit is set when `CAN_CEC.TXECNT` exceeds 96. The error warning level can be programmed using the error warning register (`CAN_EWR`).

Additionally, interrupt requests can occur for all of these levels by unmasking them in the global CAN interrupt mask register (`CAN_GIM`). These sources include: the bus-off interrupt (`CAN_GIM.BOIM`), the error-passive interrupt (`CAN_GIM.EPIM`), the error warning receive interrupt (`CAN_GIM.EWRIM`), and the error warning transmit interrupt (`CAN_GIM.EWTIM`).

During the bus-off recovery sequence, internal logic sets the configuration mode request `CAN_CTL.CCR` bit. The CAN core module does not automatically come out of the bus-off mode. The `CAN_CTL.CCR` bit cannot be reset until the bus-off recovery sequence completes.

NOTE: Set the `CAN_CTL.ABO` bit to override this behavior. After exiting the bus-off or configuration modes, the CAN error counters are reset.

CAN Debug and Test Modes

The CAN module contains test mode features that aid in the debugging of the CAN software and system.

NOTE: When using these features, the CAN module does not always comply to the CAN specification. Enable or disable all test modes only when the module is in configuration mode (`CAN_STAT.CCA`=1) or suspend mode (`CAN_STAT.CSA`=1).

The `CAN_DBG.CDE` bit provides access to all of the debug features. Set this bit to enable the test mode. Write to the bit first before writing to the `CAN_DBG` register. When the `CAN_DBG.CDE` bit is cleared, all debug features are disabled.

When the `CAN_DBG.CDE` bit is set, it enables writes to the other bits of the `CAN_DBG` register. It also enables these features, which are not compliant to the CAN standard:

- Bit timing registers can be changed anytime, not only during configuration mode. The group includes the `CAN_CLK` and `CAN_TIMING` registers.
- Write access is allowed to the normally read-only `CAN_CEC` register.

The following list describes other bits in the debug register.

- The CAN module uses the `CAN_DBG.MRB` bit to enable the read back mode. In this mode, a message transmitted on the CAN bus (or through an internal loopback mode) is received back directly to the internal receive buffer. After a correct transmission, the internal logic treats this transfer as a normal receive message. This feature allows testing of most of the CAN features without an external device.
- The `CAN_DBG.MAA` bit allows the CAN module to generate its own acknowledge during the ACK slot of the CAN frame. No external devices or connections are necessary to read back a transmit message. In this mode, the sent message is automatically stored in the internal receive buffer. In auto-acknowledge mode, the module itself transmits the acknowledge. This acknowledge can be programmed to appear on the `CAN_TX` pin, if `CAN_DBG.DIL`=1 and `CAN_DBG.DTO`= 0. If the acknowledge is only used internally, then set these test mode bits to `CAN_DBG.DIL`= 0 and `CAN_DBG.DTO`=1.
- The CAN module uses the `CAN_DBG.DIL` bit to internally enable the transmit output to be routed back to the receive input.
- The CAN module uses the `CAN_DBG.DTO` bit to disable the `CAN_TX` output pin. When this bit is set, the `CAN_TX` pin continuously drives recessive bits.
- The CAN module uses the `CAN_DBG.DRI` bit to disable the `CAN_RX` input. When set, the internal logic receives recessive bits or receives the internally-generated transmit value in the case of the internal loop enabled (`CAN_DBG.DIL`= 0). In either case, the value on the `CAN_RX` input pin is ignored.
- The CAN module uses the `CAN_DBG.DEC` bit to disable the transmit and receive error counters in the `CAN_CEC` register. When this bit is set, the `CAN_CEC` holds its current contents and is not allowed to increment or decrement the error counters. This mode does not conform to the CAN specification.

NOTE: Write to the error counter registers in debug mode only. Write-access during reception can lead to undefined values. The maximum value which can be written into the error counters is 255. Therefore, the error counter value of 256, which forces the module into the bus off state, cannot be written into the error counter registers.

Table 25-6: Common CAN Test Mode Bit Combinations

MRB	MAA	DIL	DTO	DRI	CDE	Functional Description
X	X	X	X	X	0	Normal mode, not debug mode
0	X	X	X	X	X	No readback of transmit message

Table 25-6: Common CAN Test Mode Bit Combinations (Continued)

MRB	MAA	DIL	DTO	DRI	CDE	Functional Description
1	0	1	0	0	1	Normal transmission on CAN bus line. Read back. External acknowledge from external device required.
1	1	1	0	0	1	Normal transmission on CAN bus line. Read back. No external acknowledge required. Transmit message and acknowledge are transmitted on CAN bus line. `CAN_RX` input is enabled.
1	1	0	0	0	1	Normal transmission on CAN bus line. Read back. No external acknowledge required. Transmit message and acknowledge transmit on CAN bus line. `CAN_RX` input and internal loop are enabled (internal OR of TX and RX)
1	1	0	0	1	1	Normal transmission on CAN bus line. Read back. No external acknowledge required. Transmit message and acknowledge are transmitted on CAN bus line. `CAN_RX` input is ignored. Internal loop is enabled.
1	1	0	1	1	1	No transmission on CAN bus line. Read back. No external acknowledge required. Nether transmit message nor acknowledge are transmitted on `CAN_TX`. `CAN_RX` input is ignored. Internal loop is enabled.

ADSP-SC58x CAN Register Descriptions

Controller Area Network (CAN) contains the following registers.

Table 25-7: ADSP-SC58x CAN Register List

Name	Description
`CAN_AA1`	Abort Acknowledge 1 Register

`CAN_UCCNT`	Universal Counter Register
`CAN_UCRC`	Universal Counter Reload/Capture Register

Abort Acknowledge 1 Register

The `CAN_AA1` register indicates a transmission abort (due to lost arbitration or a CAN error) for mailboxes 8 through 15. Each bit in this register indicates a transmission abort for the corresponding mailbox when set (=1). Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	FDF	Filter on Delay Field. The `CAN_AM[nn]H.FDF` bit selects the operation of the `CAN_AM[nn]H` register and `CAN_AM[nn]L` register when the `CAN_CTL.DNM` bit is enabled. If the `CAN_AM[nn]H.FDF` bit is set, the corresponding `CAN_AM[nn]L.EXTID` bits hold the data field mask. If the `CAN_AM[nn]H.FDF` bit is cleared, the corresponding `CAN_AM[nn]L.EXTID` bits hold the high bits of the extended identifier mask.
14 (R/W)	FMD	Full Mask Data. The `CAN_AM[nn]H.FMD` bit works with the `CAN_AM[nn]H.FDF` bit to determine data field filtering. For information about data field filtering, see the Receive Operation section.
13 (R/W)	AMIDE	Acceptance Mask Identifier Extension. The `CAN_AM[nn]H.AMIDE` bit enables the comparison of the received message ID to the value in the `CAN_AM[nn]H.EXTID` and `CAN_AM[nn]L.EXTID` bits.
12:2 (R/W)	BASEID	Base Identifier. The `CAN_AM[nn]H.BASEID` bits hold the base ID for acceptance mask operations.
1:0 (R/W)	EXTID	Extended Identifier. The `CAN_AM[nn]H.EXTID` bits hold the extended ID (upper two bits) for acceptance mask operations.

Acceptance Mask (L) Register

The `CAN_AM[nn]L` register and `CAN_AM[nn]H` register manage acceptance mask operation. For information about acceptance mask operation, see the Receive Operation section.

Figure 25-16: CAN_AM[nn]L Register Diagram

Table 25-11: CAN_AM[nn]L Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	EXTID	Extended Identifier/Data Field Mask. The `CAN_AM[nn]L.EXTID` bits hold the extended ID (lower 16 bits) for data field mask in acceptance mask operations.

Error Counter Register

The `CAN_CEC` register, `CAN_ESR` register, and `CAN_EWR` register control CAN warnings and errors. For detailed information about error and warning operations, see the Event Control section.

The `CAN_CEC` register holds an error counter for transmit (`CAN_CEC.TXECNT`) and an error counter for receive (`CAN_CEC.RXECNT`). After initialization, both counters are 0. Each time a bus error occurs, one of the counters is incremented by either 1 or 8, depending on the error situation (documented in Version 2.0 of CAN Specification). Successful transmit and receive operations decrement the respective counter by 1.

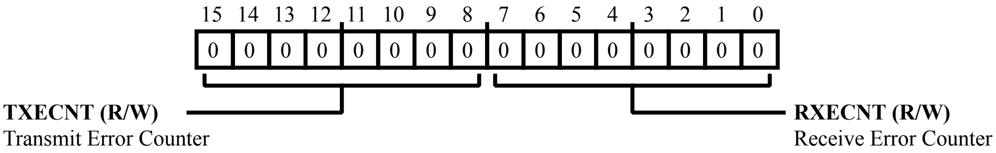

Figure 25-17: CAN_CEC Register Diagram

Table 25-12: CAN_CEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	TXECNT	Transmit Error Counter. The `CAN_CEC.TXECNT` bits hold the transmit error counter, which is incremented for errors (by either 1 or 8) and is decremented (by 1) for successful transmit operations.
7:0 (R/W)	RXECNT	Receive Error Counter. The `CAN_CEC.RXECNT` bits hold the receive error counter, which is incremented for errors (by either 1 or 8) and is decremented (by 1) for successful receive operations.

Clock Register

The CAN_CLK register selects the bit rate prescaler for calculating the time quantum (TQ), which is used to derive the CAN clock from the system clock (CDU0_CLKO4). For more information about bit timing and clock operation, see the CAN Operating Modes section.

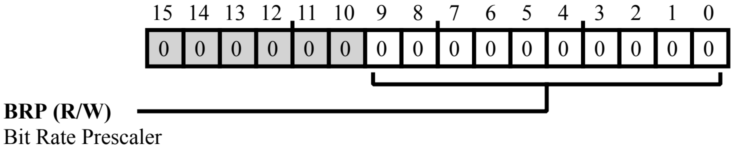

Figure 25-18: CAN_CLK Register Diagram

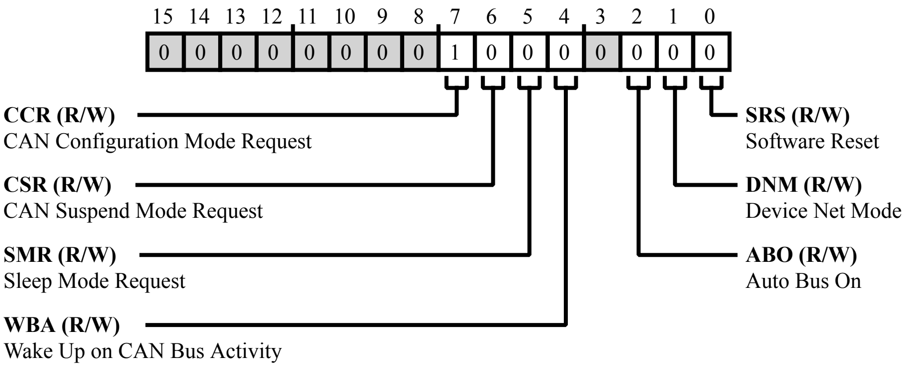
Table 25-13: CAN_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	BRP	Bit Rate Prescaler. The `CAN_CLK.BRP` bits select the bit rate prescaler value, which is used to calculate the time quantum for CAN bit timing. The formula using `CAN_CLK.BRP` to calculate the time quantum is: TQ = (BRP+1) / CDU0_CLKO4 Note that it is recommended that the `CAN_CLK.BRP` value be greater than or equal to 4. For more information about bit timing, see the Operating Modes section.

CAN Master Control Register

The CAN_CTL register controls CAN mode requests, including soft reset.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 25-19: CAN_CTL Register Diagram

Table 25-14: CAN_CTL Register Fields

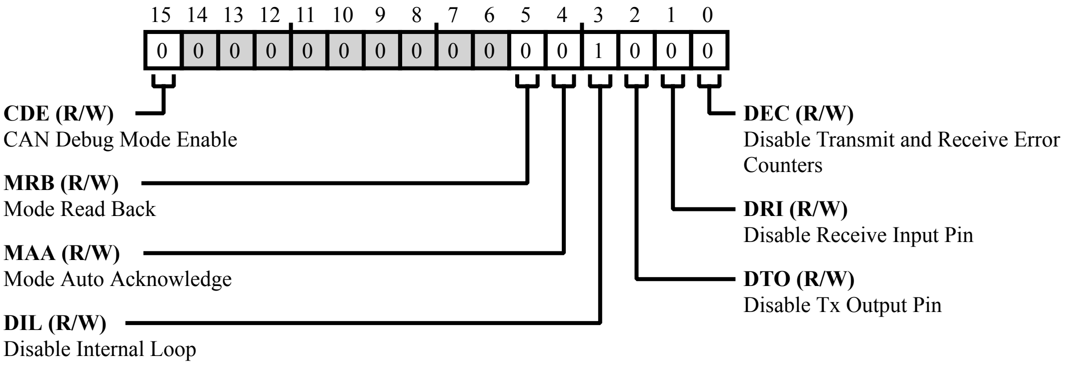
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CCR	CAN Configuration Mode Request. The `CAN_CTL.CCR` bit requests that the CAN enter configuration mode. Note that the CAN should always be put in configuration mode before modifying the CAN_CLK or CAN_TIMING registers.	
		0	No Request (Exit Configuration Mode)
		1	Request Configuration Mode
6 (R/W)	CSR	CAN Suspend Mode Request. The `CAN_CTL.CSR` bit requests that the CAN enter suspend mode. The CAN enters suspend mode after the current operation of the CAN bus is finished.	
		0	No Request (Exit Suspend Mode)
		1	Request Suspend Mode
5 (R/W)	SMR	Sleep Mode Request. The `CAN_CTL.SMR` bit requests that the CAN enter sleep mode. The CAN enters sleep mode after the current operation of the CAN bus is finished.	
		0	No Request (Exit Sleep Mode)
		1	Request Sleep Mode

Table 25-14: CAN_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	WBA	Wake Up on CAN Bus Activity. The `CAN_CTL.WBA` bit enables wake on CAN bus activity. When enabled, a dominant bit on the `CAN_RX` pin ends sleep mode (also, the default wake up condition of a write to the `CAN_INT` register).	
		0	Disable Wake on Bus Activity
		1	Enable Wake on Bus Activity
2 (R/W)	ABO	Auto Bus On. The `CAN_CTL.ABO` bit selects whether (if enabled) the CAN enters active mode after the bus-off recovery sequence or (if disabled) the CAN enters configuration mode after the bus-off recovery sequence.	
		0	Disable Auto Bus On
		1	Enable Auto Bus On
1 (R/W)	DNM	Device Net Mode. The `CAN_CTL.DNM` bit enables mailbox filtering on a data field. The filtering is done on the standard ID of the message and data fields. For more information, see the `CAN_AM[nn]H.FDF` bit description.	
		0	Disable Device Net Mode
		1	Enable Device Net Mode
0 (R/W)	SRS	Software Reset. The `CAN_CTL.SRS` bit resets the CAN, bringing all control registers to a defined state. Soft reset is entered immediately after software has set the `CAN_CTL.SRS` bit.	
		0	No Action
		1	Reset CAN

Debug Register

The CAN_DBG register controls CAN debug modes, including CAN_TX and CAN_RX pin enable and disable.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0

MRB (R/W)
Mode Read Back
MAA (R/W)
Mode Auto Acknowledge
DIL (R/W)
Disable Internal Loop
DEC (R/W)
Disable Transmit and Receive Error Counters
DRI (R/W)
Disable Receive Input Pin
DTO (R/W)
Disable Tx Output Pin

Figure 25-20: CAN_DBG Register Diagram

Table 25-15: CAN_DBG Register Fields

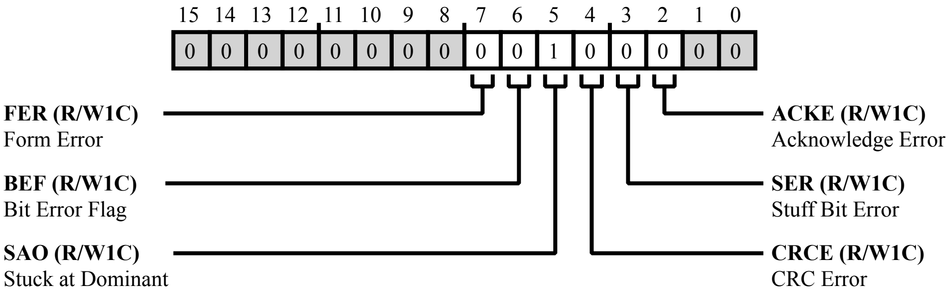
Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	CDE	CAN Debug Mode Enable. The CAN_DBG.CDE bit enables debug mode. This bit must be written first before subsequent writes to the CAN_DBG register. When the CAN_DBG.CDE bit is cleared, all CAN debug features are disabled.	
		0	Disable Debug Mode
		1	Enable Debug Mode
5 (R/W)	MRB	Mode Read Back. The CAN_DBG.MRB bit enables read back mode. When enabled, a message transmitted on the CAN bus or through an internal loop back mode is received back directly to the internal receive buffer.	
		0	Disable Read Back Mode
		1	Enable Read Back Mode
4 (R/W)	MAA	Mode Auto Acknowledge. The CAN_DBG.MAA bit enables auto acknowledge mode, allowing the CAN to generate its own acknowledge during the ACK slot of the CAN frame. The CAN_DBG.MAA acknowledge appears on the CAN_TX pin if CAN_DBG.DIL =1 and CAN_DBG.DTO =0. If the acknowledge is only going to be used internally, these test mode bits should be set to CAN_DBG.DIL = 0 and CAN_DBG.DTO =1.	
		0	Disable Auto Acknowledge Mode
		1	Enable Auto Acknowledge Mode

Table 25-15: CAN_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DIL	Disable Internal Loop. The `CAN_DBG.DIL` bit disables internal loop mode, which routes the transmit output to the receive input.	
		0	Enable Internal Loop
		1	Disable Internal Loop
2 (R/W)	DTO	Disable Tx Output Pin. The `CAN_DBG.DTO` bit disables the `CAN_TX` pin.	
		0	Enable Tx Output Pin
		1	Disable Tx Output Pin, Drive Recessive
1 (R/W)	DRI	Disable Receive Input Pin. The `CAN_DBG.DRI` bit disables the `CAN_RX` pin.	
		0	Enable Rx Input Pin
		1	Disable Rx Input Pin, Drive Recessive Internally
0 (R/W)	DEC	Disable Transmit and Receive Error Counters. The `CAN_DBG.DEC` bit disables the transmit and receive error counters in the `CAN_CEC` register. When set, the `CAN_CEC` holds its current contents and is not allowed to increment or decrement the error counters. Note that this mode does not conform to the CAN specification.	
		0	Enable CEC Tx and Rx Error Counters
		1	Disable CEC Tx and Rx Error Counters

Error Status Register

The CAN_ESR register, CAN_CEC register, and CAN_EWR register control CAN warnings and errors. All bits in the CAN_ESR register are W1C. Note that the CAN updates the CAN_CEC register when error status is detected in the CAN_ESR register. For detailed information about error and warning operations, see the Operating Modes section.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

SAO (R/W1C)
Stuck at Dominant
ACKE (R/W1C)
Acknowledge Error
SER (R/W1C)
Stuff Bit Error
CRCE (R/W1C)
CRC Error

Figure 25-21: CAN_ESR Register Diagram

Table 25-16: CAN_ESR Register Fields

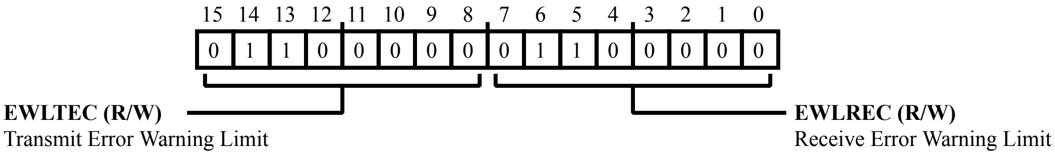
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	FER	Form Error. The `CAN_ESR.FER` bit indicates when a form error occurs, indicating that a fixed-form bit position in the CAN frame contains one or more illegal bits. This occurs when a dominant bit is detected at a delimiter or end-of-frame bit position.	
		0	No Status
		1	Form Error
6 (R/W1C)	BEF	Bit Error Flag. The `CAN_ESR.BEF` bit indicates (detected by the transmitting node only) when the value on the `CAN_RX` pin does not equal what is being transmitted on the `CAN_TX` pin. When a node is transmitting, it continuously monitors its receive pin (`CAN_RX`) and compares the received data with the transmitted data. The node postpones the transmission (during the arbitration phase) if the received and transmitted data do not match. After the arbitration phase (`CAN_MB[nn]_ID1.RTR` bit sent successfully), a bit error is signaled when the value on the `CAN_RX` pin does not equal what is being transmitted on the `CAN_TX` pin.	
		0	No Status
		1	Bit Error Flag

Table 25-16: CAN_ESR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1C)	SAO	Stuck at Dominant. The `CAN_ESR.SAO` bit indicates when the `CAN_RX` pin sticks at dominant level, indicating that shorted wires are likely.	
		0	No Status
		1	Stuck At Dominant
4 (R/W1C)	CRCE	CRC Error. The `CAN_ESR.CRCE` bit indicates when a CRC error occurs. This error may occur when a receiver calculates the CRC on the data it received and finds the value different than the CRC that was transmitted on the bus.	
		0	No Status
		1	CRC Error
3 (R/W1C)	SER	Stuff Bit Error. The `CAN_ESR.SER` bit indicates when a stuff bit error (stuffed 6th consecutive bit value is the same as the previous five bits) occurs. The CAN specification requires that the transmitter insert an extra stuff bit of opposite value after 5 bits have been transmitted with the same value. The receiver disregards the value of these stuff bits. The receiver takes advantage of the signal edge to re-synchronize itself. A stuff bit error occurs on receiving nodes when the 6th consecutive bit value is the same as the previous five bits.	
		0	No Status
		1	Stuff Bit Error Receive
2 (R/W1C)	ACKE	Acknowledge Error. The `CAN_ESR.ACKE` bit indicates when an acknowledge error occurs, indicating that a message is sent and no receivers drive an acknowledge bit.	
		0	No Status
		1	Acknowledge Error

Error Counter Warning Level Register

The `CAN_EWR` register, `CAN_CEC` register, and `CAN_ESR` register control CAN warnings and errors. For detailed information about error and warning operations, see the Operating Modes section.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	EWLTEC	Transmit Error Warning Limit. The `CAN_EWR.EWLTEC` bits select the transmit error warning limit, which is used as a condition for the `CAN_GIS.EWTIS` interrupt.
7:0 (R/W)	EWLREC	Receive Error Warning Limit. The `CAN_EWR.EWLREC` bits select the receive error warning limit, which is used as a condition for the `CAN_GIS.EWRIS` interrupt.

Global CAN Interrupt Flag Register

The CAN_GIF register, CAN_GIF register, and CAN_GIM register control CAN interrupt requests. For detailed information about interrupt operations, see the Event Control section.

The CAN_GIF register holds the interrupt flag. The `CAN_INT.GIRQ` bit is only asserted if a bit in the CAN_GIF is set. The `CAN_INT.GIRQ` bit remains set as long as at least one bit in the CAN_GIF register is set. All bits in this register are W1C.

		0	No Interrupt Flag
		1	Interrupt Flag Set (Latched)

Global CAN Interrupt Mask Register

The `CAN_GIM` register, `CAN_GIF` register, and `CAN_GIF` register control CAN interrupt requests. For detailed information about interrupt operations, see the Event Control section.

The `CAN_GIM` register holds the interrupt mask. The interrupt mask bits only affect the content of the `CAN_GIF` register. If the mask bit is not set (enabled/unmasked), the corresponding flag bit is not set when the event occurs.

		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
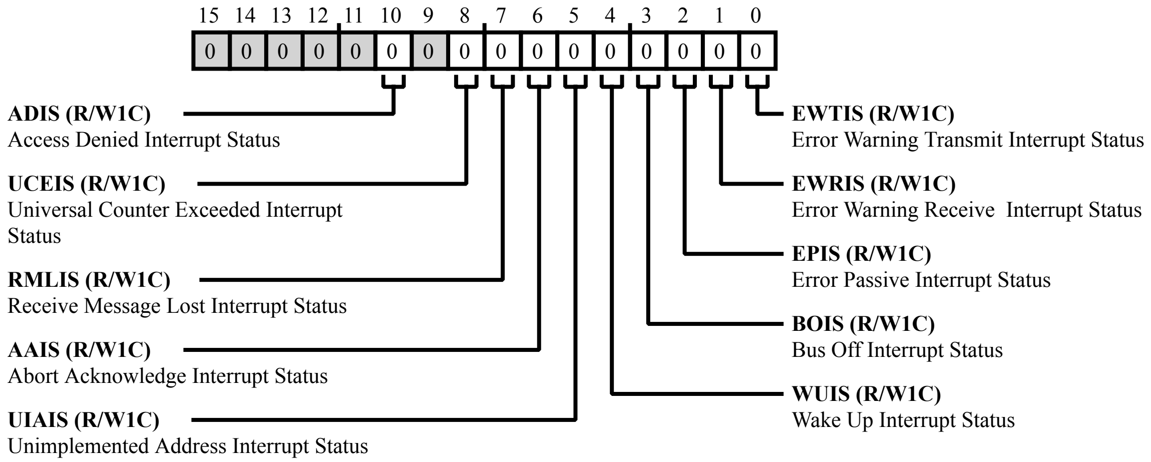
1 (R/W)	EWRIM	Error Warning Receive Interrupt Mask. The `CAN_GIM.EWRIM` bit enables (unmasks) the error warning receive interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)
0 (R/W)	EWTIM	Error Warning Transmit Interrupt Mask. The `CAN_GIM.EWTIM` bit enables (unmasks) the error warning transmit interrupt request.	
		0	Disable Interrupt (Mask)
		1	Enable Interrupt (Unmask)

Global CAN Interrupt Status Register

The CAN_GIS register, CAN_GIF register, and CAN_GIM register control CAN interrupt requests. For detailed information about interrupt operations, see the Event Control section.

The CAN_GIS register holds the interrupt status. All bits in this register are W1C.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 25-25: CAN_GIS Register Diagram

Table 25-20: CAN_GIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W1C)	ADIS	Access Denied Interrupt Status. The CAN_GIS.ADIS bit indicates when at least one access to the mailbox RAM occurred during a data update by internal logic.	
		0	No Interrupt Pending
		1	Interrupt Pending
8 (R/W1C)	UCEIS	Universal Counter Exceeded Interrupt Status. The CAN_GIS.UCEIS bit indicates when there has been an overflow of the universal counter (in time stamp mode or event counter mode) or the counter has reached the value 0x0000 (in watchdog mode).	
		0	No Interrupt Pending
		1	Interrupt Pending

Table 25-20: CAN_GIS Register Fields (Continued)

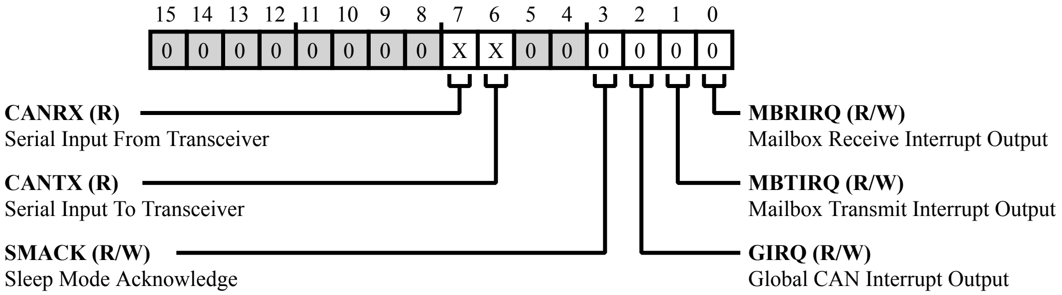
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	RMLIS	Receive Message Lost Interrupt Status. The `CAN_GIS.RMLIS` bit indicates when a message is received for a mailbox that currently contains unread data. At least one bit in the receive message lost register (`CAN_RML1` or `CAN_RML2`) is set. If the bit in `CAN_GIS` (and `CAN_GIF`) is reset and there is at least one bit in `CAN_RML1` or `CAN_RML2` still set, the bit in `CAN_GIF` (and `CAN_GIF`) is not set again. The internal interrupt source signal is only active if a new bit in `CAN_RML1` or `CAN_RML2` is set.	
		0	No Interrupt Pending
		1	Interrupt Pending
6 (R/W1C)	AAIS	Abort Acknowledge Interrupt Status. The `CAN_GIS.AAIS` bit indicates when At least one abort acknowledge bit is set in the `CAN_AA1` or the `CAN_AA2` registers. If the bit in `CAN_GIS` (and `CAN_GIF`) is reset and there is at least one bit in `CAN_AA1` or `CAN_AA2` still set, the bit in `CAN_GIS` (and `CAN_GIF`) is not set again. The internal interrupt source signal is only active if a new bit in `CAN_AA1` or `CAN_AA2` is set. The abort acknowledge bits maintain state even after the corresponding mailbox n is disabled.	
		0	No Interrupt Pending
		1	Interrupt Pending
5 (R/W1C)	UIAIS	Unimplemented Address Interrupt Status. The `CAN_GIS.UIAIS` bit indicates when there was a processor core access to an address that is not implemented in the CAN.	
		0	No Interrupt Pending
		1	Interrupt Pending
4 (R/W1C)	WUIS	Wake Up Interrupt Status. The `CAN_GIS.WUIS` bit indicates when the CAN has left the sleep mode because of detected activity on the CAN bus line.	
		0	No Interrupt Pending
		1	Interrupt Pending
3 (R/W1C)	BOIS	Bus Off Interrupt Status. The `CAN_GIS.BOIS` bit indicates when the CAN has entered the bus-off state. This interrupt source is active if the status of the CAN changes from normal operation mode to the bus-off mode. If the bit in `CAN_GIS` (and `CAN_GIF`) is reset and the bus-off mode is still active, this bit is not set again. If the module leaves the bus-off mode, the bit in `CAN_GIS` (and `CAN_GIF`) remains set.	
		0	No Interrupt Pending
		1	Interrupt Pending

Table 25-20: CAN_GIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	EPIS	Error Passive Interrupt Status. The `CAN_GIS.EPIS` bit indicates when the CAN has entered the error passive state. This interrupt source is active if the status of the CAN changes from the error active mode to the error passive mode. If the bit in `CAN_GIS` (and `CAN_GIF`) is reset and the error passive mode is still active, this bit is not set again. If the CAN leaves the error passive mode, the bit in `CAN_GIS` (and `CAN_GIF`) remains set.	
		0	No Interrupt Pending
		1	Interrupt Pending
1 (R/W1C)	EWRIS	Error Warning Receive Interrupt Status. The `CAN_GIS.EWRIS` bit indicates when the `CAN_CEC.RXECNT` has reached the warning limit. If the bit in `CAN_GIS` (and `CAN_GIF`) is reset and the error warning mode is still active, this bit is not set again. If the CAN leaves the error warning mode, the bit in `CAN_GIS` (and `CAN_GIF`) remains set.	
		0	No Interrupt Pending
		1	Interrupt Pending
0 (R/W1C)	EWTIS	Error Warning Transmit Interrupt Status. The `CAN_GIS.EWTIS` bit indicates when the `CAN_CEC.TXECNT` has reached the warning limit. If the bit in `CAN_GIS` (and `CAN_GIF`) is reset and the error warning mode is still active, this bit is not set again. If the CAN leaves the error warning mode, the bit in `CAN_GIS` (and `CAN_GIF`) remains set.	
		0	No Interrupt Pending
		1	Interrupt Pending

Interrupt Pending Register

The `CAN_INT` register indicates the status of pending CAN interrupts and indicates the state of the `CAN_RX` and `CAN_TX` pins. Though this register is read-only, a write is allowed to exit the built-in sleep mode of the module on processors supporting this feature.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 25-26: CAN_INT Register Diagram

Table 25-21: CAN_INT Register Fields

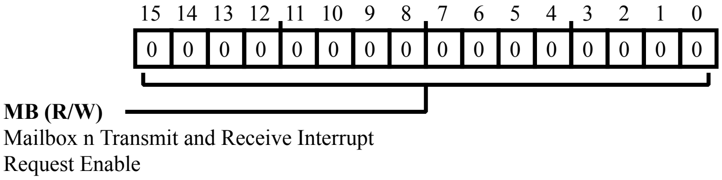
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	CANRX	Serial Input From Transceiver. The `CAN_INT.CANRX` bit indicates the logic value that the CAN detects on the `CAN_RX` pin. Note that the reset/default value for `CAN_INT.CANRX` is dependent on pin values.	
		0	Dominant Value (Low Active)
		1	Recessive Value (High Active)
6 (R/NW)	CANTX	Serial Input To Transceiver. The `CAN_INT.CANTX` bit indicates the logic value that the CAN detects on the `CAN_TX` pin. Note that the reset/default value for `CAN_INT.CANTX` is dependent on pin values.	
		0	Dominant Value (Low Active)
		1	Recessive Value (High Active)
3 (R/W)	SMACK	Sleep Mode Acknowledge. The `CAN_INT.SMACK` bit indicates when the CAN has entered sleep mode.	
		0	Not in Sleep Mode
		1	Sleep Mode

Table 25-21: CAN_INT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	GIRQ	Global CAN Interrupt Output. The `CAN_INT.GIRQ` bit indicates when at least one bit is set in the `CAN_GIF` register, indicating at least one unmasked CAN is flagged (latched). The `CAN_INT.GIRQ` bit remains set as long as at least one bit is set in the `CAN_GIF` register.	
		0	No CAN Global Interrupt Flag Set
		1	CAN Global Interrupt Flag (1 or More) Set
1 (R/W)	MBTIRQ	Mailbox Transmit Interrupt Output. The `CAN_INT.MBTIRQ` bit indicates when any bits are set in the `CAN_MBTIF1` register or `CAN_MBTIF2` register, indicating transmit.	
		0	No CAN Transmit Flags Set
		1	CAN Transmit Flags Set (1 or More)
0 (R/W)	MBRIRQ	Mailbox Receive Interrupt Output. The `CAN_INT.MBRIRQ` bit indicates when any bits are set in the `CAN_MBRIF1` register or `CAN_MBRIF2` register, indicating receive.	
		0	No CAN Receive Flags Set
		1	CAN Receive Flags Set (1 or More)

Mailbox Interrupt Mask 1 Register

The `CAN_MBIM1` register enables transmit and receive interrupt requests for mailboxes 0 through 15. Each bit in this register requests enables the transmit or receive interrupt request for the corresponding mailbox when set (=1).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 25-23: CAN_MBIM2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Transmit and Receive Interrupt Enable.

Mailbox Receive Interrupt Flag 1 Register

The `CAN_MBRIF1` register indicates when a receive interrupt request is pending---due to successful reception (corresponding `CAN_RMP1` bit set) and the interrupt is enabled (corresponding `CAN_MBIM1` bit set)---for mailboxes 0 through 15. Each bit in this register indicates the receive interrupt pending status for the corresponding mailbox when set (=1). When any bit in `CAN_MBRIF1` is set, the CAN receive interrupt request is raised (`CAN_INT.MBRIRQ` bit set). To clear the interrupt request, all of the set bits in `CAN_RMP1` must be cleared by software, then the associated bits set in `CAN_MBRIF1` must be cleared (W1C).

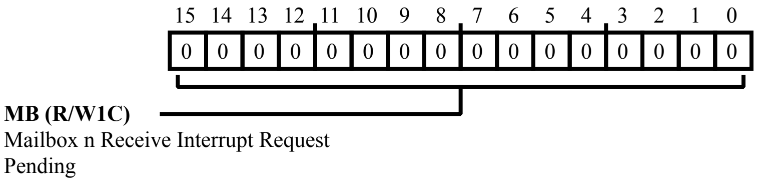

Figure 25-29: CAN_MBRIF1 Register Diagram

Table 25-24: CAN_MBRIF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	MB	Mailbox n Receive Interrupt Request Pending.

Mailbox Receive Interrupt Flag 2 Register

The `CAN_MBRIF2` register indicates when a receive interrupt request is pending---due to successful reception (corresponding `CAN_RMP2` bit set) and the interrupt is enabled (corresponding `CAN_MBIM2` bit set)---for mailboxes 16 (bit 0) through 23 (bit 7). Each bit in this register indicates the receive interrupt pending status for the corresponding mailbox when set (=1). When any bit in `CAN_MBRIF2` is set, the CAN receive interrupt request is raised (`CAN_INT.MBRIRQ` bit set). To clear the interrupt request, all of the set bits in `CAN_RMP2` must be cleared by software, then the associated bits set in `CAN_MBRIF2` must be cleared (W1C). Bits 8 through 15 are reserved and read-only, as the corresponding mailboxes (24 through 31) are transmit-only mailboxes.

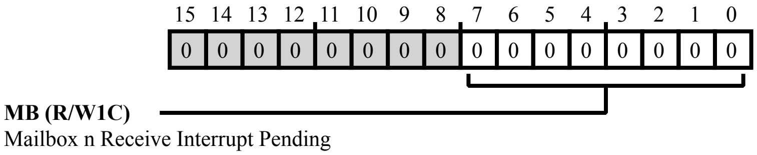

Figure 25-30: CAN_MBRIF2 Register Diagram

Table 25-25: CAN_MBRIF2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W1C)	MB	Mailbox n Receive Interrupt Pending.

Temporary Mailbox Disable Register

The CAN_MBTD register supports temporarily and selectively disabling CAN mailboxes. For more information about this feature, see the Operating Modes section.

TDR (R/W)
Temporary Disable Request
TDA (R)
Temporary Disable Acknowledge
TDPTR (R/W)
Temporary Disable Pointer

Figure 25-31: CAN_MBTD Register Diagram

Table 25-26: CAN_MBTD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	TDR	Temporary Disable Request. The `CAN_MBTD.TDR` bit holds the pointer to mailbox, which is disabled when the `CAN_MBTD.TDR` bit is set.	
		0	No Request
		1	Request Temporary Mailbox Disable
6 (R/NW)	TDA	Temporary Disable Acknowledge. The `CAN_MBTD.TDA` bit indicates when the mailbox (to which the `CAN_MBTD.TDPTR` bit points) is disabled. When this bit is set for a mailbox, only the data field of that mailbox may be updated. Accesses that mailboxs control bits and the identifier are denied.	
		0	No Acknowledge
		1	Acknowledge Temporary Mailbox Disable
4:0 (R/W)	TDPTR	Temporary Disable Pointer. The `CAN_MBTD.TDPTR` bits hold the pointer to mailbox, which is disabled when the `CAN_MBTD.TDR` bit is set.	

Mailbox Transmit Interrupt Flag 1 Register

The `CAN_MBTIF1` register indicates when a transmit interrupt request is pending---due to successful transmission (corresponding `CAN_TA1` bit is set) and the interrupt is enabled (corresponding `CAN_MBIM1` bit is set)---for mailboxes 8 through 15. Each bit in this register indicates the transmit interrupt pending status for the corresponding mailbox when set (=1). When any bit in `CAN_MBTIF1` is set, the CAN transmit interrupt request is raised (`CAN_INT.MBTIRQ` bit set). To clear the interrupt request, all of the set bits in `CAN_MBTIF1` must be cleared by software (W1C). Also, software must clear the associated bits set in `CAN_TA1` or set the associated bits in `CAN_TRS1` bit to clear the interrupt source asserting the bits in `CAN_MBTIF1`. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

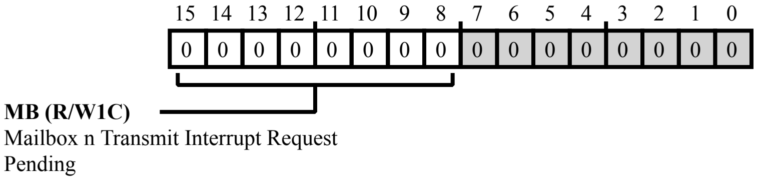

Figure 25-32: CAN_MBTIF1 Register Diagram

Table 25-27: CAN_MBTIF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W1C)	MB	Mailbox n Transmit Interrupt Request Pending.

Mailbox Transmit Interrupt Flag 2 Register

The CAN_MBTIF2 register indicates when a transmit interrupt request is pending---due to successful transmission (corresponding CAN_TA2 bit is set) and the interrupt is enabled (corresponding CAN_MBIM2 bit is set)---for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register indicates the transmit interrupt pending status for the corresponding mailbox when set (=1). When any bit in CAN_MBTIF2 is set, the CAN transmit interrupt request is raised (CAN_INT.MBTIRQ bit is set). To clear the interrupt request, all of the set bits in CAN_MBTIF2 must be cleared by software (W1C). Also, software must clear the associated bits set in CAN_TA2 or set the associated bits in CAN_TRS2 bit to clear the interrupt source asserting the bits in CAN_MBTIF2.

Table 25-33: CAN_MB[nn]_ID0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	EXTID	Extended Identifier/Data Field Acceptance Code. The `CAN_MB[nn]_ID0.EXTID` bits hold the lower 16 bits of the 18-bit extended ID.

Mailbox ID 1 Register

The `CAN_MB[nn]_ID1` register contains the identifier bits of mailbox. The 11-bit BASE_ID is mapped to The `CAN_MB[nn]_ID1.BASEID` field. It also enables the extended identification and contains upper two bits of 18-bit extended identifier.

Identifier Extension
EXTID (R/W)
Extended Identifier
BASEID (R/W)
Base Identifier

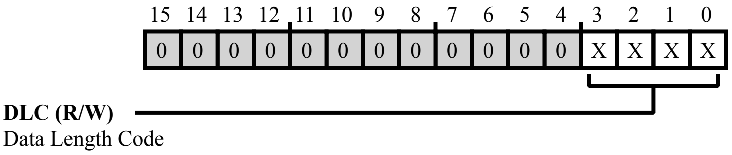
Figure 25-39: CAN_MB[nn]_ID1 Register Diagram

Table 25-34: CAN_MB[nn]_ID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	AME	Acceptance Mask Enable. The `CAN_MB[nn]_ID1.AME` bit enables acceptance mask operations if the mailbox is configured as receiver. When enabled (=1), only those bits that have the corresponding mask bit cleared are compared to the received message ID. A bit position that is set in the mask register does not need to match. This bit should be set to 0 when the mailbox is configured in transmit mode.
14 (R/W)	RTR	Remote Transmission Request. The `CAN_MB[nn]_ID1.RTR` bit selects whether the frame contains data (data frame) or contains a request for data associated with the message identifier in the frame being sent (remote frame).
13 (R/W)	IDE	Identifier Extension. The `CAN_MB[nn]_ID1.IDE` bit enables the comparison of the received message ID to the value in the `CAN_MB[nn]_ID1.EXTID` and `CAN_MB[nn]_ID0.EXTID` bits. When configured as transmitter, it sends the extended identifier in addition to the base identifier.
12:2 (R/W)	BASEID	Base Identifier. The `CAN_MB[nn]_ID1.BASEID` bits hold the base identifier for acceptance mask operations.
1:0 (R/W)	EXTID	Extended Identifier. The `CAN_MB[nn]_ID1.EXTID` bits hold the upper two bits of 18-bit extended identifier.

Mailbox Length Register

The `CAN_MB[nn]_LENGTH` register holds the data length code for the received remote frame. For more information about remote frames, see the Remote Frame Handling section.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 X X X X
DLC (R/W)
Data Length Code

Figure 25-40: CAN_MB[nn]_LENGTH Register Diagram

Table 25-35: CAN_MB[nn]_LENGTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	DLC	Data Length Code. The `CAN_MB[nn]_LENGTH.DLC` bits hold the DLC value of the received remote frame. The received value overwrites any previous value.

Mailbox Time Stamp Register

The `CAN_MB[nn]_TIMESTAMP` register holds an indication of the time of reception or transmission for each message, when the universal counter is in time stamp mode (`CAN_UCCNF.UCCNF` =0x1). In this mode, the CAN writes the value of the counter (`CAN_UCCNT`) to the `CAN_MB[nn]_TIMESTAMP` register when a received message is stored or a message is transmitted. For more information about time stamps, see the Time Stamps section.

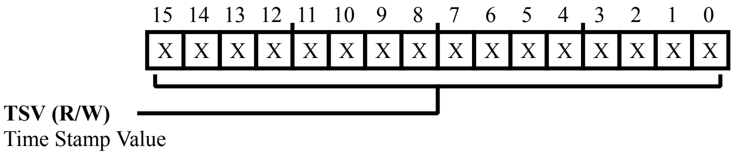


Figure 25-41: CAN_MB[nn]_TIMESTAMP Register Diagram

Table 25-36: CAN_MB[nn]_TIMESTAMP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TSV	Time Stamp Value. The `CAN_MB[nn]_TIMESTAMP.TSV` bits hold the message time stamp value.

Mailbox Configuration 1 Register

The `CAN_MC1` register enables mailboxes 0 through 15. Each bit in this register enables or disables the corresponding mailbox. For all bits, set the bit (=1) to enable the mailbox, and clear the bit (=0) to disable the mailbox.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the `CAN_TRS1` bit associated with a disabled mailbox may result in erroneous behavior. Similarly, disabling a mailbox before the associated `CAN_TRS1` bit is reset by the internal logic can cause unpredictable results.

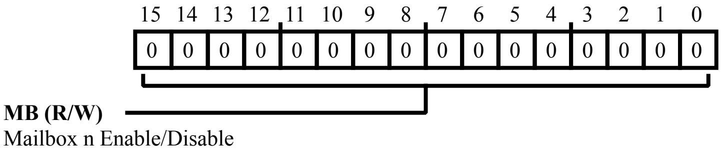

Figure 25-42: CAN_MC1 Register Diagram

Table 25-37: CAN_MC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Enable/Disable.

Mailbox Configuration 2 Register

The `CAN_MC2` register enables mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register enables or disables the corresponding mailbox. For all bits, set the bit (=1) to enable the mailbox, and clear the bit (=0) to disable the mailbox.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the `CAN_TRS2` bit associated with a disabled mailbox may result in erroneous behavior. Similarly, disabling a mailbox before the associated `CAN_TRS2` bit is reset by the internal logic can cause unpredictable results.

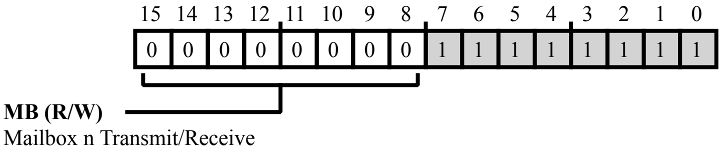
Table 25-38: CAN_MC2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Enable/Disable.

Mailbox Direction 1 Register

The `CAN_MD1` register selects the data transfer direction for mailboxes 0 through 15. Each bit in this register selects receive mode or transmit mode for the corresponding mailbox. For all bits, set the bit (=1) for receive mode from the mailbox, and clear the bit (=0) for transmit mode to the mailbox. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Mailbox Direction 2 Register

The `CAN_MD2` register selects the data transfer direction for mailboxes 16 (bit 0) through 23 (bit 7). Each bit in this register selects receive mode or transmit mode for the corresponding mailbox. For all bits, set the bit (=1) for receive mode from the mailbox, and clear the bit (=0) for transmit mode to the mailbox. Bits 8 through 15 are read-only, as the corresponding mailboxes (24 through 31) are transmit-only mailboxes.

Overwrite Protection/Single Shot Transmission 1 Register

The `CAN_OPSS1` register enables overwrite protection for mailboxes 0 through 15. Each bit in this register enables overwrite protection for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote overwrite protection, see the detailed feature description in the CAN Functional Description section. For more information about how this feature affects transmit and receive operations, see the CAN Operating Modes sections, describing transmit and receive operations.

Overwrite Protection/Single Shot Transmission 2 Register

The `CAN_OPSS2` register enables overwrite protection for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register enables overwrite protection for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote overwrite protection, see the detailed feature description in the CAN Functional Description section. For more information about how this feature affects transmit and receive operations, see the CAN Operating Modes sections, describing transmit and receive operations.

Table 25-42: CAN_OPSS2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MB	Mailbox n Overwrite Protection Enable.

Remote Frame Handling 1 Register

The `CAN_RFH1` register enables remote frame handling for mailboxes 8 through 15. Each bit in this register enables remote frame handling for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote frame handling, see the CAN Operating Modes sections, describing transmit and receive operations. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

Remote Frame Handling 2 Register

The `CAN_RFH2` register enables remote frame handling for mailboxes 16 (bit 0) through 31 (bit 15). Each bit in this register enables remote frame handling for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote frame handling, see the CAN Operating Modes sections, describing transmit and receive operations.

Receive Message Lost 1 Register

The `CAN_RML1` register indicates when a message is lost---due to a message coming while there is pending data (corresponding `CAN_RMP1` bit set) and overwrite protection is disabled (`CAN_OPSS1` bit cleared)---for mailboxes 0 through 15. Each bit in this register indicates the message lost status for the corresponding mailbox when set (=1).

		0	Not in Receive Mode
		1	Receive Mode
14 (R/NW)	TRM	Transmit Mode. The `CAN_STAT.TRM` bit indicates whether the CAN is in transmit mode.	
		0	Not in Transmit Mode
		1	Transmit Mode
12:8 (R/NW)	MBPTR	Mailbox Pointer. The `CAN_STAT.MBPTR` bits represent the mailbox number of the current transmit message. After a successful transmission, these bits remain unchanged.	
		0-31	Processing Mailbox 0 to31 Message
7 (R/NW)	CCA	CAN Configuration Mode Acknowledge. The `CAN_STAT.CCA` bit indicates whether the CAN is in configuration mode.	
		0	Not in Configuration Mode
		1	Configuration mode

Table 25-49: CAN_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/NW)	CSA	CAN Suspend Mode Acknowledge. The `CAN_STAT.CSA` bit indicates whether the CAN is in suspend mode.	
		0	Not in Suspend Mode
		1	Suspend mode
3 (R/NW)	EBO	CAN Error Bus Off Mode. The `CAN_STAT.EBO` bit indicates whether the CAN is in error bus off mode.	
		0	TXECNT Below 256
		1	TXECNT Above Bus Off Limit
2 (R/NW)	EP	CAN Error Passive Mode. The `CAN_STAT.EP` bit indicates whether the CAN is in error passive mode.	
		0	TXECNT and RXECNT Below 128
		1	TXECNT or RXECNT Above EP Level
1 (R/NW)	WR	CAN Receive Warning Flag. The `CAN_STAT.WR` bit indicates whether the CAN has detected a receive warning flag condition.	
		0	RXECNT Below Limit
		1	RXECNT at Limit
0 (R/NW)	WT	CAN Transmit Warning Flag. The `CAN_STAT.WT` bit indicates whether the CAN detected a transmit warning flag condition.	
		0	TXECNT Below Limit
		1	TXECNT at Limit

Transmission Acknowledge 1 Register

The CAN_TA1 register indicates transmission success for mailboxes 8 through 15. Each bit in this register indicates transmission success for the corresponding mailbox when set (=1). Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

Timing Register

The CAN_TIMING register select the time segments, sampling, and synchronization for CAN bit timing. For more information about bit timing and clock operation, see the CAN Operating Modes section.

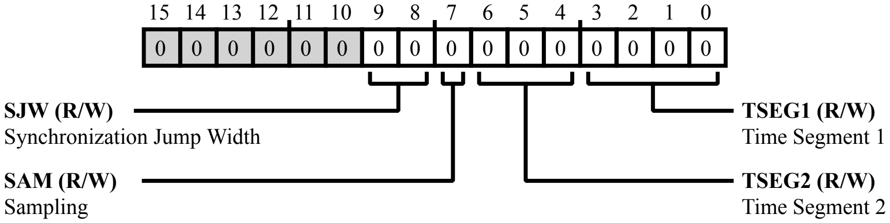

Figure 25-57: CAN_TIMING Register Diagram

Table 25-52: CAN_TIMING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:8 (R/W)	SJW	Synchronization Jump Width. The CAN_TIMING.SJW bits select the maximum number of time quanta, ranging from 1 to 4(SJW + 1). This selection allows for a re-synchronization attempt when the CAN detects a recessive-to-dominant edge outside the synchronization segment. The re-synchronization automatically moves the sampling point such that the CAN bit is still handled properly. Note that the CAN_TIMING.SJW value should not exceed CAN_TIMING.TSEG2 or CAN_TIMING.TSEG1.
7 (R/W)	SAM	Sampling. The CAN_TIMING.SAM bit selects whether the CAN performs normal sampling (once at the sampling point described by the CAN_TIMING register) or performs over sampling. If CAN_TIMING.SAM is set, the CAN over samples the input signal at three times at the CDU0_CLKO4 rate. The resulting value is generated by a majority decision of the three sample values. Note that the CAN_TIMING.SAM bit should always be cleared if the CAN_CLK.BRP value is less than 4.
6:4 (R/W)	TSEG2	Time Segment 2. The CAN_TIMING.TSEG2 bits and CAN_TIMING.TSEG1 bits control how many time quanta of which the CAN bits consist, resulting in the CAN bit rate. For more information about bit timing and clock operation, see the CAN Operating Modes section. Note that the CAN_TIMING.TSEG1 value should always be greater than or equal to the CAN_TIMING.TSEG2 value.
3:0 (R/W)	TSEG1	Time Segment 1. The CAN_TIMING.TSEG1 bits and CAN_TIMING.TSEG2 bits control how many time quanta of which the CAN bits consist, resulting in the CAN bit rate. For more information about bit timing and clock operation, see the CAN Operating Modes section. Note that the CAN_TIMING.TSEG1 value should always be greater than or equal to the CAN_TIMING.TSEG2 value.

Transmission Request Reset 1 Register

The `CAN_TRR1` register requests transmit abort for mailboxes 8 through 15. Bits in this register request transmit abort for the corresponding mailbox when set (=1). When a transmission completes, the corresponding bits in the transmit request set register (`CAN_TRS1`) and in the `CAN_TRR1` are cleared. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

Transmission Request Set 1 Register

The `CAN_TRS1` register requests transmit for mailboxes 8 through 15. Bits in this register request transmit for the corresponding mailbox when set (=1). After writing the data and the identifier into the mailbox area, the message is sent after mailbox n is enabled (with the corresponding bit in `CAN_MC1` = 1), and (subsequently) the corresponding transmit request bit is set (in `CAN_TRS1`). When a transmission completes, the corresponding bits in `CAN_TRS1` and in the transmit request reset register (`CAN_TRR1`) are cleared. Bits 0 through 7 are read-only, as the corresponding mailboxes are receive-only mailboxes.

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	COUNT	Count Value. The `CAN_UCCNT.COUNT` bits hold the current universal count value.

Universal Counter Reload/Capture Register

The `CAN_UCRC` register holds the period value (universal count), which is used in auto-transmit mode as the period for sending the message in mailbox 11 (broadcast heartbeat) to all CAN nodes. Accordingly, messages sent this way usually have high priority.

The period value is written to the `CAN_UCRC` register. When auto-transmit mode is enabled (`CAN_UCCNF.UCCNF` = 0x3), the CAN loads the counter with the value in `CAN_UCRC`. The counter decrements to 0 at the CAN bit clock rate, then is reloaded. Each time the counter decrements to 0, the CAN sets the `CAN_TRS1.MB` bit for mailbox 11 and sends the corresponding message from mailbox 11.

Note that for auto-transmit mode, mailbox 11 must be configured as a transmit mailbox and must contain valid data (identifier, control bits, and data). This setup must occur before the counter first expires after this mode is enabled.

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	UCVAL	Universal Counter Value. The `CAN_UCRC.UCVAL` bits hold the value for the universal count period, which is used in auto-transmit mode.

26 Mobile Storage Interface (MSI)

The mobile storage interface (MSI) is a fast, synchronous controller that uses various protocols to communicate with MMC, SD, and SDIO cards. It addresses the growing storage need in embedded systems, handheld, and consumer electronics applications that require low power. The MSI is compatible with the following protocols.

- MMC (Multimedia Card) bus protocol
- SD (Secure Digital) bus protocol
- SDIO (Secure Digital Input Output) bus protocol

All of these storage solutions use similar interface protocols. The main difference between MMC and SD support is the initialization sequence. The main difference between SD and SDIO support is the use of interrupt and read wait signals for SDIO.

NOTE: The MSI does not support the SPI bus protocol.

MSI Features

The MSI includes the following features.

- Supports Secure Digital memory protocol (version 3.0)
- Supports Secure Digital I/O protocol (version 3.0)
- Supports Multimedia Card protocol (MMC version 4.41, eMMC version 4.5)
- Support for a single SD or SDIO card
- Support for a single MMC device (removable or embedded)
- Support for 1-bit and 4-bit SD modes (SPI mode is not supported)
- Support for 1-, 4-, and 8-bit MMC modes (SPI mode is not supported)
- Supports MMC boot operation
- Supports SDIO interrupts
- Supports command completion signal and interrupt to host processor

- Supports CRC generation and error detection
- 1024-byte transmit/receive FIFO
- Integrated DMA controller
- Card detection capabilities
- Programmable clock frequency
- Supports power management and clock control.

MSI Functional Description

This section provides information on the function of the MSI module.

MMC booting

Normal boot operation is applicable to MMC4.3, MMC4.4, and MMC4.41 cards and is performed in push-pull mode. Also alternate Boot Operation; removable MMC4.3 card.

CRC generation and error detection

Cyclic redundancy codes (CRC) are used to protect commands, responses, and data transfers from transmission errors.

FIFO controller

Interfaces the internal FIFO to the host or DMA interface and the card controller unit. The FIFO depth is configured for 1024 bytes

Integrated DMA controller

Contains a single transmit or receive engine, which transfers data from host memory to the device port and conversely. The controller uses a descriptor to move data efficiently from source to destination with minimal core intervention

Power management and clock control

A low-power mode is available. A clock control block provides the clock frequencies required for SD/MMC cards

ADSP-SC58x MSI Register List

The Mobile Storage Interface (MSI) supports access to mobile memory and devices. A set of registers governs MSI operations. For more information on MSI functionality, see the MSI register descriptions.

MSI Architectural Concepts

The following sections describe the functions and features of the MSI controller as well as the MMC, SD, and SDIO protocols.

Communication is through a master and slave configuration, where the MSI is the master device and the card is the slave device. The MSI communicates with the device using a message-based bus protocol in which the host sends commands serially using the `MSI_CMD` signal. Some commands require that the card provide a response back to the host. This response is also sent serially on the `MSI_CMD` signal.

Data transfers, both to and from the card, occur using the data signals. The number of data lines used for the data transfer can be configured to 1 (`MSI_D0`), 4 (`MSI_D3`–`MSI_D0`), or 8 (`MSI_D7`–`MSI_D0`). All `MSI_CMD` and `MSI_D7`–`MSI_D0` transfers are synchronous with `MSI_CLK`. Cyclic redundancy codes (CRC) are used to protect commands, responses, and data transfers from transmission errors. A CRC7 code is generated for every command sent by the host and for almost every response returned by the card on the `MSI_CMD` signal.

The MSI architecture can be described in terms of its submodules. The primary parts of the architecture are:

- Bus Interface Unit (BIU). This unit provides the host interface to the registers through the Host Interface Unit (HIU). Additionally, it provides independent data FIFO access through a DMA interface.

- Internal Direct Memory Access Controller (IDMAC). This unit is responsible for exchanging data between the FIFO and the host memory. A set of IDMAC registers is accessible to the host for controlling the IDMAC operation.
- Card Interface Unit (CIU). This unit controls the card-specific protocols. Within the CIU, the command path control unit and datapath control unit interface the controller to the command and data ports of the SD/MMC/SDIO cards. The CIU also provides clock control.

Bus Interface Unit (BIU)

The BIU provides the following functions:

- Host interface
- Interrupt control
- Register access
- FIFO access
- Power and pull-up control and card detection

Host Interface Unit (HIU)

The Host Interface Unit (HIU) is a slave bus interface, which provides the interface between the MSI and the processor system bus. It supports the burst accesses to the data FIFO address region only. The register address region is accessed through the standard accesses.

Interrupt Controller Unit

The interrupt controller unit generates an interrupt that depends on the controller interrupt status, the interrupt-mask register, and the global interrupt-enable register bit. Once an interrupt condition is detected, the software sets the corresponding interrupt bit in the interrupt status register. The interrupt status bit remains set until the software clears it by writing a 1 to the interrupt bit (a 0 leaves the bit unchanged).

NOTE: Before enabling the interrupt, programs must write 32'hFFFF_FFFF to the interrupt status register (`MSI_ISTAT`) in order to clear any pending unserviced interrupts. When clearing interrupts during normal operation, only clear the interrupt bits that are serviced.

Register Unit

The register unit is part of the Bus Interface Unit (BIU). It provides read and write access to the registers.

All registers reside in the BIU clock domain. When a command is sent to a card by setting the `MSI_CMD.STARTCMD` bit, all relevant registers needed for the CIU operation are transferred to the CIU block. (The `MSI_CMD.STARTCMD` bit is bit[31] of the `MSI_CMD` register). During this time, software must not write to the registers that are transferred from the BIU to the CIU. The software must wait for the hardware to clear the start bit before writing to these registers again. The register unit has a hardware locking feature to prevent illegal writes to registers.

Once a command start is issued by setting the `MSI_CMD.STARTCMD` bit, the following registers cannot be reprogrammed until the Card Interface Unit (CIU) accepts the command:

- `MSI_CMD` – Command
- `MSI_CMDARG` – Command Argument
- `MSI_BYTCNT` – Byte Count
- `MSI_BLKSIZ` – Block Size
- `MSI_CLKDIV` – Clock Divider
- `MSI_CLKEN` – Clock Enable
- `MSI_TMOUT` – Timeout
- `MSI_CTYPE` – Card Type

The hardware resets the `MSI_CMD.STARTCMD` bit once the CIU accepts the command. If a host writes to any of these registers during this locked time, then the write is ignored and the hardware lock error bit is set in the `MSI_ISTAT` (status) register. Additionally, if the interrupt is enabled and not masked for a hardware lock error, then an interrupt is sent to the host.

Once a command is accepted, software can send another command to the CIU which has a one-deep command queue under the following conditions:

- If the previous command was not a data transfer command, the new command is sent to the card once the previous command completes.
- If the previous command is a data transfer command and if the `MSI_CMD.WTPRIVDATA` bit is set for the new command, the new command is sent to the card only when the data transfer completes.
- If the `MSI_CMD.WTPRIVDATA` is 0, then the new command is sent to the card as soon as the previous command is sent. Typically, software uses this option only to stop or abort a previous data transfer or query the card status in the middle of a data transfer.

FIFO Controller Unit

The FIFO controller interfaces the internal FIFO to the host or DMA interface and the card controller unit. The FIFO depth is configured for 1024 bytes. A single shared FIFO is used for read and write operations because read and write transfers to the cards do not occur simultaneously.

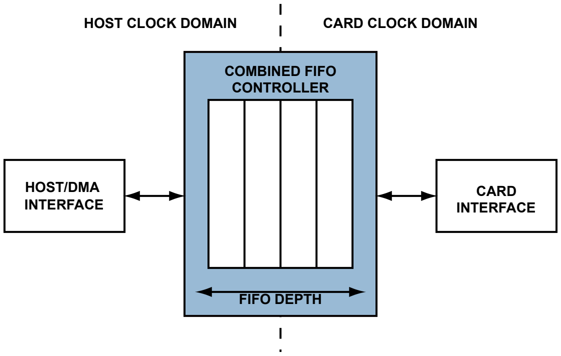

Figure 26-2: Combined Transmit and Receive FIFO

Power and Pull-up Control and Card Detection Unit

The card detection unit looks for any changes in the card-detect signal for card insertion or card removal. The unit filters out the debounce associated with mechanical insertion or removal, and generates one interrupt to the host. The debounce filter value is programmed through the `MSI_DEBNCE` register.

On power-on, the controller reads in the `MSI_CDETECT` register and stores the value in the memory. Upon receiving a card-detect interrupt, the controller again reads the `MSI_CDETECT` register to decide whether card was removed or inserted. The ***Card-Detect Signals*** figure shows the timing for the card-detect signal.

debounce time, which is typically 5ms to 25ms
CARD_DETECT_INT

Figure 26-3: Card-Detect Signals

Internal Direct Memory Access Controller (IDMAC)

The Internal Direct Memory Access Controller (IDMAC) contains a single transmit or receive engine, which transfers data from the host memory to the device port and conversely. The controller uses a descriptor to move data efficiently from source to destination with minimal core intervention. Programs can configure the controller to interrupt the core in situations such as data transmit and receive transfer completion from the card, as well as other normal or error conditions.

The IDMAC and the core communicate through a single data structure. The IDMAC transfers the data received from the card to the data buffer in the host memory, and it transfers transmit data from the data buffer in the host memory to the MSI FIFO. Descriptors that reside in the memory act as pointers to these buffers.

A data buffer resides in physical memory space of the processor and consists of complete data or partial data. Buffers contain only data, while buffer status is maintained in the descriptor. Data chaining refers to data that spans multiple data buffers. However, a single descriptor cannot span multiple data.

A single descriptor is used for both reception and transmission. The base address of the list is written into descriptor list base address register (`MSI_DBADDR`). A descriptor list is forward-linked. The last descriptor can point back to the first entry creating a ring structure. The descriptor list resides in the physical memory address space of the host. Each descriptor can point to a maximum of two data buffers.

Programs can enable or disable the IDMAC using the `MSI_CTL.INTDMAC` bit of the BIU.

DMA Descriptors

The IDMAC uses two types of descriptor structures:

- Dual-Buffer Structure – The skip length value programmed in the `MSI_BUSMODE.DSL` bit field determines the distance between two descriptors.
- Chain Structure – Each descriptor points to a unique buffer and the next descriptor.

The ***Dual-Buffer Descriptor Structure*** and ***Chain Descriptor Structure*** figures show these descriptor structures.

Figure 26-5: Chain Descriptor Structure

The ***Descriptor Format*** figure illustrates the internal format of a descriptor. The descriptor addresses must align with the 32-bit bus width. Each descriptor contains 16 bytes of control and status information. DES0 is a notation used to denote the [31:0] bits, DES1 to denote [63:32] bits, DES2 to denote [95:64] bits, and DES3 to denote [127:96] bits in a descriptor.

DES3

Figure 26-6: Descriptor Format

The following tables provide descriptor bit descriptions. Bits not shown are reserved. The DES0 descriptor in the IDMAC (described in the ***IDMAC DES0 Descriptor*** table) contains control and status information.

Table 26-5: IDMAC DES0 Descriptor

Bits	Name	Description
31	OWN	When set, this bit indicates that the IDMAC owns the descriptor. When this bit is reset, it indicates that the host owns the descriptor. The IDMAC clears this bit when it completes the data transfer.
30	Card Error Summary (CES)	This error bit indicates the status of the transaction to or from the card. This bit is also present in the `MSI_ISTAT` register and indicates the logical OR of the following bits: EBE: End bit error RTO: Response timeout RCRC: Response CRC SBE: Start bit error DRTO: Data Read timeout DCRC: Data CRC for receive RE: Response error
5	End of Ring (ER)	When set, this bit indicates that the descriptor list reached its final descriptor. The IDMAC returns to the base address of the list, creating a descriptor ring. This feature is meaningful for only a dual-buffer descriptor structure.
4	Second Address Chained (CH)	When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, BS2 (DES1[25:13]) is all zeros.
3	First Descriptor (FS)	When set, this bit indicates that this descriptor contains the first buffer of the data. If the size of the first buffer is 0, next descriptor contains the beginning of the data.
2	Last Descriptor (LD)	This bit is associated with the last block of a DMA transfer. When set, the bit indicates that the buffers pointed to by this descriptor are the last buffers of the data. After this descriptor is completed, the remaining byte count is 0. In other words, after the descriptor with the LD bit set is completed, the remaining byte count is 0.
1	Disable Interrupt on Completion (DIC)	When set, this bit prevents the setting of the TI/RI bit of the IDMAC Status Register (IDSTS) for the data that ends in the buffer pointed to by this descriptor.

The DES1 descriptor (described in the ***IDMAC DES1 Descriptor*** table) contains the buffer size.

Table 26-6: IDMAC DES1 Descriptor

Bits	Name	Description
25:13	Buffer 2 Size (BS2)	These bits indicate the second data buffer byte size which must be a multiple of 4. In the case where the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and proceeds to the next buffer if there is a dual-buffer structure. This field is not valid for chain structure; that is, if DES0[4] is set.
12:0	Buffer 1 Size (BS1)	Indicates the data buffer byte size which must be a multiple of 4. In the case where the buffer size is not a multiple of 4, the resulting behavior is undefined. This field must not be zero. Note: If there is only one buffer to be programmed, use only the buffer 1, and not buffer 2.

The DES2 descriptor (described in the ***IDMAC DES2 Descriptor*** table) is the address pointer to the data buffer.

Table 26-7: IDMAC DES2 Descriptor

Bits	Name	Description
31:0	Buffer Address Pointer 1 (BAP1)	These bits indicate the physical address of the first data buffer. The IDMAC ignores DES2 [1:0], internally.

The DES3 descriptor (described in the ***IDMAC DES3 Descriptor*** table) is the address pointer to the next descriptor when the present descriptor is not

- the last descriptor in a chained descriptor structure, or
- the second buffer address for a dual-buffer structure

Table 26-8: IDMAC DES3 Descriptor

Bits	Name	Description
31:0	Buffer Address Pointer 2/ Next Descriptor Address (BAP2)	These bits indicate the physical address of the second buffer when the dual-buffer structure is used. If the Second Address Chained (DES0[4]) bit is set, then this address contains the pointer to the physical memory where the next descriptor is present. If this pointer is not the last descriptor, then the next descriptor address pointer must be bus-width aligned (DES3[1:0] = 0. Internally, the LSBs are ignored.

Initialization

IDMAC initialization occurs as follows.

1. Write to IDMAC bus mode register (`MSI_BUSMODE`) to set host bus access parameters.
2. Write to IDMAC interrupt enable register (`MSI_IDINTEN`) to mask unnecessary interrupt causes.
3. The software driver creates either the transmit or the receive descriptor list. Then it writes to IDMAC descriptor list base address register (`MSI_DBADDR`), which provides the IDMAC the starting address of the list.
4. The IDMAC engine attempts to acquire descriptors from the descriptor lists.

Host Bus Burst Access

The IDMAC executes fixed-length burst transfers on the bus interface when the `MSI_BUSMODE.FB` bit =1. The maximum burst length is indicated and limited by the `MSI_BUSMODE.PBL` bit field. The descriptors are always accessed in the maximum burst-size for the 16-bytes to be read (4-word burst).

The IDMAC initiates a data transfer only when sufficient space to accommodate the configured burst is available in the FIFO or the number of bytes to the end of data, when less than the configured burst-length. The IDMAC indicates the start address and the number of transfers required to the bus interface. When the bus interface is configured for fixed-length bursts, it transfers data using the best combination of INCR4/8/16 and SINGLE transactions. Otherwise, in no fixed-length bursts, it transfers data using INCR (undefined length) and SINGLE transactions.

The transmit and receive data buffers must be aligned to data bus width (32-bit).

NOTE: Due to the bus protocol limitation, the burst mode address should not cross the 1 KB boundary. Address [31:10] should not change during a burst.

Buffer Size Calculations

The software knows the amount of data to transmit or receive. For transmitting to the card, the IDMAC transfers the exact number of bytes to the FIFO, indicated by the buffer size field of DES1.

If a descriptor is not marked as last (LS bit of DES0), then the corresponding buffers of the descriptor are full. Its buffer size field indicates the amount of valid data in a buffer. If a descriptor is marked as last, then the buffer cannot be full, as indicated by the buffer size in DES1. The software is aware of the number of locations that are valid in this case.

Data Transmit/Receive

IDMAC transmission occurs as follows:

1. The software sets up the descriptor (DES0–DES3) for transmission and sets the OWN bit (DES0[31]). The software also prepares the data buffer.
2. The software programs the write data command in the `MSI_CMD` register in the BIU.
3. The software also programs the required transmit threshold level (`MSI_FIFOTH.TXWM` bit field).
4. The IDMAC determines that a write data transfer must occur as a consequence of step 2.
5. The IDMAC engine fetches the descriptor and checks the OWN bit. If the OWN bit is not set, it means that the software owns the descriptor. In this case, the IDMAC enters the suspend state and asserts the `MSI_IDSTS.DU` bit. The software must release the IDMAC by writing any value to the poll demand register.
6. It then waits for command done (`MSI_ISTAT.CMDDONE`) bit and no errors from BIU which indicates that a transfer can occur.
7. The IDMAC engine waits for a DMA interface request from the BIU. This request is generated based on the programmed transmit threshold value. For the last bytes of data which cannot be accessed using a burst, SINGLE transfers are performed.
8. The IDMAC fetches the transmit data from the data buffer and transfers it to the FIFO for transmission to the card.
9. When data spans across multiple descriptors, the IDMAC fetches the next descriptor and continues with its operation with the next descriptor. The last descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.
10. When data transmission is complete, status information is updated in IDMAC status register (`MSI_IDSTS`) by setting the transmit interrupt, when enabled. Also, the IDMAC performs a write transaction to DES0 to clear the OWN bit.

IDMAC reception occurs as follows:

1. The software sets up the Descriptor (DES0–DES3) for reception, sets the OWN bit (DES0[31]).

2. The software programs the read data command in the `MSI_CMD` register in the BIU.
3. The software programs the required receive threshold level (`MSI_FIFOTH.RXWM` bit field).
4. The IDMAC determines that a read data transfer must occur as a consequence of step 2.
5. The IDMAC engine fetches the descriptor and checks the OWN bit. If the OWN bit is not set, it means that the host owns the descriptor. In this case, the DMA enters suspend state and asserts the release the IDMAC by writing any value to the poll demand register.
6. It then waits for the command done (`MSI_ISTAT.CMDDONE`) bit and no errors from BIU which indicates that a transfer can occur.
7. The IDMAC engine waits for a DMA interface request from the BIU. This request is generated based on the programmed receive threshold value. For the last bytes of data which cannot be accessed using a burst, SINGLE transfers are performed.
8. The IDMAC fetches the data from the FIFO and transfers to the memory.
9. When data spans across multiple descriptors, the IDMAC fetches the next descriptor and continues with its operation with the next descriptor. The last descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.
10. When data reception is complete, status information is updated in the IDMAC status register (`MSI_IDSTS`) by setting the receive interrupt, when enabled. Also, the IDMAC performs a write transaction to DES0 to clear the OWN bit.

Interrupts

Interrupts can be generated as a result of various DMAC events. The IDMAC status register (`MSI_IDSTS`) contains all the bits that can cause an interrupt. The IDMAC interrupt enable register (`MSI_IDINTEN`) contains an enable bit for each of the events that can cause an interrupt.

There are two groups of summary interrupts—normal and abnormal—as outlined in the `MSI_IDSTS` register. Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared.

Interrupts are not queued and if the interrupt event occurs before the software has responded to it, no additional interrupts are generated. For example, the receive interrupt (`MSI_IDSTS.RI`) indicates that one or more data was transferred to the buffer. An interrupt is generated only once for simultaneous, multiple events. The software must scan the `MSI_IDSTS` register for the interrupt cause.

NOTE: The final interrupt signal from MSI is a logical OR of the interrupt from the BIU and the IDMAC.

Finite State Machine (FSM)

The IDMAC finite state machine can be in any one of the states reflected in the `MSI_IDSTS.FSM` bit field.

The FSM uses the following sequence.

1. IDMAC performs four accesses for fetching the descriptor.

2. Stores descriptors in internal register and also issues a FIFO reset when it is first descriptor.
3. Each bit is checked for correctness. In case of bit mismatches, appropriate error bit is set. If it is first descriptor, then issues a FIFO reset and wait until FIFO reset is complete. The error status indicates one of the following:
   - Response timeout
   - Response CRC error
   - Data receive timeout
   - Response error
4. The FSM waits in current state until DMA request is asserted, which implies that, FIFO:
   - For DMA write request wait – Holds the number of data, indicated by FIFO RX watermark. In case of error due to response timeout or error, FSM goes to DESC_CLOSE state to close descriptor.
   - For DMA read request wait – Holds number of data, indicated by FIFO TX watermark. In case of error, FSM goes to DESC_CLOSE state to close descriptor.
5. FSM performs the following:
   - For DMA write – Requests a write to SCB. If number of beats in one transfer is greater than PBL, then one of the following occurs:

     Burst count to SCB is PBL value

     Single transfers are initiated
   - For DMA read – Requests a read from SCB. If number of beats in one transfer is greater than PBL, then one of the following occurs:

     Burst count to SCB is PBL value

     Single transfers are initiated
6. After the programmed transfer count is accessed from the memory, the OWN bit in descriptor is closed. If a transfer spans more than one descriptor, the FSM fetches the next descriptor. If the transfer ends with the current descriptor, the FSM goes to the idle state after setting the receive or transmit interrupt. Depending on the descriptor structure—dual buffer or chained—the appropriate starting address of descriptor is loaded. If it is the second data buffer of the dual buffer, the descriptor is not fetched again.

Abort Operation

The host issues CMD12 when a data transfer on the card data lines is in progress. The FSM closes the present descriptor after completing the transfer of data until a DTO interrupt is asserted. Once an abort command is issued, the DMAC performs single burst transfers.

1. For a card write, the FSM keeps pushing data to the FIFO after fetching it from the memory until a DTO interrupt is asserted. The controller asserts a busy clear interrupt after the DTO interrupt. It ensures that the card has completed driving the busy signal. This sequence occurs to keep the card clock running so that CMD12 is reliably sent to the card.

2. For a card read, the FSM keeps popping data from the FIFO and writes to the memory until a DTO interrupt is generated. This sequence is required since the DTO interrupt is not generated until and unless all the FIFO data is emptied.

NOTE: If an FBE occurs, the IDMAC FSM does not close the current descriptor and the remaining unread descriptors.

If a write abort occurs, the IDMAC FSM closes only the current descriptor during which the abort occurred. The IDMAC FSM does not close the current descriptor and the remaining unread descriptors.

If a read abort occurs, the IDMAC FSM pops the data out of the FIFO and writes it to the corresponding descriptor data buffers. The remaining unread descriptors are not closed.

FIFO Overflow and Underflow

During normal data transfer conditions, FIFO overflow and underflow do not occur. If there is a programming error, then a FIFO overflow or underflow can result as shown in the following examples.

Transmit settings: `MSI_BUSMODE.PBL` =4, `MSI_FIFOTH.TXWM` =1

In this example, if the FIFO has only one location empty, it issues a DMA request to the IDMAC FSM. Because `MSI_BUSMODE.PBL` =4, the IDMAC FSM performs 4 pushes into the FIFO which results in a FIFO overflow interrupt.

Receive settings: `MSI_BUSMODE.PBL` =4, `MSI_FIFOTH.RXWM` =1

In this example, if the FIFO has only one location filled, it issues a DMA request to the IDMAC FSM. Because `MSI_BUSMODE.PBL` =4, the IDMAC FSM performs 4 pops to the FIFO which results in a FIFO underflow interrupt.

The software must ensure that the number of bytes to be transferred as indicated in the descriptor are a multiple of 4. For example, if the `MSI_BYTCNT` register =13, the number of bytes indicated in the descriptor must be 16.

Card Interface Unit

The Card Interface Unit (CIU) interfaces with the Bus Interface Unit (BIU) on one side and with the SD/MMC/SDIO cards or devices on other side. The software writes command parameters to the MSI BIU control registers, and these parameters are then passed to the CIU. Depending on control register values, the CIU generates card command and data traffic on a selected card bus according to card protocol.

As shown in the MSI Block Diagram, the CIU consists of the following primary functional blocks:

- Command path
- Datapath
- SDIO interrupt control
- Clock control
- Multiplex or demultiplex unit

The following software restrictions must be met for proper CIU operation:

- Only one data transfer command can be issued at a time.
- During an open-ended card write operation, if the card clock is stopped because the FIFO is empty, the software must first fill the data into the FIFO and start the card clock. It can then issue only a stop or abort command to the card.
- During an SDIO card transfer, if the card function is suspended and the software wants to resume the suspended transfer, it must first reset the FIFO and start the resume command as if it were a new data transfer command.
- When issuing card reset commands (CMD0, CMD15 or CMD52) while a card data transfer is in progress, the software must set the `MSI_CMD.STPABORTCMD` bit so that the MSI can stop the data transfer after issuing the card reset command.
- When the data end error bit (`MSI_ISTAT.EBE`) is set, the MSI does not guarantee SDIO interrupts. The software must ignore the SDIO interrupts and issue the stop or abort command to the card, so that the card stops sending the read data.
- If the card clock is stopped because the FIFO is full during a card read, the software or DMA must read at least two FIFO locations to start the card clock.

Command Path

The command path performs the following functions.

- Loads clock parameters
- Loads card command parameters
- Sends commands to card bus
- Receives responses from card bus
- Sends responses to BIU
- Drives the P-bit on command line

A new command is issued to the MSI by programming the BIU registers and setting the `MSI_CMD.STARTCMD` bit. The command path loads this new command (command, command argument, timeout) and sends acknowledge to the BIU.

Once the new command is loaded, the command path state machine sends a command to the SD/MMC bus (this includes the internally generated CRC7). The command path state machine receives a response if there is any. The state machine then sends the received response and signals to the BIU that the command is done, and then waits for eight clock cycles before loading a new command.

Load Command Parameters

One of the following commands or responses is loaded in the command path:

- New command from BIU when the `MSI_CMD.STARTCMD` bit is set.

- Internally generated auto-stop command when the data path ends, the stop command request is loaded.
- IRQ response with RCA =0x000 when the command path is waiting for an IRQ response from the MMC card, then the `MSI_CTL.IRQRESP` bit is set.

Loading a new command from the BIU in the command path depends on the following `MSI_CMD` register bit settings:

- Update clock registers only using the `MSI_CMD.UCLKREGS` bit. If the `MSI_CMD.UCLKREGS` bit =1, the command path updates only the clock enable and clock divider registers. If `MSI_CMD.UCLKREGS` =0, the command path loads the command, command argument, and timeout registers, then starts processing the new command.
