- Wait for previous data to complete using the `MSI_CMD.WTPRIVDATA` bit. If the `MSI_CMD.WTPRIVDATA` bit =1, the command path loads the new command under one of the following conditions:
  - Immediately, if the data path is free (that is, there is no data transfer in progress), or if an open-ended data transfer is in progress (`MSI_BYTCNT` =0).
  - After completion of the current data transfer, if a predefined data transfer is in progress.

Send Command and Receive Response

Once a new command is loaded in the command path with `MSI_CMD.UCLKREGS` bit =0, the command path state machine sends out a command on the SD/MMC bus. The ***SD_MMC Command Path State Machine*** figure illustrates the command path state machine.

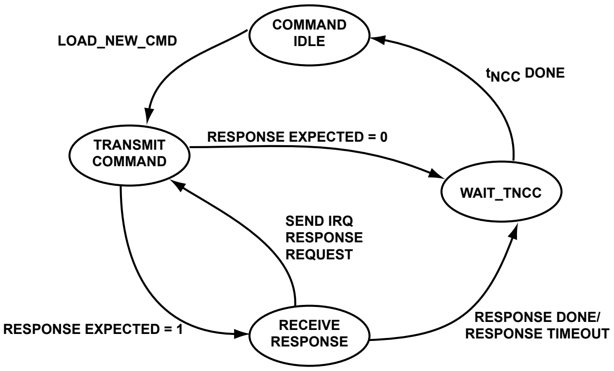

Figure 26-7: SD_MMC Command Path State Machine

The command path state machine performs the following functions, according to following command register bit values:

1. `MSI_CMD.SENDINIT` (send initialization). Initialization sequence of 80 clocks is sent before sending the command.
2. `MSI_CMD.RXPECT` (response expected). A response is expected for the command. After the command is sent out, the command path state machine receives a 48-bit or 136-bit response and sends it to the BIU. If the start

bit of the card response is not received within the number of clocks programmed in the timeout register, then the `MSI_ISTAT.RTO`(response timeout) and `MSI_ISTAT.CD` (command done) bits are set as a signal to the BIU. If the `MSI_CMD.RXPECT` bit is not set, the command path sends out a command and signals a response done to the BIU, that is, the `MSI_ISTAT.CD` bit is set.

3. `MSI_CMD.RLEN` (response length). If =1, a 136-bit response is received; if =0, a 48-bit response is received.
4. `MSI_CMD.CHKRESPCRC` (check response CRC). If =1, the command path compares CRC7 received in the response with the internally-generated CRC7. If the two do not match, the response CRC error is signaled to the BIU, that is, the response CRC error bit (`MSI_ISTAT.RCRC`) is set.

Send Response to BIU

If the `MSI_CMD.RXPECT` bit =1, the received response is sent to the BIU. The `MSI_RESP0` register is updated for a short response, and the `MSI_RESP3`, `MSI_RESP2`, `MSI_RESP1`, and `MSI_RESP0` registers are updated on a long response, after which the `MSI_ISTAT.CMDDONE` bit is set. If the CIU sends an auto-stop command as a response, the response is saved in the `MSI_RESP1` register, after which the `MSI_ISTAT.ACD` (auto command done) bit is set.

Additionally, the command path checks for the following.

- Transmission bit =0
- Command index in response matches command index of the sent command
- End bit =1 in received card response

The command index is not checked for a 136-bit response or if the `MSI_CMD.CHKRESPCRC` bit is cleared. For a 136-bit response and reserved CRC 48-bit responses, the command index is reserved (=111111).

Driving a P-bit on CMD Line

The command path drives a P-bit =1 on the CMD line between two commands when a response is not expected. If a response is expected, the P-bit is driven after the response is received and before the start of the next command.

Datapath

The datapath block pops the data FIFO and transmits data on MSI data lines during a write data transfer. Or, it receives data from data lines and pushes it into the FIFO during a read data transfer. Whenever a data transfer command is not in-progress, the datapath loads new data parameters;

- data expected
- read/write data transfer
- stream or block transfer
- block size
- byte count

- card type
- timeout registers

If the `MSI_CMD.DXPECT` bit =1, the new command is a data transfer command and the datapath starts one of the following:

- Data transmit if the `MSI_CMD.RDWR` (read/write) bit =1
- Data receive if `MSI_CMD.RDWR` (read/write) bit 0

Auto-Stop

The MSI internally generates a stop command and is loaded in the command path when the `MSI_CMD.SENDASTOP` bit is set. The auto-stop command helps to send an exact number of data bytes using a stream read or write for the MMC, and a multiple-block read or write for the SD memory transfer for SD cards.

The software must set the `MSI_CMD.SENDASTOP` bit according to details listed in the ***Auto-Stop Generation*** table.

Table 26-9: Auto-Stop Generation

Card Type	Transfer Type	Byte Count	**`MSI_CMD.SENDASTOP` bit =1**	Comments
MMC	Stream read	0	No	Open-ended stream
	Stream read	>0	Yes	Auto-stop after all bytes transfer
	Stream write	0	No	Open-ended stream
	Stream write	>0	Yes	Auto-stop after all bytes transfer
	Single-block read	>0	No	Byte count = 0 is illegal
	Single-block write	>0	No	Byte count = 0 is illegal
	Multiple-block read	0	No	Open-ended multiple block
	Multiple-block read	>0	Yes[*1]	Pre-defined multiple block
	Multiple-block write	0	No	Open-ended multiple block
	Multiple-block write	>0	Yes	Pre-defined multiple block
SDMEM	Single-block read	>0	No	Byte count = 0 is illegal
	Single-block write	>0	No	Byte count = 0 is illegal
	Multiple-block read	0	No	Open-ended multiple block
	Multiple-block read	>0	Yes	Auto-stop after all bytes transfer
	Multiple-block write	0	No	Open-ended multiple block
	Multiple-block write	>0	Yes	Auto-stop after all bytes transfer
SDIO	Single-block read	>0	No	Byte count = 0 is illegal
	Single-block write	>0	No	Byte count = 0 is illegal

Table 26-9: Auto-Stop Generation (Continued)

Card Type	Transfer Type	Byte Count	`MSI_CMD.SENDASTOP` bit =1	Comments
	Multiple-block read	0	No	Open-ended multiple block
	Multiple-block read	>0	No	Pre-defined multiple block
	Multiple-block write	0	No	Open-ended multiple block
	Multiple-block write	>0	No	Pre-defined multiple block

*1 The condition under which the transfer mode blocks transfer and `byte_count` equals block size is treated as a single-block data transfer command for both MMC and SD cards. If byte_count = n × block_size (n = 2, 3, …), the condition is treated as a predefined multiple-block data transfer command. For an MMC card, the host software can perform a predefined data transfer in two ways:

1. Issue the CMD23 command before issuing CMD18/CMD25 commands to the card – in this case, issue CMD18/CMD25 commands without setting the `MSI_CMD.SENDASTOP` bit.
2. Issue CMD18/CMD25 commands without issuing CMD23 command to the card, with the `MSI_CMD.SENDASTOP` bit set. In this case, an internally generated auto-stop command after the programmed byte count terminates the multiple-block data transfer.

The following list explains different conditions for the auto-stop command.

- Stream read for MMC card with byte count greater than 0. The MSI generates an internal stop command and loads it into the command path. The end bit of the stop command is sent out when the last byte of data is read from the card and no extra data byte is received. If the byte count is less than 6 (48 bits), a few extra data bytes are received from the card before the end bit of the stop command is sent.
- Stream write for MMC card with byte count greater than 0. The MSI generates an internal stop command and loads it into the command path. The end bit of the stop command is sent when the last byte of data is transmitted on the card bus and no extra data byte is transmitted. If the byte count is less than 6 (48 bits), the datapath transmits the data last in order to meet the above condition.
- Multiple-block read memory for SD card with byte count greater than 0. If the block size is less than 4 (single-bit data bus), 16 (4-bit data bus), or 32 (8-bit data bus) bytes, the auto-stop command is loaded in the command path after all the bytes are read. Otherwise, the stop command is loaded in the command path so that the end bit of the stop command is sent after the last data block is received.
- Multiple-block write memory for SD card with byte count greater than 0. If the block size is less than 3 (single-bit data bus), 12 (4-bit data bus), or 24 (8-bit data bus), the auto-stop command is loaded in the command path after all data blocks are transmitted. Otherwise, the stop command is loaded in the command path so that the end bit of the stop command is sent after the end bit of the CRC status is received.
- Precaution for host software during auto-stop. Whenever an auto-stop command is issued, the host software must not issue a new command to the MSI until the MSI sends the auto-stop command and the data transfer completes. If the host issues a new command during a data transfer with the auto-stop in progress, an auto-stop command can be sent after the new command is sent and its response is received. This process can delay sending the stop command, which transfers extra data bytes. For a stream write, extra data bytes are erroneous data

that can corrupt the card data. If the host wants to terminate the data transfer before the data transfer is complete, it can issue a stop or abort command. In this case, the MSI does not generate an auto-stop command.

Non-Data Transfer Commands that Use Datapath

Some non-data transfer commands (non-read/write commands) also use the datapath. The ***Non-Data Transfer Commands and Requirements*** table lists the commands and register programming requirements.

Table 26-10: Non-Data Transfer Commands and Requirements

	CMD27	CMD30	CMD42	ACMD13	ACMD22	ACMD51

*1 Number of bytes specified as per the lock card data structure (Refer to the SD specification and the MMC specification).

SDIO Interrupt Control

Interrupts for SD cards are reported to the BIU by asserting an interrupt signal for two clock cycles. SDIO cards signal an interrupt by asserting `MSI0_D1` low during the interrupt period; The interrupt control state machine determines an interrupt period for the selected card. An interrupt period is always valid for cards in 1-bit data mode. An interrupt period for a wide-bus active or selected card is valid for the following conditions:

- Card is idle
- Non-data transfer command in progress

- Third clock after end bit of data block between two data blocks
- From two clocks after end bit of last data until end bit of next data transfer command

Bear in mind that, in the following situations, the MSI does not sample the SDIO interrupt of the selected card when the card data width is 4 bits. Since the SDIO interrupt is level-triggered, it is sampled in a further interrupt period and the host does not lose any SDIO interrupt from the card.

1. Read/write resume. The CIU treats the resume command as a normal data transfer command. SDIO interrupts during the resume command are handled similarly to other data commands. According to the SDIO specification, for the normal data command the interrupt period ends after the command end bit of the data command. For the resume command, it ends after the response end bit. For the resume command, the MSI stops the interrupt sampling period after the resume command end bit, instead of stopping after the response end bit of the resume command.
2. Suspend during read transfer. If the host suspends the read data transfer, the host sets the `MSI_CTL.RDABORT` bit to reset the data state machine. In the CIU, the SDIO interrupts are handled such that the interrupt sampling starts after the host sets the `MSI_CTL.RDABORT` bit. In this case, the MSI does not sample SDIO interrupts between the period from response of the suspend command.

Clock Control

The clock control block provides the clock frequencies required for SD/MMC cards.

The source clock for the MSI block and the input clock for clock dividers of the clock control block is clocked by CLK09 clock from CDU module. Refer to CDU chapter for more details on CLK09 clock.

The source clock is used to generate the card clock frequencies. The card clock can have different clock frequencies, since the SD card can be a low-speed SD card or a full-speed SD card. The MSI allows the card to operate at different clock frequencies.

The clock frequency of a card depends on the following clock control registers:

- Clock divider register (`MSI_CLKDIV`). An internal clock divider is used to generate different clock frequencies required for the card. The clock divider is an 8-bit value that provides a clock division factor from 1 to 510. A value of 0 represents a clock-divider bypass, a value of 1 represents a divide by 2, a value of 2 represents a divide by 4, and so on.
- Clock control register (`MSI_CLKEN`). The MSI module can enable or disable the card clock under the following conditions:
  - The clock for a card is enabled when the `MSI_CLKEN.EN0` bit for a card is programmed (= 1) or disabled (= 0).
  - Setting the `MSI_CLKEN.LP0` =1. enables the low-power mode of a card. If low-power mode is enabled to save card power, the clock signal is disabled when the card is idle for at least 8 card clock cycles. It is enabled when a new command is loaded and the command path goes to a non-idle state.

Additionally, the clock of the card is disabled when:

- An internal FIFO is full on a card read (no more data can be received from card)
- The FIFO is empty on a card write (no data is available for transmission).

Disabling the clock in these situations helps to avoid FIFO overrun and underrun conditions.

Under the following conditions, the card clock is stopped or disabled for the card:

- The clock can be disabled by writing to the clock enable `MSI_CLKEN` register.
- If low-power mode is selected and a card is idle, or not selected for 8 clocks.
- The FIFO is full and data path cannot accept more data from the card and data transfer is incomplete to avoid FIFO overrun.
- The FIFO is empty and data path cannot transmit more data to the card and data transfer is incomplete to avoid FIFO underrun.

NOTE: The host software must take care while changing the `MSI_CLKDIV` register values. The card clock must be disabled through the `MSI_CLKEN` register before changing the values of the `MSI_CLKDIV` register.

MSI Data Transfer Modes

The following sections provide information on data transfer using the MSI interface.

Data Transmit

The data transmit state machine starts data transmission two clocks after a response for the data write command is received. The transmission occurs even if the command path detects a response error or response CRC error. See the ***Data Transmit State Machine*** figure. If a response is not received from the card because of a response timeout, data is not transmitted. Depending upon the value of the `MSI_CMD.XFRMODE` bit, the data transmit state machine puts data on the card data bus in a stream or in blocks.

Stream Data Transmit

If the `MSI_CMD.XFRMODE` bit =1, it is a stream-write data transfer. The data path pops the FIFO from the BIU and transmits in a stream to the card data bus. If the FIFO becomes empty, the card clock is stopped and restarted once data is available in the FIFO.

If the `MSI_BYTCNT` register is programmed to 0, it is an open-ended stream-write data transfer. During this data transfer, the data path continuously transmits data in a stream until the host software issues a stop command. A stream data transfer is terminated when the end bit of the stop command and end bit of the data match over two clocks.

If the `MSI_BYTCNT` register is programmed with a non-zero value and the `MSI_CMD.SENDASTOP` bit is set, the stop command is internally generated. The command is loaded in the command path when the end bit of the stop command occurs after a match with the last byte of the stream-write transfer. This data transfer can also terminate if the software issues a stop command before all the data bytes transfer to the card bus.

Single Block Data

If the `MSI_CMD.XFRMODE` bit =0 and the `MSI_BYTCNT` register value is equal to the value of the `MSI_BLKSIZ` register, a single-block write-data transfer occurs. The data transmit state machine sends data in a single block, where the number of bytes equals the block size, including the internally-generated CRC16.

If the `MSI_CTYPE` register bit is set for a 1-bit, 4-bit, or 8-bit data transfer, the data transmits on 1, 4, or 8 data lines, respectively. CRC16 is separately generated and transmitted for 1, 4, or 8 data lines, respectively.

After a single data block is transmitted, the data transmit state machine receives the CRC status from the card and signals a data transfer to the BIU. This operation happens when the `MSI_ISTAT.DTO` bit =1. If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the `MSI_ISTAT.DCRC` bit.

Additionally, if the start bit of the CRC status is not received before two clocks after the end of the data block, a CRC status start bit error is signaled to the BIU. The `MSI_ISTAT.EBE` bit is set.

Multiple Block Data

A multiple-block write-data transfer occurs if the `MSI_CMD.XFRMODE` bit =0 and the value in the `MSI_BYTCNT` register is not equal to the value of the `MSI_BLKSIZ` register. The data transmit state machine sends data in blocks, where the number of bytes in a block equals the block size, including the internally-generated CRC16.

If the `MSI_CTYPE` register bit is set to 1-bit, 4-bit, or 8-bit data transfer, the data transmits on 1, 4, or 8 data lines, respectively. CRC16 is separately generated and transmitted on 1, 4, or 8 data lines, respectively.

After one data block is transmitted, the data transmit state machine receives the CRC status from the card. If the remaining `MSI_BYTCNT` becomes 0, the data path signals to the BIU that the data transfer is complete. This operation happens when the `MSI_ISTAT.DTO` bit =1. If the remaining data bytes are greater than 0, the data path state machine starts to transmit another data block.

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the `MSI_ISTAT.DCRC` bit. The block continues further data transmission until all the bytes are sent. Additionally, if the CRC status start bit is not received within two clocks after the end of a data block, a CRC status start bit error is signaled to the BIU. The `MSI_ISTAT.EBE` bit is set. Further data transfer is terminated.

If the `MSI_CMD.SENDASTOP` is set, the stop command is internally generated during the transfer of the last data block. No extra bytes are transferred to the card. The end bit of the stop command does not always exactly match the end bit of the CRC status in the last data block.

If the block size is less than 4, 16, or 32 for card data widths of 1 bit, 4 bits, or 8 bits, respectively, the data transmit state machine terminates the data transfer when all the data has transferred. The internally generated stop command is loaded in the command path.

If the `MSI_BYTCNT` register =0 (the block size must be greater than 0), it is an open-ended block transfer. The data transmit state machine for this type of data transfer continues the block-write data transfer until the host software issues a stop or abort command.

Data Receive

The data-receive state machine receives data two clock cycles after the end bit of a data read command, even if the command path detects a response error or response CRC error. See the ***Data Receive State Machine*** figure. If a response is not received from the card because a timeout error occurs, the BIU does not receive the signal that the data transfer is complete. This error happens when the command sent by the MSI is an illegal operation for the card. The error prevents the card from starting a read data transfer.

If data is not received before the data timeout, the data path signals a data timeout to the BIU and an end to the data transfer done. Based on the value of the `MSI_CMD.XFRMODE` bit, the data-receive state machine gets data from the card data bus in a stream or blocks.

Stream Data Read

A stream-read data transfer occurs if the `MSI_CMD.XFRMODE` bit =1, at which time the data path receives data from the card and pushes it to the FIFO. If the FIFO becomes full, the card clock stops and restarts once the FIFO is no longer full.

An open-ended stream-read data transfer occurs when the `MSI_BYTCNT` register equals 0. During this type of data transfer, the data path continuously receives data in a stream until the host software issues a stop command. A stream data transfer terminates two clock cycles after the end bit of the stop command.

If the `MSI_BYTCNT` register contains a non-zero value and the `MSI_CMD.SENDASTOP` bit =1, a stop command is internally generated and loaded into the command path. In the command path, the end bit of the stop command occurs after the last byte of the stream data transfer is received. This data transfer can terminate if the host issues a stop or abort command before all the data bytes are received from the card.

Single Block Data Read

A single-block read-data transfer occurs if the `MSI_CMD.XFRMODE` bit =0 and the value of the `MSI_BYTCNT` register is equal to the value of the `MSI_BLKSIZ` register. When a start bit is received before the data times out, data bytes equal to the block size and CRC16 are received and checked with the internally-generated CRC16.

If the `MSI_CTYPE` register bit for the card is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively. CRC16 is separately generated and checked for 1, 4, or 8 data lines, respectively. If there is a CRC16 mismatch, the data path signals a data CRC error to the BIU. If the received end bit is not 1, the BIU receives an end-bit error.

Multiple Block Data Read

If the `MSI_CMD.XFRMODE` =0 and the value of the `MSI_BYTCNT` register is not equal to the value of the `MSI_BLKSIZ` register, it is a multiple-block read-data transfer. The data-receive state machine receives data in blocks, where the number of bytes in a block is equal to the block size, including the internally-generated CRC16.

If the `MSI_CTYPE` register bit for the card is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively. CRC16 is separately generated and checked for 1, 4, or 8 data lines, respectively. After a data block is received, if the remaining `MSI_BYTCNT` becomes 0, the data path signals a data transfer to the BIU.

If the remaining data bytes are greater than 0, the data path state machine causes another data block to be received. If CRC16 of a received data block does not match the internally-generated CRC16, a data CRC error to the BIU and data reception continue further data transmission until all bytes are transmitted. Additionally, if the end of a received data block is not 1, data on the data path signals terminate the bit error to the CIU. The data-receive state machine terminates data reception, waits for a data timeout, and signals to the BIU that the data transfer is complete.

If the `MSI_CMD.SENDASTOP` bit =1, the stop command is internally generated when the last data block is transferred, where no extra bytes are transferred from the card. The end bit of the stop command does not always exactly match the end bit of the last data block.

If the requested block size for data transfers to cards is less than 4, 16, or 32 bytes for 1-bit, 4-bit, or 8-bit data transfer modes, respectively, the data-transmit state machine terminates the data transfer when all data transfers. The internally-generated stop command is loaded in the command path. The data path ignores any subsequent data received from the card.

If the `MSI_BYTCNT` =0 (the block size must be greater than 0), it is an open-ended block transfer. For this type of data transfer, the data-receive state machine continues the block-read data transfer until the host software issues a stop or abort command.

Data Transfer Commands

Data transfer commands transfer data between the memory card and the MSI. To send a data command, the MSI needs a command argument, total data size, and block size.

Prior to a data transfer command, software must confirm that the card is not busy and is in a transfer state. This confirmation uses the CMD13 and CMD7 commands, respectively. For the data transfer commands, it is important that the same bus width that is programmed in the card is set in the `MSI_CTYPE` register.

The MSI generates an interrupt for different conditions during data transfer, which are reflected in the `MSI_ISTAT` register.

NOTE: The DCRC, SBEBCI, EBE, and SBEBCI conditions indicate that the received data could have errors. If there was a response timeout, then no data transfer occurred. For more information, see the Register Descriptions section.

Transmission and Reception with Internal DMAC (IDMAC)

The general sequence of events for transmit and receive is as follows.

1. Program the required programming in the bus mode register (`MSI_BUSMODE`). If the `MSI_CTL.INTDMAC` bit is disabled during the middle of an IDMAC transfer, it has no effect. It only takes effect for a new data transfer command. Issuing a software reset immediately terminates the transfer. It is recommended that the software issue a reset to the DMA interface by setting the `MSI_CTL.DMARST` bit and then issuing an IDMAC software reset using the `MSI_CTL.CTLRST` bit. Program the fixed burst bit (`MSI_BUSMODE.FB`) appropriately for system performance.
2. When a descriptor unavailable interrupt is asserted, the software must form the descriptor, appropriately set its own bit and then write to poll the demand register for the IDMAC to refetch the descriptor.
3. It is always appropriate for the application to enable abnormal interrupts since any errors related to the transfer are reported to the application.

MSI Event Control

The following sections describe MSI events.

Dedicated Interrupt Pins

Interrupt lines are defined for only eSDIO devices, which are connected to the controller interrupt line in MSI. These interrupt lines can operate even when the card clock is switched off and can be used only during an asynchronous interrupt period.

MSI Status and Error Signals

The following provides information on MSI errors.

Error Detection

The MSI has an error detection mechanism which operates for any of the following situations.

Response

- Response timeout – Response expected with the response start bit is not received within programmed number of clocks in timeout register.
- Response CRC error – Response is expected and check response CRC requested; response CRC7 does not match with the internally-generated CRC7.
- Response error – Response transmission bit is not 0, command index does not match with the command index of the send command, or response end bit is not 1.

Data Transmit

- No CRC status – During a write data transfer, if the CRC status start bit is not received two clocks after the end bit of the data block is sent out, the datapath does the following:
  - Signals no CRC status error to the BIU
  - Terminates further data transfer
  - Signals data transfer done to the BIU
- Negative CRC – If the CRC status received after the write data block is negative (that is, not 010), a data CRC error is signaled to the BIU and further data transfer is continued.
- Data starvation due to empty FIFO – If the FIFO becomes empty during a write data transmission, or if the card clock is stopped and the FIFO remains empty for data timeout clocks, then a data-starvation error is signaled to the BIU. The datapath continues to wait for data in the FIFO.

Data Receive

- Data timeout – During a read-data transfer, if the data start bit is not received before the number of clocks that are programmed in the timeout register, the datapath does the following.
  - Signals data-timeout error to the BIU
  - Terminates further data transfer
  - Signals data transfer done to BIU

- Data start bit error – During a 4-bit or 8-bit read-data transfer, when an SBE occurs, the application or driver must issue CMD12 for SD/MMC cards and CMD52 for a SDIO card to exit the error condition. After a CMD done is received, the application or driver must reset IDMAC and CIU (if required) to clear the condition. The FIFO must be reset before issuing any data transfer commands in general.
- Data CRC error – During a read-data-block transfer, if the received CRC16 does not match with the internally-generated CRC16, the datapath signals a data CRC error to the BIU and continues further data transfer.
- Data end-bit error – During a read-data transfer, if the end bit of the received data is not 1, the datapath signals an end-bit error to the BIU, terminates further data transfer, and signals to the BIU that the data transfer is done.
- Data starvation due to FIFO full – During a read data transmission and when the FIFO becomes full, the card clock is stopped. If the FIFO remains full for data timeout clocks, a data starvation error is signaled to the BIU. The datapath continues to wait for the FIFO to start to empty. (The data starvation by host timeout bit is set in the `MSI_ISTAT` register.)

NOTE: In an error situation, DTO generation depends on when the error has occurred, since the descriptors are closed after the error scenarios as follows.

- If the data remains in the FIFO when the DMA detects the error scenario, then a DTO is not generated.
- If the data is completely read out before the error occurs, then a DTO is generated. CMD12 ensures DTO generation in error situations; therefore, issuing CMD12 is recommended.

Error Handling

The MSI implements error checking. Errors are reflected in the `MSI_ISTAT` register and can be communicated to the software through an interrupt, or the software can poll these bits. On power-on, interrupts are disabled, and all the interrupts are masked (bits 31:0 of the `MSI_IMSK` register are all 0). The MSI module captures the following errors:

- Response and data timeout errors. For response timeout, software can retry the command. For a data timeout error, the MSI has not received the data start bit - either for the first block or the intermediate block - within the timeout period. Software can either retry the whole data transfer again or retry from a specified block onwards. By reading the contents of the `MSI_TCBCNT` register later, the software can decide how many bytes remain to be copied.
- Response errors. Set when an error is received during response reception. In this case, the response that copied in the response registers is invalid. Software can retry the command.
- Data errors. Set when error in data reception is observed. For example, this error can occur in the data CRC, when the start bit is not found, when the end bit is not found, and so on. These errors could be set for any block-first block, intermediate block, or last block. On receipt of an error, the software can issue a STOP or ABORT command and retry the command for either whole data or partial data.

- Hardware locked error. Set when the MSI cannot load a command issued by software. When software sets the `MSI_CMD.STARTCMD` bit, the MSI tries to load the command. If the command buffer is already filled with a command, this error is generated. The software then has to reload the command.
- FIFO underrun or overrun error. If the FIFO is full and DMA tries to write data into the FIFO, then an overrun error is set. Conversely, if the FIFO is empty and the DMA tries to read data from the FIFO, an underrun error is set.
- Data starvation by host timeout. Raised when the MSI is waiting for software intervention to transfer the data to or from the FIFO, but the software does not transfer within the stipulated timeout period. Under this condition and when a read transfer is in progress, the software must read data from the FIFO and create space for further data reception. When a transmit operation is in process, the software must fill data in the FIFO to start transferring data to the card.
- CRC Error on command. If a CRC error is detected for a command.

NOTE: During a multiple-block data transfer, if a negative CRC status is received from the device, the datapath signals a data CRC error to the BIU by setting the data `MSI_ISTAT.DCRC` register. It then continues further data transmission until all the bytes are transmitted.

Fatal Bus Errors (FBE)

An FBE occurs due to an error response from SCB. This response is a system error, so the software driver must not perform any further programming of the MSI. The only recovery mechanism from such scenarios is to do one of the following.

- Issue a hard reset.
- Do a controller reset by writing to the `MSI_CTL.CTLRST` bit.

MSI Programming Model

This section provides procedures that allow programmers to use the MSI properly. These procedures include MSI initialization, single and multiple block reads and writes and many others.

MSI Programming Concepts

Using the features, operating modes, and event control for the MSI to their greatest potential requires an understanding of the following MSI-related concepts.

Software and Hardware Restrictions

Before issuing a new data transfer command, the software should ensure that the card is not busy due to any previous data transfer command. Before changing the card clock frequency, the software must ensure that there are no data or command transfers in progress.

To avoid glitches in the card clock outputs, use the following steps when changing the card clock frequency.

1. Before disabling the clocks, ensure that the card is not busy due to any previous data command. To determine this status, check for 0 in the `MSI_STAT.DBUSY` bit.
2. Update the `MSI_CLKEN` register to disable all clocks. To ensure completion of any previous command before this update, send a command to the CIU to update the clock registers by setting the `MSI_CMD.STARTCMD` bit, the `MSI_CMD.WTPRIVDATA` bits, and the `MSI_CMD.UCLKREGS` bit.
3. Set the `MSI_CMD.STARTCMD` bit to update the clock divider register, and send a command to the CIU in order to update the clock registers. Wait for the CIU to take the command.
4. Set the `MSI_CMD.STARTCMD` to update the `MSI_CLKEN` register to enable the required clocks and send a command to the CIU to update the clock registers. Wait for the CIU to take the command.

If the software issues a controller reset command by setting the `MSI_CTL.CTLRST` bit, all the CIU state machines are reset and the FIFO is not cleared. The DMA sends all remaining bytes to the host. In addition to a card-reset, if a FIFO reset is also issued (`MSI_CTL.FIFORST`), then:

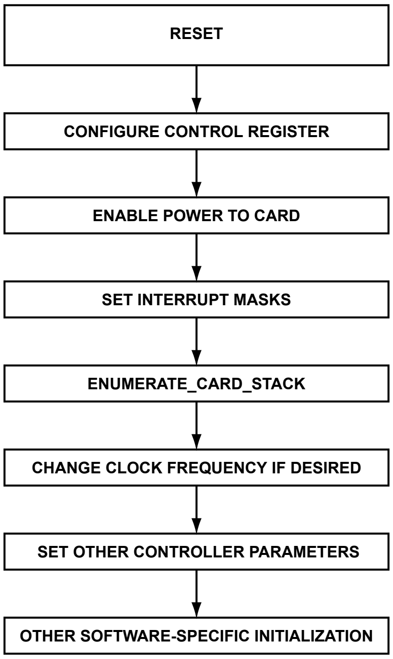
- Any pending DMA transfer on the bus completes correctly
- DMA data reads are ignored
- Write data is unknown (x)

Additionally, if a DMA reset is also issued (`MSI_CTL.DMARST`), any pending DMA transfer is abruptly terminated.

If any of the previous data commands do not properly terminate, then the software must issue the FIFO reset. The reset removes any residual data, if any, in the FIFO. After asserting the FIFO reset, the program waits until this bit is cleared. One data transfer requirement between the FIFO and host is that the number of transfers must be a multiple of the FIFO data width. For example, if the FIFO data width = 32-bit and the program must write only 15 bytes to the card, the host must program the DMA to do 16-byte transfers to the card. (The program writes to the card using the `MSI_BYTCNT` register.)

Initializing the MSI

After the power-up, the MSI is reset. The reset initializes the registers, ports, FIFO-pointers, DMA interface controls, and state-machine. After power-on reset, the software performs the following steps which are reflected in the ***Data Transmit State Machine*** figure.



RESET
CONFIGURE CONTROL REGISTER
ENABLE POWER TO CARD
SET INTERRUPT MASKS
ENUMERATE_CARD_STACK
CHANGE CLOCK FREQUENCY IF DESIRED
SET OTHER CONTROLLER PARAMETERS
OTHER SOFTWARE-SPECIFIC INITIALIZATION

Figure 26-10: Data Transmit State Machine

1. Configure the control register (`MSI_CTL`).
2. Set masks for interrupts by clearing appropriate bits in the interrupt mask register. Set the global `MSI_CTL.INTEN` bit. It is recommended that programs write 0xFFFF_FFFF to the `MSI_ISTAT` register to clear any pending interrupts before setting the `MSI_CTL.INTEN` bit.
3. Enumerate the card stack. Each card is enumerated according to card type. For details, refer to Enumerating the Card Stack. For enumeration, restrict the clock frequency to 400 kHz in accordance with SD/MMC standards.
4. Set the card frequency using the `MSI_CLKDIV` register.
5. Set other parameters, which normally do not need changing with every command, with a typical value such as response and data timeout values. Set the values according to the SD/MMC specifications and the FIFO threshold value.

Enumerating the Card Stack

The card stack does the following:

- Enumerates the connected card
- Sets the RCA for the connected card
- Reads card-specific information
- Stores card-specific information locally

Each card is enumerated separately. The identification procedure depends on whether the card connected is SD, SDIO, or MMC.

Identifying Card Types

The MSI can have an MMC, SD, or SDIO type of card connected to it. All types of SDIO cards are supported; that is, SDIO_IO_ONLY, SDIO_MEM_ONLY, and SDIO_COMBO cards. Each card is enumerated separately. The enumeration sequence includes the following steps:

1. Check if the card is connected.
2. Clear the bits in the `MSI_CTYPE` register to configure the controller in 1-bit mode
3. Identify the card type; that is, SD, MMC, SDIO, or COMBO card.
    a. Send CMD5 with argument 0.

    b. Read the response register (`MSI_RESP0`), which gives the voltage window that the card supports-the response to CMD5 gives the voltages that the card supports.

    c. Send CMD5 again with the desired voltage window set in the argument. This CMD5 is used to set the voltage window and move the card state m/c out of the initialization state.

    d. Check the response [27] bit. If this bit = 1, this response indicates that the memory is present and the SDIO card is a COMBO card.

    e. If the card is SDIO go to Step 4. If the card is combinational logic (COMBO) or if the response is not received, continue with the following steps.

    f. Send CMD8 with the following argument:

    ```
    Bit[31:12] = 20'h0; // Reserved bits
    Bit[11:8] = 4'b0001 // VHS value
    Bit[7:0] = 8'b10101010 // Preferred Check Pattern by SD2.0
    ```

    g. If the response is received, the card supports high capacity SD2.0; send ACMD41 with the following argument:

    ```
    Bit[31] = 1'b0; // Reserved bits
    Bit[30] = 1'b1; // High Capacity Status
    Bit[29:25] = 6'h0; // Reserved bits
    Bit[24] = 1'b0;
    Bit[23:0] = Supported Voltage Range
    ```

    h. If the response is received for ACMD41, then the card is SD; otherwise the card is MMC.

    i. If the response is not received for initial CMD8, then the card does not support high capacity SD2.0. Issue CMD0 followed byMD41 with the following argument:

    ```
    Bit[31] = 1'b0; // Reserved bits
    Bit[30] = 1'b0; // High Capacity Status
    ```

```
Bit[29:24] = 6'h0; // Reserved bits
Bit[23:0] = Supported Voltage Range
```

j. If the response is received for ACMD41, then the card is SD. Otherwise, the card is MMC.

4. Enumerate the card according to the card type.
5. Use a card clock frequency = f_{OD} (that is, 400 kHz) and use the following enumeration command sequence:
   - SD card – Send CMD0, CMD8, ACMD41, CMD2, CMD3.
   - SDIO – Send CMD5; if the function count is valid, CMD3. For the SDIO memory section, follow the same commands as for the SD card.
   - MMC – Send CMD0, CMD1, CMD2, CMD3.

The card clock frequency can be configured after enumeration.

Programming Card Clocks

The MSI supports programming the desired operational frequency for the card. The clock for the card can also be enabled or disabled. Registers that support this feature are:

- `MSI_CLKDIV`: Programs clock source frequency.
- `MSI_CLKEN`: Enables or disables clock for the card and enables low-power mode, which automatically stops the clock to a card when the card is idle for more than 8 clocks.

The MSI loads each of these registers only when the `MSI_CMD.STARTCMD` bit and the `MSI_CMD.UCLKREGS` bit in the CMD register are set. When a command is successfully loaded, the MSI clears the `MSI_CMD.STARTCMD` bit. This operation happens unless the MSI already has another command in the queue, at which point it generates a Hardware Locked Error (HLE).

Software must look for the `MSI_CMD.STARTCMD` and the `MSI_CMD.UCLKREGS` bits, and set the `MSI_CMD.WTPRIVDATA` bit to ensure that clock parameters do not change during data transfer.

NOTE: Even though `MSI_CMD.STARTCMD` is set for updating clock registers, the MSI does not raise the `MSI_DONE` signal upon command completion.

Use the following procedure to program the clock-related registers.

1. Confirm that the card is not engaged in any transaction; if there is a transaction, wait until it finishes.
2. Stop all clocks by writing 0 to the `MSI_CLKEN` register.
3. Set the `MSI_CMD.STARTCMD`, `MSI_CMD.UCLKREGS`, and the `MSI_CMD.WTPRIVDATA` bits.
4. Wait until the `MSI_CMD.STARTCMD` bit is cleared or an HLE is set; in case of an HLE, repeat the command.
5. Program the `MSI_CLKDIV` register.

6. Set the `MSI_CMD.STARTCMD`, `MSI_CMD.UCLKREGS`, and `MSI_CMD.WTPRIVDATA` bits.
7. Wait until the `MSI_CMD.STARTCMD` is cleared or an HLE is set; in case of an HLE, repeat the command.
8. Re enable all clocks by programming the `MSI_CLKEN` register.
9. Set the `MSI_CMD.STARTCMD`, `MSI_CMD.UCLKREGS`, and the `MSI_CMD.WTPRIVDATA` bits.
10. Wait until the `MSI_CMD.STARTCMD` bit is cleared or a HLE is set; in case of a HLE, repeat the command.

Sending Non-Data Commands With or Without a Response Sequence

To send any non-data command, the software must program the `MSI_CMD` register and the `MSI_CMDARG` register with appropriate parameters. Using these two registers, the MSI forms the command and sends it to the command bus. The MSI reflects the errors in the command response through the error bits of the `MSI_ISTAT` register. The ***Command Register Settings for No-Data Command*** table shows the `MSI_CMD` bit settings.

When the MSI receives a response, either erroneous or valid, it sets the `MSI_ISTAT.CMDDONE` bit. A short response is copied in the `MSI_RESP0` register, while a long response is copied to all four response registers. The `MSI_RESP3` register bit 31 represents the MSB, and the `MSI_RESP0` register bit 0 represents the LSB of a long response.

Table 26-11: Command Register Settings for No-Data Command

Parameter	Value	Comment
Default		
start_cmd	1	
use_hold_reg	1/0	Choose value based on speed mode in use; refer to "MSI Register Descriptions"
update_clk_regs_only	0	No clock parameters update command
data_expected	0	No data command
card_number	*n*CardNo	Actual card number
cmd_index	command index	
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
response_length	0	Can be 1 for R2 (long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
user-selectable		
wait_prvdata_complete	0	Before sending a command on a command line, the host must wait for the completion of any data command in process, if any. (It is recommended to set this bit always, unless the current command is to query status or stop data transfer when transfer is in progress)
check_response_crc	1	If host crosschecks, CRC of response received

Use the following procedure to issue basic commands or non-data commands.

1. Program the `MSI_CMD` register with the appropriate command argument parameter.
2. Program the `MSI_CMD` register with the settings in the ***Command Register Settings for No-Data Command*** table.
3. Wait for command acceptance by host. When software loads the command into the MSI:
   - The MSI accepts the command for execution and clears the `MSI_CMD.STARTCMD` bit. This process occurs unless one command is in process. Then, the MSI can load and keep the second command in the buffer.
   - If the MSI is unable to load the command, then it generates an HLE (hardware locked error). (For example, a command is already in progress, a second command is in the buffer, and a third command is attempted).
4. Check if there is an HLE.
5. Wait for command execution to complete. After receiving either a response from a card or response timeout, the MSI sets the `MSI_ISTAT.CMDDONE` bit. Software can either poll for this bit or respond to a generated interrupt.
6. Check if the response timeout error, response CRC error, or response error is set. This confirmation can be done either by responding to an interrupt raised by these errors or by polling bits RE, RCRC, and RTO from the `MSI_ISTAT` register. If no response error is received, then the response is valid. If necessary, the software can copy the response from the response registers. Software must not modify clock parameters while a command is executing.

Single-Block or Multiple-Block Read

Use the following procedure to perform a single-block or multiple-block read.

1. Write the data size in bytes in the `MSI_BYTCNT` register.
2. Write the block size in bytes in the `MSI_BLKSIZ` register.

   ADDITIONAL INFORMATION: The MSI expects data from the card in blocks of size BLKSIZ each.
3. If card has a round-trip delay of more than 0.5 card clock period, program the `MSI_CDTHRCTL.RDTHR` bit field. The programming ensures that the card clock does not stop in the middle of a block of data transferring from the card to the host.

   ADDITIONAL INFORMATION: For programming guidelines, refer to the Card Read Threshold section. If the card read threshold feature is not enabled for such cards, then the program must ensure that the Rx FIFO does not become full during a read data transfer. The Rx FIFO must drain out at a rate faster than the rate that data is pushed into the FIFO.

4. Program the MSI_CMDARG register with the data address of the beginning of a data read. Program the MSI_CMD register with the parameters listed in the ***Command Register Settings for Single-Block or Multiple-Block Read*** table.

   ADDITIONAL INFORMATION: For SD and MMC cards, use CMD17 for a single-block read and CMD18 for a multiple-block read. For SDIO cards, use CMD53 for both single-block and multiple-block transfers.

   After writing to the MSI_CMD register, the MSI starts executing the command. When the command is sent to the bus, the CMDONE interrupt is generated.

5. Software looks for data error interrupts on bits 7, 9, 13, and 15 of the MSI_ISTAT register. If required, software can terminate the data transfer by sending a STOP command.

6. Software or the DMA looks for a receive FIFO data request or data starvation by host timeout conditions. In both cases, the DMA reads data from the FIFO and makes space in the FIFO for receiving more data.

When all the data is received, a DTO (Data Transfer Over) interrupt is generated.

Table 26-12: Command Register Settings for Single-Block or Multiple-Block Read

Parameter	Value	Comment
Default		
start_cmd	1	
use_hold_reg	1/0	Choose value based on speed mode in use; refer to “MSI Register Descriptions”
update_clk_regs_only	0	No clock parameters update command
card_number	*n*CardNo	Actual card number
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
send_auto_stop	0 or 1	See Auto-Stop
transfer_mode	0	Block transfer
read_write	0	Read from card
data_expected	1	Data command
response_length	0	Can be 1 for R2 (long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
user-selectable		
cmd_index	command index	Can be 1 for commands to stop data transfer, such as CMD12
wait_prvdata_complete	1	0 = sends command immediately. 1 = sends command after previous data transfer ends

Table 26-12: Command Register Settings for Single-Block or Multiple-Block Read (Continued)

Parameter	Value	Comment
check_response_crc	1	0 = MSI does not check response CRC 1 = MSI checks response CRC

Single-Block or Multiple-Block Write

Use the following procedure to perform a single-block or multiple-block write.

1. Write the data size in bytes in the `MSI_BYTCNT` register.
2. Write the block size in bytes in the `MSI_BLKSIZ` register.

   ADDITIONAL INFORMATION: The MSI sends data in blocks of size BLKSIZ each.
3. Program `MSI_CMDARG` register with the data address to which data is written.
4. Write data in the FIFO; it is best to start filling data the full depth of the FIFO.
5. Program the `MSI_CMD` register with the parameters listed the ***Command Register Settings for Single-Block or Multiple-Block Read*** table.

   ADDITIONAL INFORMATION: For SD and MMC cards, use CMD24 for a single-block write and CMD25 for a multiple-block write. For SDIO cards, use CMD53 for both single-block and multiple-block transfers. After writing to the `MSI_CMD` register, the MSI starts executing a command; when the command is sent to the bus, a CMDONE interrupt is generated.
6. Software looks for data error interrupts in the `MSI_ISTAT.DCRC`, `MSI_ISTAT.DRTO`, and `MSI_ISTAT.EBE` bits. If necessary, software can terminate the data transfer by sending the STOP command.
7. Software looks for a transmit FIFO data request or timeout conditions from data starvation by the host. In both cases, the software or the DMA writes data into the FIFO.
8. When a DTO interrupt is received, the data command is over. For an open-ended block transfer, if the byte count is 0, the software must send the STOP command. If the byte count is not 0, then on completion of a transfer of a given number of bytes, the MSI sends the STOP command, if necessary. The `MSI_ISTAT.ACD` bit reflects the completion of the AUTO-STOP command. A response to AUTO_STOP is stored in the `MSI_RESP1` register.
9. Wait for the busy clear interrupt.

The card can drive the busy clear interrupt on the DAT line; the host controller generates the interrupt after the busy is completed.

Table 26-13: Command Register Settings for Single-Block or Multiple-Block Write

Parameter	Value	Comment
Default		
start_cmd	1	
use_hold_reg	1 or 0	Choose value based on speed mode in use; refer to "MSI Register Descriptions"
update_clk_regs_only	0	No clock parameters update command
card_number	*n*CardNo	Actual card number
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
send_auto_stop	0 or 1	See Auto-Stop
transfer_mode	0	Block transfer
read_write	1	Write to card
data_expected	1	Data command
response_length	0	Can be 1 for R2 (long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
User-selectable		
cmd_index	command index	Can be 1 for commands to stop data transfer, such as CMD12
wait_prvdata_complete	1	0 – sends command immediately 1 – sends command after previous data transfer ends
check_response_crc	1	0 – MSI does not check response CRC 1 – MSI checks response CRC

Stream Reads and Writes

Stream reads and writes are like the block reads and writes described in the previous sections except for the following bits in the `MSI_CMD.XFRMODE` register:

- For reads, the transfer mode (`MSI_CMD.XFRMODE` bit) =1 and the command index =CMD20.
- For writes, the transfer mode (`MSI_CMD.XFRMODE` bit) =1 and the command index =CMD11.

In a stream transfer, if the byte count is 0, then the software must send the STOP command. If the byte count is not 0, when a given number of bytes completes a transfer, the MSI sends the STOP command

Packed Commands

In order to reduce overhead, read and write commands can be packed in groups of commands. The groups are either all read or all write. The software transfers the data for all commands in the group in one transfer on the bus.

Packed commands can be of two types:

- Packed write – CMD23 > CMD25
- Packed read – CMD23 > CMD25 >CMD23 > CMD18

The application software puts packed commands in packets. The packets are transparent to the core. For more information on packed commands, refer to the eMMC specification.

Sending Stop or Abort in Middle of Transfer

The STOP command can terminate a data transfer between a memory card and the MSI. The ABORT command can terminate an I/O data transfer for only the SDIO_IOONLY and SDIO_COMBO cards.

- Send STOP command. Can be sent on the command line while a data transfer is in-progress. This command can be sent at any time during a data transfer. For information on sending this command, refer to Sending Non-Data Commands With or Without a Response Sequence. Programs can use an extra setting for this command to set the `MSI_CMD` register bits (5–0) to CMD12 and set the `MSI_CMD.STPABORTCMD` bit to 1. If the `MSI_CMD.STPABORTCMD` bit is not set to 1, the MSI does not know that the program stopped a data transfer. Reset the `MSI_CMD.WTPRIVDATA` bit to 0 in order to make the MSI send the command at once, even though there is a data transfer in progress.
- Send ABORT command. Can be used with only an SDIO_IOONLY or SDIO_COMBO card. To abort the function that is transferring data, program the function number in ASx bits (CCCR register of card, address 0x06, bits (0–2)) using CMD52. This command is a non-data command. For information on sending this command, refer to Sending Non-Data Commands With or Without a Response Sequence.

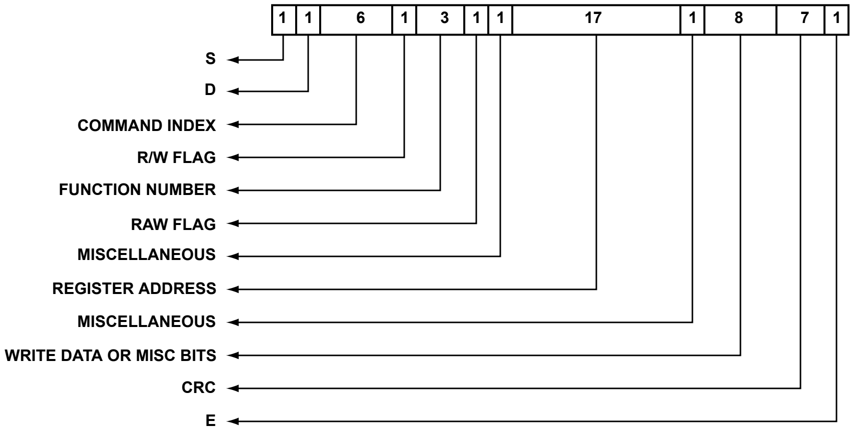


Figure 26-11: Command Format for CMD52

1. Program the `MSI_CMDARG` register with the appropriate command argument parameters listed in the ***Parameters for CMDARG Register*** table.
2. Program the `MSI_CMD` register using the command index as CMD52. Similar to the STOP command, set the `MSI_CMD.STPABORTCMD` bit =1, to inform the MSI that the program aborted the data transfer. Reset the

`MSI_CMD.WTPRIVDATA` bit =0 in order to make the MSI send the command at once, even though a data transfer is in progress.

3. Wait for command transfer over.
4. Check response (R5) for errors.

Table 26-14: Parameters for CMDARG Register

MSI_CMDARG Bits	Contents	Value
31	R/W flag	1
30–28	Function number	0 = for CCCR access
27	RAW flag	1 = if needed to read after write
26	Do-not-care	N/A
25-9	Register address	0x06
8	Do-not-care	N/A
7–0	Write data	Function number to be aborted

Suspend or Resume Sequence

In an SDIO card, the data transfer between an I/O function and the MSI can be temporarily halted using the SUSPEND command. This command can be necessary to perform a high-priority data transfer with another function. When desired, the data transfer can be resume using the RESUME command.

The following functions can be implemented by programming the appropriate bits in the CCCR register of the SDIO card. To read from or write to the CCCR register, use the CMD52 command.

1. SUSPEND data transfer – Non-data command.
    a. Check if the SDIO card supports the SUSPEND or RESUME protocol; this verification can be done through the SBS bit in the CCCR @0x08 register of the card.
    b. Check if the data transfer for the required function number is in process; the function number that is currently active is reflected in bits 0–3 of the CCCR register @0x0D. If the BS (bus status) bit is 1, then only the function number given by the FSx bits is valid.
    c. To suspend the transfer, set BR (bit 2) of the CCCR register @0x0C.
    d. Poll for clear status of bits BR (bit 1) and BS (bit 0) of the CCCR @0x0C. The BS bit is 1 when the currently selected function uses the data bus; the BR (bus release) bit remains 1 until the bus release is complete. When the BR and BS bits =0, the data transfer from the selected function has been suspended.
    e. During a read-data transfer, the MSI can be waiting for the data from the card. If the data transfer is a read from a card, then the MSI must be informed after the successful completion of the SUSPEND command. The MSI then resets the data state machine and comes out of the wait state. To achieve this state, set the `MSI_CTL.RDABORT` bit.

   f. Wait for data completion. Get pending bytes to transfer by reading the `MSI_TCBCNT` register.
   g. For a write data transfer, wait for the busy clear interrupt after the Data Transfer Over (DTO) interrupt.

2. RESUME data transfer – This command is a data command.
   a. Check that the card is not in a transfer state, which confirms that the bus is free for data transfer.
   b. If the card is in a disconnect state, select it using CMD7. The card status can be retrieved in response to CMD52/CMD53 commands.
   c. Check that a function to be resumed is ready for data transfer. Confirm the readiness by reading the RFx flag in CCCR @0x0F. If RF =1, then the function is ready for data transfer.
   d. To resume the transfer, use CMD52 to write the function number at the FSx bits (0–3) in the CCCR register @0x0D. Form the command argument for CMD52 and write it in the `MSI_CMDARG` register. The ***Parameters for CMDARG Register*** table lists the bit values.
   e. Write the block size in the `MSI_BLKSIZ` register. Data transfers in units of this block size.
   f. Write the byte count in the `MSI_BYTCNT` register. This amount is the total size of the data; that is, the remaining bytes for transfer. It is the responsibility of the software to handle the data.
   g. Program the `MSI_CMD` register similarly to a block transfer. For details, refer to the block read and write sections.
   h. When the `MSI_CMD` register is programmed, the command is sent and the function resumes data transfer. Read the DF flag (Resume Data Flag). If it is 1, then the function has data for the transfer and begins a data transfer as soon as the function or memory is resumed. If it is 0, then the function has no data for the transfer.
   i. If the DF flag is 0, the MSI waits for data for a read. After the data timeout period, it gives a data timeout error.

Table 26-15: Parameters for CMDARG Register

CMDARG Bits	Contents	Value
31	R/W flag	1
30–28	Function number	0 = for CCCR access
27	RAW flag	1 = read after write
26	Do-not-care	N/A
25-9	Register address	0x0D
8	Do-not-care	N/A
7–0	Write data	Function number that is to be resumed

Read Wait Sequence

Read_wait is used only with SDIO cards. It can temporarily stall the data transfer either from function or memory and allow the host to send commands to any function within the SDIO device. The host can stall this transfer for as long as required. The MSI provides the facility to signal this stall transfer to the card.

1. Check if the card supports the read_wait facility; read SRW (bit 2) of the CCCR register in SDIO card. If this bit is 1, then all functions in the card support the read_wait facility. Use CMD52 to read this bit.
2. If the card supports the read_wait signal, then assert it by setting the `MSI_CTL.RDWAIT` bit.
3. Clear the `MSI_CTL.RDWAIT` bit.

Card Read Threshold

When an application must perform a single or multiple block read command, the application must program the `MSI_CDTHRCTL` register with the appropriate card read threshold size. It also must set the card `MSI_CDTHRCTL.RDTHREN` (read threshold enable) bit. This additional programming ensures that the controller sends a read command only if there is space equal to the `MSI_CDTHRCTL.RDTHR` (card read threshold) available in the Rx FIFO. This programming in turn ensures that the card clock is not stopped in the middle a block of data being transmitted from the card. The card read threshold can be set to the block size of the transfer. This size guarantees that there is a minimum of one block size of space in the Rx FIFO before the controller enables the card clock.

Recommended Usage Guidelines for Card Read Threshold

1. Program the `MSI_CDTHRCTL` register before the programming the CMD register for a data read command.
2. Do not program the `MSI_CDTHRCTL` register when a data transfer command is in progress.
3. Program the `MSI_CDTHRCTL.RDTHR` value greater than or equal to the block size of the read transfer. This programming ensures that the card clock does not stop in between a block of data.
4. If round-trip delay > 0.5 card clock, then enable the card read threshold and program the card threshold as per guideline #3. This programming guarantees that the card clock does not stop in between a block of data. The controller samples data incorrectly if the card clock stops in between a block of data if round-trip delay > 0.5 card clock.
5. `MSI_CDTHRCTL.RDTHR` is greater than or equal to `MSI_BLKSIZ` (recommended). Program the card read threshold size (`MSI_CDTHRCTL.RDTHR`) to at least 1 × BlockSize of the multi-block transfer. This programming guarantees that the card clock does not stop in between a block of data due to the Rx FIFO becoming full during the read transfer.
6. `MSI_CDTHRCTL.RDTHR` is less than `MSI_BLKSIZ`. If the `MSI_CDTHRCTL.RDTHR` bit is programmed to less than the `MSI_BLKSIZ` of the transfer, then the system must ensure that the receive FIFO never becomes full and overflows during the read transfer. This programming can cause the card clock from the MSI to stop. The MSI is not able to guarantee that the card clock does not stop during a read transfer.

NOTE: If the `MSI_CDTHRCTL.RDTHR`, `MSI_FIFOTH.RXWM`, and `MSI_FIFOTH.DMAMSZ` values are programmed incorrectly, then the card clock can stop indefinitely and no interrupts are generated from the controller.

Card Read Threshold Programming Sequence

Most cards, such as SDHC or SDXC, typically support block sizes that are specified in the card or are fixed to 512 bytes. For SDIO cards, standard capacity SD cards that support READ_BL_PARTIAL =1 and MMC cards, the block size is variable. The application can choose block size.

Use the following steps for the card read threshold feature. The steps guarantee that the card clock does not stop because of a FIFO full condition in the middle of a block of data being read from the card.

1. Choose the block size (configured using the `MSI_BLKSIZ` register). The block size requested by the application from the card for the read transfer card must be 32-bit aligned.
2. Enable the card read threshold feature. The card read threshold can be enabled only if the block size for the given transfer is less than the total depth of the FIFO (*BlkSiz* ≤ *FifoDepth*)

   Where: *BlkSiz* = (block size in bytes) × 8 ÷ 32; that is, the number of the block size in terms of FIFO locations

   FifoDepth = total number of FIFO locations.
3. Choose the card read threshold.
   - If *BlkSiz* ≥ ½ *FifoDepth*, configure `MSI_CDTHRCTL.RDTHR` such that the value ≤ *BlkSize* in bytes
   - If *BlkSiz* < ½ *FifoDepth*, configure `MSI_CDTHRCTL.RDTHR` such that the value = *BlkSize* in bytes
4. Choose the DMA multiple transaction size using the `MSI_FIFOTH.DMAMSZ` bit field. The possible values for the bit fields are 1, 4, 8, 16, 32, 64, 128, and 256 transfers. Choose the value of `MSI_FIFOTH.DMAMSZ` from the transfer values so that BlkSiz is a multiple of DMAMSZ. BlkSize% (DMAMSZ) = 0. Note the following special cases:
   - When an MSIZE transfer =1 (configured using the `DMA_CFG.MSIZE` bit field). The `MSI_FIFOTH.DMAMSZ` is equal to 1 when the block size chosen in Step 1 is not a multiple of the FIFO width (in bytes). If DMAMSZ =1 is not acceptable and a higher burst size is desired-that is, a higher DMAMSZ. Return to Step 1 and recalculate the block size.
   - Internal DMA (IDMAC). The size of the data buffer (in bytes) for each descriptor must be a multiple of DMAMSZ × 4.
5. Choose the RX watermark using the `MSI_FIFOTH.RXWM` bit field.

   If DMAMSZ = 1, then the RXWM = 1 or RXWM = BlkSize – 1

   Additionally, for all DMA modes the RXWM must be a multiple of the chosen DMAMSZ.

MSI Programming Model, Boot Operation

This section discusses details on programming the MSI for boot operation.

Normal Boot Operation

Normal boot operation is applicable to MMC4.3, MMC4.4, and MMC4.41 cards. It is performed in push-pull mode. The *Normal Boot Timing* figure shows the timing for the transmit state machine in a normal boot mode.

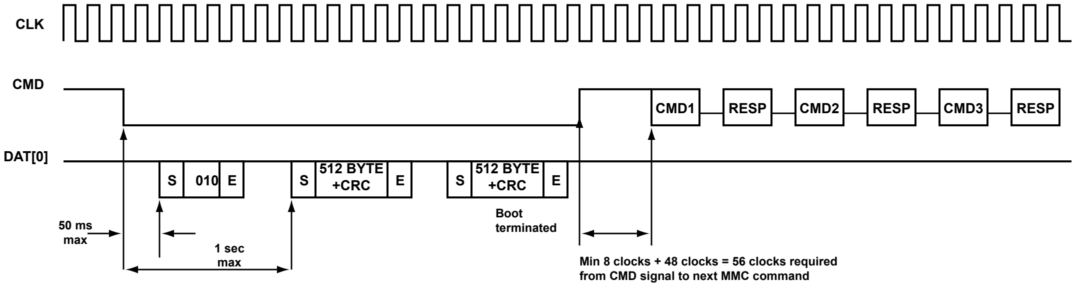

Figure 26-12: Normal Boot Timing

Normal Boot Operation; eMMC

Normal boot operation is applicable to MMC4.3, MMC4.4, and MMC4.41 cards. It must be performed in push-pull mode. See the *Normal Boot Timing* figure.

Software must adhere to the following steps when working with eMMC or removable MMC 4.3 cards for boot operation. Note that the software knows that the card supports boot operation (the BOOT_PARTITION_ENABLE bit set) in the card.

The software also knows the BOOT_SIZE_MULT value in the card and the data bus width to use during boot operation: cExtend CSD register byte [177] bit[0:1].

1. Set the masks for interrupts by clearing appropriate bits in the `MSI_IMSK` register.
2. Set the `MSI_CTL.INTEN` bit. Before this bit is set, programs should write 0xFFFF_FFFF to the `MSI_ISTAT` and `MSI_IDSTS` registers to clear any pending interrupts. For internal DMAC, unmask all the relevant fields in the `MSI_IDINTEN` register.
3. Set the and `MSI_CTL.INTEN` bits =1. In order to use the internal DMAC to transfer the boot data received, it must also set up the descriptors and program the `MSI_CTL.INTDMAC` bit =1.
4. Set the card frequency to 400 kHz using the clock-divider register.
5. Set Data Time Out = $(10 \times ((TAAC \times f_{OP}) + (100 \times NSAC))$; this is NAC.
6. Program the `MSI_BLKSIZ` register with 0x200 (512 bytes).
7. Program the `MSI_BYTCNT` register with multiples of 128K bytes, as indicated by the BOOT_SIZE_MULT value in the card.

8. Program the Rx FIFO threshold value in bytes in the `MSI_FIFOTH` register. Typically, the threshold value can be set to half the FIFO depth.
9. Program the following fields: `MSI_CMD.STARTCMD` =1'b1, `MSI_CMD.BOOTEN` =1'b1, `MSI_CMD.XPECTBOOTACK` (for start-acknowledge pattern ACK from the card) and `MSI_CMD.DXPECT` =1'b1.
10. If `MSI_CMD.XPECTBOOTACK` =1'b1, the software driver must start a timer after step 9; the terminal value is 50 ms.
    - Before this timer elapses, the BAR interrupt should be received from the MSI. If this action does not occur, program the CMD register as follows:

      `MSI_CMD.STARTCMD` =1'b1

      `MSI_CMD.BOOTDIS` =1'b1

      All other fields = 0
    - The MSI generates a Command Done (CD) interrupt after de-asserting the CMD line of the card. In IDMAC:

      Descriptor is closed

      `MSI_IDSTS.CES` =1, indicating BAR timeout

      `MSI_IDSTS.RI` =0
    - If the BAR interrupt is received, the software should clear this interrupt by writing a 1 to it. The software should then start another timer with a terminal value of 1 – 0.05 = 0.95 seconds. Before this timer elapses, the BDS interrupt should be received from the MSI. If this action does not occur, the software driver must program the CMD register as follows:

      `MSI_CMD.STARTCMD` =1'b1

      `MSI_CMD.BOOTDIS` =1'b1

      All other fields =0
    - The MSI generates a CD interrupt after de-asserting the CMD line of the card. In IDMAC:

      Descriptor is closed

      `MSI_IDSTS.CES` =1, indicating BDS timeout

      `MSI_IDSTS.RI` =0
    - If the BDS interrupt is received, it indicates that the boot data is being received from the card. The IDMAC engine starts transferring the data from the FIFO to the system memory as soon as the programmed RX_WMark level is attained. At the end of a successful boot data transfer from the card, the following interrupts are generated:

      Command Done (CD) with the `MSI_ISTAT.CMDDONE` bit

Data Transfer Over (DTO) with the `MSI_ISTAT.DTO` bit

Receive Interrupt (RI) with the `MSI_IDSTS.RI` bit

- If an error occurs in Boot Ack pattern (010) or an end bit error occurs

  Controller automatically aborts boot by pulling CMD line high

  Controller generates CD interrupt

  Controller does not generate BAR interrupt

  Application aborts boot transfer

- In IDMAC:

  If the software creates more descriptors than the boot data received, the MSI does not close the extra descriptors.

  If the software creates less descriptors than the boot data received, the MSI generates a Descriptor Unavailable (DU) interrupt and does not transfer any further data to system memory.

- If between data block transfers NAC is violated, DRTO (Data Read Timeout) is asserted. If there are errors associated with start or end bits, SBE/EBE interrupts are also generated.

11. If `MSI_CMD.XPECTBOOTACK` =1'b0, the software should start a timer after the step 9 where the terminal value is 1 second.

    - Before this timer elapses, a BDS interrupt should be received from the MSI. If the interrupt is not received, the software must program their CMD register with the following fields:

      `MSI_CMD.STARTCMD` =1'b1

      `MSI_CMD.BOOTDIS` =1'b1

      All other fields =0

    ADDITIONAL INFORMATION: MSI generates a CD interrupt after de-asserting the CMD line of the card. In IDMAC mode, the descriptor is closed and the `MSI_IDSTS.CES` bit =1, indicating a BDS timeout.

    - If a BDS interrupt is received, it indicates that the boot data is being received from the card. At the end of a successful boot data transfer from card, the following interrupts are generated.

      Command Done (CD) with the `MSI_ISTAT.CMDDONE` bit

      Data Transfer Over (DTO) with the `MSI_ISTAT.DTO` bit

      Receive Interrupt (RI) with the `MSI_IDSTS.RI` bit

Normal Boot Operation; Removable MMC4.3, MMC4.4, and MMC4.41 Cards

Removable MMC4.3, MMC4.4, and MMC4.41 cards are different than eMMC in that the software is not aware whether these cards support the boot mode of operation when plugged in. Thus, the software must:

- Enumerate these cards as it would enumerate MMC4.0/4.1/4.2 cards for the first time
- Know the card characteristics
- Decide whether to perform a boot operation or not

Use the following procedure when booting with these card types,

1. Enumerate the card.
2. Read the EXT_CSD register of the card and examine the following fields:
    - BOOT_PARTITION_ENABLE
    - BOOT_SIZE_MULT
    - BOOT_INFO
3. If necessary, the controller can manipulate the boot information in the card.
4. If the controller must perform a boot operation at the next power-up cycle, it can manipulate the EXT_CSD register contents by using a SWITCH (CMD6) command.
5. From this point, use the same steps as in Normal Boot Operation; eMMC.

Alternate Boot Operation; eMMC

The alternate boot operation differs from the normal boot operation in that CMD0 is used to boot the card rather than holding down the CMD-line of the card. The alternate boot operation can occur only if bit 0 in the extended CSD byte[228] (BOOT_INFO) is set to 1.

Figure 26-13: Alternate Boot Timing

Use the following procedure when working with eMMC or removable MMC 4.3 cards for the alternative boot operation. The software is aware that the card supports the Alternate Boot operation—the BOOT_INFO bit is set in the card. Also, the software is aware of the BOOT_SIZE_MULT value in the card and the data bus width to use during the boot operation-extend CSD register byte[177] bit[0:1].

1. Set the masks for interrupts by clearing appropriate bits in the Interrupt Mask register.
2. Set the `MSI_CTL.INTEN` bit =1.

ADDITIONAL INFORMATION: Set the `MSI_CTL.INTEN` bit. Before this bit is set, programs should write 0xFFFF_FFFF to the `MSI_ISTAT` and `MSI_IDSTS` registers to clear any pending interrupts. Software also must unmask all the relevant fields in `MSI_IDINTEN` register.

3. Configure the following bits in the control register.
    a. `MSI_CTL.INTEN` = 1'b1
    b. Other fields are 1'b0
    c. For IDMAC, set up the descriptors.
    d. Program the `MSI_CTL.INTDMAC` bit to 1
4. Set the card frequency to 400 kHz using the clock-divider register

    ADDITIONAL INFORMATION: Wait for a time that ensures that at least 74 card clock cycles have occurred on the card interface.
5. Set Data Time Out = (10 × ((TAAC × f_{OP}) + (100 × NSAC)); this is NAC
6. Program the `MSI_BLKSIZ` register with 0x200 (512 bytes).
7. Program the `MSI_BYTCNT` register with multiples of 128K bytes, as indicated by the BOOT_SIZE_MULT value in the card
8. Program the Rx FIFO threshold value in bytes in the `MSI_FIFOTH` register. Typically, the threshold value is set to half the FIFO depth; that is, `MSI_FIFOTH.RXWM` = (FIFO_DEPTH/2) – 1.
9. Program CMDARG = 0xFFFFFFFA.
10. Program the following fields.
    a. `MSI_CMD.STARTCMD` = 1'b1
    b. `MSI_CMD.BOOTMODE`= 1'b1
    c. `MSI_CMD.XPECTBOOTACK` depending on whether a start-acknowledge pattern is expected from the card.
    d. `MSI_CMD.DXPECT` = 1'b1
    e. `MSI_CMD.INDX` = 0
    f. Remainder of `MSI_CMD` register fields = 1'b0

    ADDITIONAL INFORMATION: Wait for the Command Done (CD) interrupt.
11. If `MSI_CMD.XPECTBOOTACK` = 1'b1 in step 10, the software driver must start a timer with a terminal value of 50 ms.
    a. Before this timer elapses, the BAR interrupt should be received from the MSI. If this action does not occur, the software must infer that the start-pattern has not been received and must discontinue the boot process and start with normal enumeration. In IDMAC:

  - Descriptor is closed
  - `MSI_IDSTS.CES` =1, indicating BAR timeout
  - `MSI_IDSTS.RI` =0

b. If the BAR interrupt is received, the software driver should clear this interrupt by writing a 1 to it. The software driver then starts another timer with a terminal value of 1 - 0.05 = 0.95 seconds. Before this timer elapses, the BDS interrupt should be received from the MSI. If this action does not occur, the software driver discontinues the boot process and start with normal enumeration.

  - Descriptor is closed
  - `MSI_IDSTS.CES` =1, indicating BDS timeout
  - `MSI_IDSTS.RI` =0

c. If the BDS interrupt is received, it indicates that the boot data is being received from the card. The IDMAC engine starts transferring the data from the FIFO to the system memory as soon as the programmed `MSI_FIFOTH.RXWM` level is hit.

d. It is the responsibility of the software driver to terminate the boot operation by programming the MSI to send a CMD0 by programming the registers `MSI_CMDARG` =0 and the command register bits `MSI_CMD.STARTCMD` =1, `MSI_CMD.INDX` =0, all_other_fields = 0.

e. At the end of a successful boot data transfer from the card, the following status bits are set:

  - Command Done (CD) with the `MSI_ISTAT.CMDDONE` bit
  - Data Transfer Over (DTO) with the `MSI_ISTAT.DTO` bit
  - Receive Interrupt (RI) with the `MSI_IDSTS.RI` bit

f. If an error occurs in Boot Ack pattern (010) or an end bit error occurs:

  - Controller does not generate BAR interrupt
  - Controller detects boot data start and generates BDS interrupt
  - Controller continues to receive boot data
  - Application must abort boot after receiving BDS interrupt

g. In IDMAC:

  - If the software driver creates more descriptors than the boot data received, the extra descriptors are not closed by the MSI.
  - If the software driver creates less descriptors than the boot data received, the MSI generates a Descriptor Unavailable (DU) interrupt and does not transfer any further data to system memory.

h. If between data block transfers NAC is violated, DRTO (Data Read Timeout) is asserted. Apart from this, if there are errors associated with Start/End bits, SBE/EBE interrupts are also generated.

12. If `MSI_CMD.XPECTBOOTACK` =1'b0 in Step 10, the software should start a timer after Step 10with a terminal value of 1 second.
    a. Before this timer elapses, the BDS interrupt should be received from the MSI. If this does not occur, the software driver should discontinue the boot process and start with normal enumeration. In IDMAC:
        - Descriptor is closed
        - `MSI_IDSTS.CES` =1, indicating BDS timeout
        - `MSI_IDSTS.RI` =0
    b. If the BDS interrupt is received, it indicates that the boot data is being received from the card. The IDMAC engine starts transferring the data from the FIFO to the system memory as soon as the programmed `MSI_FIFOTH.RXWM` level is hit.
    c. It is the responsibility of the software to terminate the boot operation. Software programs the MSI to send a CMD0 through the `MSI_CMDARG` register =0 and command register bits `MSI_CMD.STARTCMD` =1, `MSI_CMD.INDX` =0, and all_other_fields =0.
    d. At the end of a successful boot data transfer from card, the following interrupts are generated.
        - Command Done (CD) with the `MSI_ISTAT.CMDDONE` bit
        - Data Transfer Over (DTO) with the `MSI_ISTAT.DTO` bit
        - Receive Interrupt (RI) with the `MSI_IDSTS.RI` bit
    e. In IDMAC
        - If the software driver creates more descriptors than the boot data received, the MSI does not close the extra descriptors.
        - If the software driver creates less descriptors than the boot data received, the MSI generates a Descriptor Unavailable (DU) interrupt and does not transfer any further data to system memory.

Alternate Boot Operation; Removable MMC4.3 Card

Removable MMC4.3 cards are different than eMMC in that software is not aware whether these cards support the boot mode of operation. The software must:

- Enumerate these cards as it would enumerate MMC4.0/4.1/4.2 cards for the first time
- Know the card characteristics
- Decide whether to perform a boot operation

Use the following procedure when working with removable MMC 4.3 cards for the Alternative Boot operation.

1. Enumerate the card.
2. Read the EXT_CSD register of the card and examine the following fields:

   a. BOOT_PARTITION_ENABLE
   b. BOOT_SIZE_MULT
   c. BOOT_INFO

3. If necessary, the controller can also manipulate the boot information in the card.
4. If the host controller must perform a boot operation at the next power-up cycle, it can manipulate the EXT_CSD register contents by using a SWITCH (CMD6) command.
5. From this point, use the same steps as in Alternate Boot Operation; eMMC.

ADSP-SC58x Product Specific Information

The ADSP-SC589 MSI pins support programmable Pull-up control to prevent the pins from floating. The on-chip pulls to Data and CMD lines are programmable.

- The pullup for MSI_DATA[3:0] and MSI_CMD is controlled by the bit PUMSIDLC in PADS_PCFG0
- The pullup for MSI_DATA[7:4] is controlled by PUMSIDH bit in PADS_PCFG0

The PADS_PCFG0 register in the GPIO chapter has more details on bit assignments.

ADSP-SC58x MSI Register Descriptions

Mobile Storage Interface (MSI) contains the following registers.

Table 26-16: ADSP-SC58x MSI Register List

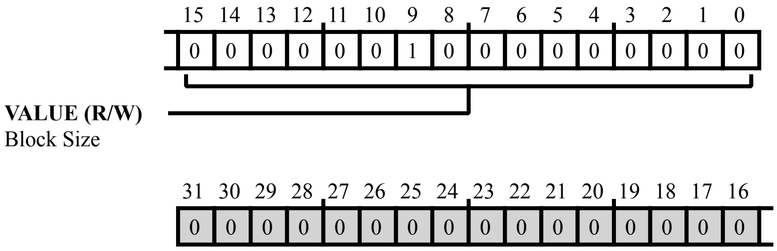
Name	Description
MSI_BLKSIZ	Block Size Register
MSI_BUFADDR	Current Buffer Descriptor Address Register
MSI_BUSMODE	Bus Mode Register
MSI_BYTCNT	Byte Count Register
MSI_CDETECT	Card Detect Register
MSI_CDTHRCTL	Card Threshold Control Register
MSI_CLKDIV	Clock Divider Register
MSI_CLKEN	Clock Enable Register
MSI_CMD	Command Register
MSI_CMDARG	Command Argument Register
MSI_CTL	Control Register
MSI_CTYPE	Card Type Register
MSI_DBADDR	Descriptor List Base Address Register

Table 26-16: ADSP-SC58x MSI Register List (Continued)

Name	Description
MSI_DEBNCE	Debounce Count Register
MSI_DSCADDR	Current Host Descriptor Address Register
MSI_ENSHIFT	Enable Phase Shift Register
MSI_FIFOTH	FIFO Threshold Watermark Register
MSI_IDINTEN	Internal DMA Interrupt Enable Register
MSI_IDSTS	Internal DMA Status Register
MSI_IMSK	Interrupt Mask Register
MSI_ISTAT	Raw Interrupt Status Register
MSI_MSKISTAT	Masked Interrupt Status Register
MSI_PLDMND	Poll Demand Register
MSI_RESP0	Response Register 0
MSI_RESP1	Response Register 1
MSI_RESP2	Response Register 2
MSI_RESP3	Response Register 3
MSI_STAT	Status Register
MSI_TBBCNT	Transferred Host to BIU-FIFO Byte Count Register
MSI_TCBCNT	Transferred CIU Card Byte Count Register
MSI_TMOUT	Timeout Register

Block Size Register

The MSI_BLKSIZ register provides bits that configure data block sizes. Sizes supported are 1 to 65,535 bytes.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 1 0 0 0 0 0 0 0 0 0

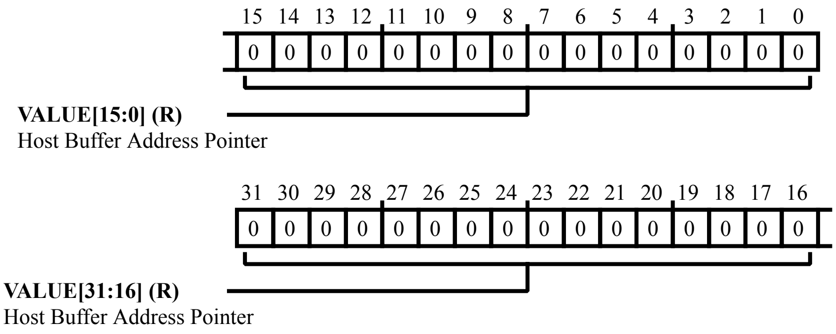
Table 26-17: MSI_BLKSIZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Block Size. The `MSI_BLKSIZ.VALUE` bit field configures data block size in bytes. Sizes supported are 1 to 65,535 bytes.

Current Buffer Descriptor Address Register

The `MSI_BUFADDR` register points to the data buffer address of the current descriptor read by the IDMAC.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R)
Host Buffer Address Pointer

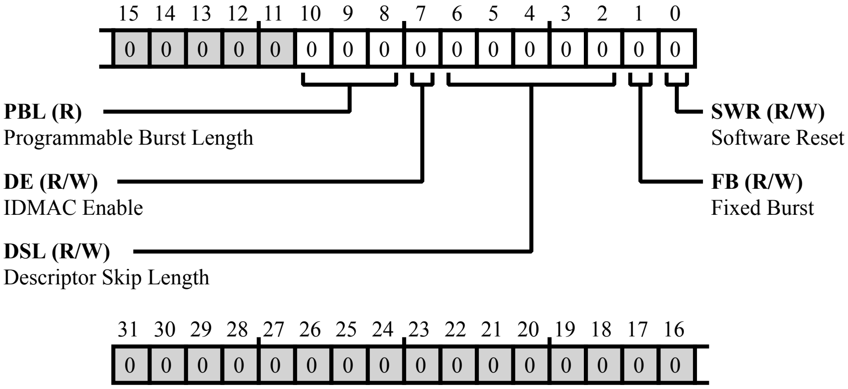
Figure 26-15: MSI_BUFADDR Register Diagram

Table 26-18: MSI_BUFADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Host Buffer Address Pointer. The `MSI_BUFADDR.VALUE` bit field points to the data buffer address of the current descriptor read by the IDMAC.

Bus Mode Register

The `MSI_BUSMODE` register provides bits that control the burst mode, descriptor skip length, and IDMAC. This register also provides a software reset bit.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 26-16: MSI_BUSMODE Register Diagram

Table 26-19: MSI_BUSMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10:8 (R/NW)	PBL	Programmable Burst Length. The `MSI_BUSMODE.PBL` bit field indicate the maximum number of beats to be performed in one IDMAC transaction. The IDMAC always attempts to burst as specified in PBL each time it starts a burst transfer on the host bus. This value is the mirror of the `MSI_FIFOTH.DMAMSZ` bits. In order to change this value, write the required value to `MSI_FIFOTH.DMAMSZ` bit field. The units for transfer are 32-bit.	
		0	1 transfer
		1	4 transfers
		2	8 transfers
		3	16 transfers
		4	32 transfers
		5	64 transfers
		6	128 transfers
		7	256 transfers
7 (R/W)	DE	IDMAC Enable. Setting the `MSI_BUSMODE.DE` bit enables the internal DMA interface.	
		0	Disable internal DMA
		1	Enable internal DMA

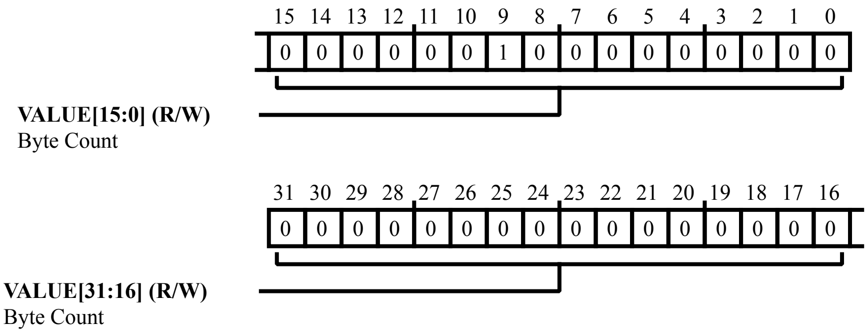
Table 26-19: MSI_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:2 (R/W)	DSL	Descriptor Skip Length. The `MSI_BUSMODE.DSL` bit field specifies the number of words to skip between two unchained descriptors. This is applicable only for dual buffer structures.	
1 (R/W)	FB	Fixed Burst. The `MSI_BUSMODE.FB` bit controls whether the peripheral bus master interface performs fixed burst transfers or not. When set, the peripheral bus uses only SINGLE, INCR4, INCR8 or INCR16 during the start of normal burst transfers. When reset, the peripheral bus uses SINGLE and INCR burst transfer operations.	
		0	Use SINGLE and INCR
		1	Use SINGLE, INCR4, INCR8 or INCR16
0 (R/W)	SWR	Software Reset. When the `MSI_BUSMODE.SWR` bit is set, the DMA controller resets all its internal registers. The `MSI_BUSMODE.SWR` bit is automatically cleared after 1 clock cycle.	
		0	No reset
		1	Reset internal registers

Byte Count Register

The MSI_BYTCNT register provides bits that configure the byte count to be transferred.

In SDIO mode, if a single transfer is greater than 4 bytes and non-DWORD-aligned, the transfer should be broken where only the last transfer is non-DWORD-aligned and less than 4 bytes. For example, if a transfer of 129 bytes must occur, then the driver should start at least two transfers; one with 128 bytes and the other with 1 byte.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 1 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Byte Count
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Byte Count

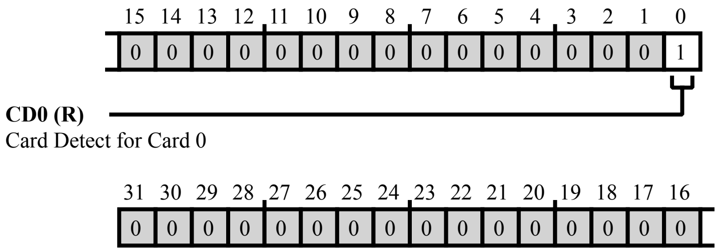
Figure 26-17: MSI_BYTCNT Register Diagram

Table 26-20: MSI_BYTCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Byte Count. The MSI_BYTCNT.VALUE bit field provides bits that configure the byte count to be transferred.

Card Detect Register

The `MSI_CDETECT` register configures the value on card_detect_n input ports (1 bit per card).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1

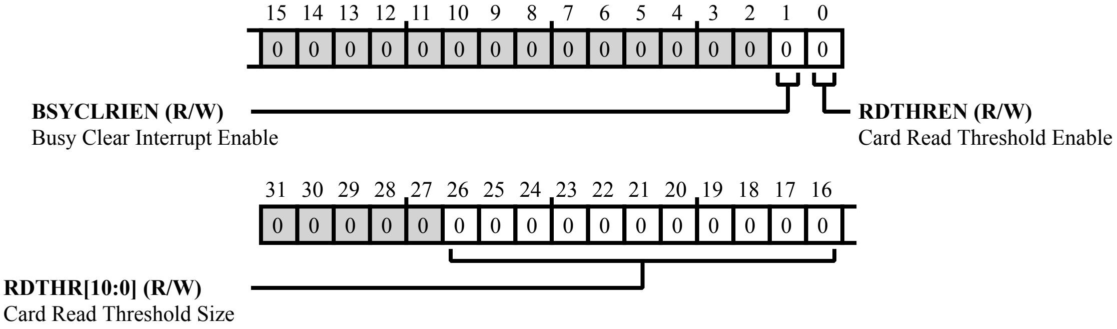
Table 26-21: MSI_CDETECT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	CD0	Card Detect for Card 0. The `MSI_CDETECT.CD0` bit sets the value on card_detect_n input ports.

Card Threshold Control Register

The `MSI_CDTHRCTL` register sets the card read threshold size and enables card read threshold. This register also has a Busy Clear interrupt generation bit.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BSYCLRIEN (R/W)
Busy Clear Interrupt Enable
RDTHREN (R/W)
Card Read Threshold Enable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RDTHR[10:0] (R/W)
Card Read Threshold Size

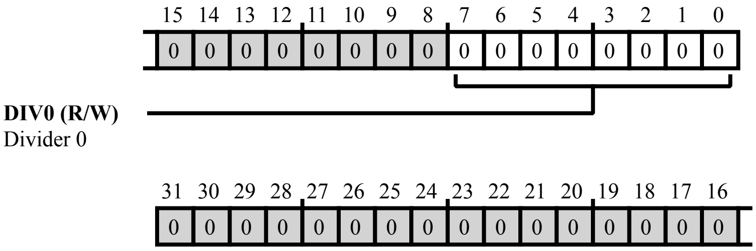
Figure 26-19: MSI_CDTHRCTL Register Diagram

Table 26-22: MSI_CDTHRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
26:16 (R/W)	RDTHR	Card Read Threshold Size. The `MSI_CDTHRCTL.RDTHR` bit configures the card read threshold size. For information on using this feature, see the "Card Read Threshold" section in the MSI chapter.	
1 (R/W)	BSYCLRIEN	Busy Clear Interrupt Enable. The `MSI_CDTHRCTL.BSYCLRIEN` bit indicates the completion of a busy driven by the card after a write data transfer.	
		0	Busy clear interrupt disabled
		1	Busy clear interrupt enabled
0 (R/W)	RDTHREN	Card Read Threshold Enable. The `MSI_CDTHRCTL.RDTHREN` bit enables the card read threshold size feature.	
		0	Card read threshold disabled
		1	Card read threshold enabled

Clock Divider Register

The `MSI_CLKDIV` register provides clock divider bit fields. The bit field value is: clock division = 2 x n.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
DIV0 (R/W)
Divider 0
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

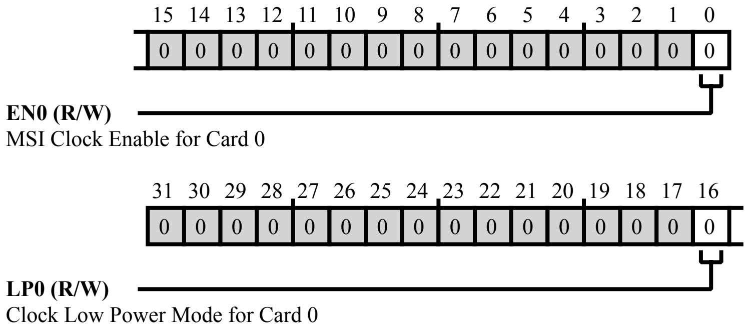
Figure 26-20: MSI_CLKDIV Register Diagram

Table 26-23: MSI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	DIV0	Divider 0. The `MSI_CLKDIV.DIV0` bit field provides clock division. The value is 2 x n. For example, a value of 0 means divide by 2 x 0 = 0 (no division, bypass), a value of 1 means divide by 2 x 1 = 2, and a value of 0xFF means divide by 2 x 255 = 510, and so on.

Clock Enable Register

The `MSI_CLKEN` register enables clock control. This register also provides low-power control for the card clock.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
EN0 (R/W)
MSI Clock Enable for Card 0
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LP0 (R/W)
Clock Low Power Mode for Card 0

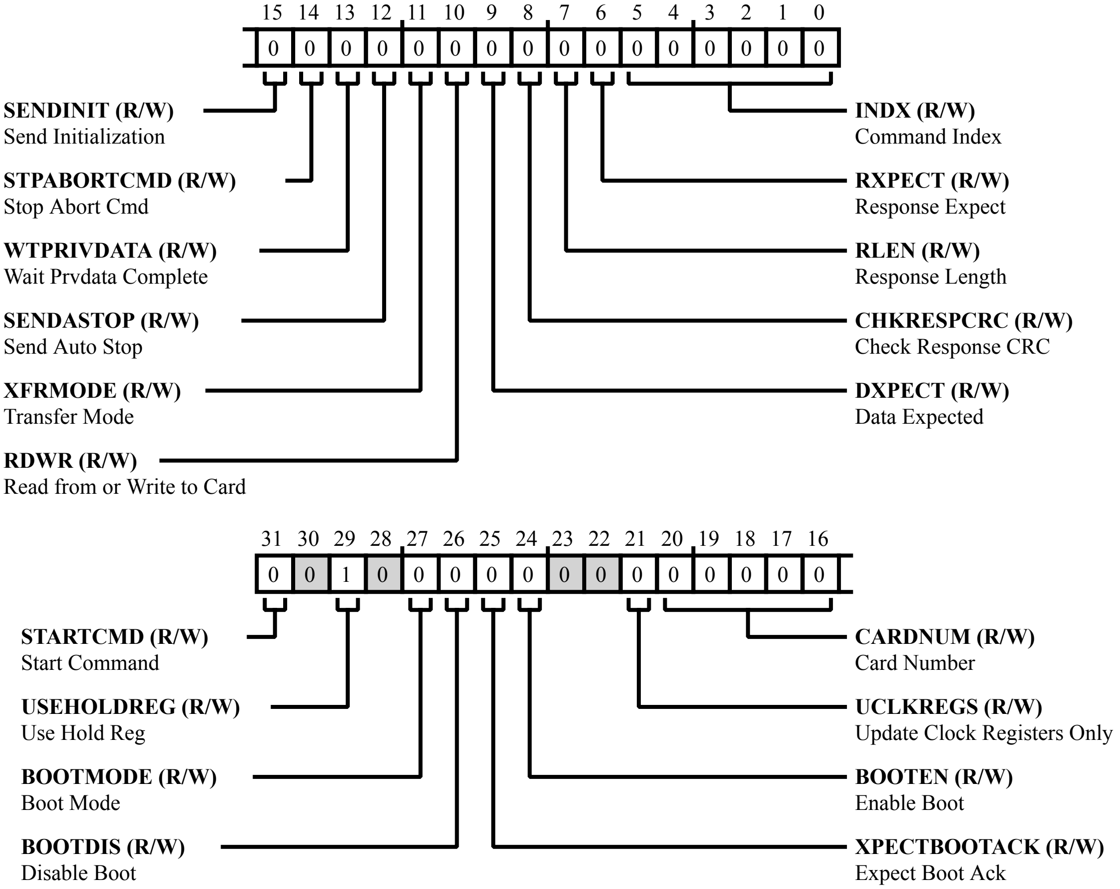
Figure 26-21: MSI_CLKEN Register Diagram

Table 26-24: MSI_CLKEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	LP0	Clock Low Power Mode for Card 0. Setting the `MSI_CLKEN.LP0` bit puts the card clock into low-power mode; it stops the clock when the card is in IDLE (it should be normally set to only MMC and SD memory cards. For SDIO cards, if interrupts must be detected, the clock should not be stopped). Clearing the `MSI_CLKEN.LP0` bit puts the cards into non-low power mode.
0 (R/W)	EN0	MSI Clock Enable for Card 0. The `MSI_CLKEN.EN0` bit is the clock-enable control for the card clock.

Command Register

The `MSI_CMD` register provides bits that configure various command parameters such as boot modes, data transfer modes, and command response settings.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SENDINIT (R/W)
Send Initialization
STPABORTCMD (R/W)
Stop Abort Cmd
WTPRIVDATA (R/W)
Wait Prvdata Complete
SENDASTOP (R/W)
Send Auto Stop
XFRMODE (R/W)
Transfer Mode
RDWR (R/W)
Read from or Write to Card
INDX (R/W)
Command Index
RXPECT (R/W)
Response Expect
RLEN (R/W)
Response Length
CHKRESPCRC (R/W)
Check Response CRC
DXPECT (R/W)
Data Expected
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0
STARTCMD (R/W)
Start Command
USEHOLDREG (R/W)
Use Hold Reg
BOOTMODE (R/W)
Boot Mode
BOOTDIS (R/W)
Disable Boot
CARDNUM (R/W)
Card Number
UCLKREGS (R/W)
Update Clock Registers Only
BOOTEN (R/W)
Enable Boot
XPECTBOOTACK (R/W)
Expect Boot Ack

Figure 26-22: MSI_CMD Register Diagram

Table 26-25: MSI_CMD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	STARTCMD	Start Command. Once the command is taken by CIU, the `MSI_CMD.STARTCMD` bit is cleared. When this bit is set, the host should not attempt to write to any command registers. If a write is attempted, a hardware lock error is set in the raw interrupt register. Once the command is sent and a response is received from the SD_MMC cards, the Command Done bit is set in the raw interrupt register.

Table 26-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	USEHOLDREG	Use Hold Reg. When the `MSI_CMD.USEHOLDREG` bit is set, CMD and DATA are sent to the card through the HOLD register. When the `MSI_CMD.USEHOLDREG` bit is cleared, CMD and DATA are sent to the card bypassing the HOLD register.	
		0	CMD and DATA sent to card bypassing the HOLD register
		1	CMD and DATA sent to card through the HOLD register
27 (R/W)	BOOTMODE	Boot Mode. When the `MSI_CMD.BOOTMODE` bit is set, the MSI has an alternate boot operation. When the `MSI_CMD.BOOTMODE` bit is cleared, the MSI has a mandatory boot operation.	
		0	Mandatory Boot
		1	Alternate Boot
26 (R/W)	BOOTDIS	Disable Boot. When the `MSI_CMD.BOOTDIS` bit is set with the `MSI_CMD.STARTCMD` bit, the CIU terminates the boot operation. Do NOT set `MSI_CMD.BOOTDIS` and `MSI_CMD.BOOTEN` together.	
		0	No action
		1	Terminate boot
25 (R/W)	XPECTBOOTACK	Expect Boot Ack. When the `MSI_CMD.XPECTBOOTACK` bit is set with with the `MSI_CMD.BOOTEN` bit, the CIU expects a boot acknowledge start pattern of 0-1-0 from the selected card.	
		0	No ACK expected
		1	ACK expected
24 (R/W)	BOOTEN	Enable Boot. The `MSI_CMD.BOOTEN` bit should be set only for mandatory boot mode. When software sets this bit along with the `MSI_CMD.STARTCMD` bit, CIU starts the boot sequence for the corresponding card by asserting the CMD line low. Do NOT set the `MSI_CMD.BOOTEN` bit and the `MSI_CMD.BOOTDIS` bit together.	

Table 26-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	UCLKREGS	Update Clock Registers Only. When the `MSI_CMD.UCLKREGS` bit is set, do not send commands. Update the clock register value into card clock domain. When cleared, the normal command sequence is used. The following register values are transferred into card clock domain: CLKDIV, and CLKENA. Changes card clocks (change frequency, truncate off or on, and set low-frequency mode); provided in order to change clock frequency or stop clock without having to send command to cards. During the normal command sequence, when update_clock_registers_only = 0, the following control registers are transferred from BIU to CIU: CMD, CMDARG, TMOUT, CTYPE, BLKSIZ, BYTCNT. CIU uses new register values for new command sequence to card(s). When the `MSI_CMD.UCLKREGS` bit is set, there are no Command Done interrupts because no command is sent to SD_MMC cards.	
		0	Normal command sequence
		1	Do not send commands, just update clock register value
20:16 (R/W)	CARDNUM	Card Number. The `MSI_CMD.CARDNUM` bit represents the physical slot number of the card being accessed.	
15 (R/W)	SENDINIT	Send Initialization. When the `MSI_CMD.SENDINIT` bit is set, send an initialization sequence before sending this command. When the `MSI_CMD.SENDINIT` bit is cleared, do not send an initialization sequence (80 clocks of 1) before sending this command. After power-on, 80 clocks must be sent to the card for initialization before sending any commands to the card. The bit should be set while sending the first command to the card, so that the controller will initialize clocks before sending a command to the card. This bit should not be set for either of the boot modes (alternate or mandatory).	
		0	Do not send initialization sequence
		1	Send initialization sequence

Table 26-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	STPABORTCMD	Stop Abort Cmd. When the `MSI_CMD.STPABORTCMD` bit is set, the stop or abort command is intended to stop the current data transfer in progress. When an open-ended or predefined data transfer is in progress, and the host issues a stop or abort command to stop the data transfer, the `MSI_CMD.STPABORTCMD` bit should be set, so that the command/data state-machines of CIU can return correctly to an idle state. This is also applicable for boot mode transfers. To abort boot mode, this bit should be set along with CMD[26] = disable_boot. When cleared, neither stop nor abort command to stop current data transfer in progress. If abort is sent to function-number currently selected or not in data-transfer mode, then the bit should be set to 0.	
		0	Neither stop nor abort command
		1	Stop or abort command
13 (R/W)	WTPRIVDATA	Wait Prvdata Complete. When the `MSI_CMD.WTPRIVDATA` bit is set, wait for the previous data transfer to complete before sending a command. When the `MSI_CMD.WTPRIVDATA` bit is cleared, send the command at once, even if the previous data transfer has not completed. The `MSI_CMD.WTPRIVDATA` = 0 option is typically used to query the status of the card during data transfer or to stop the current data transfer; the card number should be the same as in the previous command.	
		0	Send command at once
		1	Wait for previous data transfer completion
12 (R/W)	SENDASTOP	Send Auto Stop. When the `MSI_CMD.SENDASTOP` bit is set, MSI sends the stop command to SD_MMC cards at the end of the data transfer. Refer to the Auto Stop section in the chapter to determine: • When the `MSI_CMD.SENDASTOP` bit should be set, since some data transfers do not need explicit stop commands • When software should explicitly send a stop command during open-ended transfers Additionally, when resuming suspended memory access of SD-Combo card, the `MSI_CMD.SENDASTOP` bit should be set correctly to send a stop command. The bit does not need to be set if no data is expected from the card.	
		0	No stop command sent at end of data transfer
		1	Send stop command at end of data transfer

Table 26-25: MSI_CMD Register Fields (Continued)

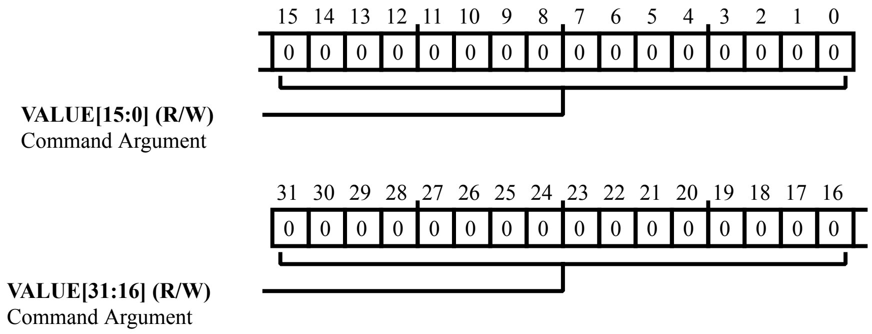
Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	XFRMODE	Transfer Mode. When the `MSI_CMD.XFRMODE` bit is set, stream data transfer command. If no data expected, do-not-care.	
		0	Block data transfer command
		1	Stream data transfer command
10 (R/W)	RDWR	Read from or Write to Card. When the `MSI_CMD.RDWR` bit is set, write to the card. When the `MSI_CMD.RDWR` bit is cleared, read from the card.	
		0	Read from card
		1	Write to card
9 (R/W)	DXPECT	Data Expected. When the `MSI_CMD.DXPECT` bit is set, data transfer is expected. When the `MSI_CMD.DXPECT` bit is cleared, no data transfer is expected.	
		0	No data transfer expected
		1	Data transfer expected
8 (R/W)	CHKRESPCRC	Check Response CRC. When the `MSI_CMD.CHKRESPCRC` bit is set, check the response CRC. When cleared, do not check the response. Some of the command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller.	
		0	Do not check response
		1	Check response
7 (R/W)	RLEN	Response Length. When the `MSI_CMD.RLEN` bit is set, a long response is expected from the card. When cleared, a short response is expected.	
		0	Short response expected
		1	Long response expected
6 (R/W)	RXPECT	Response Expect. When the `MSI_CMD.RXPECT` bit is set, a response is expected from the card. When cleared, no response is expected.	
		0	No response expected
		1	Response expected

Table 26-25: MSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/W)	INDX	Command Index.

Command Argument Register

The MSI_CMDARG register provides bits that specify the command argument to be passed to the card.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Command Argument
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Command Argument

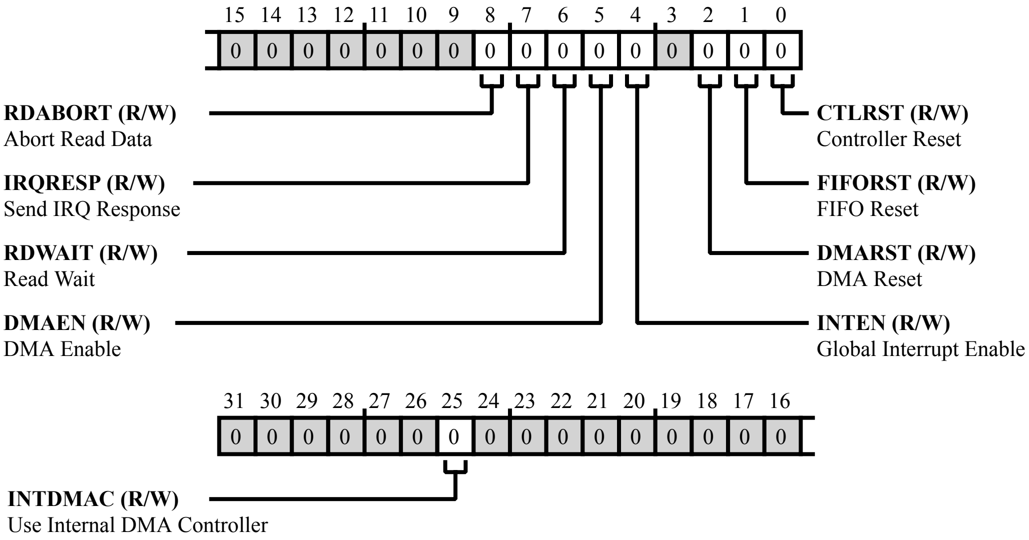
Figure 26-23: MSI_CMDARG Register Diagram

Table 26-26: MSI_CMDARG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Argument. The MSI_CMDARG.VALUE bit field specifies the command argument to be passed to the card.

Control Register

The MSI_CTL register controls the various settings used by the MSI module.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RDABORT (R/W)
Abort Read Data
IRQRESP (R/W)
Send IRQ Response
RDWAIT (R/W)
Read Wait
DMAEN (R/W)
DMA Enable
CTLRST (R/W)
Controller Reset
FIFORST (R/W)
FIFO Reset
DMARST (R/W)
DMA Reset
INTEN (R/W)
Global Interrupt Enable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
INTDMAC (R/W)
Use Internal DMA Controller

Figure 26-24: MSI_CTL Register Diagram

Table 26-27: MSI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	INTDMAC	Use Internal DMA Controller. The MSI_CTL.INTDMAC bit is present only for the internal DMAC configuration and determines whether the host or DMA is used for data transfers.	
		0	Host performs transfers
		1	DMA performs transfers
8 (R/W)	RDABORT	Abort Read Data. Setting the MSI_CTL.RDABORT bit after the suspend command is issued during a read-transfer operation, software polls the card to find out when the suspend happened. Once the suspend occurs, software sets the bit to reset data state-machine, which is waiting for next block of data. The bit automatically clears once the data state machine resets to idle. It is used in the SDIO card suspend sequence.	
		0	No change
		1	Reset data state machine

Table 26-27: MSI_CTL Register Fields (Continued)

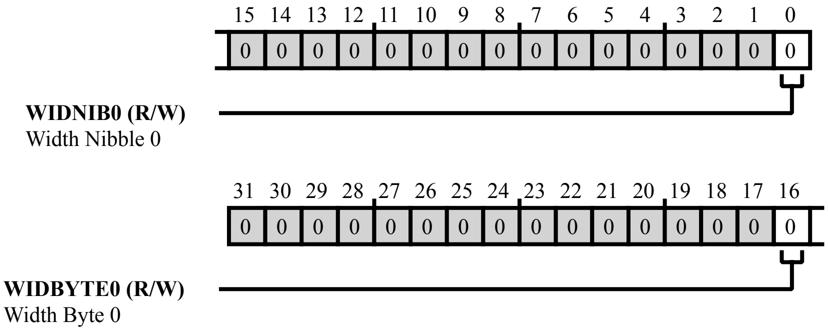
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	IRQRESP	Send IRQ Response. Setting the `MSI_CTL.IRQRESP` bit sends an auto IRQ response. It is cleared once the response is sent. To wait for MMC card interrupts, the host issues CMD40, and the MSI waits for an interrupt response from the MMC card(s). In the meantime, if the host wants the MSI to exit waiting for interrupt state, it can set the `MSI_CTL.IRQRESP` bit, at which time the MSI command state-machine sends the CMD40 response on the bus and returns to the idle state.	
		0	No change
		1	Send auto IRQ response
6 (R/W)	RDWAIT	Read Wait. Setting the `MSI_CTL.RDWAIT` bit allows sending read-wait to SDIO cards.	
		0	Clear read wait
		1	Assert read wait
5 (R/W)	DMAEN	DMA Enable. Setting the `MSI_CTL.DMAEN` bit enables DMA transfer mode.	
		0	Disable
		1	Enable
4 (R/W)	INTEN	Global Interrupt Enable. Setting the `MSI_CTL.INTEN` bit enables global interrupts. The int port is 1 only when this bit is 1 and one or more unmasked interrupts are set.	
		0	Disable
		1	Enable
2 (R/W)	DMARST	DMA Reset. Setting the `MSI_CTL.DMARST` bit resets internal DMA interface control logic. To reset the DMA interface, firmware should set this bit to 1. This bit is auto-cleared after two peripheral clocks.	
		0	No change
		1	Reset

Table 26-27: MSI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FIFORST	FIFO Reset. Setting the `MSI_CTL.FIFORST` bit provides a reset to data FIFO to reset FIFO pointers. To reset FIFO, firmware should set bit to 1. This bit is auto-cleared after completion of reset operation.	
		0	No change
		1	Reset
0 (R/W)	CTLRST	Controller Reset. Setting the `MSI_CTL.CTLRST` bit resets the MSI. To reset the controller, firmware should set the bit to 1. This bit is auto-cleared after two peripheral bus and two cclk_in clock cycles. This resets the: • BIU/CIU interface • CIU and state machines • `MSI_CTL.RDABORT`, `MSI_CTL.IRQRESP`, and `MSI_CTL.RDWAIT` bits • `MSI_CMD.STARTCMD` bit It does not affect any registers or DMA interface, or FIFO or host interrupts.	
		0	No change
		1	Reset

Card Type Register

The `MSI_CTYPE` register provides bits that configure card widths.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
WIDNIB0 (R/W)
Width Nibble 0
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
WIDBYTE0 (R/W)
Width Byte 0

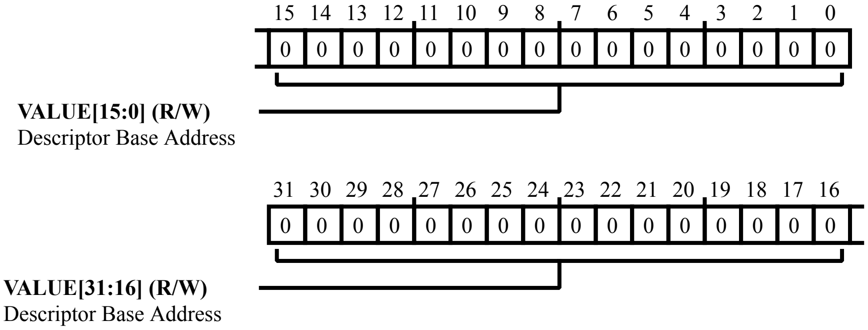
Figure 26-25: MSI_CTYPE Register Diagram

Table 26-28: MSI_CTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	WIDBYTE0	Width Byte 0. The `MSI_CTYPE.WIDBYTE0` bit enables 8-bit mode for card 0.
0 (R/W)	WIDNIB0	Width Nibble 0. The `MSI_CTYPE.WIDNIB0` bit enables 4-bit mode for card 0.

Descriptor List Base Address Register

The `MSI_DBADDR` register contains the base address of the first descriptor. The LSB bits [1:0] bits are ignored and taken as all-zero by the IDMAC internally and these LSB bits are read-only.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Descriptor Base Address
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Descriptor Base Address

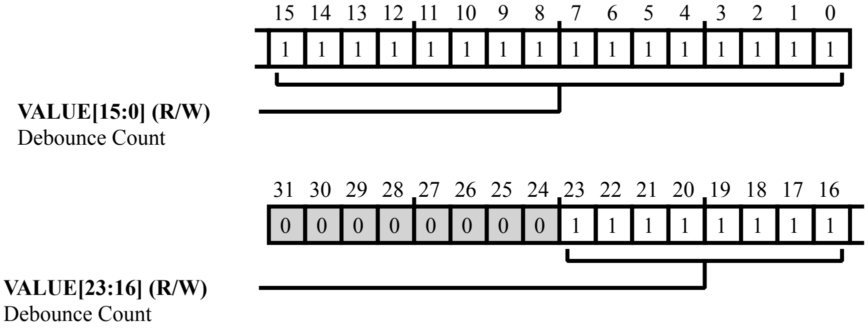
Figure 26-26: MSI_DBADDR Register Diagram

Table 26-29: MSI_DBADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Descriptor Base Address. The `MSI_DBADDR.VALUE` bit field contains the base address of the first descriptor.

Debounce Count Register

The `MSI_DEBNCE` register provides the number of host clocks (clk) used by debounce filter logic; typical debounce time is 5-25 ms.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
VALUE[15:0] (R/W)
Debounce Count
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1
VALUE[23:16] (R/W)
Debounce Count

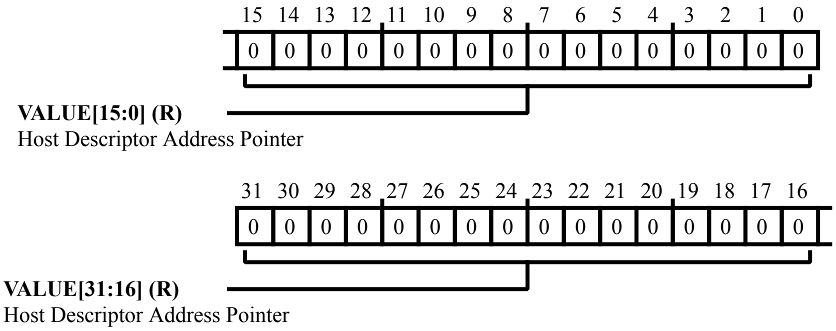
Figure 26-27: MSI_DEBNCE Register Diagram

Table 26-30: MSI_DEBNCE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/W)	VALUE	Debounce Count. The `MSI_DEBNCE.VALUE` bit field provides the number of host clocks (clk) used by debounce filter logic.

Current Host Descriptor Address Register

The MSI_DSCADDR register points to the start address of the current descriptor read by the IDMAC.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R)
Host Descriptor Address Pointer
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R)
Host Descriptor Address Pointer

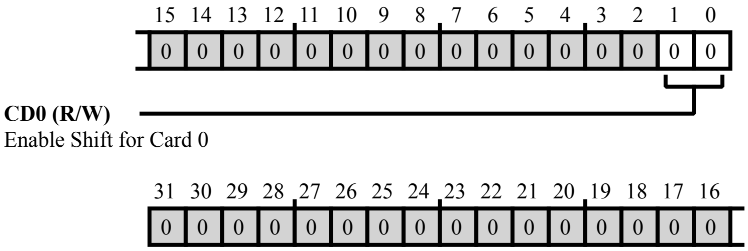
Figure 26-28: MSI_DSCADDR Register Diagram

Table 26-31: MSI_DSCADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Host Descriptor Address Pointer. The `MSI_DSCADDR.VALUE` bit field points to the start address of the current descriptor read by the IDMAC.

Enable Phase Shift Register

The `MSI_ENSHIFT` register provides control for the amount of phase shift provided on the default enables in the design. Two bits are assigned for each card/slot.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CD0 (R/W)
Enable Shift for Card 0
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

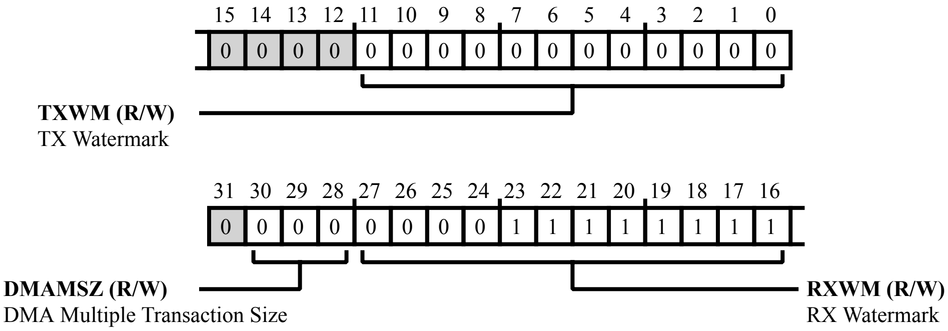
Figure 26-29: MSI_ENSHIFT Register Diagram

Table 26-32: MSI_ENSHIFT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	CD0	Enable Shift for Card 0. The `MSI_ENSHIFT.CD0` bit field provides control for the amount of phase shift provided on the default enables in the design.

FIFO Threshold Watermark Register

The MSI_FIFOTH register provides bits that manage the FIFO transactions.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TXWM (R/W)
TX Watermark
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1
DMAMSZ (R/W)
DMA Multiple Transaction Size
RXWM (R/W)
RX Watermark

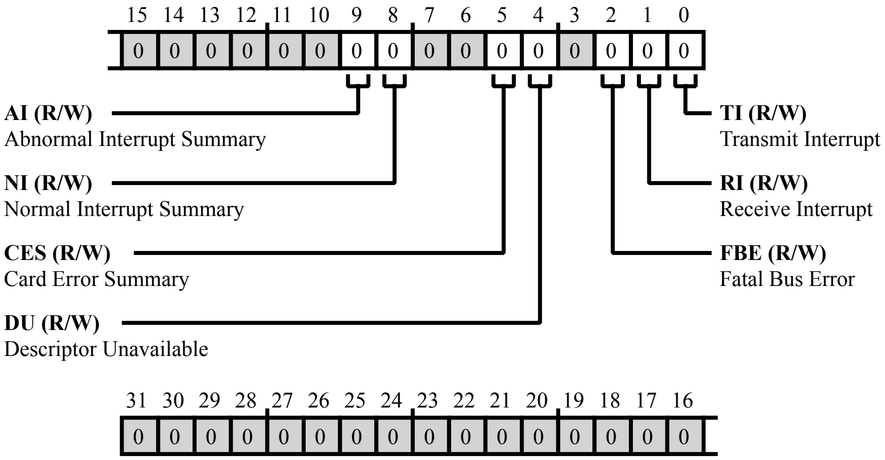
Figure 26-30: MSI_FIFOTH Register Diagram

Table 26-33: MSI_FIFOTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:28 (R/W)	DMAMSZ	DMA Multiple Transaction Size. The MSI_FIFOTH.DMAMSZ bit field configures the burst size of a multiple transaction. The units for transfer are 32-bit.	
		0	1 transfer
		1	4 transfers
		2	8 transfers
		3	16 transfers
		4	32 transfers
		5	64 transfers
		6	128 transfers
		7	256 transfers
27:16 (R/W)	RXWM	RX Watermark. The MSI_FIFOTH.RXWM bit field sets the FIFO threshold watermark level when receiving data to card. When the FIFO data count is greater than this number, a DMA/FIFO request is raised.	
11:0 (R/W)	TXWM	TX Watermark. The MSI_FIFOTH.TXWM bit field sets the FIFO threshold watermark level when transmitting data to card. When the FIFO data count is less than or equal to this number, a DMA/FIFO request is raised.	

Internal DMA Interrupt Enable Register

The `MSI_IDINTEN` register provides bits for setting various interrupts in DMA mode.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 26-34: MSI_IDINTEN Register Fields

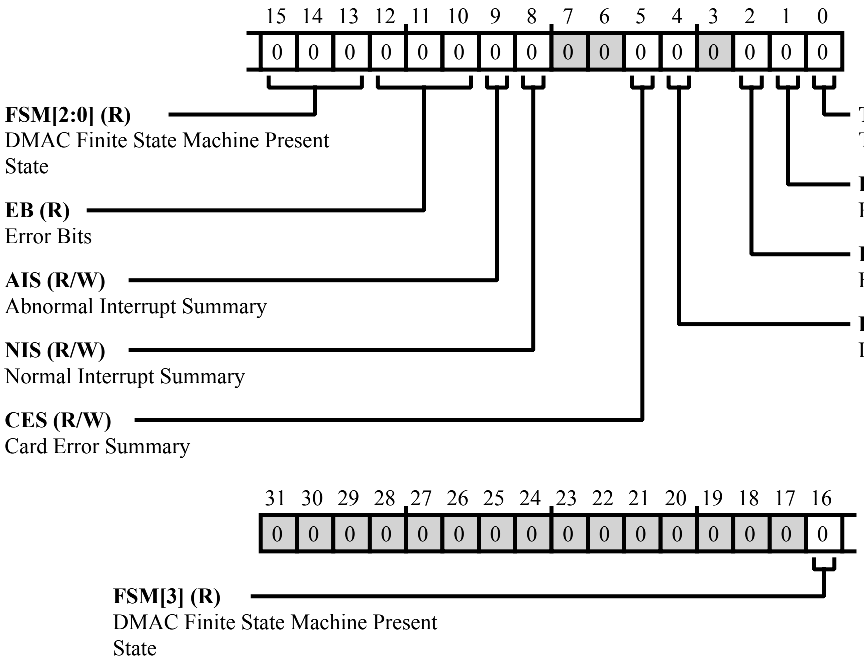
Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	AI	Abnormal Interrupt Summary. Setting the `MSI_IDINTEN.AI` bit enables the abnormal interrupt summary. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
8 (R/W)	NI	Normal Interrupt Summary. Setting the `MSI_IDINTEN.NI` bit enables the normal interrupt summary. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
5 (R/W)	CES	Card Error Summary. Setting the `MSI_IDINTEN.CES` bit enables the card error summary interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled

Table 26-34: MSI_IDINTEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DU	Descriptor Unavailable. Setting the `MSI_IDINTEN.DU` bit enables the descriptor unavailable interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
2 (R/W)	FBE	Fatal Bus Error. Setting the `MSI_IDINTEN.FBE` bit enables the FBE interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
1 (R/W)	RI	Receive Interrupt. Setting the `MSI_IDINTEN.RI` bit enables the receive interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled
0 (R/W)	TI	Transmit Interrupt. Setting the `MSI_IDINTEN.TI` bit enables the transmit interrupt. See the bit descriptions in the `MSI_IDSTS` register for interrupt descriptions.	
		0	Interrupt disabled
		1	Interrupt enabled

Internal DMA Status Register

The `MSI_IDSTS` register provides DMA status information. This register is updated only when the DMA is active.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 26-35: MSI_IDSTS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16:13 (R/NW)	FSM	DMAC Finite State Machine Present State. The `MSI_IDSTS.FSM` bit field indicates the present state of the finite state machine IDMAC (DMA controller).	
		0	DMA Idle
		1	DMA suspend
		2	DESC_RD
		3	DESC_CHK
		4	DMA_RD_REQ_WAIT
		5	DMA_WR_REQ_WAIT
		6	DMA_RD
		7	DMA_WR
		8	DESC_CLOSE

Table 26-35: MSI_IDSTS Register Fields (Continued)

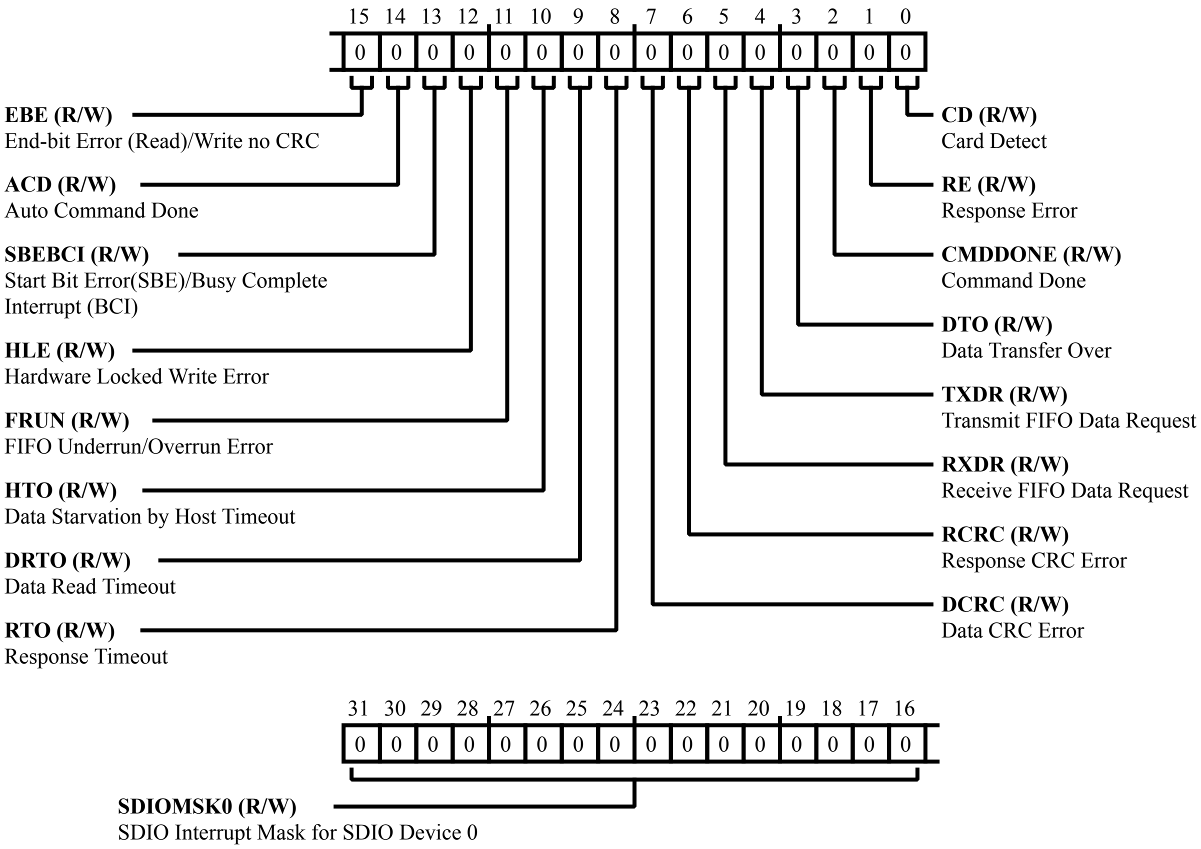
Bit No. (Access)	Bit Name	Description/Enumeration	
12:10 (R/NW)	EB	Error Bits. The `MSI_IDSTS.EB` bit field indicates the type of error that caused a bus error. It is valid only with `MSI_IDSTS.FBE` set. This field does not generate an interrupt. The `MSI_IDSTS.EB` bit field is read-only.	
		0	3'b001 - Host abort received during transmission
		1	3'b010 - Host abort received during reception
9 (R/W)	AIS	Abnormal Interrupt Summary. The `MSI_IDSTS.AIS` bit field is a logical OR of the following: IDSTS[2] - Fatal Bus Interrupt IDSTS[4] - DU bit Interrupt Only unmasked bits affect this bit. This is a sticky bit and must be cleared each time a corresponding bit that causes `MSI_IDSTS.AIS` to be set is cleared. Writing a 1 clears this bit.	
8 (R/W)	NIS	Normal Interrupt Summary. The `MSI_IDSTS.NIS` bit field is a logical OR of the following: IDSTS[0] - Transmit Interrupt IDSTS[1] - Receive Interrupt Only unmasked bits affect this bit. This is a sticky bit and must be cleared each time a corresponding bit that causes `MSI_IDSTS.NIS` to be set is cleared. Writing a 1 clears this bit.	
5 (R/W)	CES	Card Error Summary. The `MSI_IDSTS.CES` bit indicates the logical OR of the following bits: • EBE - End Bit Error • RTO - Response Timeout/Boot Ack Timeout • RCRC - Response CRC • SBE - Start Bit Error • DRTO - Data Read Timeout/BDS timeout • DCRC - Data CRC for Receive • RE - Response Error Writing a 1 clears this bit.	
		0	No error occurred
		1	Error occurred

Table 26-35: MSI_IDSTS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DU	Descriptor Unavailable Interrupt. The `MSI_IDSTS.DU` bit indicates a descriptor unavailable error. If software creates less descriptors than the boot data received, the MSI generates this interrupt and does not transfer any further data to system memory.	
		0	No error occurred
		1	Error occurred
2 (R/W)	FBE	Fatal Bus Error Interrupt. The `MSI_IDSTS.FBE` bit indicates a fatal bus error error. An FBE occurs due to an error response from the SCB. Because this is a system error, the software driver should not perform any further programming of the MSI. The only recovery mechanism from such an error is to issue a hard reset or to perform a controller reset by writing to the `MSI_CTL.CTLRST` bit.	
		0	No error occurred
		1	Error occurred
1 (R/W)	RI	Receive Interrupt. The `MSI_IDSTS.RI` bit indicates that data reception is finished for a descriptor.	
		0	No event occurred
		1	Event occurred
0 (R/W)	TI	Transmit Interrupt. The `MSI_IDSTS.TI` bit indicates that data transmission is finished for a descriptor.	
		0	No event occurred
		1	Event occurred

Interrupt Mask Register

The MSI_IMSK register provides bits that allow the masking of unwanted interrupts.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SDIOMSK0 (R/W)
SDIO Interrupt Mask for SDIO Device 0

Figure 26-33: MSI_IMSK Register Diagram

Table 26-36: MSI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/W)	SDIOMSK0	SDIO Interrupt Mask for SDIO Device 0. The MSI_IMSK.SDIOMSK0 bits mask SDIO interrupts, one bit for one card. When masked, SDIO interrupt detection for that card is disabled. A 0 masks an interrupt, and 1 enables an interrupt.	
15 (R/W)	EBE	End-bit Error (Read)/Write no CRC. The MSI_IMSK.EBE bit masks the end bit read/write no CRC error.	
		0	Masked
		1	Enabled

Table 26-36: MSI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ACD	Auto Command Done. The `MSI_IMSK.ACD` bit masks the auto command done error.	
		0	Masked
		1	Enabled
13 (R/W)	SBEBCI	Start Bit Error(SBE)/Busy Complete Interrupt (BCI). The `MSI_IMSK.SBEBCI` bit masks the start bit/busy complete error.	
		0	Masked
		1	Enabled
12 (R/W)	HLE	Hardware Locked Write Error. The `MSI_IMSK.HLE` bit masks the hardware locked write error.	
		0	Masked
		1	Enabled
11 (R/W)	FRUN	FIFO Underrun/Overrun Error. The `MSI_IMSK.FRUN` bit masks the FIFO overrun or underrun error.	
		0	Masked
		1	Enabled
10 (R/W)	HTO	Data Starvation by Host Timeout. The `MSI_IMSK.HTO` bit masks the host timeout error.	
		0	Masked
		1	Enabled
9 (R/W)	DRTO	Data Read Timeout. The `MSI_IMSK.DRTO` bit masks the data read timeout error.	
		0	Masked
		1	Enabled
8 (R/W)	RTO	Response Timeout. The `MSI_IMSK.RTO` bit masks the response timeout error.	
		0	Masked
		1	Enabled

Table 26-36: MSI_IMSK Register Fields (Continued)

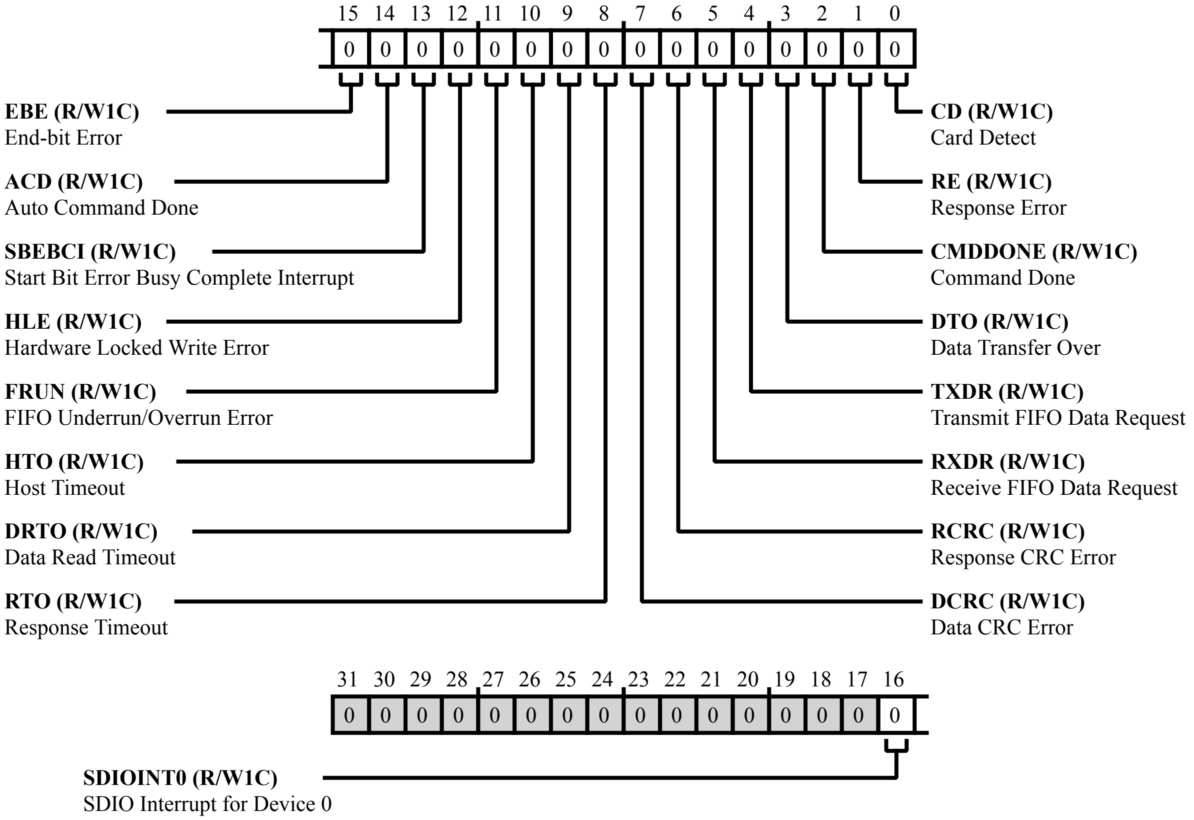
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	DCRC	Data CRC Error. The `MSI_IMSK.DCRC` bit masks the data CRC error where the received data CRC does not match with locally-generated CRC in CIU. The error can also occur if the write CRC status is incorrectly sampled by the host.	
		0	Masked
		1	Enabled
6 (R/W)	RCRC	Response CRC Error. The `MSI_IMSK.RCRC` bit masks the response CRC error which is set when the response CRC does not match with the locally-generated CRC in the CIU.	
		0	Masked
		1	Enabled
5 (R/W)	RXDR	Receive FIFO Data Request. The `MSI_IMSK.RXDR` bit masks the receive FIFO data request interrupt which is set during write operation to card when FIFO level reaches less than or equal to transmit-threshold level.	
		0	Masked
		1	Enabled
4 (R/W)	TXDR	Transmit FIFO Data Request. The `MSI_IMSK.TXDR` bit masks the transmit FIFO data request interrupt which is set during write operation to card when FIFO level reaches less than or equal to transmit-threshold level.	
		0	Masked
		1	Enabled
3 (R/W)	DTO	Data Transfer Over. The `MSI_IMSK.DTO` bit masks the data transfer over interrupt which indicates the data transfer completed. Though on detection of errors such as the start bit error, the data CRC error, and so on, DTO may or may not be set; the application must issue CMD12, which ensures that DTO is set.	
		0	Masked
		1	Enabled

Table 26-36: MSI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	CMDDONE	Command Done. The `MSI_IMSK.CMDDONE` bit masks the command done interrupt where a command is sent to a card and received a response from the card, even if a response error or a CRC error occurs.	
		0	Masked
		1	Enabled
1 (R/W)	RE	Response Error. The `MSI_IMSK.RE` masks a response error. This is an error in received response set if one of following occurs: transmission bit != 0, command index mismatch, End-bit != 1.	
		0	Masked
		1	Enabled
0 (R/W)	CD	Card Detect. The `MSI_IMSK.CD` bit masks the card detect interrupt. On power-on, the controller should read in the card_detect port and store the value in the memory. Upon receiving a card-detect interrupt, it should again read the card_detect port and XOR with the previous card-detect status to find out which card has interrupted.	
		0	Masked
		1	Enabled

Raw Interrupt Status Register

The `MSI_ISTAT` register provides bits that clear interrupts. Conditions 6 through 9 indicate that the received data may have errors. If there was a response timeout, then no data transfer occurred.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

SDIOINT0 (R/W1C)
SDIO Interrupt for Device 0

Figure 26-34: MSI_ISTAT Register Diagram

Table 26-37: MSI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	SDIOINT0	SDIO Interrupt for Device 0. The `MSI_ISTAT.SDIOINT0` bit indicates that an interrupt occurred on an SDIO card.	
15 (R/W1C)	EBE	End-bit Error. The `MSI_ISTAT.EBE` bit indicates that the start bit of the CRC status was not received by two clocks after the end of the data block. A CRC error is indicated by the card.	
		0	No error
		1	Error occurred

Table 26-37: MSI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W1C)	ACD	Auto Command Done.	
		0	No error
		1	Error occurred
13 (R/W1C)	SBEBCI	Start Bit Error Busy Complete Interrupt. The `MSI_ISTAT.SBEBCI` bit indicates the completion of a busy signal driven by the card after a write data transfer.	
		0	No error
		1	Error occurred
12 (R/W1C)	HLE	Hardware Locked Write Error.	
		0	No error
		1	Error occurred
11 (R/W1C)	FRUN	FIFO Underrun/Overrun Error.	
		0	No error
		1	Error occurred
10 (R/W1C)	HTO	Host Timeout. The `MSI_ISTAT.HTO` bit indicates that the FIFO is empty during transmission or is full during reception. Unless software/DMA writes data for an empty condition or reads data for a full condition, the MSI cannot continue with data transfer. The clock to the card is stopped.	
		0	No error
		1	Error occurred
9 (R/W1C)	DRTO	Data Read Timeout. The `MSI_ISTAT.DRTO` bit indicates that the card has not sent data within the timeout period.	
		0	No error
		1	Error occurred
8 (R/W1C)	RTO	Response Timeout.	
		0	No error
		1	Error occurred

Table 26-37: MSI_ISTAT Register Fields (Continued)

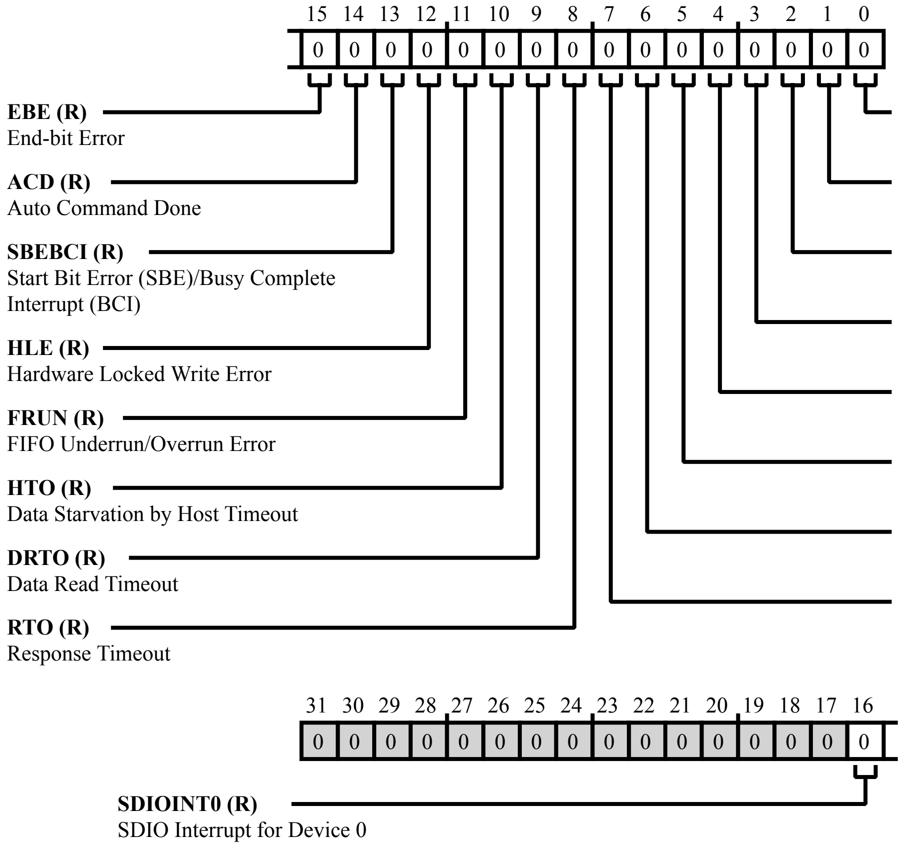
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	DCRC	Data CRC Error. The `MSI_ISTAT.DCRC` bit indicates that a data CRC error where the received data CRC does not match with the locally-generated CRC in the CIU. This error can also occur if the write CRC status is incorrectly sampled by the host.	
		0	No error
		1	Error occurred
6 (R/W1C)	RCRC	Response CRC Error. The `MSI_ISTAT.RCRC` bit indicates that the response CRC error which is caused when the response CRC does not match with the locally-generated CRC in the CIU.	
		0	No error
		1	Error occurred
5 (R/W1C)	RXDR	Receive FIFO Data Request. The `MSI_ISTAT.RXDR` bit indicates that the FIFO threshold for receiving data was reached and software/DMA is expected to read data from the FIFO.	
		0	No error
		1	Error occurred
4 (R/W1C)	TXDR	Transmit FIFO Data Request. The `MSI_ISTAT.TXDR` bit indicates that the FIFO threshold for transmitting data was reached and is less than or equal to transmit-threshold level. Software/DMA is expected to write data, if available, in the FIFO. This interrupt is set during a write operation to the card.	
		0	No error
		1	Error occurred
3 (R/W1C)	DTO	Data Transfer Over. The `MSI_ISTAT.DTO` bit indicates the data transfer completed. If there is a response timeout error, then the MSI does not attempt any data transfer and this bit is never set.	
		0	No error
		1	Error occurred
2 (R/W1C)	CMDDONE	Command Done. The `MSI_ISTAT.CMDDONE` bit indicates that a command that was sent to a card received a response from the card, even a response error or CRC error occurred.	
		0	No error
		1	Error occurred

Table 26-37: MSI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	RE	Response Error. The `MSI_ISTAT.RE` bit indicates that an error was received during response reception. In this case, the response that copied in the response registers is invalid. Software can retry the command.	
		0	No error
		1	Error occurred
0 (R/W1C)	CD	Card Detect. The `MSI_ISTAT.CD` bit indicates a card detect interrupt.	
		0	No error
		1	Error occurred

Masked Interrupt Status Register

The `MSI_MSKISTAT` register indicates the status for the bits which are unmasked in the `MSI_IMSK` register. In other words, `MSI_MSKISTAT` = `MSI_ISTAT` and `MSI_IMSK`.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

SDIO Interrupt for Device 0

Figure 26-35: MSI_MSKISTAT Register Diagram

Table 26-38: MSI_MSKISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	SDIOINT0	SDIO Interrupt for Device 0. The `MSI_MSKISTAT.SDIOINT0` bit indicates an interrupt occurred on the SDIO interrupt for device 0 masked interrupt.	
		0	No interrupt
		1	Interrupt occurred

Table 26-38: MSI_MSKISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	EBE	End-bit Error. The `MSI_MSKISTAT.EBE` bit indicates an interrupt occurred on the end-bit error (read)/write no CRC masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
14 (R/NW)	ACD	Auto Command Done. The `MSI_MSKISTAT.ACD` bit indicates an interrupt occurred on the auto command done masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
13 (R/NW)	SBEBCI	Start Bit Error (SBE)/Busy Complete Interrupt (BCI). The `MSI_MSKISTAT.SBEBCI` bit indicates an interrupt occurred on the start bit error/busy complete masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
12 (R/NW)	HLE	Hardware Locked Write Error. The `MSI_MSKISTAT.HLE` bit indicates an interrupt occurred on the hardware locked write error masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
11 (R/NW)	FRUN	FIFO Underrun/Overrun Error. The `MSI_MSKISTAT.FRUN` bit indicates an interrupt occurred on the FIFO underrun/overrun error masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
10 (R/NW)	HTO	Data Starvation by Host Timeout. The `MSI_MSKISTAT.HTO` bit indicates an interrupt occurred on the data starvation by host timeout masked interrupt.	
		0	No interrupt
		1	Interrupt occurred

Table 26-38: MSI_MSKISTAT Register Fields (Continued)

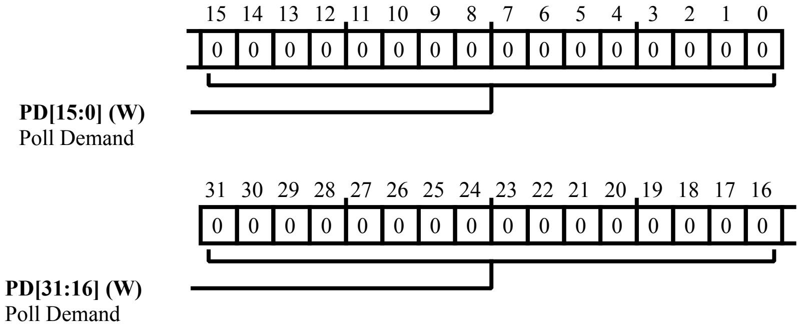
Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	DRTO	Data Read Timeout. The `MSI_MSKISTAT.DRTO` bit indicates an interrupt occurred on the data read timeout masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
8 (R/NW)	RTO	Response Timeout. The `MSI_MSKISTAT.RTO` bit indicates an interrupt occurred on the response timeout masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
7 (R/NW)	DCRC	Data CRC Error. The `MSI_MSKISTAT.DCRC` bit indicates an interrupt occurred on the data CRC error request masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
6 (R/NW)	RCRC	Response CRC Error. The `MSI_MSKISTAT.RCRC` bit indicates an interrupt occurred on the response CRC error data request masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
5 (R/NW)	RXDR	Receive FIFO Data Request. The `MSI_MSKISTAT.RXDR` bit indicates an interrupt occurred on the receive FIFO data request masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
4 (R/NW)	TXDR	Transmit FIFO Data Request. The `MSI_MSKISTAT.TXDR` bit indicates an interrupt occurred on the transmit FIFO data request masked interrupt.	
		0	No interrupt
		1	Interrupt occurred

Table 26-38: MSI_MSKISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	DTO	Data Transfer Over. The `MSI_MSKISTAT.DTO` bit indicates an interrupt occurred on the data transfer over masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
2 (R/NW)	CMDDONE	Command Done. The `MSI_MSKISTAT.CMDDONE` bit indicates an interrupt occurred on the command done masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
1 (R/NW)	RE	Response Error. The `MSI_MSKISTAT.RE` bit indicates an interrupt occurred on the response error masked interrupt.	
		0	No interrupt
		1	Interrupt occurred
0 (R/NW)	CD	Card Detect. The `MSI_MSKISTAT.CD` bit indicates an interrupt occurred on the card detect masked interrupt.	
		0	No interrupt
		1	Interrupt occurred

Poll Demand Register

If the OWN bit of a descriptor is not set, the FSM goes into the suspend state. The host needs to write any value into the `MSI_PLDMND` register for the IDMAC FSM to resume normal descriptor fetch operation. This is a write-only register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

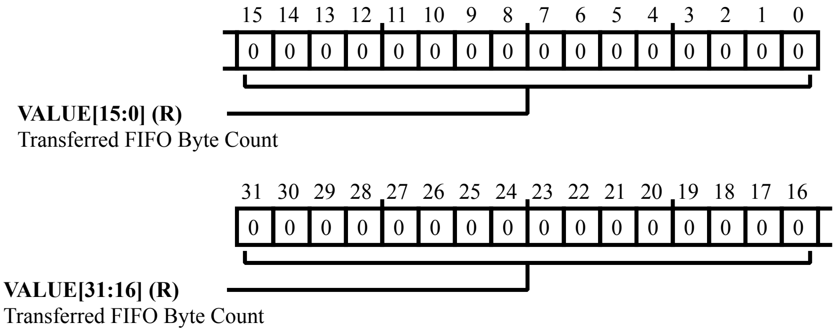
		15	Wait; CMD-to-response turnaround

Table 26-44: MSI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	FIFOFULL	FIFO Full. The `MSI_STAT.FIFOFULL` bit indicates that the FIFO is full.	
2 (R/NW)	FIFOEMPTY	FIFO Empty. The `MSI_STAT.FIFOEMPTY` bit indicates that the FIFO is empty.	
1 (R/NW)	FIFOTXWM	FIFO Tx Watermark. The `MSI_STAT.FIFOTXWM` bit indicates that the FIFO reached the transmit watermark level and is not qualified with data transfer.	
		0	Did not reach watermark level
		1	Reached watermark level
0 (R/NW)	FIFORXWM	FIFO Rx Watermark. The `MSI_STAT.FIFORXWM` bit indicates that the FIFO reached the receive watermark level and is not qualified with data transfer.	
		0	Did not reach watermark level
		1	Reached watermark level

Transferred Host to BIU-FIFO Byte Count Register

The MSI_TBBCNT register provides the number of bytes transferred between host/DMA memory and BIU FIFO. The register should be accessed in full to avoid read-coherency problems.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Transferred FIFO Byte Count
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R)
Transferred FIFO Byte Count

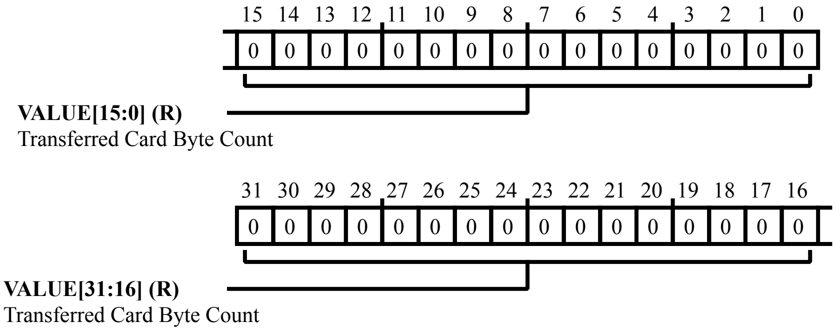
Figure 26-42: MSI_TBBCNT Register Diagram

Table 26-45: MSI_TBBCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Transferred FIFO Byte Count. The `MSI_TBBCNT.VALUE` bit field provides the number of bytes transferred between the host/DMA memory and the BIU FIFO.

Transferred CIU Card Byte Count Register

The `MSI_TCBCNT` register provides the number of bytes transferred by the CIU unit to a card. This register should be accessed in full to avoid read-coherency problems. Both the `MSI_TCBCNT` and `MSI_TBBCNT` registers share the same coherency register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Transferred Card Byte Count
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R)
Transferred Card Byte Count

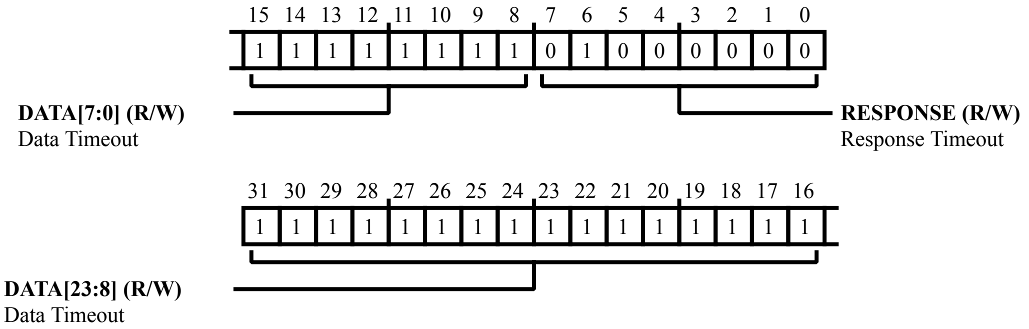
Figure 26-43: MSI_TCBCNT Register Diagram

Table 26-46: MSI_TCBCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Transferred Card Byte Count. The `MSI_TCBCNT.VALUE` bit field provides the number of bytes transferred by the CIU unit to a card.

Timeout Register

The `MSI_TMOUT` register provides bits that configure card data read and response timeout values.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 1 1 1 1 0 1 0 0 0 0 0 0
DATA[7:0] (R/W)
Data Timeout
RESPONSE (R/W)
Response Timeout
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
DATA[23:8] (R/W)
Data Timeout

Figure 26-44: MSI_TMOUT Register Diagram

Table 26-47: MSI_TMOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/W)	DATA	Data Timeout. The `MSI_TMOUT.DATA` bit field configures the value for the card data read timeout; the same value is also used for the data starvation by host timeout. The timeout counter is started only after the card clock is stopped. The value is in number of card output clocks cclk_out of a selected card.
7:0 (R/W)	RESPONSE	Response Timeout. The `MSI_TMOUT.RESPONSE` bit field configures the response timeout in number of card output clocks.

27 Universal Serial Bus (USB)

The USB OTG controller provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras, and MP3 players. It allows these devices to transfer data using a point-to-point USB connection without the need for a personal computer host.

The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On-The-Go (OTG) supplement to the USB 2.0 Specification.

NOTE: See the On-The-Go Supplement to the USB 2.0 Specification, Rev 1.0a; June 24, 2003; USB-IF and the Universal Serial Bus Specification 2.0.

The USB module supports:

- Host mode transfers at high-speed (480 Mbp/sec) rate
- Host mode transfers at full-speed (12 Mbp/sec) rate
- Host mode transfers at low-speed (1.5 Mbp/sec) rates. The connection to low-speed devices is only possible through a full-speed hub.
- Peripheral mode transfers at high-speed (480 Mbp/sec) rate
- Peripheral mode transfers at full-speed (12 Mbp/sec) rate

The USB controller uses a peripheral bus slave interface to access its control and status registers as well as read and write to the endpoint packet buffers. Data transfers to and from the USB controller through the 11 transmit and 11 receive endpoint FIFOs (EP1 – EP11), providing a total of 22 data endpoints.

USB Features

The USB controller provides the following features:

- Low-speed, full-speed, and high-speed rates supported
- One bidirectional control endpoint
- 11 transmit and 11 receive unidirectional endpoints
- 16 KB dynamically configured FIFO RAM

- Eight DMA master channels
- Two top-level maskable general-purpose interrupts
- Low-power wake-up on activity
- VBUS control interrupts for external analog VBUS control
- Session request protocol (SRP) and host negotiation protocol (HNP) capability
- Host transaction scheduling in hardware
- Soft connect or disconnect feature
- Full- and high-speed physical layer UTMI+ level 3 interface for on-chip PHY
- Backwards compatible with existing USB 1.1 hosts
- Support for Battery Charging Specification Revision 1.1

Only device requirements or system bandwidth limit the number of active endpoints at one time because each endpoint operates independently from the next. Software determines the type of transfer for each endpoint individually and also the manner in which it is transferred between the USB controller and memory (DMA or interrupt-based). The USB uses endpoint zero solely for receive and transmit control transfer. These transfers are used for device configuration and information gathering.

USB Functional Description

The following sections describe the function of the USB OTG interface.

USB Architectural Concepts

The USB controller operates in either of two USB operation modes (peripheral or host mode) at a given time.

In peripheral mode, the USB controller encodes, decodes, checks, and directs all USB packets sent and received, responding appropriately to host requests. Data is transferred from the processor core memory into the Tx FIFOs of the device onto USB as IN packets. In the other direction, USB OUT packets are received into the Rx FIFOs (having been sent from the host) and transferred to system memory for processing or storage. In peripheral mode, the USB controller acts as a slave device to another USB host; either a personal computer or another OTG host controller.

When operating in host mode, the USB controller uses simple hosting capabilities to master point-to-point connections with another USB peripheral, initiating transfers on the bus for the peripheral to respond. USB IN packets are received into the Rx FIFOs for transfer into the processor core memory. Data written into Tx FIFOs is transmitted onto the bus as USB OUT packets. In this mode, the USB controller encodes, decodes, and checks USB packets sent and received. The controller automatically schedules isochronous and interrupt transfers from the endpoint buffers. It performs one transaction every *n* frames, where n represents the polling interval programmed for the endpoint.

Any of the endpoints can be programmed to be written to or read from using the DMA master channels. This configuration provides the most efficient means of transferring data between the controller and on-chip memory.

USB endpoints 0 through 11 have DMA interrupt lines (`USB_DMA_IRQ`) providing a total of eight DMA request lines.

The USB provides two top-level maskable interrupts, each of which can be sourced from any or all of transmit endpoint status, receive endpoint status or global USB status. See Interrupt Signals for details.

The RAM interface of the USB controller supports a single block of synchronous single-port RAM used to buffer the USB packets.

16K bytes of SRAM are available.

The UTMI+ level 3 PHY interface provides a means of connecting a selection of high- or full-speed PHYs to the controller, from device-only PHYs through full OTG-compliant PHYs.

For details of the PHY interface, See UTMI Interface.

ATTENTION: Check the processor data sheet for requirements regarding minimum system clock frequency needed for proper USB operation.

The USB controller is configured as either a USB OTG A device or B device depending on the type of plug inserted into its USB receptacle. The state of the `USB_ID` (connector ID) pin determines this configuration.

The USB controller uses an asynchronous wake-up circuit to detect when another B device is asserting its D+ pull-up. This activity initiates the SRP (session request protocol) when all other clocks are off.

This slow clock is derived from SCLK0_0 and enabled using the `USB_PHY_CTL.EN` bit.

Use of the controller for OTG functionality requires the capability to:

- Drive VBUS (as a default A device powering the bus)
- Discharge VBUS (speeding up the time for VBUS to fall below the *SessionEnd* threshold as a B device checking initial conditions)
- Charge VBUS to 2.1 V (when initiating SRP as a B device).

The UTMI interface drives these controls, but the controller also provides a separate interrupt register, `USB_VBUS_CTL`, which represents the drive VBUS, discharge VBUS, and charge VBUS signaling. See the register section for more information on these controls.

Multi-Point Support

The USB controller has the facility, when operating in host mode, to act as the host to a range of USB peripheral devices.

High-speed, full-speed, or low-speed devices connect to the USB controller through a USB hub.

The USB controller, as part of its support for multiple devices, permits individual allocation of the functions of the target to the different Rx and Tx endpoints implemented. Furthermore, the USB controller can make this allocation dynamically, allowing the devices from the targeted peripheral list to be used in different combinations. The numbers of Tx and Rx endpoints implemented in the controller limit the combinations of peripheral devices that can be used together. Devices can only be added where the required endpoints remain available.

On-Chip Bus Interfaces

The USB controller uses two 32-bit wide independent bus interfaces, a master and a slave, to communicate with a processor-based subsystem. The slave interface allows the processor core to access the control and status registers (including DMA master registers) and the endpoint FIFOs. The integrated DMA uses the master interface to drive data into or out of the endpoint FIFOs with minimal processor core interaction. For more information, see USB Block Diagram.

FIFO Configuration

Each bidirectional endpoint (provided as two unidirectional endpoints) has its own endpoint number (0 for control, 1 on up for data transfer). Although two endpoints could use the same number, the endpoints can support different transfer types. Each of these bidirectional endpoints has a fixed region of the SRAM in the USB controller to which it has access. This feature dictates to some extent the types of transfers that can be used for that particular endpoint. This restriction follows from the maximum size of USB packets, which varies with each transfer type. The ***FIFO Sizes and Transfer Types*** table lists the endpoint FIFO configuration, with an indication of the transfer types possible for that particular buffer size.

Table 27-1: FIFO Sizes and Transfer Types

Bidirectional Endpoint (Rx and Tx)	FIFO Size (each direction)	USB Transfer Types
0	64 bytes	Size fixed for control transfers
1–4	Dynamically configured in powers of 2 from 8 to 8192 bytes	Bulk, Interrupt, Isochronous
1–11	Dynamically configured in powers of 2 from 8 to 8192 bytes	Bulk, Interrupt, Isochronous

Each endpoint FIFO can buffer one or two packets (in double-buffered mode). Double-buffering is recommended for most applications to improve efficiency by reducing the frequency of servicing for each endpoint.

Double-buffering bulk transactions means that data transfers over the USB are not slowed when packets are loaded or unloaded from the FIFO in the time it takes to transfer a packet. Double-buffering isochronous transactions allows more time to load or unload the FIFO. It also allows the usage of the SOF interrupt to service the endpoint rather than the endpoint interrupt. This functionality has the following advantages:

- Easy detection of lost packets
- Regular interrupt timing (making it easier to source or sink the data)
- If the USB controller uses more than one isochronous endpoint, one interrupt can service all the endpoints.

The USB controller uses the transmit or receive FIFO address registers to specify the address of each endpoint FIFO.

Clocking

The USB controller uses the system clock SCLK0_0 to generate an internal clock (CLK) used to clock the USB registers.

For proper operation, refer to device datasheet for minimum system clock SCLK0_0 value.

NOTE: For best performance (best signal integrity), follow the guidelines in the data sheet for selecting an input clock frequency.

When the controller is in the SUSPEND state and when no session is active, the clock and much of the USB controller is stopped to reduce power consumption. The clock becomes operational again when RESUME signaling is detected on the USB lines.

UTMI Interface

The interface to the on-chip PHY uses the industry-standard UTMI+ (universal transceiver macro interface) level 3.

This interface provides full- and high-speed device and OTG functionality and supports communication to a hub.

The PHY is a mixed-signal block and includes the following:

- Full-speed and high-speed drivers and receivers (single-ended and differential)
- Full-speed and high-speed CDR
- Full-speed or high-speed shift registers, NRZI encode or decode and bit-stuff encode or decode
- Data line pull-up and pull-down resistors
- VBUS and `USB_ID` level detection
- Host disconnect detection

Although the UTMI specification indicates that VBUS charging, driving and discharging happen inside the PHY, for process-restricting and power reasons, implement these functions off-chip in a separate USB charge-pump chip.

ADSP-SC58x USB Register List

The Universal Serial Bus controller (USB) is a multi-point high-speed dual-role USB 2.0-compliant controller. The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On-The-Go (OTG) supplement to the USB 2.0 Specification, Rev 1.0a; June 24, 2003; USB-IF. A set of registers governs USB controller operations. For more information on USB controller functionality, see the USB controller register descriptions.

USB Definitions

A list of common USB terms and their definitions as used in this specification and based on the USB controller follows:

'A' Device

The USB device with a mini-A plug inserted into its receptacle. The A device always supplies power to VBUS.

'B' Device

The USB device with a standard-B or mini-B plug inserted into its receptacle. The B device starts a session as the peripheral.

Bidirectional endpoint

An endpoint that can concurrently support both receive and transfer packets.

Control endpoint

An endpoint used only for transfer of USB control packets for setup and configuration. In all USB devices, the control endpoint refers to the bidirectional endpoint 0.

Dual role device

A USB device that can operate either as the USB host in an OTG session or as a traditional USB peripheral.

Endpoint

A single physical communication channel for USB, implemented as a FIFO and control logic for that endpoint. Each endpoint has an associated USB transfer type, maximum packet size, bandwidth requirement, endpoint number, and (often) a fixed transfer direction.

Frame

A regular, fixed 1 ms timeslot that can contain several transactions. The transfer type determines the permissible transactions for a given endpoint.

HNP

Host negotiation protocol. Part of the USB OTG supplement that allows the host function to be transferred between two connected dual role devices.

Packet

The lowest level of data exchange on USB. The transfer type and buffer size of the USB peripheral determine the size.

PHY

The PHY is a transceiver circuit that implements the physical layer of USB. For full speed USB OTG, this circuit includes line drivers and receivers, pull-up, or pull-down resistors as well as device ID and VBUS level detection.

Session

A period during which USB transfers take place within an OTG connection. The A device (drives VBUS) or B device (initiates SRP) can initiate this period. VBUS is powered during a session.

SRP

Session request protocol. Part of the USB OTG supplement that allows a B device to turn on VBUS and initiate a USB session.

Transaction

Collection of one or more packets in sequence

Transfer

Collection of one or more transfers in sequence

Unidirectional endpoint

Endpoint with its direction fixed in a single direction (for example, it can only receive packets from the USB) in both host and peripheral modes.

USB References

The following references provide further information regarding the USB.

- *On-The-Go Supplement to the USB 2.0 Specification*, Rev 1.0a, June 24, 2003, USB-IF
- *Universal Serial Bus Specification 2.0*

USB Operating Modes

The USB OTG interface can operate in peripheral mode or host mode.

When the USB controller operates in peripheral mode, the controller can be attached to a conventional host (such as a personal computer) or another OTG device operating in host mode. The second device can be high speed or full speed. When linked to another peripheral device, the USB controller can also act as the host. If the other device is also a dual role controller, the two devices can switch roles, as needed.

The role the USB controller takes depends on the way the devices are cabled together. Each USB cable has an A and a B device end. If the A end of the cable is plugged into the device containing the USB controller, the USB controller takes the role of the host device. It goes into host mode (in this case, the `USB_DEV_CTL.HOSTMODE` bit is set to 1). If the B of the cable is plugged in, the USB controller goes instead into peripheral mode (and the `USB_DEV_CTL.HOSTMODE` bit remains at 0).

When both devices contain dual role controllers, signaling can be used to switch the roles of the two devices, without switching the cable connecting the two devices. See Host Negotiation Protocol for details on the conditions under which the USB controller can switch between peripheral and host mode.

NOTE: The multi-point capability of the USB controller is associated with a range of registers recording the allocation of device functions to individual endpoints and device function characteristics. These characteristics include endpoint number, operating speed, and transaction type on an endpoint-by-endpoint basis. These registers are principally associated with the use of the USB controller as the host to a number of devices. However, set the registers when the core is used as the host for a single target device.

To enable the USB:

1. Configure the USB PLL multiplier settings in the USB PLL control register. Check the processor data sheet for the requirements for input clock frequency.
2. Enable the USB PHY by setting the `USB_PHY_CTL.EN` bit.
3. Poll the bit in the USB PLL control register to ensure that the USB PLL has locked to the new frequency.

Peripheral Mode

USB OTG interface operations for the peripheral mode differ from host mode in a number of ways. The following sections describe peripheral mode operations.

Endpoint Setup

In peripheral mode, the USB uses a few endpoint-specific configuration bits when setting up an endpoint for transfer for all types of peripheral transfer. The configuration determines how the processor core interacts with the endpoint FIFO.

One key parameter required before a transfer can occur through an endpoint is the maximum USB packet size that the endpoint can support. The software sets this value. It depends on various system constraints. These constraints include the size of hardware FIFO available and system latencies as well as the USB transfer type and class used. The `USB_EP[n]_TXMAXP` or `USB_EP[n]_RXMAXP` registers define the maximum amount of data that can be transferred to the selected endpoint in a single frame. The value must match the programmed maximum individual packet size (*MaxPktSize*) of the standard endpoint descriptor for the endpoint.

For transmit endpoints, program the maximum packet size using the `USB_EP[n]_TXMAXP`. For receive endpoints, the USB uses the `USB_EP[n]_RXMAXP` register. The maximum packet size must not exceed the actual hardware endpoint FIFO size.

The settings in the USB_RXFIFOSZ or USB_TXFIFOSZ register determine the corresponding sizes of the transmit or receive FIFOs, as well as, single or double buffered mode for endpoints 1 to 11.

Because the USB controller uses a 32-bit interface, choose an even number for the value of *MaxPktSize*. This selection simplifies transferring data between FIFOs and the processor core.

Configure more setup parameters using the USB_EP[n]_TXCSR_H or USB_EP[n]_RXCSR_H register (depending on whether the endpoint in question is for receive or transmit). The USB uses the USB_EP[n]_RXCSR_H.DMAREQEN bit in this register to enable the assertion of the appropriate DMA request whenever the endpoint is able to receive or transmit another packet. The USB uses the USB_EP[n]_RXCSR_H.AUTOCLR and USB_EP[n]_RXCSR_H.AUTOREQ bits to set the FIFO ready triggers (USB_EP[n]_RXCSR_H.RXPKTRDY and USB_EP[n]_TXCSR_H.TXPKTRDY) automatically whenever a packet is transferred to streamline DMA operation for transfers that span multiple packets. Note, however, that the USB cannot use USB_EP[n]_RXCSR_H.AUTOCLR and USB_EP[n]_RXCSR_H.AUTOREQ bits with high-bandwidth endpoints. Refer to the following register sections for more information: USB_EP[n]_TXCSR_H,USB_EPI[N]_RXCSR_P,USB_EPI[N]_RXCSR_H,USB_EP[n]_TXCSR_P.

IN Transactions as a Peripheral

When the USB controller operates in peripheral mode, the transmit FIFOs handle data for IN transactions. The maximum size of data packet that can be placed in a FIFO for a transmit endpoint is programmable. When applicable, the value written to the USB_EP[n]_TXMAXP register for that endpoint determines the size (maximum payload multiplied by the number of transactions per micro-frame).

The maximum packet size set for any endpoint must not exceed the FIFO size. (See FIFO Configuration.)

ATTENTION: Do not write to the USB_EP[n]_TXMAXP register while there is data in the FIFO, as unexpected results can occur.

The following sections describe the two types of packet buffering used for IN transactions.

Single packet buffering. Set the USB_EP[n]_TXCSR_P.TXPKTRDY bit as each packet for transmission is loaded into the transmit FIFO. If the USB_EP[n]_TXCSR_P.AUTOSET bit is set, the USB_EP[n]_TXCSR_P.TXPKTRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, and where auto-set cannot be used (high-bandwidth isochronous or interrupt transactions), always set the USB_EP[n]_TXCSR_P.TXPKTRDY bit manually (for example by the processor core).

When the USB_EP[n]_TXCSR_P.TXPKTRDY bit is set, either manually or automatically, the USB_EP[n]_TXCSR_P.NEFIFO bit is also set and the packet is ready to be sent. When the packet is successfully sent, both the USB_EP[n]_TXCSR_P.TXPKTRDY and USB_EP[n]_TXCSR_P.NEFIFO bits are cleared. The USB controller generates the appropriate transmit endpoint interrupt (if enabled). The next packet can then be loaded into the FIFO.

Double packet buffering. Set the USB_EP[n]_TXCSR_P.TXPKTRDY bit as each packet for transmission is loaded into the transmit FIFO. If the USB_EP[n]_TXCSR_P.AUTOSET bit is set, the USB_EP[n]_TXCSR_P.TXPKTRDY bit is automatically set when a maximum-sized packet is loaded into the

FIFO. For packet sizes less than the maximum, and where auto-set cannot be used (high-bandwidth isochronous or interrupt transactions), always set the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit manually (for example by the processor core).

When the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is set, either manually or automatically, the `USB_EP[n]_TXCSR_P.NEFIFO` bit also is set. The `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is then immediately cleared (and an interrupt generated, if enabled). A second packet can now be loaded into the transmit FIFO and the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is set again (either manually or automatically if the packet is the maximum size). Both packets are now ready for transmission.

When the first packet is successfully sent, the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is cleared. The USB controller generates the appropriate transmit endpoint interrupt (if enabled) to signal that another packet can now be loaded into the transmit FIFO. The state of the `USB_EP[n]_TXCSR_P.NEFIFO` bit indicates how many packets can be loaded. If the `USB_EP[n]_TXCSR_P.NEFIFO` bit is set, then there is another packet in the FIFO and only one more packet can be loaded. If the `USB_EP[n]_TXCSR_P.NEFIFO` bit is cleared, then there are no packets in the FIFO and two more packets can be loaded.

OUT Transactions as a Peripheral

When the USB controller operates in peripheral mode, the receive FIFOs handle data for OUT transactions.

The value written to the `USB_EP[n]_RXMAXP` register for an endpoint determines the maximum amount of data received by a receive endpoint in any frame. The value is programmable. The maximum packet size must not exceed the FIFO size.

The value written to the `USB_EP[n]_RXMAXP` register for an endpoint determines maximum amount of data received by a receive endpoint in any micro-frame (in high-speed mode). The value is programmable. It is the maximum payload multiplied by the number of transactions per micro-frame. The maximum packet size must not exceed the FIFO size.

If the size of the receive endpoint FIFO is less than twice the maximum packet size for this endpoint, only one data packet can be buffered in the FIFO. Single buffering is selected. (The size is set in the `USB_EP[n]_RXMAXP` register.) When a packet is received and placed in the receive FIFO, the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit and the `USB_EP[n]_RXCSR_P.FIFOFULL` bit are set. The USB controller generates the appropriate receive endpoint interrupt (if enabled) to signal that a packet can now be unloaded from the FIFO. After the packet is unloaded, clear the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit to allow reception of more packets. If the `USB_EP[n]_RXCSR_P.AUTOCLR` bit is set and a maximum-sized packet is unloaded from the FIFO, the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is cleared automatically. The `USB_EP[n]_RXCSR_P.FIFOFULL` bit is also cleared. For packet sizes less than the maximum, clear the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit manually (for example by the processor core).

If double packet buffering is enabled, then two data packets can be buffered. When the first packet for reception is loaded into the receive FIFO, the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is set. The USB controller generates the appropriate receive endpoint interrupt (if enabled) to signal that a packet can now be unloaded from the FIFO. The `USB_EP[n]_RXCSR_P.FIFOFULL` bit is not set. This bit is only set if a second packet is received and loaded into the receive FIFO.

After the first packet is unloaded, clear the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit to allow reception of further packets. If the `USB_EP[n]_RXCSR_P.AUTOCLR` bit is set and a maximum-sized packet is unloaded from the FIFO, the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is cleared automatically. For packet sizes less than the maximum, clear the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit manually (for example by the processor core).

If the `USB_EP[n]_RXCSR_P.FIFOFULL` bit is set to 1 when `USB_EP[n]_RXCSR_P.RXPKTRDY` is cleared, the USB controller first clears the `USB_EP[n]_RXCSR_P.FIFOFULL` bit. The controller then sets the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit again, indicating that there is another packet waiting in the FIFO for unloading.

High-Bandwidth Isochronous or Interrupt Transactions

High-bandwidth isochronous or interrupt transactions use much the same protocol as other isochronous or interrupt transactions. There are, however, some special features to conducting high-bandwidth transactions.

- When setting the maximum packet size handled by the endpoint in the `USB_EP[n]_TXMAXP`/ `USB_EP[n]_RXMAXP` registers, set the maximum number of transactions per micro-frame using the `USB_EP[n]_TXMAXP.MULTM1` and `USB_EP[n]_RXMAXP.MULTM1` bits.

  The maximum number of transactions (2 or 3) also represents the maximum number of sections in which any single high-bandwidth packet can be transferred. The configuration sets the maximum size of the packet to 2 or 3 times the maximum payload specified for the endpoint in the same register.

  NOTE: The maximum payload that can be sent in any transaction is 1K byte.

- When sending packets, set the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit using the application software. Similarly, when unloading packets from the receive endpoint FIFO, clear the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit using the application software.

  CAUTION: The AutoSet and AutoClear functions cannot be used to set and clear these bits in high-bandwidth transactions.

- The transmission of packets as a number of sections introduces a further type of error – the transmission of incomplete packets.

  For transmit endpoints, transmitting incomplete packets principally applies when the interface is in peripheral mode. It occurs when the transmission fails to receive enough IN tokens from the host to send all the parts of the data packet. It can also apply to high-bandwidth interrupt transactions in host mode where the core does not receive any response from the device to which the packet is transmitted. In both cases, the `USB_EP[n]_TXCSR_P.INCOMPTX` bit is set.

  For receive endpoints, an incomplete packet issue can occur. The PIDs of the received parts of the data packet show that one or more parts of the data packet have not been received. When this event happens, the `USB_EP[n]_RXCSR_P.INCOMPRX` bit is set. Usually this bit is set in peripheral mode. However, it can also be set in host mode (using the `USB_EP[n]_RXCSR_H.INCOMPRX` bit). This event occurs when the USB communicates with a device that fails to respond in accordance with the USB protocol.

High Bandwidth Isochronous or Interrupt IN Endpoints

In high-speed mode, transmit endpoints configured for high-bandwidth isochronous or interrupt transactions can transmit up to three USB packets in any micro-frame. The transmission occurs with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per micro-frame.

The ***High Bandwidth IN Endpoints*** figure provides an overview of high-bandwidth IN endpoints in USB.

Single packet of up to OutMaxP (max. 3072 bytes) read from FIFO

Figure 27-2: High Bandwidth IN Endpoints

The USB controller supports these transfers by permitting the loading of data packets with up to three times the normal packet size into the associated FIFO in a single transaction. From the software viewpoint in the processor core, the ***High Bandwidth IN Endpoints*** figure describes the operation for single or double packet buffering (as appropriate). One exception is that the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit must always be set manually (for example by the processor core) as the auto set feature does not operate with high-bandwidth isochronous transfers.

The USB controller automatically splits any data packet loaded into the FIFO that is larger than the maximum into USB packets of the maximum payload, or smaller, for transmission. The following settings define the number of USB packets transmitted per micro-frame and the maximum payload in each packet:

- Use the `USB_EP[n]_TXMAXP.MAXPAY` bits to set the maximum payload in any USB packet
- Use the `USB_EP[n]_TXMAXP.MULTM1` bits to set the maximum number of such packets for transmission in one micro-frame (2 or 3)

Together, these settings define the maximum size of packet that can be loaded into the FIFO.

At least one USB packet always is sent. The number of further USB packets sent in the same micro-frame depends on the amount of data loaded into the FIFO. The `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is cleared and an interrupt is generated only when all the packets have been sent. Each USB packet is sent in response to an IN token. If, at the end of a micro-frame, the USB controller has not received enough IN tokens to send all the USB packets, the remaining data is flushed from the FIFO. (For example, one of the IN tokens received is corrupt). The `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is cleared and the `USB_EP[n]_TXCSR_P.INCOMPTX` bit is set to indicate that not all of the data loaded into the FIFO transmitted.

High-Bandwidth Isochronous or Interrupt OUT Endpoints

In high-speed mode, isochronous receive endpoints can receive up to three USB packets in any micro-frame. The reception occurs with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per micro-frame. Similarly, the USB controller can receive high-bandwidth interrupt transactions in host mode, but there is no support for high-bandwidth interrupt transactions in peripheral mode.

The ***High-Bandwidth OUT Endpoints*** figure shows an overview of high-bandwidth OUT endpoints.

The USB controller supports this rate by automatically combining all the USB packets received during a micro-frame into a single packet of up to 3 normal packets within the receive FIFO. From the software viewpoint in the processor core, the ***High Bandwidth IN Endpoints*** figure describes the operation for single or double packet buffering (as appropriate). One exception is that the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit always must be cleared manually (for example by the processor core) because the auto-clear function does not operate with high-bandwidth isochronous transfers.

The maximum number of USB packets that can be received in any micro-frame and the maximum payload of these packets are configured as follows:

- Use the `USB_EP[n]_RXMAXP.MAXPAY` bits to set the maximum payload in any USB packet
- Use the `USB_EP[n]_RXMAXP.MULTM1` bits to set the maximum number of these packets that can be received in a micro-frame (2 or 3)

Figure 27-3: High-Bandwidth OUT Endpoints

The number of USB packets sent in any micro-frame depends on the amount of data for transfer, and is indicated through the PIDs used for the individual packets. If the indicated number of packets have not been received by the end of a micro-frame, the `USB_EP[n]_RXCSR_P.INCOMPRX` bit is set to indicate that the data in the FIFO is incomplete. An interrupt is still generated to allow the data that has been received to be read from the FIFO.

Peripheral Transfer Work Flows

The USB transfer types (control, bulk, isochronous, and interrupt transfers) have different system requirements as well as individual USB transfer-specific features. Software handles each type differently. There is no uniform way of doing transfers across all transfer types using the USB controller.

The following sections provide some guidelines for peripheral mode transfer flows for each of the transfer types, in both IN (transmit) and OUT (receive) directions. For bulk endpoints, the optimal transfer flow depends on whether the final size of the transfer is known or unknown. The USB driver class in use determines whether the transfer size is known or not. Some drivers define the complete transfer size, and others operate on a packet-by-packet basis using a short packet to denote the end of a transfer. (A short packet is less than the value configured in the `USB_EP[n]_TXMAXP` register or less than the value configured in the `USB_EP[n]_RXMAXP` register.)

Each of the work flows uses the following common steps.

1. Configure the endpoint control and status registers and the `USB_EP[n]_TXMAXP` or `USB_EP[n]_RXMAXP` value.
2. Configure the appropriate data transfer mechanism (DMA or interrupt setup).
3. Data transfer occurs.

The work flows do not describe the actions of the USB controller immediately preceding the endpoint setup. (For example, the reception of an IN/OUT token from the host, token validity checking, or NAK generation, among others.) Note also that there is no error-handling contained in the work flows (for example, checking the `USB_EP[n]_RXCSR_P.FIFOFULL` bit before writing data).

The proceeding sections use terms packets, frames, and transfers with their strict USB definitions (see USB Definitions).

Control Transactions as a Peripheral

Endpoint 0 is the main control endpoint of the USB controller. As such, the routines required to service endpoint 0 are more complicated than the routines required to service other endpoints.

The software is required to handle all the standard device requests that the USB controller sends or receives through endpoint 0. The *Universal Serial Bus Specification*, Revision 2.0, Chapter 9 describes the requirements. The protocol for these device requests involves different numbers and types of transactions per transfer. To accommodate this functionality, the processor must take a state machine approach to command decoding and handling.

The standard device requests a USB peripheral receives fits into three categories:

- Zero data requests (in which the command includes all the information)
- Write requests (in which extra data follows the command)
- Read requests (in which the device sends data back to the host)

The following sections describe the sequence of actions that the software must perform to process these different types of device request.

Write Requests

The host sends an 8-byte command followed by a write request that contains an extra packet (or packets) of data. An example of a write standard device request is `SET_DESCRIPTOR`.

As with all requests, the sequence of events begins when the software receives an endpoint 0 interrupt. The `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is also set. The host then reads and decodes the 8-byte command from the endpoint 0 FIFO.

As with a zero data request, write to the `USB_EP0_CSR[n]_P` register to set the `USB_EP0_CSR[n]_P.SPKTRDY` bit. (The event indicates that the host read the command from the FIFO.) But, in this case, do not set the `USB_EP0_CSR[n]_P.DATAEND` bit (indicating that more data is expected).

When a second endpoint 0 interrupt is received, the `USB_EP0_CSR[n]_P` register is read to check the endpoint status. The `USB_EP0_CSR[n]_P.RXPKTRDY` bit is set to indicate that a data packet is received. Read the `USB_EP0_CNT[n]` register to determine the size of this data packet. The data packet can then be read from the endpoint 0 FIFO.

If the length of the data associated with the request is greater than the maximum packet size for endpoint 0, the host sends more data packets. (The `WLENGTH` field in the command indicates the length of the data.) In this case, the `USB_EP0_CSR[n]_P.SPKTRDY` bit is set, but do not set the `USB_EP0_CSR[n]_P.DATAEND` bit.

When all the expected data packets have been received, software writes to the `USB_EP0_CSR[n]_P` register to set the `USB_EP0_CSR[n]_P.SPKTRDY` bit and to set the `USB_EP0_CSR[n]_P.DATAEND` bit (indicating that no more data is expected).

When the host moves to the status stage of the request, software generates another endpoint 0 interrupt to indicate that the request has completed. No further action is required from the software; the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or cannot be executed, then when the host decodes it, software must write to the `USB_EP0_CSR[n]_P` register. This operation sets the `USB_EP0_CSR[n]_P.SPKTRDY` bit and the `USB_EP0_CSR[n]_P.SENDSTALL` bit. When the host sends more data, the USB controller sends a stall to tell the host that the request was not executed. Software generates an endpoint 0 interrupt and the `USB_EP0_CSR[n]_P.SENTSTALL` bit is set.

If the host sends more data after the `USB_EP0_CSR[n]_P.DATAEND` has been set, then the USB controller sends a stall. Software generates an endpoint 0 interrupt and the `USB_EP0_CSR[n]_P.SENTSTALL` bit is set.

Read Requests

The function sends the 8-byte command followed by read requests containing a packet (or packets) of data to the host. Examples of standard device requests for read are:

- `GET_CONFIGURATION`
- `GET_INTERFACE`
- `GET_DESCRIPTOR`
- `GET_STATUS`
- `SYNCH_FRAME`

As with all requests, the sequence of events begins when the software receives an endpoint 0 interrupt. The `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is also set. The host then reads and decodes the 8-byte command from the endpoint 0 FIFO. Write the `USB_EP0_CSR[n]_P.SPKTRDY` bit (indicating that the command has been read from the FIFO).

The data to transmit to the host is written to the endpoint 0 FIFO. If the size of the transmit data is greater than the maximum packet size for endpoint 0, only the maximum packet size is written to the FIFO. The `USB_EP0_CSR[n]_P.TXPKTRDY` bit is then set (indicating that there is a packet in the FIFO to be sent). When the packet has been sent to the host, software generates another endpoint 0 interrupt. The next data packet can be written to the FIFO.

When the last data packet has been written to the FIFO, software writes to the `USB_EP0_CSR[n]_P` register to set the `USB_EP0_CSR[n]_P.TXPKTRDY` bit and to set the `USB_EP0_CSR[n]_P.DATAEND` bit. (This activity indicates that there is no more data after this packet.)

When the host moves to the status stage of the request, software generates another endpoint 0 interrupt to indicate that the request has completed. No further action is required from the software; the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when the host decodes it, software must write to the `USB_EP0_CSR[n]_P` register. This operation sets the `USB_EP0_CSR[n]_P.SPKTRDY` bit and the `USB_EP0_CSR[n]_P.SENDSTALL` bit. When the host requests data, the USB controller sends a stall to tell the host that the request was not executed. Software generates an endpoint 0 interrupt and the `USB_EP0_CSR[n]_P.SENTSTALL` bit is set.

If the host requests more data after `USB_EP0_CSR[n]_P.DATAEND` is set, then the USB controller sends a stall. Software generates an endpoint 0 interrupt and the `USB_EP0_CSR[n]_P.SENTSTALL` bit is set.

Zero Data Requests

Zero data requests have all their information included in the 8-byte command and do not require transfer of extra data.

Examples of standard device requests for zero data are:

- `SET_FEATURE`
- `CLEAR_FEATURE`
- `SET_ADDRESS`
- `SET_CONFIGURATION`
- `SET_INTERFACE`

As with all requests, the sequence of events begins when the software receives an endpoint 0 interrupt. The `USB_EP0_CSR[n]_P.RXPKTRDY` bit is also set. The host must then read and decode the 8-byte command from the endpoint 0 FIFO, and take appropriate action. For example, if the command is `SET_FEATURE`, the host writes 7-bit address value contained in the command to the `USB_FADDR` register.

Software must set the `USB_EP0_CSR[n]_P.SPKTRDY` bit (indicating that the command has been read from the FIFO) and the `USB_EP0_CSR[n]_P.DATAEND` bit (indicating that no further data is expected for this request).

When the host moves to the status stage of the request, the USB controller generates a second endpoint 0 interrupt, indicating that the request has completed. No further action is required from the software; the second interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when the host decodes it, the `USB_EP0_CSR[n]_P.SPKTRDY` bit is set which sets the `USB_EP0_CSR[n]_P.SENDSTALL` bit. When the host moves to the status stage of the request, the USB controller sends a stall to tell the host that the request was not executed. The USB controller generates a second endpoint 0 interrupt and sets the `USB_EP0_CSR[n]_P.SENTSTALL` bit.

If the host sends more data after the `USB_EP0_CSR[n]_P.DATAEND` bit is set, then the USB controller sends a stall. It generates an endpoint 0 interrupt and sets the `USB_EP0_CSR[n]_P.SENTSTALL` bit.

Endpoint 0 States

When the USB operates as a peripheral, the endpoint 0 control has three modes (IDLE, Tx, and Rx). The modes correspond to the phases of the control transfer and the state that endpoint 0 enters during phases of the transfer. (See Endpoint 0 Service Routine as Peripheral.)

IDLE is the default mode on power-up or reset. The processor sets `RxPktRdy` bit when endpoint 0 is in IDLE state, indicating a new device request. Once the processor unloads the device request from the FIFO, the USB decodes the descriptor. It determines whether there is a data phase and, if so, the direction of the data phase of the control transfer (to set the FIFO direction).

Depending on the direction of the data phase, endpoint 0 goes into either Tx state or Rx state. If there is no data phase, endpoint 0 remains in IDLE state to accept the next device request.

The processor must take different actions at the different phases of the possible transfers (for example, loading the FIFO, setting `TxPktRdy`). The ***Endpoint 0 Control States*** figure shows the actions for the phase. The USB changes the FIFO direction depending on the direction of the data phase, independently of the processor.

Figure 27-4: Endpoint 0 Control States

Endpoint 0 Service Routine as Peripheral

The USB controller generates an endpoint 0 interrupt when:

- The USB controller sets the `USB_EP0_CSR[n]_P.RXPKTRDY` bit after a valid token has been received and data has been written to the FIFO.

- The USB controller clears the `USB_EP0_CSR[n]_P.TXPKTRDY` bit after the data packet in the FIFO has been successfully transmitted to the host.
- The USB controller sets the `USB_EP0_CSR[n]_P.SENTSTALL` bit after a control transaction is ended due to a protocol violation.
- The USB controller sets the `USB_EP0_CSR[n]_P.SETUPEND` bit because a control transfer has ended before `USB_EP0_CSR[n]_P.DATAEND` is set.

Whenever the endpoint 0 service routine is entered, the firmware must first check whether the current control transfer has been ended. The transfer can end due to either a stall condition or a premature end-of-control transfer. If the control transfer ends due to a stall condition, the USB controller sets the `USB_EP0_CSR[n]_P.SENTSTALL` bit. If the control transfer ends due to a premature end-of-control transfer, the USB controller sets `USB_EP0_CSR[n]_P.SETUPEND`. In either case, the firmware must abort processing the current control transfer and set the state to IDLE.

Once the firmware has determined that an illegal bus state did not generate the interrupt, the next action depends on the endpoint state.

If endpoint 0 is in IDLE state, the only valid reason the USB controller can generate an interrupt is due to the core receiving data from the USB bus. The service routine must check for this state by testing the `USB_EP0_CSR[n]_P.RXPKTRDY` bit. If the USB controller sets the bit, then the core has received a setup packet. The processor unloads this packet from the FIFO and decodes it to determine the next action. Depending on the command contained within the setup packet, endpoint 0 enters one of the following three states.

- If the command is a single packet transaction (`SET_ADDRESS`, `SET_INTERFACE` and the others) without a data phase, the endpoint remains in the IDLE state.
- If the command has an OUT data phase (`SET_DESCRIPTOR` and others), the endpoint enters the Rx state.
- If the command has an IN data phase (`GET_DESCRIPTOR` and others), the endpoint enters the Tx state.

NOTE: Command transactions all include a field that indicates the amount of data the host expects to receive or send.

If the endpoint is in Tx state, the interrupt indicates that the core has received an IN token and data from the FIFO has been sent. The firmware must respond to this event by:

- Placing more data in the FIFO when the host still expects more data
- Setting the `USB_EP0_CSR[n]_P.DATAEND` bit to indicate that the data phase is complete

Once the data phase of the transaction completes, endpoint 0 returns to the IDLE state to await the next control transaction.

If the endpoint is in the Rx state, the interrupt indicates that a data packet has been received. The firmware must respond by unloading the received data from the FIFO. The firmware must then determine whether it has received all of the expected data. If it has, the firmware must set the `USB_EP0_CSR[n]_P.DATAEND` bit and return endpoint 0 to IDLE state. If more data is expected, the firmware must set the `USB_EP0_CSR[n]_P.SPKTRDY` bit to indicate that it has read the data in the FIFO and leave the endpoint in the Rx state.

IDLE Mode

The endpoint 0 control must select IDLE mode at power-on or reset. The endpoint 0 control returns to this mode when the Rx and Tx modes terminate.

As shown in the ***Endpoint 0 Idle Mode (SETUP Phase)*** figure, the SETUP phase of control transfer is handled in IDLE mode.

Tx Mode

Refer to the ***Endpoint 0 Tx Mode*** figure. When the endpoint is in Tx state, all arriving IN tokens must be treated as part of a data phase until the required amount of data has been sent to the host. If either a SETUP or an OUT token is received while the endpoint is in the Tx state, a `USB_EP0_CSR[n]_P.SETUPEND` condition occurs. The core expects only IN tokens.

Three events can cause the Tx mode to terminate before the expected amount of data has been sent:

- The host sends an invalid token which sets the `USB_EP0_CSR[n]_P.SETUPEND` bit.
- The firmware sends a packet containing less than the maximum packet size for endpoint 0.
- The firmware sends an empty data packet.

Until the transaction is terminated, when the firmware receives an interrupt which indicates that a packet has been sent from the FIFO, it simply loads the FIFO. An interrupt is generated when the USB controller clears `USB_EP0_CSR[n]_P.TXPKTRDY`.

When the firmware forces the termination of a transfer (by sending a short or empty data packet), it must set the `USB_EP0_CSR[n]_P.DATAEND` bit. This event indicates to the core that the data phase is complete and that the core will receive an acknowledge packet next.

Rx Mode

Refer to the ***Endpoint 0 Rx Mode*** figure. In Rx mode, all arriving data must be treated as part of a data phase until the expected amount of data is received. If either a SETUP or an IN token is received while the endpoint is in Rx state, a `USB_EP0_CSR[n]_P.SETUPEND` condition occurs since the core expects only OUT tokens.

Three events can cause the Rx mode to terminate before the expected amount of data is received:

- The host sends an invalid token which sets the `USB_EP0_CSR[n]_P.SETUPEND` bit.
- The host sends a packet which contains less than the maximum packet size for endpoint 0.
- The host sends an empty data packet.

The transaction terminates when the firmware receives an interrupt which indicates that new data has arrived (`USB_EP0_CSR[n]_P.RXPKTRDY` bit is set). Until the transaction terminates, firmware must unload the FIFO and clear `USB_EP0_CSR[n]_P.RXPKTRDY` by setting the `USB_EP0_CSR[n]_P.SPKTRDY` bit.

When the firmware detects the termination of a transfer (by receiving either the expected amount of data or an empty data packet), it must set the `USB_EP0_CSR[n]_P.DATAEND` bit. This event indicates to the core that the data phase is complete and that the core will receive an acknowledge packet next.

Figure 27-8: Endpoint 0 Rx Mode

Peripheral Mode, Bulk IN, Transfer Size Known

For this process, the maximum size of an individual packet (*MaxPktSize*) in bytes and the complete transfer size (*TxferSize*) in bytes, must be known.

1. Load *MaxPktSize* into the `USB_EP[n]_TXMAXP` register.
2. Set the following bits: `USB_EP[n]_TXCSR_P.DMAREQEN` = 1, `USB_EP[n]_TXCSR_P.AUTOSET` = 1, `USB_EP[n]_TXCSR_P.ISO` = 0, `USB_EP[n]_TXCSR_P.FRCDATATGL`= 0.
3. Load the *TxferSize* value into the `USB_DMA[n]_CNT` register.
4. Configure the DMA controller to write the data into the corresponding Tx FIFO address.
5. On each `USB_DMA[n]_CNT` transition, the DMA controller writes a new packet into the FIFO. The `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is automatically set when each new packet is written.

   ADDITIONAL INFORMATION: Repeat Step 5 for each full packet of the transfer. Even if the final packet is a short packet, the USB controller automatically detects the packet because the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is set.

Peripheral Mode, Bulk IN, Transfer Size Unknown

For this process, assume the maximum individual packet size (*MaxPktSize*) in bytes is an even number of bytes.

1. Load *MaxPktSize* into the `USB_EP[n]_TXMAXP` register.
2. Set the following bits: `USB_EP[n]_TXCSR_P.DMAREQEN` = 1, `USB_EP[n]_TXCSR_P.AUTOSET` = 1, `USB_EP[n]_TXCSR_P.ISO` = 0, `USB_EP[n]_TXCSR_P.FRCDATATGL`= 0.

3. Configure the DMA controller to write *MaxPktSize*/2 half words into the corresponding Tx FIFO address on each `USB_DMA[n]_CNT`.
4. Set up an ISR, sensitive to the DMA work-block-complete interrupt, that writes a remaining short packet into the Tx FIFO using processor core DMA. Then, set the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit or toggle the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit to send a zero-length packet.
5. On each `USB_DMA[n]_CNT` transition, the DMA controller writes a new packet into the FIFO. The `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is set automatically when each new packet is written.

   ADDITIONAL INFORMATION: Repeat step 5 for each full packet of the transfer. The ISR from step 4 manages the final short or zero-length packet.

Peripheral Mode, ISO IN, Small MaxPktSize

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is less than 128 bytes and is an even number of bytes. Assume that double buffering is enabled, and the auto-set feature is not used (because packets are often less than *MaxPktSize*).

1. Load *MaxPktSize* into the `USB_EP[n]_TXMAXP` register.
2. Set the following bits: `USB_EP[n]_TXCSR_P.ISO` = 1.
3. Preload the first two packets into the endpoint Tx FIFO and set the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit.
4. Set up an ISR, sensitive to the `USB_IRQ.SOF` interrupt, which writes a new packet into the Tx FIFO and sets the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit.
5. Set the `USB_IEN.SOF` bit = 1 to generate an interrupt on each start of frame.

   ADDITIONAL INFORMATION: Repeat step 5 for each ISO packet.

Peripheral Mode, ISO IN, Large MaxPktSize

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is greater than 128 bytes and is an even number of bytes. Assume that double buffering is enabled, and the auto-set feature is not used (because packets are often less than *MaxPktSize*).

1. Load *MaxPktSize* into the `USB_EP[n]_TXMAXP` register.
2. Set the `USB_EP[n]_TXCSR_P.ISO` bit = 1.
3. Set the `USB_POWER.ISOUPDT` bit = 1 to prevent the initial packet loaded into the FIFO from transmitting on the USB until the next 1ms frame.
4. Load the total number of bytes for the first two packets into the `USB_DMA[n]_CNT` register.
5. Configure the DMA controller to pre-load the two packets into the corresponding Tx FIFO address and set the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit.

6. Set up an ISR, sensitive to the `USB_IRQ.SOF` interrupt, which writes a new packet into the Tx FIFO by configuring the DMA controller to load the packet.
7. Set the `USB_IEN.SOF` bit = 1 to generate an interrupt on each start of frame.

   ADDITIONAL INFORMATION: Repeat step 7 for each ISO packet.

Peripheral Mode, Bulk OUT, Transfer Size Known

For this process, the maximum individual packet size (*MaxPktSize*) in bytes and the complete transfer size (*TxferSize*) in bytes must be known.

1. Load *MaxPktSize* into `USB_EP[n]_RXMAXP`.
2. Set the following bits: `USB_EP[n]_RXCSR_P.DMAREQEN` = 1, `USB_EP[n]_RXCSR_P.AUTOCLR`= 1, `USB_EP[n]_RXCSR_P.ISO` = 0, `USB_EP[n]_RXCSR_P.CLRDATATGL` = 0, `USB_EP[n]_RXCSR_P.DMAREQMODE` = 0.
3. Configure the DMA controller to read the full *TxferSize*/2 half words from the corresponding Rx FIFO address.
4. On each `USB_DMA[n]_CNT` transition, the DMA controller reads another packet from the FIFO. The USB controller automatically clears the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit when each new packet is read.

   ADDITIONAL INFORMATION: Repeat step 5 for each full packet of the transfer. If *TxferSize* is not an exact multiple of *MaxPktSize*, the final `USB_DMA[n]_CNT` transition causes the DMA controller to read out only the short packet that remains.

Peripheral Mode, Bulk OUT, Transfer Size Unknown

For this process, the maximum individual packet size (*MaxPktSize*) in bytes must be known.

1. Load *MaxPktSize* into `USB_EP[n]_RXMAXP`.
2. Set the following bits: `USB_EP[n]_RXCSR_P.DMAREQEN`= 1, `USB_EP[n]_RXCSR_P.AUTOCLR` = 1, `USB_EP[n]_RXCSR_P.ISO` = 0, `USB_EP[n]_RXCSR_P.CLRDATATGL`= 0, `USB_EP[n]_RXCSR_P.DMAREQMODE` = 1.
3. Set the appropriate bit in the `USB_INTRRXE` register.
4. Configure the DMA controller to read *MaxPktSize*/2 half words from the corresponding Rx FIFO address on each `USB_DMA[n]_CNT` transition.
5. Set up an ISR, sensitive to the Rx interrupt, which reads the `USB_EP[n]_RXCNT` register and then transfers `USB_EP[n]_RXCNT` bytes (in half words) from the Rx FIFO to the processor core.

   ADDITIONAL INFORMATION: Depending on the number of bytes in the FIFO, configure the DMA to read the data, or read it with the processor core.

ADDITIONAL INFORMATION: On each `USB_DMA[n]_CNT` transition, the DMA controller reads a packet from the FIFO. The USB controller automatically clears the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit when each new packet is read.

ADDITIONAL INFORMATION: Repeat step 5 for each full packet of the transfer.

6. If a packet is received that is less than *MaxPktSize*, the Rx interrupt goes high, and the ISR from step 5 reads out the remaining short packet.

Peripheral Mode, ISO OUT, Small MaxPktSize

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is less than 128 bytes. Assume that double buffering is enabled.

1. Load the *MaxPktSize* value into the `USB_EP[n]_RXMAXP` register.
2. Set the `USB_EP[n]_RXCSR_P.ISO` bit = 1.
3. Set up an ISR, sensitive to the `USB_IRQ.SOF` interrupt, that reads the `USB_EP[n]_RXCSR_P.FIFOFULL` bit and then reads the `USB_EP0_CNT[n].RXCNT` status register. The ISR removes one or two packets (equal to the `USB_EP0_CNT[n].RXCNT` number of bytes) from the FIFO. It then clears the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit.
4. Set the `USB_IEN.SOF` bit = 1 to generate an interrupt on each start of frame.

   ADDITIONAL INFORMATION: Repeat step 4 for each ISO packet.

Peripheral Mode, ISO OUT, Large MaxPktSize

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is greater than 128 bytes. Assume that double buffering is enabled.

1. Load *MaxPktSize* into the `USB_EP[n]_RXMAXP` register.
2. Set the `USB_EP[n]_RXCSR_P.ISO` bit = 1.
3. Set up an ISR (sensitive to the `USB_IRQ.SOF` interrupt), that reads the `USB_EP[n]_RXCSR_P.FIFOFULL` bit, and then reads the `USB_EP[n]_RXCNT` status register. The ISR configures the DMA controller to remove one or two packets (equal to the `USB_EP[n]_RXCNT` number of bytes) from the FIFO.
4. Set up an ISR, sensitive to the DMA work-block-complete interrupt to clear the `USB_EP[n]_RXCSR_P.RXPKTRDY`.
5. Set the `USB_IEN.SOF` bit = 1 to generate an interrupt on each start of frame.

   ADDITIONAL INFORMATION: Repeat step 5 for each ISO packet.

Peripheral Mode Suspend

When no activity has occurred on the USB for 3 ms, the USB controller enters suspend mode. If the suspend interrupt (`USB_IRQ.SUSPEND`) is enabled, an interrupt is generated.

When resume signaling is detected, the USB controller exits suspend mode. If the `USB_IRQ.RESUME` interrupt is enabled, an interrupt is generated. The processor core can also force the USB controller to exit suspend mode by setting the `USB_POWER.RESUME` bit. This event initiates a remote wake-up. When this bit is set, the USB controller exits suspend mode and drives resume signaling onto the bus. The processor core must clear this bit after 10 ms (a maximum of 15 ms) to end resume-signaling.

NOTE: The `USB_IRQ.RESUME` interrupt is not generated when the processor core exits suspend mode. This interrupt is not generated when the software initiates remote wake-up.

Start of Frame (SOF) Packets

When the USB controller operates in peripheral mode, it receives a start of frame packet from the host every millisecond when in full-speed mode, or every 125 microseconds when in high-speed mode.

When the USB controller receives a SOF packet, it writes the 11-bit frame number contained in the packet into the `USB_FRAME` register. An output pulse, lasting one USB clock bit period, is generated. A start of frame interrupt is also generated (if enabled by the `USB_IRQ.SOF` bit).

After the USB controller has started to receive SOF packets, the controller expects one every millisecond (faster in high-speed mode). If the USB controller does not receive an SOF packet after 1.00358 ms (faster in high-speed mode), it is assumed that the packet is lost. A start of frame pulse (together with a `USB_IRQ.SOF` interrupt) is still generated even though the `USB_FRAME` register is not updated. The USB controller continues to generate an SOF pulse every millisecond (faster in high-speed mode). It resynchronizes these pulses to the received SOF packets when it successfully receives these packets again.

Soft Connect/Soft Disconnect

In peripheral mode, the USB controller sets or clears the `USB_POWER.SOFTCONN` bit to switch between normal mode and non-driving mode. When `USB_POWER.SOFTCONN`=1, the USB controller is in normal mode and the D+/D– lines of the USB bus are enabled. When the `USB_POWER.SOFTCONN`=0, the PHY is put into non-driving mode and D+ and D– are three-stated. The USB controller appears to have been disconnected from the USB bus.

After system reset, `USB_POWER.SOFTCONN`=0. From that point, the USB controller appears disconnected until the software has set `USB_POWER.SOFTCONN` =1. The application software can then choose when to set the PHY to its normal mode. Systems with a lengthy initialization procedure can use this functionality to ensure that initialization is complete and the system is ready to perform enumeration before connecting to the USB. Once the `USB_POWER.SOFTCONN` bit is set to 1, the software can also clear this bit to 0 to simulate a disconnect.

Error Handling As a Peripheral

The host can abort a control transfer due to a protocol error on the USB. The function controller software can also abort the transfer (for example, because it cannot process the command).

The USB controller automatically detects protocol errors and sends a stall packet to the host under the following conditions.

1. The host sends more data during the OUT data phase of a write request than specified in the command. This condition is detected when the host sends an OUT token after the `USB_EP0_CSR[n]_P.DATAEND` bit is set.
2. The host requests more data during the IN data phase of a read request than specified in the command. This condition is detected when the host sends an IN token after the `USB_EP0_CSR[n]_P.DATAEND` bit is set.
3. The host sends more than *MaxPktSize* data bytes in an OUT data packet.
4. The host sends a non-zero length DATA1 packet during the status phase of a read request.

When the USB controller has sent the stall packet, it sets the `USB_EP0_CSR[n]_P.SENTSTALL` bit and generates an interrupt. When the software receives an endpoint 0 interrupt with the `USB_EP0_CSR[n]_P.SENTSTALL` bit set, it aborts the current transfer, clears the `USB_EP0_CSR[n]_P.SENTSTALL` bit, and returns to the IDLE state.

If the host enters the status phase before all the data for the request transfers, or sends a new SETUP packet before completing the current transfer, then it prematurely ends the transfer. The `USB_EP0_CSR[n]_P.SETUPEND` bit is set and an endpoint 0 interrupt is generated. When the software receives an endpoint 0 interrupt with the `USB_EP0_CSR[n]_P.SETUPEND` bit set, it aborts the current transfer, sets the `USB_EP0_CSR[n]_P.SSETUPEND` bit, and returns to the IDLE state. If the `USB_EP0_CSR[n]_P.RXPKTRDY` bit is set, it indicates that the host has sent another SETUP packet and the software must then process this command.

If the software wants to abort the current transfer, because it cannot process the command or has some other internal error, then it must set the `USB_EP0_CSR[n]_P.SENTSTALL` bit. The USB controller then sends a stall packet to the host, sets the `USB_EP0_CSR[n]_P.SENTSTALL` bit, and generates an endpoint 0 interrupt.

Stalls Issued to Control Transfers

In peripheral mode, the USB controller automatically issues a stall handshake to a control transfer under the following conditions:

1. The host sends more data during an OUT data phase of a control transfer than specified in the device request during the SETUP phase. The USB controller detects this condition when the host sends an OUT token (instead of an IN token) after the processor core unloads the last OUT packet and sets the `USB_EP0_CSR[n]_P.DATAEND` bit.
2. The host requests more data during an IN data phase of a control transfer than specified in the device request during the SETUP phase. The USB controller detects this condition when the host sends an IN token (instead of an OUT token) after the processor core clears `USB_EP[n]_TXCSR_P.TXPKTRDY` and sets `USB_EP0_CSR[n]_P.DATAEND`. The processor sets `USB_EP0_CSR[n]_P.DATAEND` in response to the host-issued ACK for the last packet.
3. The host sends more than *MaxPktSize* data with an OUT data token.

4. The host sends the wrong PID (packet identifier) for the OUT status phase of a control transfer.
5. The host sends more than a zero length data packet for the OUT status phase.

Zero Length OUT Data Packets in Control Transfers

The USB controller uses a zero-length OUT data packet to indicate the end of a control transfer. In normal operation, such packets must only be received after the entire length of the device request transfers (for example, after the processor core has set the `USB_EP0_CSR[n]_P.DATAEND` bit). If the host sends a zero-length OUT data packet before the entire length of device request transfers, this packet signals the premature end of the transfer. In this case, the USB controller automatically flushes any IN token the processor core has loaded for the data phase from the FIFO and sets the `USB_EP0_CSR[n]_P.SETUPEND` bit.

Host Mode

USB OTG interface operations in host mode differ from peripheral mode in a number of ways. The following sections describe host mode operations.

Transaction Scheduling

When operating as a host, the USB controller maintains a frame counter.

If the target function is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame or micro-frame.

If the target function is a low-speed device, a K state is transmitted on the bus to act as a *keep-alive*. It stops the low-speed device from going into suspend mode.

After the SOF packet is transmitted, the USB controller cycles through all the endpoints looking for active transactions. An active transaction is defined as an Rx endpoint for which the `USB_EP[n]_RXCSR_H.REQPKT` bit is set or a Tx endpoint for which the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit is set.

An active isochronous or interrupt transaction only starts if:

- It is found on the first transaction scheduler cycle of a frame.
- The interval counter for that endpoint has counted down to zero.

This functionality ensures that only one interrupt or isochronous transaction occurs per endpoint per *n* frames or micro frames (or, up to three, if high-bandwidth support is selected). *n* is the interval set in the `USB_EP[n]_TXINTERVAL` or `USB_EP[n]_RXINTERVAL` register for that endpoint.

An active bulk transaction starts immediately, provided there is sufficient time left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried, then it is not retried until the transaction scheduler has checked all the other endpoints for active transactions first. (For example, the transaction is retried because a NAK was received or the target function did not respond.) This check ensures that an endpoint that is sending many NAKs does not block other transactions on the bus. The USB controller permits specifying a limit (`USB_EP[n]_TXINTERVAL` or `USB_EP[n]_RXINTERVAL` registers) to the length of time in which NAKs can be received from a particular target before the endpoint is timed out.

Endpoint Setup and Data Transfer

When the `HOST_MODE` bit is set to 1, the USB controller operates as a host for point-to-point communications with another USB device. Or, when attached to a hub, the USB controller operates as a host for communication with a range of devices in a multi-point set-up.

The USB controller supports high-speed, full-speed, and low-speed USB functions, both for point-to-point communication and for operation through a hub.

Where necessary, the core automatically carries out the necessary transaction translation to allow usage of a low-speed or full-speed device with a USB 2.0 hub.

The USB controller supports control, bulk, isochronous, or interrupt transactions.

Transfers between the subsystem and endpoint FIFOs in host mode are similar to peripheral mode. See the descriptions of processor core-to-FIFO data transfer in Peripheral Mode.

Control Transaction as a Host

Host control transactions are conducted through endpoint 0. The software handles all the standard device requests that are sent or received through endpoint 0 (as described in *Universal Serial Bus Specification*, Revision 2.0, Chapter 9).

For a USB peripheral, there are three categories of standard device requests:

- ***Zero data requests.*** Comprised of a SETUP command followed by an IN status phase. The command includes all the information.
- ***Write requests.*** Comprised of a SETUP command, followed by an OUT data phase followed by an IN status phase. Extra data follows the command.
- ***Read requests*** Comprised of a SETUP command, followed by an IN data phase followed by an OUT status phase. The device is required to send data back to the host.

A timeout can be set to limit the length of time during which the USB controller retries a transaction that the target continually NAKs. This limit can be between 2 and 2^{15} frames or micro frames and is set through the `USB_EP0_NAKLIMIT[n]` register.

The following sections describe the steps taken in different phases of a control transaction and the actions of the core when issuing standard device requests.

Set up Phase as a Host

The processor core driving the host device performs the following actions for the SETUP phase of a control transaction.

1. Load the 8 bytes of the required device request command into the endpoint 0 FIFO.
2. Set the `USB_EP0_CSR[n]_H.SETUPPKT` bit and `USB_EP0_CSR[n]_H.TXPKTRDY` bit. These bits must be set together.

The USB controller then sends a SETUP token followed by the 8-byte command to endpoint 0 of the addressed device, retrying as necessary.

3. At the end of the attempt to send the data, the USB controller generates an endpoint 0 interrupt (for example, set `USB_INTRTXE.EP0`). The processor core then reads the `USB_EP0_CSR[n]_H` register to establish whether the `USB_EP0_CSR[n]_H.RXSTALL`, `USB_EP0_CSR[n]_H.TOERR`, or the `USB_EP0_CSR[n]_H.NAKTO` bits are set.

   If `USB_EP0_CSR[n]_H.RXSTALL`=1, the target did not accept the command (for example, because the target device does not support it) and issues a stall response.

   If `USB_EP0_CSR[n]_H.TOERR`=1, the USB controller tried to send the SETUP packet and the following data packet three times without getting a response.

   If `USB_EP0_CSR[n]_H.NAKTO`=1, the USB controller received a NAK response to each attempt to send the SETUP packet, for longer than the time set in the `USB_EP0_NAKLIMIT[n]` register. Direct the USB controller to either clear the `USB_EP0_CSR[n]_H.NAKTO` bit to continue trying this transaction (until it times out again) or to flush the FIFO to abort the transaction before clearing the `USB_EP0_CSR[n]_H.NAKTO` bit.

4. If none of `USB_EP0_CSR[n]_H.RXSTALL`, `USB_EP0_CSR[n]_H.TOERR` or `USB_EP0_CSR[n]_H.NAKTO` bits are set, the SETUP phase is correctly acknowledged. The processor core can proceed to the following IN data phase, OUT data phase or IN status phase specified for the particular standard device request.

IN Data Phase as a Host

The processor core driving the host device performs the following actions for the IN data phase of a control transaction.

1. Set the `USB_EP0_CSR[n]_H.REQPKT` bit.

2. Wait while the USB controller sends the IN token and then receives the required data back.

3. When the USB controller generates the endpoint 0 interrupt (for example, by setting the `USB_INTRTXE.EP0` bit), read the `USB_EP0_CSR[n]_H` register. Determine whether the `USB_EP0_CSR[n]_H.RXSTALL` bit, the `USB_EP0_CSR[n]_H.TOERR` bit, the `USB_EP0_CSR[n]_H.NAKTO` bit, or the `USB_EP0_CSR[n]_H.RXPKTRDY` bit is set.

   If `USB_EP0_CSR[n]_H.RXSTALL`=1, the target has issued a stall response.

   If `USB_EP0_CSR[n]_H.TOERR`=1, the USB controller has tried to send the required IN token three times without getting a response.

   If `USB_EP0_CSR[n]_H.NAKTO`=1, the USB controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the `USB_EP0_NAKLIMIT[n]` register. Direct the USB controller to either clear the `USB_EP0_CSR[n]_H.NAKTO` bit to continue trying this transaction (until it times out again) or clear `USB_EP0_CSR[n]_H.REQPKT` before clearing the `USB_EP0_CSR[n]_H.NAKTO` bit to abort the transaction.

4. If the `USB_EP0_CSR[n]_H.RXPKTRDY` bit is set, the processor core reads the data from the endpoint 0 FIFO, then clears `USB_EP0_CSR[n]_H.RXPKTRDY`.
5. If further data is expected, the processor core must repeat the previous steps.

   When all the data is successfully received, the processor core can proceed to the OUT status phase of the control transaction.

OUT Data as a Host (Control)

The processor core driving the host device performs the following actions for the OUT data phase of a control transaction.

1. Load the data to be sent into the endpoint 0 FIFO.
2. Set the `USB_EP0_CSR[n]_H.TXPKTRDY` bit.

   The USB controller sends an OUT token followed by the data from the FIFO to endpoint 0 of the addressed device, retrying as necessary.
3. At the end of the attempt to send the data, the USB controller generates an endpoint 0 interrupt (for example by setting the `USB_INTRTX.EP0` bit). The processor core can then read the `USB_EP0_CSR[n]_H` to establish whether the `USB_EP0_CSR[n]_H.RXSTALL` bit, the `USB_EP0_CSR[n]_H.TOERR` bit, or the `USB_EP0_CSR[n]_H.NAKTO` bit is set.

   If `USB_EP0_CSR[n]_H.RXSTALL`=1, the target has issued a stall response.

   If `USB_EP0_CSR[n]_H.TOERR`=1 the USB controller has tried to send the OUT token and the following data packet three times without getting a response.

   If `USB_EP0_CSR[n]_H.NAKTO`=1, the USB controller has received a NAK response to each attempt to send the OUT token, for longer than the time set in the `USB_EP0_NAKLIMIT[n]` register. Direct the USB controller to either clear the `USB_EP0_CSR[n]_H.NAKTO` bit to continue trying this transaction (until it times out again) or to flush the FIFO to abort the transaction before clearing the `USB_EP0_CSR[n]_H.NAKTO` bit.

   If none of the `USB_EP0_CSR[n]_H.RXSTALL`, `USB_EP0_CSR[n]_H.TOERR`, or `USB_EP0_CSR[n]_H.NAKTO` bits are set, the OUT data is correctly acknowledged.
4. If further data must be sent, the processor core must repeat the previous steps.

   When all the data is successfully sent, the processor core proceeds to the IN status phase of the control transaction.

IN Status Phase as a Host (Following SETUP Phase or OUT Data Phase)

The processor core driving the host device performs the following actions for the IN status phase of a control transaction.

1. Set the `USB_EP0_CSR[n]_H.STATUSPKT` and `USB_EP0_CSR[n]_H.REQPKT` bits. These bits must be set together.

2. Wait while the USB controller both sends an IN token and receives a response from the USB peripheral.
3. When the USB controller generates the endpoint 0 interrupt (for example, it sets the USB_INTRTX.EP0 bit), read the USB_EP0_CSR[n]_H register to establish whether the USB_EP0_CSR[n]_H.RXSTALL, USB_EP0_CSR[n]_H.TOERR, USB_EP0_CSR[n]_H.NAKTO, or the USB_EP0_CSR[n]_H.RXPKTRDY bits are set.

   If USB_EP0_CSR[n]_H.RXSTALL=1, the target could not complete the command and so has issued a stall response.

   If USB_EP0_CSR[n]_H.TOERR=1, the USB controller has tried to send the required IN token three times without getting a response.

   If USB_EP0_CSR[n]_H.NAKTO=1, the USB controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the USB_EP0_NAKLIMIT[n] register. Direct the USB controller to either clear the USB_EP0_CSR[n]_H.NAKTO bit to continue trying this transaction (until it times out again) or clear USB_EP0_CSR[n]_H.REQPKT before clearing the USB_EP0_CSR[n]_H.NAKTO bit to abort the transaction.
4. If the USB_EP0_CSR[n]_H.RXPKTRDY bit is set, the processor core typically clears it.

OUT Status Phase as a Host (Following IN Data Phase)

The processor core driving the host device performs the following actions for the OUT status phase of a control transaction.

1. Set USB_EP0_CSR[n]_H.STATUSPKT and USB_EP0_CSR[n]_H.TXPKTRDY bits. These bits must be set together.
2. Wait while the USB controller both sends the OUT token and a zero-length DATA1 packet.
3. At the end of the attempt to send the data, the USB controller generates an endpoint 0 interrupt. The processor core then reads the USB_EP0_CSR[n]_H register to discover when the USB_EP0_CSR[n]_H.RXSTALL, USB_EP0_CSR[n]_H.TOERR, or USB_EP0_CSR[n]_H.NAKTO bits are set.

   If USB_EP0_CSR[n]_H.RXSTALL=1, the target could not complete the command and so has issued a stall response.

   If USB_EP0_CSR[n]_H.TOERR=1, the USB controller has tried to send the STATUS packet and the following data packet three times without getting a response.

   If USB_EP0_CSR[n]_H.NAKTO=1, the USB controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the USB_EP0_NAKLIMIT[n] register. Direct the USB controller to either clear the USB_EP0_CSR[n]_H.NAKTO bit to continue trying this transaction (until it times out again) or to flush the FIFO to abort the transaction before clearing the USB_EP0_CSR[n]_H.NAKTO bit.

4. If none of the `USB_EP0_CSR[n]_H.RXSTALL`, `USB_EP0_CSR[n]_H.TOERR`, or `USB_EP0_CSR[n]_H.NAKTO` bits are set, the status phase is correctly acknowledged.

Host IN Transactions

When the USB controller operates as a host, IN transactions are handled in the same way as OUT transactions are handled when the USB controller is operating as a peripheral. First, the USB controller sets `USB_EP[n]_RXCSR_H.REQPKT` bit to initiate the transaction. This bit indicates to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target function.

When the packet is received and placed in the Rx FIFO, the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is set. The appropriate Rx endpoint interrupt is generated (if enabled) to signal that the processor can now unload a packet can now from the FIFO. When the processor unloads the packet, `USB_EP[n]_RXCSR_H.RXPKTRDY` is cleared. The USB controller uses the `USB_EP[n]_RXCSR_H.AUTOCLR` bit to clear the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit automatically when the processor unloads a maximum sized packet from the FIFO. There is also an `USB_EP[n]_RXCSR_H.AUTOREQ` bit that automatically sets the `USB_EP[n]_RXCSR_H.REQPKT` bit when the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is cleared. The USB controller can use the `USB_EP[n]_RXCSR_H.AUTOCLR` and `USB_EP[n]_RXCSR_H.AUTOREQ` bits with an external DMA controller to perform complete bulk transfers without processor core intervention.

If the target function responds to a bulk or interrupt IN token with a NAK, the USB controller retries the transaction until the NAK limit set in the `USB_EP0_NAKLIMIT[n]` register is reached. If the target function responds with a stall, the USB controller does not retry the transaction, but sets the `USB_EP[n]_RXCSR_H.RXSTALL` bit to interrupt the processor core. If the target function does not respond to the IN token within the required time, the USB controller retries the transaction.(USB controller also retries the transaction if there was a CRC or bit-stuff error in the packet). If, after three attempts, the target function still has not responded, the USB controller clears the `USB_EP[n]_RXCSR_H.REQPKT` bit and interrupts the processor core with the `DATAERROR_R` bit in `USB_RXCSR` set.

Host OUT Transactions

When the USB controller operates as a host, OUT transactions are handled like IN transactions are handled when the USB controller operates as a peripheral.

The `USB_EP[n]_TXCSR_H.TXPKTRDY` bit must be set as the processor loads each packet into the Tx FIFO. The USB controller uses the `USB_EP[n]_TXCSR_H.AUTOSET` bit to cause the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit to be automatically set when the processor loads a maximum sized packet into the FIFO. The USB controller can use the `USB_EP[n]_TXCSR_H.AUTOSET` bit with an external DMA controller to perform complete bulk transfers without processor core intervention.

If the target function responds to the OUT token with a NAK, the USB controller retries the transaction until the NAK limit set in the `USB_EP0_NAKLIMIT[n]` register is reached. If the target function responds with a stall, the USB controller does not retry the transaction, but sets the `USB_EP[n]_TXCSR_H.RXSTALL` bit to interrupt the processor core. If the target function does not respond to the OUT token within the required time, the USB controller retries the transaction.(USB controller also retries the transaction if there was a CRC or bit-stuff error in the packet). If, after three attempts, the target function still has not responded, the USB controller flushes the FIFO and sets the `USB_EP[n]_TXCSR_H.TXTOERR` bit to interrupt the processor core.

Multi-Point Support

The following sections describe the multi-point support of the USB controller.

- Allocating Devices to Endpoints
- Multi-Point Operation
- Multi-Point Bandwidth Considerations

Allocating Devices to Endpoints

The separate functions of the connected devices are allocated to the endpoints within the USB controller through a group of three registers. The registers are associated with each implemented Rx or Tx endpoint (including endpoint 0).

The registers are:

- `USB_MP[n]_TXFUNCADDR`/ `USB_MP[n]_RXFUNCADDR`
- `USB_MP[n]_TXHUBADDR`/ `USB_MP[n]_RXHUBADDR`
- `USB_MP[n]_TXHUBPORT`/ `USB_MP[n]_RXHUBPORT`

The location of these registers depends on which of the endpoints is being addressed.

Record the address of the target function that is accessed through the selected endpoint in the transmit and receive function address registers. Record this information separately for each Tx and Rx endpoint used. In particular, set both `USB_MP[n]_TXFUNCADDR` and `USB_MP[n]_RXFUNCADDR` for endpoint 0.

The USB controller uses the transmit and receive hub address and hub port registers when a full-speed or low-speed device is connected to it through a high-speed USB 2.0 hub. The hub carries out the required transaction translation between high-speed transmission and low-speed or full-speed transmission. In this situation, the `USB_MP[n]_TXHUBADDR`/ `USB_MP[n]_RXHUBADDR` and `USB_MP[n]_TXHUBPORT`/ `USB_MP[n]_RXHUBPORT` registers must record the address of the hub that carries out the transaction translation. It must also record the address of the port of that hub through which the associated Tx or Rx endpoint must access the device.

If endpoint 0 is connected to a hub, then set both the Tx and the Rx versions of these registers for this endpoint. The USB controller also uses hub address registers to record whether the hub offers multiple transaction translators or just a single transaction translator. This configuration has a significant effect on the overall bandwidth that can be achieved.

In addition to recording the address of the target function, record the endpoint number and operating speed of the target device and the type of transaction that is executed. For a Tx endpoint, set this information in the `USB_EP[n]_TXTYPE` register when the index register is set to select the required endpoint. For an Rx endpoint, set this information in the `USB_EP[n]_RXTYPE` register when the index register is set to select the required endpoint. In both cases, record the endpoint number in bits [3:0], select the transaction type through bits [5:4], and select the operating speed through bits [7:6].

Set only the speed for endpoint 0 because endpoint 0 only has the facilities to handle control transactions and therefore is always associated with a device endpoint 0. Use bits [7:6] of the Type 0 register to set the speed. The register is located at address 0x1A when the index register is set to 0.

Multi-Point Operation

After allocating functions to endpoints and recording the operating speed of the target device, multi-point operations can be configured. Most operations in a multi-point set-up are the same as for the equivalent actions where the core is attached to a single other device.

However, more steps are required when:

- The option of dynamically switching the allocation of functions to endpoints is taken (for example, to allow the support of a wider range of devices).
- The control packets normally associated with endpoint 0 are handled through a different endpoint.

If dynamic allocation is used, the program must monitor the current data toggle state associated with the endpoint and with each of the devices that are allocated to that endpoint. This knowledge allows the program to select the correct data toggle state when switching occurs between one device and the other. (This action is the programs responsibility. The core cannot determine what data toggle state is expected when a function switches in and out of use.)

The data toggle state can be switched from its current state by writing to the appropriate `USB_EP[n]_TXCSR_H` or `USB_EP[n]_RXCSR_H` register. This activity sets the data toggle write enable and data toggle bits that are included in the registers when the core is in host mode.

Data toggle write enable and data toggle bits are also included in the `USB_EP0_CSR[n]_H` register. However, control operations carried out through endpoint 0 of the core normally leave the data toggle in the expected state.

Where control packets are handled through an endpoint other than endpoint 0, programs must prompt for each setup token to be sent. Programs must set the `USB_EP[n]_TXCSR_H.SETUPPKT` bit when the core operates in host mode, along with the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit. If the `USB_EP[n]_TXCSR_H.SETUPPKT` bit is not set, an OUT token is sent.

Use endpoint 0 of the USB controller to handle control packets for all of the devices attached to the controller, and to switch the allocation of this endpoint, as appropriate. Sending the correct token is ensured, as is ensuring that the data toggle is correctly set for this endpoint.

Using a different endpoint for this function is possible, as described, but note the following:

- The control function must be allocated to an Rx/Tx endpoint pair (with the same endpoint number).
- The chosen endpoints must each be associated with FIFOs that can accommodate the packet size associated with EP0 transactions at the chosen operating speed. The size is a minimum of 8 bytes for low-speed or full-speed transactions but 64 bytes for high-speed transactions.

Multi-Point Bandwidth Considerations

The available bandwidth determines the ability of a multi-point system to cope with isochronous transactions.

Once an endpoint is set up, hardware handles all scheduling. However, as with PC-based EHCI/OHCI/UHCI hosts, before opening a periodic pipe (for use by isochronous or interrupt traffic), software must determine that there is sufficient bandwidth available.

The bandwidth required for different transactions can be determined using algorithms similar to the ones used with PC-based hosts (detailed in Section 5.11.3 of the USB 2.0 Specification).

The available bandwidth is greater where the hub used supports multiple transaction translators.

Babble Interrupt

If the bus is still active at the end of a frame, the USB controller assumes that the function it is connected to has malfunctioned. It suspends all transactions, and generates a babble interrupt (`USB_IRQ.RSTBABBLE`). The USB controller does not start a transaction until the bus is inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame.

To recover from a babble error condition, the processor must take the following actions inside the interrupt service routine.

1. Turn off VBUS. Wait until the VBUS level indicator reads b#01.
2. Turn on VBUS. Wait until the VBUS level indicator reads b#11.
3. Set the `USB_IRQ.SESSREQ` bit.

The VBUS level indicator is the `USB_DEV_CTL.VBUS` bit field.

NOTE: Because VBUS is sourced external to the processor, make sure that the hardware design connects a GPIO or the dedicated `USB_VBUS` signal to the external source. This connection enables software to turn VBUS on and off.

VBUS Events

The USB On-The-Go specification defines a series of thresholds to which the devices involved in point-to-point communications must respond.

- VBUS valid (between 4.4 V and 4.75 V)
- Session valid for A device (between 0.8 V and 2.1 V)
- Session end (between 0.2 V and 0.8 V)

The critical thresholds and the processor response depend on whether the device is an A device or a B device and the circumstances of the event. The following sections describe these actions.

Actions as an A Device

VBUS >VBUS Valid with session initiated by USB controller. VBUS level indicator = b#11 and the session bit is set. When VBUS is greater than VBUS valid, the USB controller selects host mode and waits for a device to connect. It then generates a connect interrupt. The processor resets and enumerates the connected B device.

VBUS > Session valid with session initiated by B device. VBUS level indicator = b#10 and the session bit is clear. When VBUS is greater than session valid, the USB controller generates a session request interrupt. The processor sets the session bit. The USB controller either stays in host mode or changes to peripheral mode, depending upon the state of the pull-up resistor on the B device. For more information, refer to the host negotiation protocol of the OTG specification. The state of the host mode bit indicates the selected mode.

VBUS below VBUS Valid while the Session bit remains set. VBUS level indicator b#11 and the session bit is set. This event indicates a problem with the VBUS power level. For example, the battery power could have dropped too low to sustain VBUS valid. Or, the B device could be drawing more current than the A device can provide. In either case, the USB controller automatically terminates the session and generates a VBUS error interrupt.

To recover from this VBUS error condition, the processor must take the following actions inside the VBUS error interrupt handler.

- Turn off VBUS and wait until the `USB_DEV_CTL.VBUS` reads b#01.
- Turn on VBUS and wait until the `USB_DEV_CTL.VBUS` reads b#11.
- Set the `USB_DEV_CTL.SESSION` bit

The `USB_DEV_CTL.VBUS` bit field indicates the VBUS level.

NOTE: Because VBUS is sourced external to the processor, make sure that the hardware design connects a GPIO or the dedicated `DrvVBUS` signal to the external source. Then, the software can be used to turn VBUS on and off.

Actions as a B Device

VBUS > Session Valid. VBUS level indicator = b#10 and session bit is clear. This event indicates activity from the A device. The USB controller sets the session bit and disconnects the pull down resistor on the D+ line.

VBUS < Session Valid. While the session bit remains set, VBUS level indicator = b#01 and session bit is set. This event indicates that the A device has lost power (or become disconnected). The USB controller clears the session bit and generates a disconnect interrupt. The processor ends the session.

VBUS < Session End. VBUS level indicator = b#00. This event is the condition under which a B device can initiate a session request. If the session bit is set, then after 2 ms of SE0 on the bus, the USB controller starts SRP by first pulsing the data line, then pulsing the `USB_VBUS` signal.

Host Mode Reset

If the `USB_POWER.RESET` is set while the USB controller is in host mode, the USB controller generates reset signaling on the bus. The processor core must keep this bit set for 20 ms to ensure correct resetting of the target device. After the processor core clears the bit, the USB controller starts its frame counter and transaction scheduler.

Host Mode Suspend

The controller has a suspend mode that allows power savings for the processor. The mode operates as follows.

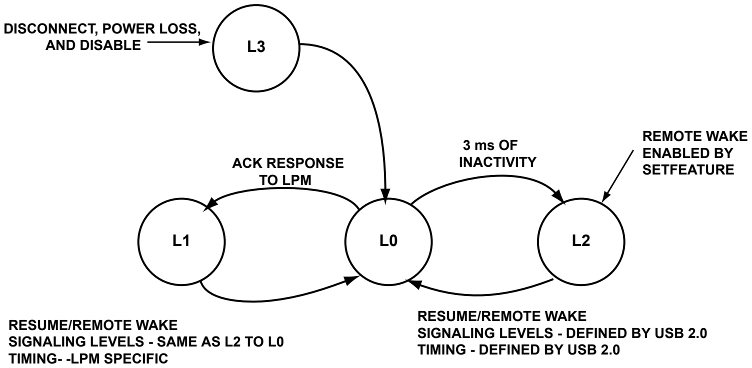
Entry into Suspend mode. When operating as a host, the USB controller can be prompted to go into suspend mode by setting the `USB_POWER.SUSPEND` bit. When this bit is set, the USB controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions start. No SOF packets are generated. If the `USB_POWER.SUSPEND` bit is set, the UTMI+ PHY goes into low-power mode when the USB controller goes into suspend mode and stops the clock.

Sending Resume Signaling. When the application requires the USB controller to leave suspend mode, it must clear and then set the `USB_POWER.RESUME` bit, and leave it set for 20 ms. While the `USB_POWER.RESUME` bit is high, the USB controller generates resume signaling on the bus. After 20 ms, the processor core must clear the `USB_POWER.RESUME` bit, at which point the frame counter and transaction scheduler start.

Responding to Remote Wake-up. If resume signaling is detected from the target while the USB controller is in suspend mode, the UTMI+ PHY is brought out of low-power mode and the clock restarts. The USB controller then exits suspend mode and automatically sets the `USB_POWER.RESUME` bit to take over generating the resume signaling from the target. If the `USB_IRQ.RESUME` bit=1, software generates an interrupt.

Suspending and Resuming the Controller

With the introduction of link power management, there are two basic methods to suspend and resume the USB controller. The ***Basic LPM transaction*** diagram demonstrates these two methods.



DISCONNECT, POWER LOSS, AND DISABLE
L3
ACK RESPONSE TO LPM
3 ms OF INACTIVITY
REMOTE WAKE ENABLED BY SETFEATURE
L1
L0
L2
RESUME/REMOTE WAKE SIGNALING LEVELS - SAME AS L2 TO L0 TIMING- -LPM SPECIFIC
RESUME/REMOTE WAKE SIGNALING LEVELS - DEFINED BY USB 2.0 TIMING - DEFINED BY USB 2.0

Figure 27-9: Basic LPM Transaction

The procedure that suspends and resumes the USB controller depends on whether the core operates as a device or a host, and the method of suspend desired. The following sections describe these options.

Suspend or Resume by Inactivity on the USB Bus (L0 to L2 State) in Peripheral Mode

The following steps occur in this mode.

1. Entry into suspend mode. When operating as a peripheral, the USB controller monitors activity on the USB and when no activity has occurred for 3 ms, the controller goes into suspend mode. If the `USB_IRQ.SUSPEND` interrupt has been enabled, the USB controller now generates an interrupt. The `USB_IRQ.SUSPEND` output also goes low (if enabled).

The *POWERDWN* signal is also asserted to indicate that the application can stop `USB_CLKIN` to save power. *POWERDWN* then remains asserted until either power is removed from the bus (indicating that the device has been disconnected) or resume signaling or reset signaling is detected on the bus.

2. When resume signaling occurs on the bus, the `USB_CLKIN` must be restarted, if necessary. The USB controller then automatically exits suspend mode. If the `USB_IRQ.RESUME` interrupt is enabled, the USB controller generates an interrupt.
3. Initiating a remote wake-up. To initiate a remote wake-up while the controller is in suspend mode, set the `USB_POWER.RESUME` bit=1. (If `USB_CLKIN` has been stopped, it must be restarted before this write can occur.) The software must leave then this bit set for approximately 10 ms (minimum of 2 ms, a maximum of 15 ms) before resetting it to 0. By this time the hub is driving resume signaling on the USB.

NOTE: The `USB_IRQ.RESUME` interrupt is not generated when the software initiates a remote wake-up.

Suspend or Resume by Inactivity on the USB Bus (L0 To L2 State) in Host Mode

The following steps occur in this mode.

1. Entry into suspend mode. When operating as a host, the USB controller can be prompted to go into suspend mode by setting the `USB_POWER.SUSPEND` bit. When this bit is set, the USB controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions start and no SOF packets are generated. If the `USB_POWER.SUSEN` bit is set, the UTMI+ PHY goes into low-power mode when the controller goes into suspend mode and stops `USB_CLKIN`.
2. Sending resume signaling. When the application requires the controller to leave suspend mode, it clears the `USB_POWER.SUSPEND` bit, sets the `USB_POWER.RESUME` bit, and leaves it set for 20 ms. While the `USB_POWER.RESUME` bit is high, the controller generates resume signaling on the bus. After 20 ms, the processor core must clear the `USB_POWER.RESUME` bit, at which point the frame counter and transaction scheduler start.
3. Responding to remote wake-up. If resume signaling is detected from the target while the USB controller is in suspend mode, the UTMI+ PHY is brought out of low-power mode and restarts `USB_CLKIN`. The controller then exits suspend mode and automatically sets the `USB_POWER.RESUME` bit to 1 to take over generating the resume signaling from the target. If the `USB_IRQ.RESUME` interrupt is enabled, the USB controller generates an interrupt.

Suspend or Resume by an LPM Transaction (L0 To L1 State) in Peripheral Mode

The following steps occur in this mode.

1. Enter into suspend mode. When operating as a peripheral, the controller never initiates an LPM suspend (transition from the L0 state to the L1 state). Rather, the controller only suspends at the request of the host. Configure the `USB_LPM_CTL` register appropriately to enable the LPM feature. The USB controller uses the register field `USB_LPM_CTL.EN` bit to enable and support extended and LPM transactions. The USB controller uses the `USB_LPM_CTL.TX` field to instruct the hardware that it is ready to suspend and to respond to the next LPM transaction with an ACK. In this case, the controller responds to the next LPM transaction with an ACK

if all other conditions are met. The ***Response to LPM Transaction*** table summarizes the response of the USB controller to an LPM transaction.

Table 27-6: Response to LPM Transaction

LPMXMT	LPMCNTRL	Data Pending (Resides in Tx FIFOs)	Response to Next LPM Transaction
1’b0, 1’b0 1’b1 1’b1	2’b00, 2’b10 2’b00 2’b10	Do-not-care	Timeout
1’b0, 1’b1	2’b01	Do-not-care	STALL
1’b0	2’b11	Do-not-care	NYET
1’b1	2’b11	Yes	NYET
1’b1	2’b11	No	ACK

For all cases in the table in which the controller responds (no timeout occurs), an LPM interrupt is generated in the `USB_LPM_IRQ` register. The controller responds with an ACK only if there is no data pending in any of the Tx endpoint FIFOs. If there is data pending, the USB controller responds with a NYET.

Once an LPM transaction is successfully received, three events occur:

a. The `USB_LPM_ATTR` register is updated with values received in the LPM transaction. See the “Register Descriptions” section of this chapter for complete information on this register.

b. The controller suspends 9 µs after transmitting the ACK. The host or the controller can drive resume signaling 50 µs after this event. During the 9 µs interval, the host can continue to transmit the LPM transaction. The controller responds with an ACK in this case regardless of the `USB_LPM_CTL.TX` bit value.

c. An interrupt is generated informing software of the response (an ACK in this case). An ACK response is the indication to software that the controller has suspended.

   Since the primary purpose of LPM is to save power, software reads the `USB_LPM_ATTR` register to determine the attributes of the suspend. Software must make a determination based on these attributes whether there are more potential power savings in the system. In making this determination, note that if the host initiates the resume signaling, the controller must respond to packet transmissions within the time specified by `USB_LPM_ATTR.HIRD` + 10 µs.

2. When resume signaling occurs on the bus. When the host resumes the bus, it drives resume signaling for a minimum time specified by the host initiated resume duration bit field (`USB_LPM_ATTR.HIRD`). The controller must be able to respond to traffic within the time HIRD + 10 µs. The controller transitions to a normal operating state automatically and a resume interrupt is generated in the `USB_LPM_IRQ` register.

However for this event to occur, the inputs *CLK* and *XCLK* must be available. To facilitate the resume timing requirement, a negative ACK (NAK) is provided using the `USB_LPM_CTL.NAK` bit. If this bit is set to 1'b1, all endpoints respond to any transaction (other then an LPM) with a NAK. This bit only takes effect after the controller has suspended LPM. Typically, this bit is asserted when the `USB_LPM_CTL.TX` field is also asserted. Using this feature can simplify the resume timing requirement because the controller only needs *XCLK* to respond (with a NAK) to traffic. Software can continue to restore the system to normal operation while the controller responds to all transactions with a NAK. After software completely restores the system, it can then clear the `USB_LPM_CTL.NAK` bit.

3. Initiating remote wake-up. To initiate a remote wake-up while in suspend mode, the controller writes a 1'b1 to the`USB_LPM_CTL.RESUME` bit. This bit is self clearing. Writing a 1'b1 drives resume signaling on the bus for 50 µs. The host responds by driving resume for 60 µs to 990 µs. 10 µs after the host stops driving resume, the controller transitions to its normal operational state and is ready for packet transmission. A resume interrupt is generated in the `USB_LPM_IRQ` register.

Suspend or Resume by an LPM Transaction (L0 to L1 State) in Host Mode

The following steps occur in this mode.

1. Enter into suspend mode. When operating as a host, the controller initiates an LPM suspend (transition from the L0 state to the L1 state) by initiating an LPM transaction as follows.
   a. Software sets up the desired attributes of the suspend in the `USB_LPM_ATTR` register. Enabling remote wake-up and a large HIRD gives the peripheral more opportunity to conserve power.
   b. Enable all LPM interrupts in the `USB_LPM_IEN` register.
   c. Software writes 0x01 to the `USB_LPM_CTL` register to initiate the transaction.
   d. An interrupt is generated to inform software of the response to the LPM transaction. If an ACK was received, then the controller suspends automatically within 8 µs. This event indicates that the controller has suspended.

   If the response from the device has a bit stuff error or a PID error, then an `USB_LPM_IRQ.LPMERR` interrupt is generated. The hardware immediately attempts the LPM transaction two more times. The device does not suspend for 8 µs after the initial LPM so it can respond to either of these subsequent LPM transactions. If an LPM timeout has occurred three times, the `USB_LPM_IRQ.LPMNC` and the `USB_LPM_IRQ.LPMERR` interrupts are set. Now, software is unaware of the device state and must deduce it by other means.

2. Send resume signaling. Software generates resume signaling as follows.
   a. Enable all LPM interrupts in the `USB_LPM_IEN` register.
   b. Software writes to the `USB_LPM_CTL.RESUME` bit which is self-clearing. This operation causes resume signaling on the bus for the time specified in the `USB_LPM_ATTR.HIRD` bit field. Hardware assumes that the last LPM transaction that caused the suspend used this value.
   c. After HIRD + 10 µs, the controller transitions to its normal operational state and is ready for packet transmission and a `USB_LPM_IRQ.LPMRES` interrupt is generated.

   NOTE: Prior to resuming, software must ensure that the system is restored from a low-power state and that the inputs *CLK* and *XCLK* are available.

3. Responding to remote wake-up. If the remote wake-up feature is enabled in the LPM transaction that caused the suspend, then the device can drive resume signaling on the bus. When this event occurs, the device drives resume signaling BUS for 50 µs. The controller immediately begins driving resume signaling on the BUS and continues for 60 µs. 10 µs after completion of the resume signaling, the controller transitions to its normal operating state and is ready for packet transmission. Then, the `USB_LPM_IRQ.LPMRES` interrupt is generated.

USB Event Control

The following sections provide information on the use of interrupts, reset, and the reporting of errors and interface status.

Interrupt Signals

The "Interrupt Table" section at the beginning of this chapter shows the two interrupts generated from the USB controller.

The software generates interrupts from control endpoint zero under the following conditions :

- When a control transaction ends before the end of the data is transferred
- When a data packet is sent or received from the endpoint 0 FIFOs

The USB controller generates interrupts from transmit endpoints (`USB_INTRTX`) under the following conditions:

- A packet is sent from the TX FIFO (host and peripheral mode)
- After three attempts at transmitting a packet, no valid handshake packet is received (host mode)

The software generates interrupts from receive endpoints (`USB_INTRRX`) under the following conditions:

- A packet is received into the RX FIFO (host and peripheral mode)
- A stall handshake is received (host mode)
- After three attempts at receiving a packet, no data packet is received (host mode)

The software generates interrupts from the USB status (`USB_IRQ`) under the following conditions:

- When VBUS drops below the VBUS valid threshold during a session (A device only)
- When SRP signaling is detected (A device only)
- When device disconnect is detected (host mode)
- When a session ends (peripheral mode)
- When a device connection is detected (host mode)
- At start of frame (SOF)
- When reset signaling is detected on USB (peripheral mode)

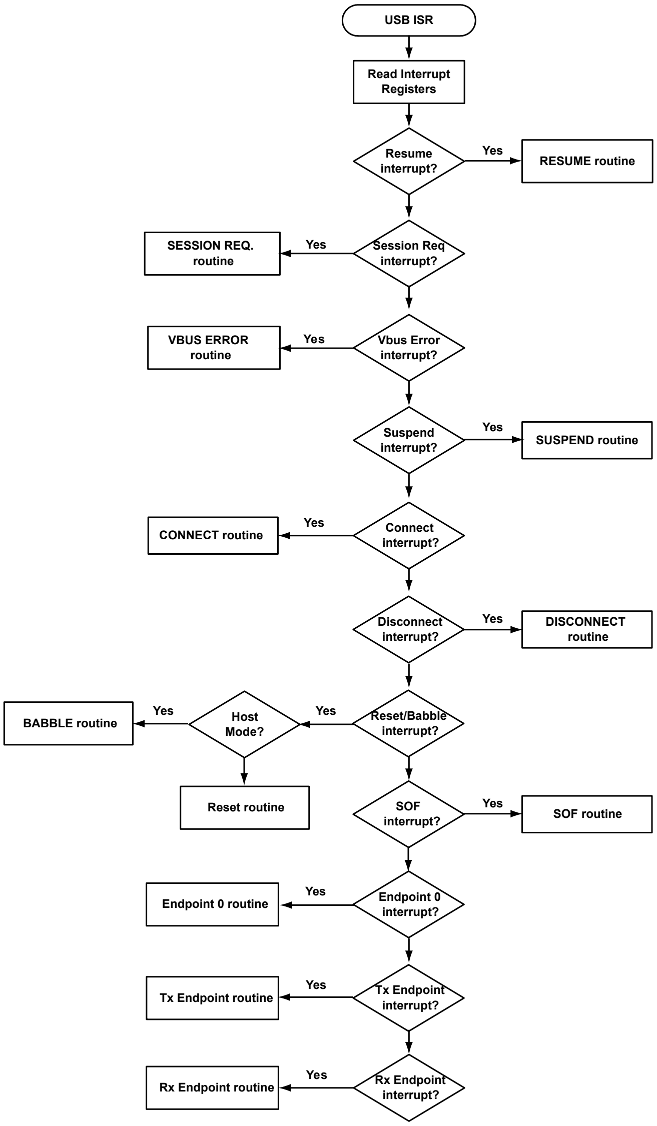
- When babble is detected (host mode)
- In suspend mode, when resume signaling is detected on USB
- When suspend signaling is detected (peripheral mode)

The software generates interrupts for the following VBUS control requests:

- Drive VBUS greater than 4.4 V (default A device)
- Stop driving VBUS
- Start charging VBUS (peripheral mode)
- Stop charging VBUS
- Start discharging VBUS (peripheral mode)
- Stop discharging VBUS

Interrupt Handling

When interrupted with a USB interrupt, the processor core must read the interrupt status register to determine which endpoints have caused the interrupt and jump to the appropriate routine. If multiple endpoints have caused the interrupt, endpoint 0 must be serviced first, followed by the other endpoints. The ***USB Interrupt Service Routine*** figure shows a flowchart for the USB interrupt service routine.



USB ISR
Read Interrupt Registers
Resume interrupt?
Yes
RESUME routine
Session Req interrupt?
Yes
SESSION REQ. routine
Vbus Error interrupt?
Yes
VBUS ERROR routine
Suspend interrupt?
Yes
SUSPEND routine
Connect interrupt?
Yes
CONNECT routine
Disconnect interrupt?
Yes
DISCONNECT routine
Reset/Babble interrupt?
Yes
Host Mode?

Reset routine
SOF interrupt?
Yes
SOF routine
Endpoint 0 interrupt?
Yes
Endpoint 0 routine
Tx Endpoint interrupt?
Yes
Tx Endpoint routine
Rx Endpoint interrupt?
Yes
Rx Endpoint routine

Figure 27-10: USB Interrupt Service Routine

Reset Signals

The USB controller includes an active-high synchronous hardware reset sourced from the processor core. Another source of peripheral reset is through the USB, when USB reset signaling is detected on the I/O lines. Per the USB 2.0 Specification, this state is entered when both the D+ and D- inputs are driven low for 2.5 ms or more. (The USB host typically holds the reset for greater than 10 ms.)

Reset in Peripheral Mode

When the USB controller detects a reset, it performs the following actions:

- Sets the `USB_FADDR` register to zero
- Sets the `USB_INDEX` register to zero

- Flushes all endpoint FIFOs
- Clears all control and status registers
- Enables all interrupts
- Generates a reset interrupt

The USB controller reset does not affect the `USB_IRQ` and `USB_VBUS_CTL` registers. These registers are only reset (along with the ones listed) during a system reset.

If the `USB_POWER.HSEN` bit was set, the USB controller also tries to negotiate for high-speed operation. The `USB_POWER.HSMODE` bit indicates whether high-speed operation is selected.

When the application software receives a reset interrupt, it closes any open pipes and waits for bus enumeration to begin.

USB Reset in Host Mode

If the `USB_POWER.RESET` bit =1 while the USB controller is in host mode, the controller generates reset signaling on the bus.

If the `USB_POWER.HSEN` bit =1, the controller also tries to negotiate for high-speed operation.

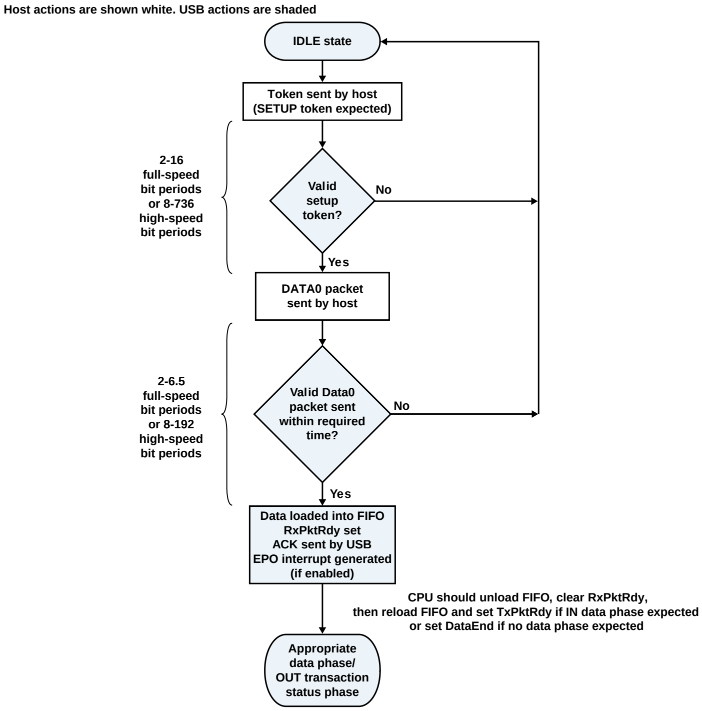
The processor core must keep the `USB_POWER.RESET` bit set for at least 20 ms to ensure correct resetting of the target device. After the processor core clears the bit, the USB controller starts its frame counter and transaction scheduler.

The USB controller uses the `USB_POWER.HSMODE` bit to select high-speed operation.

USB Programming Model

The following sections describe the USB OTG programming model.

Peripheral Mode Flow Charts



Host actions are shown white. USB actions are shaded
IDLE state
Token sent by host (SETUP token expected)
2-16 full-speed bit periods or 8-736 high-speed bit periods
Valid setup token?
No
Yes

OTG Session Request

To conserve power, the USB on-the-go supplement allows VBUS to only power-up when required and to turn off when the bus is not in use.

The A device on the bus always supplies VBUS. The USB controller samples the `USB_ID` input from the PHY to determine whether it is the A device or the B device. The signal is pulled low when an A-type plug is sensed (signifying that the USB controller is the A device). The input is taken high when a B-type plug is sensed (signifying that the USB controller is the B device).

Starting a Session

When the device containing the USB controller wants to start a session, the processor core must set the `USB_DEV_CTL.SESSION` bit. The USB controller then enables ID pin sensing. This activity results in the `USB_ID` input either being taken low if an A-type connection is detected or high if a B-type connection is detected. The `USB_DEV_CTL.BDEVICE` bit is also set to indicate whether the USB controller has adopted the role of the A device or the B device.

The USB controller is the A device. The USB controller then enters host mode (the A device is always the default host). It waits for VBUS to go above the VBUS valid threshold, as indicated when the `USB_DEV_CTL.VBUS` bits go to 11.

The USB controller then waits for a peripheral to be connected. When the USB controller detects a peripheral, it generates a connect interrupt (`USB_IRQ.CON` bit) (if enabled). It sets either the `USB_DEV_CTL.FSDEV` or `USB_DEV_CTL.LSDEV` bits, depending on whether a full-speed peripheral or a low-speed peripheral was detected. The processor core then resets this peripheral. To end the session, the processor core must clear the `USB_DEV_CTL.SESSION` bit.

The USB controller is the B device. The USB controller requests a session using the session request protocol defined in the USB on-the-go supplement. This functionality is accomplished by setting the `USB_DEV_CTL.SESSION` bit.

At the end of the session, typically the USB controller clears the `USB_DEV_CTL.SESSION` bit. But, the processor core can also clear it when the application software must perform a software disconnect. For more information, see the description of the `USB_DEV_CTL` register. The USB controller switches on the pull-up resistor on D+. This activity signals to the A device to end the session.

Detecting Activity

When the other device of the OTG set-up wants to start a session, USB controller either:

- Raises VBUS above the session valid threshold (if A device) or
- First pulses the data line, then pulses VBUS (if B device)

Depending on which of these actions happens, the USB controller can determine whether it is the A device or the B device in the current set-up and act accordingly. (The `USB_DEV_CTL.VBUS` bits=10 indicates if it is the A device.)

If VBUS is raised above the session valid threshold, the USB controller is the B device. The USB controller sets the `USB_DEV_CTL.SESSION` bit. When reset signaling is detected on the bus, a reset interrupt (`USB_IRQ.RSTBABBLE=1`) is generated (if enabled) that the processor core interprets as the start of a session. The USB controller is in peripheral mode as the B device is the default peripheral.

At the end of the session, the A device turns off the power to VBUS. When VBUS drops below the session valid threshold, the USB controller detects this state and clears the `USB_DEV_CTL.SESSION` bit to indicate that the session has ended. (The `USB_DEV_CTL.VBUS` bits=01 indicates that VBUS has dropped below the session valid threshold). A disconnect interrupt (`USB_IRQ.DISCON` bit) is also generated (if enabled).

If data line or VBUS pulsing is detected, the USB controller is the A device. The controller generates a `USB_IRQ.SESSREQ` interrupt to indicate that the B device is requesting a session. The processor core must then start a session by setting the `USB_DEV_CTL.SESSION` bit.

Host Negotiation Protocol

When the USB controller is the A device (`USB_ID` low, `USB_DEV_CTL.BDEVICE=0`), the controller automatically enters host mode when a session starts.

When the USB controller is the B device (`USB_ID` high, `USB_DEV_CTL.BDEVICE=1`), the controller automatically enters peripheral mode when a session starts. The processor core can request that the USB controller become the host by setting the `USB_DEV_CTL.HOSTREQ` bit. This bit can be set either when requesting a session start by setting the `USB_DEV_CTL.SESSION` bit or at any time after a session has started.

When the USB controller enters suspend mode (no activity on the bus for 3 ms), and assuming the `USB_DEV_CTL.HOSTREQ` bit remains set, it then enters host mode. It begins host negotiation (as specified in the USB OTG supplement), causing the PHY to disconnect the pull-up resistor on the D+ line. This event causes the A device to switch to peripheral mode and to connect its own pull-up resistor. When the USB controller detects this activity, it generates a connect interrupt (`USB_IRQ.CON` bit). The controller also sets the `USB_POWER.RESET` bit to begin resetting the A device. (The USB controller begins this reset sequence automatically to ensure that reset is started as required within 1 ms of the A device connecting its pull-up resistor.) The processor core must wait at least 20 ms, then clear the `USB_POWER.RESET` bit and enumerate the A device.

When the USB controller-based B device has finished using the bus, the processor core must put it into suspend mode by setting the `USB_POWER.SUSPEND`. The A device detects this state and either terminates the session or reverts to host mode. If the A device is USB controller-based, it generates a disconnect interrupt (`USB_IRQ.DISCON` bit) if enabled.

Data Transfer

Whether the USB controller is operating in host or peripheral mode, data channels through the endpoint FIFOs to construct packets that are sent or received over the USB. The USB controller uses the Rx FIFOs to receive OUT packets when in peripheral mode and IN packets when operating in host mode. Similarly, The USB controller uses the Tx FIFOs to transmit IN packets when in peripheral mode and OUT packets as a host.

Data can be moved between the FIFOs and memory using either DMA or core accesses. Each endpoint FIFO has its own individually programmable options so that each can be set up separately. The system must treat each transfer type differently. Data transfers of significant size almost certainly require DMA to move the data around; but the processor can handle smaller packet sizes completely.

Each data endpoint supports both double and single-buffering modes. In single-buffered operation, the processor loads and unloads FIFOs on a packet-by-packet basis. Double-buffering imposes less burden on the system by allowing two packets to be buffered in a FIFO before it is necessary to use DMA or interrupts to service the FIFO. Double-buffering mode is automatically enabled when a *MaxPktSize* is set for an endpoint that is equal to or less than half the size in bytes of that FIFO.

Loading or Unloading Packets from Endpoints

Transfers to and from the FIFOs can be 32-bit, 16-bit, or 8-bit. When using core accesses, use the same width for transfers associated with one data packet, so that data is consistently byte, half-word, or word aligned. The last transfer can, however, contain fewer bytes than the previous transfers in order to complete an 8-bit or 16-bit transfer.

When using the DMA to access the FIFOs, the starting DMA address must be word aligned, or aligned on a 32-bit boundary. The packet transfer starts with a word transfer, but half-word or byte transfers can be added at the end to handle any leftovers.

DMA Master Channels

The USB controller provides eight DMA master channels.

These channels provide a more efficient transfer of larger amounts of data between the FIFOs and the processor core, and the channels free up the processor core for other tasks. The processor uses the DMA control registers to configure and control each of these channels.

Each DMA controller can operate in one of two DMA modes: 0 or 1. When operating in mode 0, the DMA controller can only be programmed to load or unload one packet, so processor intervention is required for each packet transferred over the USB. The DMA controller can use this mode with any endpoint, whether it uses control, bulk, isochronous, or interrupt transactions.

When operating in DMA mode 1, the DMA controller can only be programmed to load or unload a complete bulk transfer, which can be many packets. After set up, the DMA controller loads or unloads the packets, interrupting the processor only when the transfer has completed. DMA mode 1 can only be used with endpoints that use bulk transactions. It is most valuable where large blocks of data are transferred to a bulk endpoint. The USB protocol requires splitting such packets into a series of packets of *MaxPktSize* for the endpoint.

The DMA controller can use mode 1 to avoid the overhead of having to interrupt the processor after each individual packet. It interrupts the processor only after the transfer completes. In some cases, the block of data transferred consists of a predefined number of these packets that the controlling software counts through the transfer process. In other cases, the last packet in the series can be less than the maximum packet size. The receiver can use this short packet to signal the end of the transfer. If the total size of the transfer is an exact multiple of the maximum packet size, the transmitting software must send a null packet for the receiver to detect.

NOTE: Each channel can be independently programmed for the selected operating mode.

For bulk OUT transfers using DMA mode 1, the DMA request line is asserted only when:

- There is an edge transition of the state of the `USB_EP[n]_RXCSR_H.RXPKTRDY`, and
- A payload of *MaxPktSize* has been received

If a data packet is in the FIFO prior to setting the DMA request mode bits, the DMA request line is not asserted when the DMA is enabled. DMA is enabled using the `USB_DMA[n]_CTL.EN` bit. (DMA request mode bits are `USB_EP[n]_RXCSR_H.DMAREQMODE` or `USB_EP[n]_RXCSR_P.DMAREQMODE`). The data is not read from the Rx FIFO in this situation, resulting in a DMA hang. However, since the packet arrived before DMA request mode and DMA request enable bits (`USB_EP[n]_RXCSR_H.DMAREQEN` or `USB_EP[n]_RXCSR_P.DMAREQEN`) were enabled, an Rx interrupt is generated for the corresponding endpoint. Therefore, the software must set the DMA request mode to request mode 0 to unload the pre-received packet. The Rx interrupt service routine can be similar to the following:

If `USB_EP[n]_RXCNT` = MaxPktSize

Switch to DMA mode 0 and unload the packet (in mode 0, the DMA request enable is always asserted, whenever there is data in the FIFO)

Set the `USB_EP[n]_RXCNT` to MaxPktSize so as to unload only one packet

If `USB_EP[n]_RXCSR_H.AUTOCLR` is set, it is not necessary to clear `USB_EP[n]_RXCSR_H.RXPKTRDY` manually

Switch back to DMA Mode 1 and set the count to

(Total_Count – MaxPktSize)

Else

Handle as normal for case of short packet

DMA transfers can be 8-bit, 16-bit, or 32-bit. All transfers associated with one packet (except for the last) must be of the same width, so that the data is consistently byte-aligned or word-aligned. The last transfer can contain fewer bytes than the previous transfers to complete an odd-byte or odd-word transfer.

DMA Bus Cycles

The DMA controller uses incrementing bursts of an unspecified length on the peripheral DMA bus. The controller starts a new burst when it is first granted bus mastership and when the peripheral address starts a new 1 KB block. (The controller is granted bus mastership at the start of a USB packet or when regaining the bus after losing it following a partial packet).

When unloading packets from the FIFOs, the DMA controller requests ahead to the USB controller. The DMA controller starts the transfer with two BUSY cycles while it is gets the first word from the FIFO. All subsequent words of the packet are immediately available and no further BUSY cycles are required. The DMA controller is associated with a two-word buffer, so it does not lose data when it loses bus mastership in the middle of unloading a packet. When the controller regains bus mastership, it can continue unloading the packet without adding any BUSY cycles.

The DMA start address (written to the `USB_DMA[n]_ADDR` register) must be word aligned. The DMA controller supports split transactions and retries.

The DMA request lines are individually enabled using the appropriate DMA request enable bit (there are four options: Tx peripheral and host and Rx peripheral and host) and operate in two modes, referred to as DMA request mode 0 and DMA request mode 1. The operating mode is configured using the appropriate DMA request mode bit (there are four options: Tx peripheral and host and Rx peripheral and host).

NOTE: When operating in host mode, if the `USB_EP[n]_TXCSR_H.RXSTALL` bit or the `USB_EP[n]_TXCSR_H.TXTOERR` is set following three failed transmit attempts, the DMA request line is disabled until the bits are cleared.

The mode selected also affects the generation of endpoint interrupts (if enabled). In DMA request mode 0, no interrupt is generated when packets are received but the appropriate endpoint interrupt is generated to prompt the loading of all packets. In DMA request mode 1, the endpoint interrupt is suppressed except following the receipt of a short packet (one less than `USB_EP[n]_RXMAXP` bytes).

Table 27-7: Endpoint Interrupt Associated with the Receive Packet Ready Bit=1

DMAReqEnab	DMAReqMode	EP Interrupt Generated?
0	X	YES
1	0	NO
1	1	Only is short packet

Table 27-8: Endpoint Interrupt Associated with the Receive Packet Ready Bit=0

DMAReqEnab	DMAReqMode	EP Interrupt Generated?
0	X	YES
1	0	YES
1	1	NO

NOTE: Set the `USB_EP[n]_TXMAXP`/`USB_EP[n]_RXMAXP` registers to an even number of bytes for proper interrupt generation in DMA mode 1.

DMA transfers can be 8-bit, 16-bit, or 32-bit as required. However, all transfers associated with one packet (except for the last) must be of the same width so that the data is consistently byte-aligned, word-aligned, or double-word-aligned. The last transfer can contain fewer bytes than the previous transfers to complete an odd-byte or odd-word transfer.

NOTE: Disable DMA requests before changing the DMA request mode bit. In particular, do not set the `USB_EP[n]_TXCSR_H.DMAREQMODE` bit to zero either before or in the same cycle as the corresponding `USB_EP[n]_TXCSR_H.DMAREQEN` bit is cleared to zero.

Transferring Packets Using DMA

Both the channel and the endpoint must be programmed appropriately to use the the DMA master channels to access the USB controller FIFOs. Many variations are possible. The following sections detail the standard set ups used for the basic actions of transferring individual and multiple packets.

Individual Rx Endpoint Packet

The transfer of individual packets normally uses DMA mode 0. Program the USB controller Rx endpoint as follows.

1. Set to 1 the relevant bit in the `USB_INTRRXE` register.
2. Set to 0 the DMA enable bit of the appropriate `USB_EP[n]_RXCSR_H.DMAREQEN`/`USB_EP[n]_RXCSR_P.DMAREQEN` register. (There is no need to set the USB controller to support DMA for this operation.)
3. When the USB controller receives a packet, it generates the appropriate endpoint interrupt (using the `USB_INTRRXE` register). The processor must then program the appropriate DMA master channel as follows.
    - Configure the `USB_DMA[n]_ADDR` register with the memory address to store the packet

- Configure the USB_DMA[n]_CNT register with the size of packet (determined by reading the USB controller USB_RQPKTCNT[n] register)
- Configure the USB_DMA[n]_CTL register using the following bit settings:USB_DMA[n]_CTL.IE=1 USB_DMA[n]_CTL.EN=1, USB_DMA[n]_CTL.DIR=0, USB_DMA[n]_CTL.MODE=0

The DMA controller then requests bus mastership and transfers the packet to memory. It interrupts the processor when it has completed the transfer. The processor then clears the USB_EP[n]_RXCSR_H.RXPKTRDY bit.

Individual Tx Endpoint Packet

Using DMA mode 0, program a USB controller Tx endpoint as follows.

1. Set to 1 the relevant bit in the USB_INTRTXE register.
2. Set to 0 the DMA enable bit of the appropriate USB_EP[n]_TXCSR_H.DMAREQEN/ USB_EP[n]_TXCSR_P.DMAREQEN register. (There is no need to set the USB controller to support DMA for this operation.)
3. When the FIFO can accommodate data, the USB controller interrupts the processor with the appropriate Tx endpoint interrupt. The processor must then program the DMA channel as follows:
   - Configure the USB_DMA[n]_ADDR register with the memory address to store the packet.
   - Configure the USB_DMA[n]_CNT register with the size of packet.
   - Configure the USB_DMA[n]_CTL register using the following bit settings: USB_DMA[n]_CTL.IE=1 USB_DMA[n]_CTL.EN=1, USB_DMA[n]_CTL.DIR=1, USB_DMA[n]_CTL.MODE=0.

The DMA controller then requests bus mastership and transfers the packet to the USB controller FIFO. When it has completed the transfer, it generates a DMA interrupt. The processor then sets the USB_EP[n]_TXCSR_H.TXPKTRDY bit.

Multiple Rx Endpoint Packets

The transfer of multiple packets normally uses DMA mode 1. Program the DMA controller using the DMA registers:

- Configure the USB_DMA[n]_ADDR register with the memory address of data block to send.
- Configure the USB_DMA[n]_CNT register with the maximum size of data buffer.
- Configure the USB_DMA[n]_CTL register using the following bit settings: USB_DMA[n]_CTL.EN=1, USB_DMA[n]_CTL.IE=1, USB_DMA[n]_CTL.DIR=0, USB_DMA[n]_CTL.MODE=1.

Program the USB controller Rx endpoint as follows:

1. Set to 1 the relevant bit in the USB_INTRRX register.
2. Set to 1 the USB_EP[n]_RXCSR_H.AUTOCLR, USB_EP[n]_RXCSR_H.DMAREQEN, and USB_EP[n]_RXCSR_H.DMAREQMODE bits of the appropriate receive control and status register (host or

peripheral). In host mode, set to 1 the USB_EP[n]_RXCSR_H.AUTOREQ and USB_EP[n]_RXCSR_H.DMAREQMODE bits.

As the USB controller receives each packet, the DMA master channel requests bus mastership and transfers the packet to memory. With USB_EP[n]_RXCSR_H.AUTOCLR set, the USB controller automatically clears its USB_EP[n]_RXCSR_H.RXPKTRDY bit. This process continues automatically until the USB controller receives a short packet (one of less than the maximum packet size for the endpoint) signifying the end of the transfer. The DMA controller does not transfer this short packet: instead the USB controller interrupts the processor by generating the appropriate endpoint interrupt. The processor can then read the USB_EP[n]_RXCNT register to see the size of the short packet. It either unloads the packet manually or reprograms the DMA controller in mode 0 to unload the packet.

The USB_DMA[n]_ADDR register is incremented as the DMA controller unloads the packets. The processor determines the size of the transfer by comparing the current value of USB_DMA[n]_ADDR with the start address of the memory buffer.

If the size of the transfer exceeds the data buffer size, the DMA controller stops unloading the FIFO and interrupts the processor.

Multiple Tx Endpoint Packets

Using DMA mode 1 for a Tx endpoint, program the DMA controller as follows:

- Configure the USB_DMA[n]_ADDR register with the memory address of data block to send.
- Configure the USB_DMA[n]_CNT register with the size of the data block.
- Configure the USB_DMA[n]_CTL register using the following bit settings: USB_DMA[n]_CTL.EN=1, USB_DMA[n]_CTL.IE=1 USB_DMA[n]_CTL.DIR=1, USB_DMA[n]_CTL.MODE=1.

Program the USB controller Tx endpoint as follows:

1. Set to 1 the relevant bit in the USB_INTRTXE register.
2. Set to 1 the USB_EP[n]_TXCSR_H.AUTOSET and USB_EP[n]_TXCSR_H.DMAREQEN bits of the appropriate transmit control and status register (host or peripheral).

When the FIFO in the USB controller becomes available, the DMA controller requests bus mastership and transfers a packet to the FIFO. With USB_EP[n]_TXCSR_H.AUTOSET set, the USB controller automatically sets the USB_EP[n]_TXCSR_H.TXPKTRDY bit. This process continues until the entire data block is transferred to the USB controller.

The DMA controller then interrupts the processor by taking the appropriate USB_DMA_IRQ register bit low.

- If the last packet loaded was less than the maximum packet size for the endpoint, the USB_EP[n]_TXCSR_H.TXPKTRDY bit is not set for this packet. The processor must respond to the DMA interrupt by setting the USB_EP[n]_TXCSR_H.TXPKTRDY bit to allow the last short packet to be sent.

- If the last packet loaded is the maximum packet size, then the appropriate action depends on whether the transfer is under the control of an application. One example is the mass storage software on Windows system that keeps count of the individual packets sent.
- If the transfer is not under such control, the processor must respond to the DMA interrupt by setting the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit. This operation sends a null packet for the receiving software to interpret as indicating the end of the transfer.

ADSP-SC58x USB Register Descriptions

Universal Serial Bus Controller (USB) contains the following registers.

Table 27-9: ADSP-SC58x USB Register List

Name	Description
`USB_BAT_CHG`	Battery Charging Control Register
`USB_CT_HHSRTN`	Host High-Speed Return to Normal Register
`USB_CT_HSBT`	High-Speed Timeout Register
`USB_CT_UCH`	Chirp Timeout Register
`USB_DEV_CTL`	Device Control Register
`USB_DMA[n]_ADDR`	DMA Channel n Address Register
`USB_DMA[n]_CNT`	DMA Channel n Count Register
`USB_DMA[n]_CTL`	DMA Channel n Control Register
`USB_DMA_IRQ`	DMA Interrupt Register

Charging Port Detected
SNSCHGDET (R/W)
Sense Charger Detection
SNSCONDET (R/W)
Sense Connection Detection
CONDET (R)
Connected Detected

Figure 27-34: USB_BAT_CHG Register Diagram

Table 27-10: USB_BAT_CHG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	DEDCHG	Dedicated Charging Port. The `USB_BAT_CHG.DEDCHG` bit is asserted if both D+ and D- are high. This can be used to determine if the attached device is a dedicated charging port. This bit is the decode of LineState[1] and LineState[0]. This bit is only valid when a session is initiated, which enables a pullup on D+ when acting as a B-device.
3 (R/NW)	CHGDET	Charging Port Detected. The `USB_BAT_CHG.CHGDET` bit indicates when a charging port is detected. This bit indicates that D+/- is above V_{DAT_REF} and below V_{LGC}.
2 (R/W)	SNSCHGDET	Sense Charger Detection. The `USB_BAT_CHG.SNSCHGDET` bit enables charger detection. Setting this bit enables VD_SRC and ID_SINK.
1 (R/NW)	CONDET	Connected Detected. The `USB_BAT_CHG.CONDET` bit is valid when `USB_BAT_CHG.SNSCONDET` is enabled. This bit reflects the inverse of D+ (!LineState[0]). If nothing is connected, D+ is pulled high. If a charger or USB port is connected, D+ is pulled low.
0 (R/W)	SNSCONDET	Sense Connection Detection. The `USB_BAT_CHG.SNSCONDET` bit enables connection detection. Enabling this bit enables I_{DP_SRC} and R_{DM_DWN}.

Host High-Speed Return to Normal Register

The `USB_CT_HHSRTN` register selects the delay from the end of the high-speed resume signaling (acting as a host) to the return to normal mode operation. This value is multiplied by 4 times the XCLK period (or 16.7 ns). The default setting corresponds to a delay of 100us.

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/W)	VALUE	Host High-Speed Return to Normal Value.

High-Speed Timeout Register

The USB_CT_HSBT register selects an amount of time to add to the minimum high-speed timeout in units of 64 bit times. The USB 2.0 specification section 7.1.19.2 states that the controller must not timeout less than 736 bit times and must timeout after 816 bit times. The value in USB_CT_HSBT is multiplied by 64-bit times and added to the minimum 736 bit times. Settings less than 1 violate the USB 2.0 specification, making the controller non-compliant.

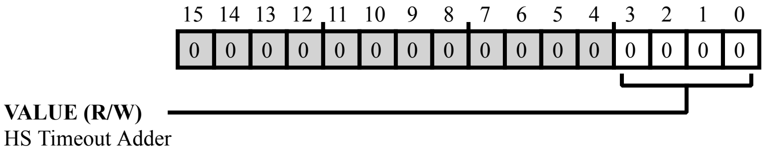

Figure 27-36: USB_CT_HSBT Register Diagram

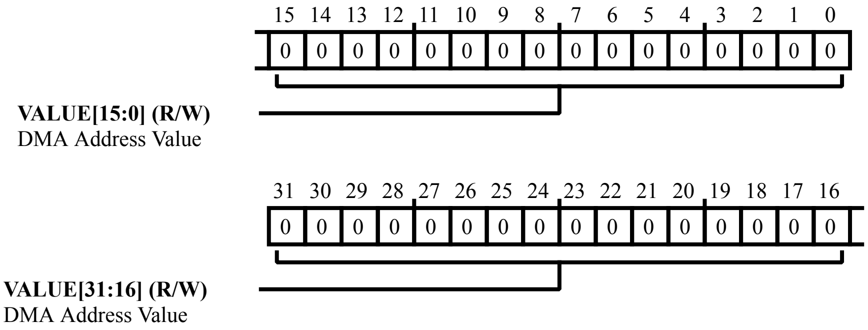
		0	Below SessionEnd
		1	Above SessionEnd, below AValid
		2	Above AValid, below VBUSValid
		3	Above VBUSValid
2 (R/NW)	HOSTMODE	Host Mode Indicator. The `USB_DEV_CTL.HOSTMODE` bit is set when the USB controller is acting as a host.	
		0	Peripheral Mode
		1	Host Mode
1 (R/W)	HOSTREQ	Host Negotiation Request. When the `USB_DEV_CTL.HOSTREQ` bit is set, the USB controller initiates the host negotiation when suspend mode is entered. This bit is cleared when host negotiation is completed. The `USB_DEV_CTL.HOSTREQ` bit applies when the USB controller is operating as a B device only.	
		0	No Request
		1	Place Request
0 (R/W)	SESSION	Session Indicator. When operating as an A device, the `USB_DEV_CTL.SESSION` bit is set or cleared by the processor core to start or end a session. When operating as a B device, the `USB_DEV_CTL.SESSION` bit is set or cleared by the USB controller when a session starts or ends. This bit is also set by the processor core to initiate the session request protocol. When the USB controller is in suspend mode, the bit may be cleared by the processor core to perform a software disconnect.	
		0	Not Detected
		1	Detected Session

DMA Channel n Address Register

The `USB_DMA[n]_ADDR` register indicates the location in on-chip memory where DMA data is written or read. The address must be aligned to 32-bit words (The lower two address bits are always zero.) This register increments as the DMA transfer progresses.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
DMA Address Value

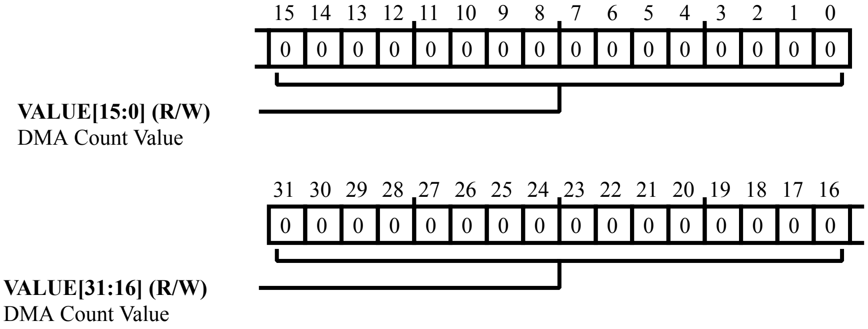
Figure 27-39: USB_DMA[n]_ADDR Register Diagram

Table 27-15: USB_DMA[n]_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Address Value. The `USB_DMA[n]_ADDR.VALUE` bits hold the address value for the location in on-chip memory where DMA data is written or read.

DMA Channel n Count Register

The `USB_DMA[n]_CNT` register holds the DMA count, indicating the number of bytes to be transferred for a given DMA work block. If this field is set to zero, no data is transferred, and an interrupt is generated.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

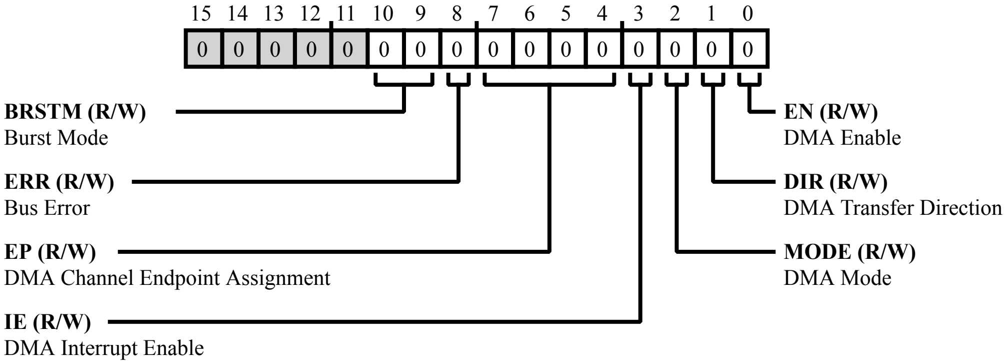
Table 27-16: USB_DMA[n]_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Count Value. The `USB_DMA[n]_CNT.VALUE` bits indicate the number of bytes to be transferred for a given DMA work block.

DMA Channel n Control Register

There is a `USB_DMA[n]_CTL` register for each DMA master channel. This register assigns, configures, and controls each endpoint with a corresponding DMA master channel.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 27-41: USB_DMA[n]_CTL Register Diagram

Table 27-17: USB_DMA[n]_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10:9 (R/W)	BRSTM	Burst Mode. The `USB_DMA[n]_CTL.BRSTM` bits select the type or length of burst transfer used by the corresponding DMA channel to transfer data.	
		0	Unspecified Length
		1	INCR4 or Unspecified Length
		2	INCR8, INCR4, or Unspecified Length
		3	INCR16, INCR8, INCR4, or Unspecified Length
8 (R/W)	ERR	Bus Error. The `USB_DMA[n]_CTL.ERR` bit indicates when a peripheral bus error has been encountered by the master channel. This bit is cleared by software.	
		0	No Status
		1	Bus Error
7:4 (R/W)	EP	DMA Channel Endpoint Assignment. The `USB_DMA[n]_CTL.EP` bits select the endpoint assignments for the DMA channel. (Enumeration values not shown are reserved.)	
		0	Endpoint 0
		1	Endpoint 1
		2	Endpoint 2
		3	Endpoint 3

Table 27-17: USB_DMA[n]_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	Endpoint 4
		5	Endpoint 5
		6	Endpoint 6
		7	Endpoint 7
		8	Endpoint 8
		9	Endpoint 9
		10	Endpoint 10
		11	Endpoint 11
		12	Endpoint 12
		13	Endpoint 13
		14	Endpoint 14
		15	Endpoint 15
3 (R/W)	IE	DMA Interrupt Enable. The `USB_DMA[n]_CTL.IE` bit enables DMA interrupts for the DMA channel, enabling operation of the channels corresponding bit in the `USB_DMA_IRQ` register.	
		0	Disable Interrupt
		1	Enable Interrupt
2 (R/W)	MODE	DMA Mode. The `USB_DMA[n]_CTL.MODE` bit selects whether the DMA channel operates in DMA mode 0 or operates in DMA mode 1. Note that DMA mode 1 may only be used with bulk endpoints.	
		0	DMA Mode 0
		1	DMA Mode 1
1 (R/W)	DIR	DMA Transfer Direction. The `USB_DMA[n]_CTL.DIR` bit selects the DMA channel transfer direction, which must be selected for use with receive endpoints (DMA write=0) or transmit endpoints (DMA read=1).	
		0	DMA Write (for Rx Endpoint)
		1	DMA Read (for Tx Endpoint)

Table 27-17: USB_DMA[n]_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	DMA Enable. The `USB_DMA[n]_CTL.EN` bit enables the DMA channel to start the DMA transfer.	
		0	Disable DMA
		1	Enable DMA (Start Transfer)

DMA Interrupt Register

The USB_DMA_IRQ register indicates which of the DMA master channels have a pending interrupt. The USB controller generates the interrupt when the corresponding DMA count register (USB_DMA[n]_CNT) reaches zero. The USB controller clears this register when it is read.

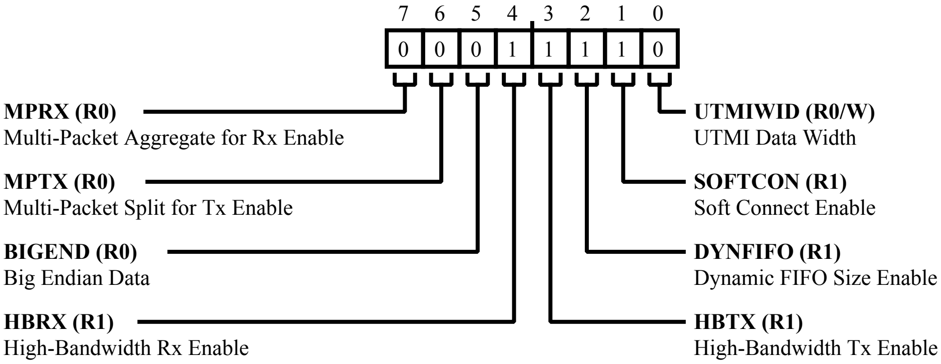
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (RC/NW)	D7	DMA 7 Interrupt Pending Status. The USB_DMA_IRQ.D7 indicates whether there is a DMA 7 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
6 (RC/NW)	D6	DMA 6 Interrupt Pending Status. The USB_DMA_IRQ.D6 indicates whether there is a DMA 6 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
5 (RC/NW)	D5	DMA 5 Interrupt Pending Status. The USB_DMA_IRQ.D5 indicates whether there is a DMA 5 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
4 (RC/NW)	D4	DMA 4 Interrupt Pending Status. The USB_DMA_IRQ.D4 indicates whether there is a DMA 4 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt

Table 27-18: USB_DMA_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (RC/NW)	D3	DMA 3 Interrupt Pending Status. The `USB_DMA_IRQ.D3` indicates whether there is a DMA 3 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
2 (RC/NW)	D2	DMA 2 Interrupt Pending Status. The `USB_DMA_IRQ.D2` indicates whether there is a DMA 2 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
1 (RC/NW)	D1	DMA 1 Interrupt Pending Status. The `USB_DMA_IRQ.D1` indicates whether there is a DMA 1 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt
0 (RC/NW)	D0	DMA 0 Interrupt Pending Status. The `USB_DMA_IRQ.D0` indicates whether there is a DMA 0 interrupt pending.	
		0	No Pending Interrupt
		1	Pending DMA Interrupt

EP0 Configuration Information Register

The `USB_EP0I_CFGDATA[N]` register describes the USB controller hardware configuration. This register only exists for endpoint 0.



7 6 5 4 3 2 1 0
0 0 0 1 1 1 1 0
MPRX (R0)
Multi-Packet Aggregate for Rx Enable
MPTX (R0)
Multi-Packet Split for Tx Enable
BIGEND (R0)

HBRX (R1)
High-Bandwidth Rx Enable
UTMIWID (R0/W)
UTMI Data Width
SOFTCON (R1)
Soft Connect Enable
DYNFIFO (R1)
Dynamic FIFO Size Enable
HBTX (R1)
High-Bandwidth Tx Enable

Figure 27-43: USB_EP0I_CFGDATA[N] Register Diagram

Table 27-19: USB_EP0I_CFGDATA[N] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R0/NW)	MPRX	Multi-Packet Aggregate for Rx Enable. The `USB_EP0I_CFGDATA[N].MPRX` bit indicates whether the USB controller aggregates receive packets into bulk packets before the processor core reads the data.	
		0	No Aggregate Rx Bulk Packets
		1	Aggregate Rx Bulk Packets
6 (R0/NW)	MPTX	Multi-Packet Split for Tx Enable. The `USB_EP0I_CFGDATA[N].MPTX` bit indicates whether the USB controller permits transmit of large packets through writing to bulk endpoints. The USB controller splits the transmit data into packets, which are appropriately sized for transmit.	
		0	No Split Tx Bulk Packets
		1	Split Tx Bulk Packets
5 (R0/NW)	BIGEND	Big Endian Data. The `USB_EP0I_CFGDATA[N].BIGEND` bit indicates whether the USB controller uses big endian configuration or little endian configuration.	
		0	Little Endian Configuration
		1	Big Endian Configuration

Table 27-19: USB_EP0I_CFGDATA[N] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R1/NW)	HBRX	High-Bandwidth Rx Enable. The `USB_EP0I_CFGDATA[N].HBRX` bit indicates whether the USB controller supports high-bandwidth receive ISO endpoint.	
		0	No High-Bandwidth Rx
		1	High-Bandwidth Rx
3 (R1/NW)	HBTX	High-Bandwidth Tx Enable. The `USB_EP0I_CFGDATA[N].HBTX` bit indicates whether the USB controller supports high-bandwidth transmit ISO endpoint.	
		0	No High-Bandwidth Tx
		1	High-Bandwidth Tx
2 (R1/NW)	DYNFIFO	Dynamic FIFO Size Enable. The `USB_EP0I_CFGDATA[N].DYNFIFO` bit indicates whether the USB controller uses dynamic FIFO size support (on products supporting this feature), enabling the dynamic FIFO registers. These registers are accessed using the configuration set in the endpoints indexed FIFO size and FIFO address registers, except for endpoint 0.	
		0	No Dynamic FIFO Size
		1	Dynamic FIFO Size
1 (R1/NW)	SOFTCON	Soft Connect Enable. The `USB_EP0I_CFGDATA[N].SOFTCON` bit indicates whether the USB controller uses soft connect.	
		0	No Soft Connect
		1	Soft Connect
0 (R0/W)	UTMIWID	UTMI Data Width. The `USB_EP0I_CFGDATA[N].UTMIWID` bit indicates whether the USB controller uses an 8-bit or 16-bit UTMI data width.	
		0	8-bit UTMI Data Width
		1	16-bit UTMI Data Width

EP0 Number of Received Bytes Register

The `USB_EP0I_CNT[N]` register indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change. It is only valid while the `USB_EP0_CSR[n]_H.RXPKTRDY` bit or `USB_EP0_CSR[n]_P.RXPKTRDY` bit is set.

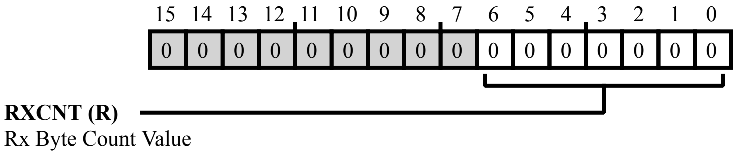

Figure 27-44: USB_EP0I_CNT[N] Register Diagram

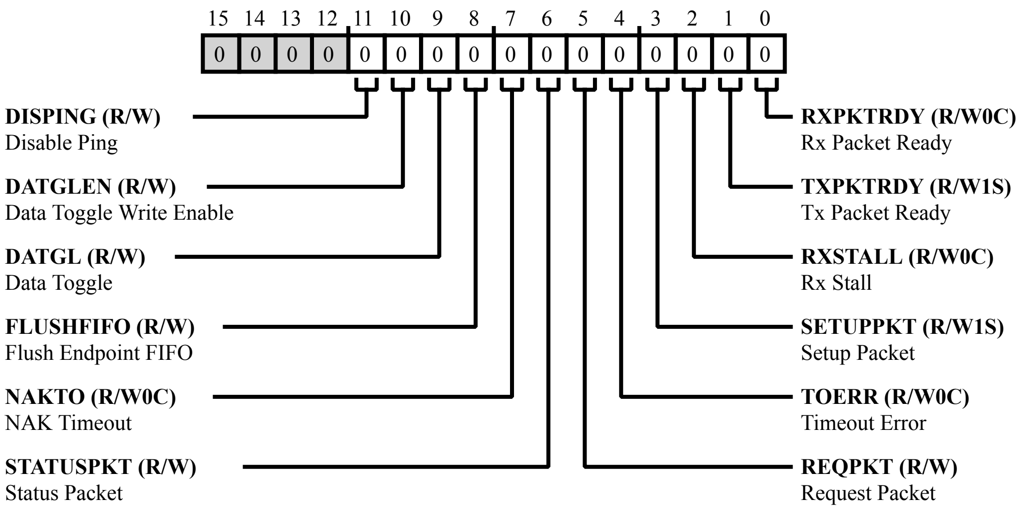
Table 27-20: USB_EP0I_CNT[N] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/NW)	RXCNT	Rx Byte Count Value. The `USB_EP0I_CNT[N].RXCNT` bits holds the number of data bytes currently in line ready to be read from the Rx FIFO. The value returned changes as the FIFO is unloaded. It is only valid while the `USB_EP0_CSR[n]_H.RXPKTRDY` bit or `USB_EP0_CSR[n]_P.RXPKTRDY` bit is set.

EP0 Configuration and Status (Host) Register

The `USB_EP0I_CSR[N]_H` register provides control and status bits for endpoint 0 in host mode. Note that some bits may be set to clear automatically.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 27-45: USB_EP0I_CSR[N]_H Register Diagram

Table 27-21: USB_EP0I_CSR[N]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	DISPING	Disable Ping. The `USB_EP0I_CSR[N]_H.DISPING` bit disables (in host mode) high-speed PING tokens for the data and status phases of a control transfer.	
		0	Issue PING tokens
		1	Do not issue PING
10 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EP0I_CSR[N]_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint 0 `USB_EP0I_CSR[N]_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL

Table 27-21: USB_EP0I_CSR[N]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	DATGL	Data Toggle. The `USB_EP0I_CSR[N]_H.DATGL` bit indicates (in host mode) the current state of the endpoint 0 data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is Set
		1	DATA1 is Set
8 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP0I_CSR[N]_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint 0 FIFO and clear the `USB_EP0I_CSR[N]_H.TXPKTRDY` and `USB_EP0I_CSR[N]_H.RXPKTRDY` bits. The `USB_EP0I_CSR[N]_H.FLUSHFIFO` bit should only be set if the `USB_EP0I_CSR[N]_H.TXPKTRDY` and `USB_EP0I_CSR[N]_H.RXPKTRDY` bits are set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
7 (R/W0C)	NAKTO	NAK Timeout. The `USB_EP0I_CSR[N]_H.NAKTO` bit indicates (in host mode) when endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the `USB_EP0_NAKLIMIT[n]` register. The processor core should clear this bit to allow the endpoint to continue.	
		0	No Status
		1	Endpoint Halted (NAK Timeout)
6 (R/W)	STATUSPKT	Status Packet. The `USB_EP0I_CSR[N]_H.STATUSPKT` bit directs (in host mode) the USB controller to perform a status stage transaction. This bit is set at the same time as the `USB_EP0I_CSR[N]_H.TXPKTRDY` and `USB_EP0I_CSR[N]_H.RXPKTRDY` bits. Setting this bit ensures that the data toggle is set to 1 so that a DATA1 packet is used for the status stage transaction.	
		0	No Request
		1	Request Status Transaction

Table 27-21: USB_EP0I_CSR[N]_H Register Fields (Continued)

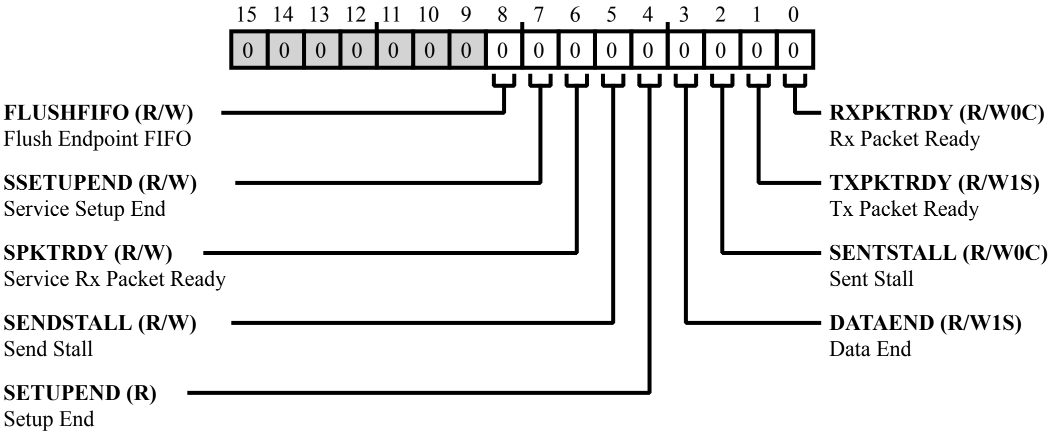
Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	REQPKT	Request Packet. The `USB_EP0I_CSR[N]_H.REQPKT` bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when the `USB_EP0I_CSR[N]_H.RXPKTRDY` bit is set.	
		0	No Request
		1	Send IN Tokens to Device
4 (R/W0C)	TOERR	Timeout Error. The `USB_EP0I_CSR[N]_H.TOERR` bit indicates (in host mode) when three attempts have been made to perform a transaction with no response from the peripheral. The processor core should clear this bit. An interrupt is generated when this bit is set.	
		0	No Status
		1	Timeout Error
3 (R/W1S)	SETUPPKT	Setup Packet. The `USB_EP0I_CSR[N]_H.SETUPPKT` bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the `USB_EP0I_CSR[N]_H.TXPKTRDY` bit is set.	
		0	No Request
		1	Send SETUP token
2 (R/W0C)	RXSTALL	Rx Stall. The `USB_EP0I_CSR[N]_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
1 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP0I_CSR[N]_H.TXPKTRDY` bit should be set (in host mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

Table 27-21: USB_EP0I_CSR[N]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP0I_CSR[N]_H.RXPKTRDY` is set (in host mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EP0 Configuration and Status (Peripheral) Register

The `USB_EP0I_CSR[N]_P` register provides control and status bits for endpoint 0 in peripheral mode. Note that some bits may be set to clear automatically.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Data End

Figure 27-46: USB_EP0I_CSR[N]_P Register Diagram

Table 27-22: USB_EP0I_CSR[N]_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP0I_CSR[N]_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint 0 FIFO and clear the `USB_EP0I_CSR[N]_P.TXPKTRDY` and `USB_EP0I_CSR[N]_P.RXPKTRDY` bits. The `USB_EP0I_CSR[N]_P.FLUSHFIFO` bit should only be set if the `USB_EP0I_CSR[N]_P.TXPKTRDY` and `USB_EP0I_CSR[N]_P.RXPKTRDY` bits are set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
7 (R/W)	SSETUPEND	Service Setup End. The `USB_EP0I_CSR[N]_P.SSETUPEND` bit is set (in peripheral mode) by the processor core to clear the `USB_EP0I_CSR[N]_P.SETUPEND`. This bit is cleared automatically.	
		0	No Action
		1	Clear SETUPEND Bit

Table 27-22: USB_EP0I_CSR[N]_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SPKTRDY	Service Rx Packet Ready. The `USB_EP0I_CSR[N]_P.SPKTRDY` bit is set (in peripheral mode) by the processor core to clear the `USB_EP0I_CSR[N]_P.RXPKTRDY` bit. This bit is cleared automatically.	
		0	No Action
		1	Clear RXPKTRDY Bit
5 (R/W)	SENDSTALL	Send Stall. The `USB_EP0I_CSR[N]_P.SENDSTALL` bit is set (in peripheral mode) by the processor core to terminate the current transaction. The STALL handshake is transmitted, then this bit automatically is cleared.	
		0	No Action
		1	Terminate Current Transaction
4 (R/NW)	SETUPEND	Setup End. The `USB_EP0I_CSR[N]_P.SETUPEND` bit indicates (in peripheral mode) when a control transaction ends before the `USB_EP0I_CSR[N]_P.DATAEND` bit is set. An interrupt is generated and the FIFO is flushed at this time. This bit is cleared when the processor core sets the `USB_EP0I_CSR[N]_P.SSETUPEND` bit.	
		0	No Status
		1	Setup Ended before DATAEND
3 (R/W1S)	DATAEND	Data End. The `USB_EP0I_CSR[N]_P.DATAEND` bit is set (in peripheral mode) by the processor core sets when the core: • Sets the `USB_EP0I_CSR[N]_P.TXPKTRDY` bit for the last data packet. • Clears the `USB_EP0I_CSR[N]_P.RXPKTRDY` bit after unloading the last data packet. • Sets the `USB_EP0I_CSR[N]_P.TXPKTRDY` bit for a zero-length data packet. The `USB_EP0I_CSR[N]_P.DATAEND` bit is cleared automatically.	
		0	No Status
		1	Data End Condition
2 (R/W0C)	SENTSTALL	Sent Stall. The `USB_EP0I_CSR[N]_P.SENTSTALL` bit is set (in peripheral mode) when a STALL handshake is transmitted. The processor core should clear this bit.	
		0	No Status
		1	Transmitted STALL Handshake

Table 27-22: USB_EP0I_CSR[N]_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP0I_CSR[N]_P.TXPKTRDY` bit should be set (in peripheral mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	
		1	Set this bit after loading a data packet into the FIFO
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP0I_CSR[N]_P.RXPKTRDY` is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core clears this bit by setting the `USB_EP0I_CSR[N]_P.SPKTRDY` bit.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EP0 NAK Limit Register

The `USB_EP0I_NAKLIMIT[N]` register determines the number of frames/micro-frames after which endpoint 0 should timeout on receiving a stream of NAK responses for bulk endpoints.

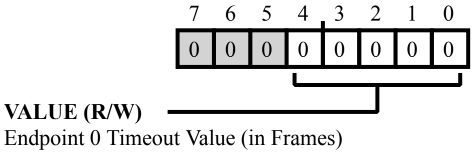

Figure 27-47: USB_EP0I_NAKLIMIT[N] Register Diagram

Table 27-23: USB_EP0I_NAKLIMIT[N] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	VALUE	Endpoint 0 Timeout Value (in Frames). The `USB_EP0I_NAKLIMIT[N].VALUE` bits hold the endpoint 0 timeout value (number of frames).

EP0 Connection Type Register

The `USB_EP0I_TYPE[N]` register selects the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub.

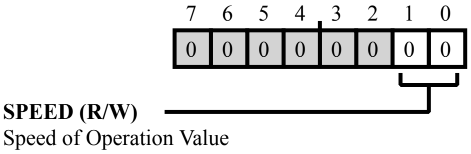

Figure 27-48: USB_EP0I_TYPE[N] Register Diagram

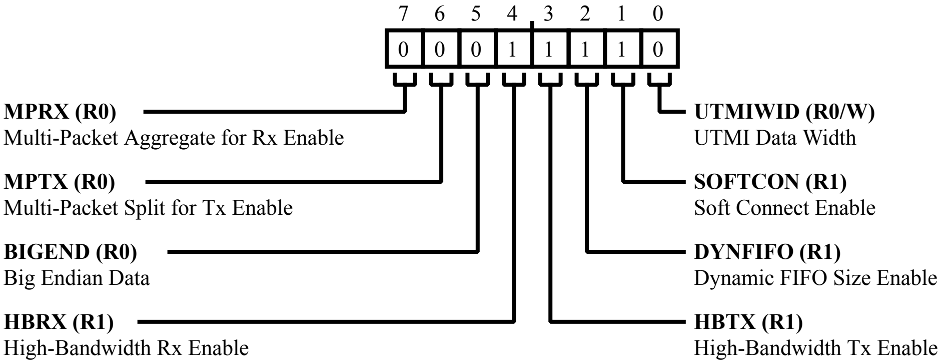
Table 27-24: USB_EP0I_TYPE[N] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	SPEED	Speed of Operation Value. The `USB_EP0I_TYPE[N].SPEED` bits select the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub. In these instances. the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00.	
		0	Same Speed as Processor Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed

EP0 Configuration Information Register

The `USB_EP0_CFGDATA[n]` register describes the USB controller hardware configuration. This register only exists for endpoint 0.



7 6 5 4 3 2 1 0

Figure 27-49: USB_EP0_CFGDATA[n] Register Diagram

Table 27-25: USB_EP0_CFGDATA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R0/NW)	MPRX	Multi-Packet Aggregate for Rx Enable. The `USB_EP0_CFGDATA[n].MPRX` bit indicates whether the USB controller aggregates receive packets into bulk packets before the processor core reads the data.	
		0	No Aggregate Rx Bulk Packets
		1	Aggregate Rx Bulk Packets
6 (R0/NW)	MPTX	Multi-Packet Split for Tx Enable. The `USB_EP0_CFGDATA[n].MPTX` bit indicates whether the USB controller permits transmit of large packets through writing to bulk endpoints. The USB controller splits the transmit data into packets, which are appropriately sized for transmit.	
		0	No Split Tx Bulk Packets
		1	Split Tx Bulk Packets
5 (R0/NW)	BIGEND	Big Endian Data. The `USB_EP0_CFGDATA[n].BIGEND` bit indicates whether the USB controller uses big endian configuration or little endian configuration.	
		0	Little Endian Configuration
		1	Big Endian Configuration

Table 27-25: USB_EP0_CFGDATA[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R1/NW)	HBRX	High-Bandwidth Rx Enable. The `USB_EP0_CFGDATA[n].HBRX` bit indicates whether the USB controller supports high-bandwidth receive ISO endpoint.	
		0	No High-Bandwidth Rx
		1	High-Bandwidth Rx
3 (R1/NW)	HBTX	High-Bandwidth Tx Enable. The `USB_EP0_CFGDATA[n].HBTX` bit indicates whether the USB controller supports high-bandwidth transmit ISO endpoint.	
		0	No High-Bandwidth Tx
		1	High-Bandwidth Tx
2 (R1/NW)	DYNFIFO	Dynamic FIFO Size Enable. The `USB_EP0_CFGDATA[n].DYNFIFO` bit indicates whether the USB controller uses dynamic FIFO size support (on products supporting this feature), enabling the dynamic FIFO registers. These registers are accessed using the configuration set in the endpoints indexed FIFO size and FIFO address registers, except for endpoint 0.	
		0	No Dynamic FIFO Size
		1	Dynamic FIFO Size
1 (R1/NW)	SOFTCON	Soft Connect Enable. The `USB_EP0_CFGDATA[n].SOFTCON` bit indicates whether the USB controller uses soft connect.	
		0	No Soft Connect
		1	Soft Connect
0 (R0/W)	UTMIWID	UTMI Data Width. The `USB_EP0_CFGDATA[n].UTMIWID` bit indicates whether the USB controller uses an 8-bit or 16-bit UTMI data width.	
		0	8-bit UTMI Data Width
		1	16-bit UTMI Data Width

EP0 Number of Received Bytes Register

The `USB_EP0_CNT[n]` register indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change. It is only valid while the `USB_EP0_CSR[n]_H.RXPKTRDY` bit or `USB_EP0_CSR[n]_P.RXPKTRDY` bit is set.

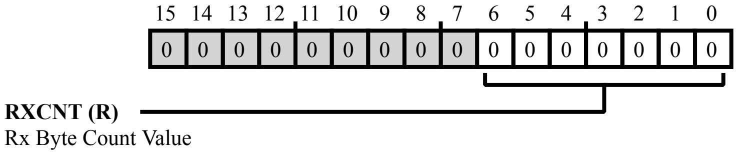

Figure 27-50: USB_EP0_CNT[n] Register Diagram

Table 27-26: USB_EP0_CNT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/NW)	RXCNT	Rx Byte Count Value. The `USB_EP0_CNT[n].RXCNT` bits holds the number of data bytes currently in line ready to be read from the Rx FIFO. The value returned changes as the FIFO is unloaded. It is only valid while the `USB_EP0_CSR[n]_H.RXPKTRDY` bit or `USB_EP0_CSR[n]_P.RXPKTRDY` bit is set.

EP0 Configuration and Status (Host) Register

The `USB_EP0_CSR[n]_H` register provides control and status bits for endpoint 0 in host mode. Note that some bits may be set to clear automatically.

Figure 27-51: USB_EP0_CSR[n]_H Register Diagram

Table 27-27: USB_EP0_CSR[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	DISPING	Disable Ping. The `USB_EP0_CSR[n]_H.DISPING` bit disables (in host mode) high-speed PING tokens for the data and status phases of a control transfer.	
		0	Issue PING tokens
		1	Do not issue PING
10 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EP0_CSR[n]_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint 0 `USB_EP0_CSR[n]_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL

Table 27-27: USB_EP0_CSR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	DATGL	Data Toggle. The `USB_EP0_CSR[n]_H.DATGL` bit indicates (in host mode) the current state of the endpoint 0 data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is Set
		1	DATA1 is Set
8 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP0_CSR[n]_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint 0 FIFO and clear the `USB_EP0_CSR[n]_H.TXPKTRDY` and `USB_EP0_CSR[n]_H.RXPKTRDY` bits. The `USB_EP0_CSR[n]_H.FLUSHFIFO` bit should only be set if the `USB_EP0_CSR[n]_H.TXPKTRDY` and `USB_EP0_CSR[n]_H.RXPKTRDY` bits are set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
7 (R/W0C)	NAKTO	NAK Timeout. The `USB_EP0_CSR[n]_H.NAKTO` bit indicates (in host mode) when endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the `USB_EP0_NAKLIMIT[n]` register. The processor core should clear this bit to allow the endpoint to continue.	
		0	No Status
		1	Endpoint Halted (NAK Timeout)
6 (R/W)	STATUSPKT	Status Packet. The `USB_EP0_CSR[n]_H.STATUSPKT` bit directs (in host mode) the USB controller to perform a status stage transaction. This bit is set at the same time as the `USB_EP0_CSR[n]_H.TXPKTRDY` and `USB_EP0_CSR[n]_H.RXPKTRDY` bits. Setting this bit ensures that the data toggle is set to 1 so that a DATA1 packet is used for the status stage transaction.	
		0	No Request
		1	Request Status Transaction

Table 27-27: USB_EP0_CSR[n]_H Register Fields (Continued)

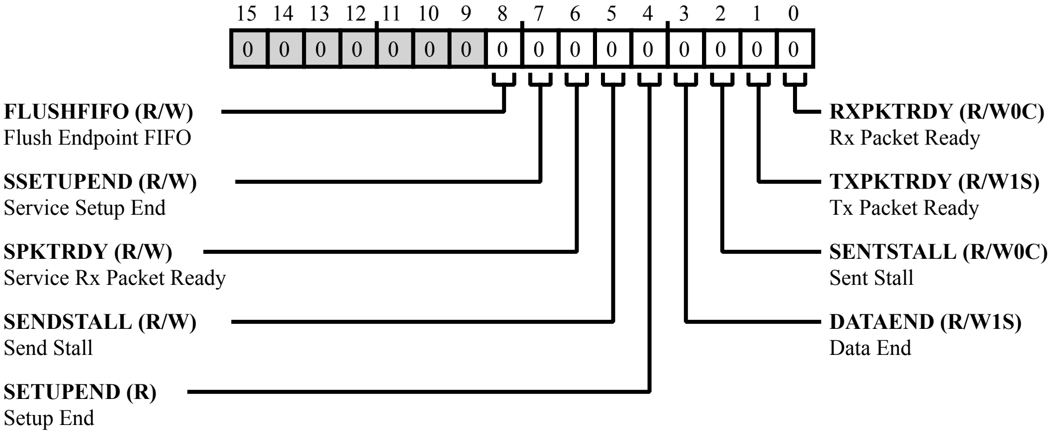
Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	REQPKT	Request Packet. The `USB_EP0_CSR[n]_H.REQPKT` bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when the `USB_EP0_CSR[n]_H.RXPKTRDY` bit is set.	
		0	No Request
		1	Send IN Tokens to Device
4 (R/W0C)	TOERR	Timeout Error. The `USB_EP0_CSR[n]_H.TOERR` bit indicates (in host mode) when three attempts have been made to perform a transaction with no response from the peripheral. The processor core should clear this bit. An interrupt is generated when this bit is set.	
		0	No Status
		1	Timeout Error
3 (R/W1S)	SETUPPKT	Setup Packet. The `USB_EP0_CSR[n]_H.SETUPPKT` bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the `USB_EP0_CSR[n]_H.TXPKTRDY` bit is set.	
		0	No Request
		1	Send SETUP token
2 (R/W0C)	RXSTALL	Rx Stall. The `USB_EP0_CSR[n]_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
1 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP0_CSR[n]_H.TXPKTRDY` bit should be set (in host mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

Table 27-27: USB_EP0_CSR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP0_CSR[n]_H.RXPKTRDY` is set (in host mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EP0 Configuration and Status (Peripheral) Register

The `USB_EP0_CSR[n]_P` register provides control and status bits for endpoint 0 in peripheral mode. Note that some bits may be set to clear automatically.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 27-52: USB_EP0_CSR[n]_P Register Diagram

Table 27-28: USB_EP0_CSR[n]_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP0_CSR[n]_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint 0 FIFO and clear the `USB_EP0_CSR[n]_P.TXPKTRDY` and `USB_EP0_CSR[n]_P.RXPKTRDY` bits. The `USB_EP0_CSR[n]_P.FLUSHFIFO` bit should only be set if the `USB_EP0_CSR[n]_P.TXPKTRDY` and `USB_EP0_CSR[n]_P.RXPKTRDY` bits are set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
7 (R/W)	SSETUPEND	Service Setup End. The `USB_EP0_CSR[n]_P.SSETUPEND` bit is set (in peripheral mode) by the processor core to clear the `USB_EP0_CSR[n]_P.SETUPEND`. This bit is cleared automatically.	
		0	No Action
		1	Clear SETUPEND Bit

Table 27-28: USB_EP0_CSR[n]_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SPKTRDY	Service Rx Packet Ready. The `USB_EP0_CSR[n]_P.SPKTRDY` bit is set (in peripheral mode) by the processor core to clear the `USB_EP0_CSR[n]_P.RXPKTRDY` bit. This bit is cleared automatically.	
		0	No Action
		1	Clear RXPKTRDY Bit
5 (R/W)	SENDSTALL	Send Stall. The `USB_EP0_CSR[n]_P.SENDSTALL` bit is set (in peripheral mode) by the processor core to terminate the current transaction. The STALL handshake is transmitted, then this bit automatically is cleared.	
		0	No Action
		1	Terminate Current Transaction
4 (R/NW)	SETUPEND	Setup End. The `USB_EP0_CSR[n]_P.SETUPEND` bit indicates (in peripheral mode) when a control transaction ends before the `USB_EP0_CSR[n]_P.DATAEND` bit is set. An interrupt is generated and the FIFO is flushed at this time. This bit is cleared when the processor core sets the `USB_EP0_CSR[n]_P.SSETUPEND` bit.	
		0	No Status
		1	Setup Ended before DATAEND
3 (R/W1S)	DATAEND	Data End. The `USB_EP0_CSR[n]_P.DATAEND` bit is set (in peripheral mode) by the processor core sets when the core: • Sets the `USB_EP0_CSR[n]_P.TXPKTRDY` bit for the last data packet. • Clears the `USB_EP0_CSR[n]_P.RXPKTRDY` bit after unloading the last data packet. • Sets the `USB_EP0_CSR[n]_P.TXPKTRDY` bit for a zero-length data packet. The `USB_EP0_CSR[n]_P.DATAEND` bit is cleared automatically.	
		0	No Status
		1	Data End Condition
2 (R/W0C)	SENTSTALL	Sent Stall. The `USB_EP0_CSR[n]_P.SENTSTALL` bit is set (in peripheral mode) when a STALL handshake is transmitted. The processor core should clear this bit.	
		0	No Status
		1	Transmitted STALL Handshake

Table 27-28: USB_EP0_CSR[n]_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP0_CSR[n]_P.TXPKTRDY` bit should be set (in peripheral mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	
		1	Set this bit after loading a data packet into the FIFO
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP0_CSR[n]_P.RXPKTRDY` is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core clears this bit by setting the `USB_EP0_CSR[n]_P.SPKTRDY` bit.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EP0 NAK Limit Register

The `USB_EP0_NAKLIMIT[n]` register determines the number of frames/micro-frames after which endpoint 0 should timeout on receiving a stream of NAK responses for bulk endpoints.

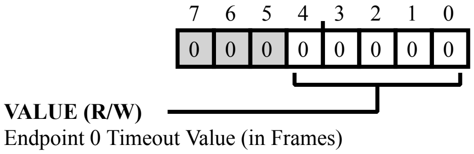

Figure 27-53: USB_EP0_NAKLIMIT[n] Register Diagram

Table 27-29: USB_EP0_NAKLIMIT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	VALUE	Endpoint 0 Timeout Value (in Frames). The `USB_EP0_NAKLIMIT[n].VALUE` bits hold the endpoint 0 timeout value (number of frames).

EP0 Connection Type Register

The `USB_EP0_TYPE[n]` register selects the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub.

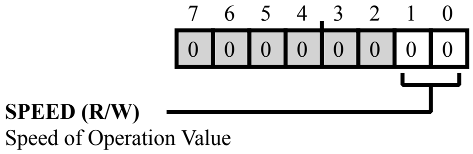

Figure 27-54: USB_EP0_TYPE[n] Register Diagram

Table 27-30: USB_EP0_TYPE[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	SPEED	Speed of Operation. The `USB_EP0_TYPE[n].SPEED` bits select the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub. In these instances. the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00.	
		0	Same Speed as Processor Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed

Endpoint Information Register

The `USB_EPINFO` register allows read-back of the number of Tx and Rx endpoints available

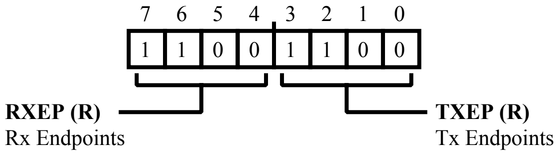

Figure 27-55: USB_EPINFO Register Diagram

Table 27-31: USB_EPINFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	RXEP	Rx Endpoints. The `USB_EPINFO.RXEP` bits indicate the number of receive endpoints. excluding EP0.
3:0 (R/NW)	TXEP	Tx Endpoints. The `USB_EPINFO.TXEP` bits indicate the number of transmit endpoints, excluding EP0.

EPn Number of Bytes Received Register

The `USB_EPI[N]_RXCNT` register indicates the number of received data bytes in the endpoint receive FIFO. The value returned changes as the contents of the FIFO change and is only valid while the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit or `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is set.

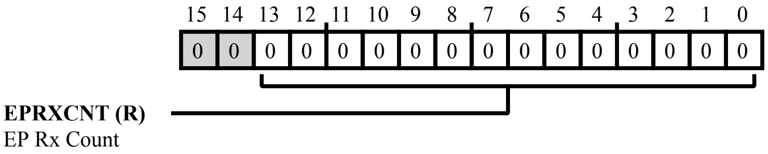

Figure 27-56: USB_EPI[N]_RXCNT Register Diagram

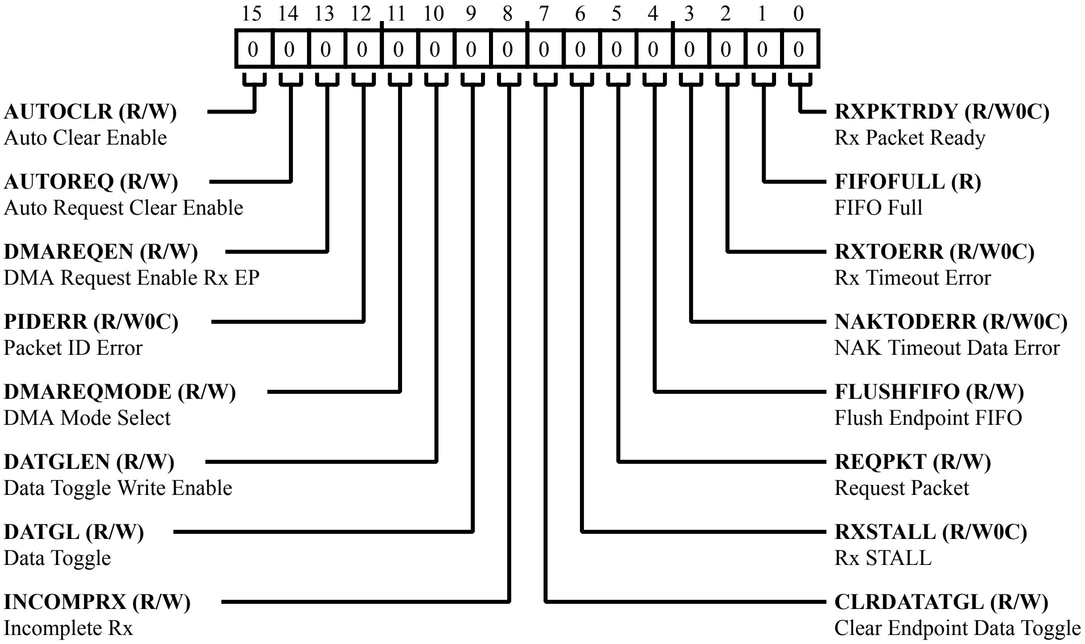
Table 27-32: USB_EPI[N]_RXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/NW)	EPRXCNT	EP Rx Count. The `USB_EPI[N]_RXCNT.EPRXCNT` bits hold the number of data bytes ready to be read from the receive FIFO.

EPn Receive Configuration and Status (Host) Register

The `USB_EPI[N]_RXCSR_H` register provides (in host mode) control and status bits for transfers through the currently selected receive endpoint.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 27-33: USB_EPI[N]_RXCSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOCLR	Auto Clear Enable. The `USB_EPI[N]_RXCSR_H.AUTOCLR` bit directs (in host mode) the USB controller to automatically clear the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit when a packet of size `USB_EP[n]_RXMAXP` bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear `USB_EPI[N]_RXCSR_H.RXPKTRDY` manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the `USB_EP[n]_RXMAXP` value. The USB controller auto clears the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.) • Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3 • Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2 • Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1 • Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP For products supporting high-speed operation, the `USB_EPI[N]_RXCSR_H.AUTOCLR` bit should not be set for high-bandwidth isochronous endpoints.	
		0	Disable Auto Clear
		1	Enable Auto Clear
14 (R/W)	AUTOREQ	Auto Request Clear Enable. The `USB_EPI[N]_RXCSR_H.AUTOREQ` bit directs (in host mode) the USB controller to automatically clear the `USB_EPI[N]_RXCSR_H.REQPKT` bit when `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit is cleared. This bit is automatically cleared when a short packet is received.	
		0	Disable Auto Request Clear
		1	Enable Auto Request Clear
13 (R/W)	DMAREQEN	DMA Request Enable Rx EP. The `USB_EPI[N]_RXCSR_H.DMAREQEN` bit enables (in host mode) DMA requests for this receive endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 27-33: USB_EPI[N]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W0C)	PIDERR	Packet ID Error. The `USB_EPI[N]_RXCSR_H.PIDERR` bit indicates (in host mode) when a PID error occurs for isochronous transactions. This bit is ignored in host mode for bulk or interrupt transactions.	
		0	No Status
		1	PID Error
11 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EPI[N]_RXCSR_H.DMAREQMODE` bit selects (in host mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the `USB_EPI[N]_RXCSR_H.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
10 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EPI[N]_RXCSR_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint `USB_EPI[N]_RXCSR_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL
9 (R/W)	DATGL	Data Toggle. The `USB_EPI[N]_RXCSR_H.DATGL` bit indicates (in host mode) the current state of the endpoint data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is Set
		1	DATA1 is Set
8 (R/W)	INCOMPRX	Incomplete Rx. The `USB_EPI[N]_RXCSR_H.INCOMPRX` bit indicates (in host mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when `USB_EPI[N]_RXCSR_H.RXPKTRDY` is cleared. For all other modes, this bit is zero.	
		0	No Status
		1	Incomplete Rx

Table 27-33: USB_EPI[N]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EPI[N]_RXCSR_H.CLRDATATGL` bit is set (in host mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
6 (R/W0C)	RXSTALL	Rx STALL. The `USB_EPI[N]_RXCSR_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
5 (R/W)	REQPKT	Request Packet. The `USB_EPI[N]_RXCSR_H.REQPKT` bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when `USB_EPI[N]_RXCSR_H.RXPKTRDY` is set.	
		0	No Request
		1	Send IN Tokens to Device
4 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EPI[N]_RXCSR_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit. The `USB_EPI[N]_RXCSR_H.FLUSHFIFO` bit should only be set if the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO

Table 27-33: USB_EPI[N]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W0C)	NAKTODERR	NAK Timeout Data Error. The `USB_EPI[N]_RXCSR_H.NAKTODERR` bit indicates (in host mode for isochronous transfers) a NAK timeout data error when the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when the `USB_EPI[N]_RXCSR_H.RXPKTRDY` bit is cleared. The `USB_EPI[N]_RXCSR_H.NAKTODERR` bit indicates (in host mod for bulk transfers) when a receive endpoint is halted following the receipt of NAK responses greater than the limit set in the `USB_EP[n]_RXINTERVAL` register. The processor should clear this bit to allow the endpoint to continue. If double packet buffering is enabled, the `USB_EPI[N]_RXCSR_H.REQPKT` bit should also be set in the same cycle as this bit is cleared.	
		0	No Status
		1	NAK Timeout Data Error
2 (R/W0C)	RXTOERR	Rx Timeout Error. The `USB_EPI[N]_RXCSR_H.RXTOERR` bit indicates (in host mode) when three attempts have been made to receive a packet and no data packet has been received. The USB controller generates an interrupt for this condition. The processor should clear this bit. Note that `USB_EPI[N]_RXCSR_H.RXTOERR` is valid only when the endpoint is operating in bulk or interrupt mode.	
		0	No Status
		1	Rx Timeout Error
1 (R/NW)	FIFOFULL	FIFO Full. The `USB_EPI[N]_RXCSR_H.FIFOFULL` bit indicates (in host mode) when no more packets can be loaded into the receive FIFO.	
		0	No Status
		1	FIFO Full
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EPI[N]_RXCSR_H.RXPKTRDY` is set (in host mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EPn Receive Configuration and Status (Peripheral) Register

The `USB_EPI[N]_RXCSR_P` register provides (in peripheral mode) control and status bits for transfers through the currently selected receive endpoint.

15 (R/W)	AUTOCLR	Auto Clear Enable. The `USB_EPI[N]_RXCSR_P.AUTOCLR` bit directs (in peripheral mode) the USB controller to automatically clear the `USB_EPI[N]_RXCSR_P.RXPKTRDY` bit when a packet of size `USB_EP[n]_RXMAXP` bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear `USB_EPI[N]_RXCSR_P.RXPKTRDY` manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the `USB_EP[n]_RXMAXP` value. The USB controller auto clears the `USB_EPI[N]_RXCSR_P.RXPKTRDY` bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.) • Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3 • Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2 • Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1 • Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP For products supporting high-speed operation, the `USB_EPI[N]_RXCSR_P.AUTOCLR` bit should not be set for high-bandwidth isochronous endpoints.	
		0	Disable Auto Clear
		1	Enable Auto Clear
14 (R/W)	ISO	Isochronous Transfers. The `USB_EPI[N]_RXCSR_P.ISO` bit selects (in peripheral mode) between isochronous transfers and bulk/interrupt transfers.	
		0	This bit should be cleared for bulk or interrupt transfers.
		1	This bit should be set for isochronous transfers.
13 (R/W)	DMAREQEN	DMA Request Enable Rx EP. The `USB_EPI[N]_RXCSR_P.DMAREQEN` bit enables (in peripheral mode) DMA requests for this receive endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 27-34: USB_EPI[N]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	DNYETPERR	Disable NYET Handshake. The `USB_EPI[N]_RXCSR_P.DNYETPERR` bit disables (in peripheral mode for high speed bulk/interrupt transactions) NYET handshakes. When this bit is set, all successful receive packets are ACK'd, including the point at which the FIFO becomes full. The `USB_EPI[N]_RXCSR_P.DNYETPERR` bit must be set for all interrupt endpoints in high speed mode.	
		0	Enable NYET Handshake
		1	Disable NYET Handshake
11 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EPI[N]_RXCSR_P.DMAREQMODE` bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the `USB_EPI[N]_RXCSR_P.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
8 (R/W)	INCOMPRX	Incomplete Rx. The `USB_EPI[N]_RXCSR_P.INCOMPRX` bit indicates (in peripheral mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when `USB_EPI[N]_RXCSR_P.RXPKTRDY` is cleared. For all other modes, this bit is zero.	
		0	No Status
		1	Incomplete Rx
7 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EPI[N]_RXCSR_P.CLRDATATGL` bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
6 (R/W0C)	SENTSTALL	Sent STALL. The `USB_EPI[N]_RXCSR_P.SENTSTALL` bit indicates (in peripheral mode) when a STALL handshake is transmitted. The processor should clear this bit.	
		0	No Status
		1	STALL Handshake Transmitted

Table 27-34: USB_EPI[N]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SENDSTALL	Send STALL. The `USB_EPI[N]_RXCSR_P.SENDSTALL` bit is set (in peripheral mode) by the processor to send a STALL handshake. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.	
		0	No Action
		1	Request STALL Handshake
4 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EPI[N]_RXCSR_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EPI[N]_RXCSR_P.RXPKTRDY` bit. The `USB_EPI[N]_RXCSR_P.FLUSHFIFO` bit should only be set if the `USB_EPI[N]_RXCSR_P.RXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
3 (R/NW)	DATAERR	Data Error. The `USB_EPI[N]_RXCSR_P.DATAERR` bit indicates (in peripheral mode for isochronous transfers) when the `USB_EPI[N]_RXCSR_P.RXPKTRDY` bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when `USB_EPI[N]_RXCSR_P.RXPKTRDY` is cleared. The `USB_EPI[N]_RXCSR_P.DATAERR` bit is always zero for bulk endpoints in peripheral mode.	
		0	No Status
		1	Data Error
2 (R/W0C)	ORUNERR	OUT Run Error. The `USB_EPI[N]_RXCSR_P.ORUNERR` bit indicates (in peripheral mode for isochronous transfers) when an OUT packet cannot be loaded into the receive FIFO. The processor should clear this bit. The `USB_EPI[N]_RXCSR_P.ORUNERR` bit always returns zero in bulk mode.	
		0	No Status
		1	OUT Run Error
1 (R/NW)	FIFOFULL	FIFO Full. The `USB_EPI[N]_RXCSR_P.FIFOFULL` bit indicates (in peripheral mode) when no more packets can be loaded into the receive FIFO.	
		0	No Status
		1	FIFO Full

Table 27-34: USB_EPI[N]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EPI[N]_RXCSR_P.RXPKTRDY` is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EPn Receive Polling Interval Register

The `USB_EPI[N]_RXINTERVAL` register defines the polling interval for the currently-selected receive endpoint for interrupt, isochronous, and bulk transfers. There is a `USB_EPI[N]_RXINTERVAL` register for each configured receive endpoint, except endpoint 0. The transfer types related to speed, interval value, and interval operation are as follows:

- Interrupt: Speed = low-speed or full -speed, `USB_EPI[N]_RXINTERVAL` = 1-255, and Operation = polling interval is m frames.
- Interrupt: Speed = high-speed, `USB_EPI[N]_RXINTERVAL` = 1-16, and Operation = polling interval is $2^{(m-1)}$ micro-frames.
- Isochronous: Speed = full-speed or high-speed, `USB_EPI[N]_RXINTERVAL` = 1-16, and Operation = polling interval is $2^{(m-1)}$ frames or micro-frames.
- Bulk: Speed = full-speed or high-speed, `USB_EPI[N]_RXINTERVAL` = 2-16, and Operation = NAK limit is $2^{(m-1)}$ frames or micro-frames.

Note that a `USB_EPI[N]_RXINTERVAL` value of 0 or 1 disables the NAK timeout function.

Not all products support high-speed operation or micro-frames. These features do not apply for products that only support low/full-speed operation.

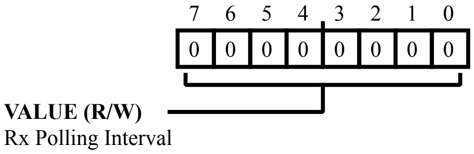

Figure 27-59: USB_EPI[N]_RXINTERVAL Register Diagram

Table 27-35: USB_EPI[N]_RXINTERVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Rx Polling Interval. The `USB_EPI[N]_RXINTERVAL.VALUE` bits define the polling interval value for interrupt and isochronous transfers and select the number of frames (or microframes, if the processor supports high-speed operation) after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.

EPn Receive Maximum Packet Length Register

The USB_EPI[N]_RXMAXP register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single frame.

Note that a value greater than the maximum allowed of 1023 for full-speed USB operation produces unpredictable results. Also, note that the total amount of data represented by the value written to this register must not exceed the receive FIFO size, and should not exceed half the FIFO size if double-buffering is required.

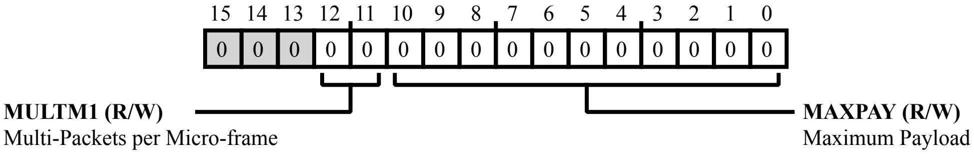

Figure 27-60: USB_EPI[N]_RXMAXP Register Diagram

Table 27-36: USB_EPI[N]_RXMAXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:11 (R/W)	MULTM1	Multi-Packets per Micro-frame. The USB_EPI[N]_RXMAXP.MULTM1 bits select the number of high-speed, high-bandwidth isochronous or interrupt packets that may be transferred in a micro-frame. The valid number of packets per micro-frame is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller combines multiple packets received within a micro-frame into a single packet in the FIFO.
10:0 (R/W)	MAXPAY	Maximum Payload. The USB_EPI[N]_RXMAXP.MAXPAY bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024, but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The USB_EPI[N]_RXMAXP.MAXPAY bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1.

EPn Receive Type Register

The `USB_EPI[N]_RXTYPE` register selects the endpoint number and transaction protocol to use for the currently selected receive endpoint. There is a `USB_EPI[N]_RXTYPE` register for each receive endpoint. Note that this register is only used in host mode.

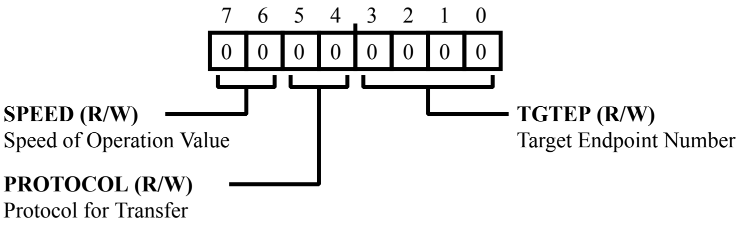

Figure 27-61: USB_EPI[N]_RXTYPE Register Diagram

Table 27-37: USB_EPI[N]_RXTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/W)	SPEED	Speed of Operation Value. The `USB_EPI[N]_RXTYPE.SPEED` bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When it is not connected to devices through a hub, program this field with 00.	
		0	Same Speed as the Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed
5:4 (R/W)	PROTOCOL	Protocol for Transfer. The `USB_EPI[N]_RXTYPE.PROTOCOL` bits select the transfer protocol for the endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
3:0 (R/W)	TGTEP	Target Endpoint Number. The `USB_EPI[N]_RXTYPE.TGTEP` bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the receive endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.)

Table 27-38: USB_EPI[N]_TXCSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOSET	TxPkRdy Autoset Enable. The USB_EPI[N]_TXCSR_H.AUTOSET bit enables (in host mode) the automatic setting of the USB_EPI[N]_TXCSR_H.TXPKTRDY bit when the maximum data packet size (USB_EP[n]_TXMAXP) is loaded into the transmit FIFO. The USB_EP[n]_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EPI[N]_TXCSR_H.TXPKTRDY bit needs to be set manually. For products supporting high-speed operation, this USB_EPI[N]_TXCSR_H.AUTOSET bit should not be set for high-bandwidth endpoints (endpoints with USB_EP[n]_TXMAXP value greater than 1).	
		0	Disable Autoset
		1	Enable Autoset
12 (R/W)	DMAREQEN	DMA Request Enable Tx EP. The USB_EPI[N]_TXCSR_H.DMAREQEN bit enables (in host mode) DMA requests for this transmit endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 27-38: USB_EPI[N]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W0C)	NAKTOINCMP	NAK Timeout Incomplete. The `USB_EPI[N]_TXCSR_H.NAKTOINCMP` bit indicates (for bulk endpoints in host mode) when the transmit endpoint is halted following the receipt of NAK responses for longer than the time set in the `USB_EP[n]_TXINTERVAL` register. The processor should clear this bit, allowing the endpoint to continue. For products supporting high-speed operation, for high-bandwidth isochronous endpoints in host mode, this bit indicates when no response is received from the device to which the packet is being sent.	
		0	No Status
		1	NAK Timeout Over Maximum
6 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EPI[N]_TXCSR_H.CLRDATATGL` bit is set (in host mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
5 (R/W0C)	RXSTALL	Rx STALL. The `USB_EPI[N]_TXCSR_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
4 (R/W)	SETUPPKT	Setup Packet. The `USB_EPI[N]_TXCSR_H.SETUPPKT` bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit is set.	
		0	No Request
		1	Send SETUP Token
3 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EPI[N]_TXCSR_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit. The `USB_EPI[N]_TXCSR_H.FLUSHFIFO` bit should only be set if the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO

Table 27-38: USB_EPI[N]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W0C)	TXTOERR	Tx Timeout Error. The `USB_EPI[N]_TXCSR_H.TXTOERR` bit indicates (in host mode) when three attempts have been made to send a packet and no handshake packet has been received. The USB controller generates an interrupt for this condition, clears the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit, and flushes the FIFO. The processor should clear this bit. Note that `USB_EPI[N]_TXCSR_H.TXTOERR` is valid only when the endpoint is operating in bulk or interrupt mode.	
		0	No Status
		1	Tx Timeout Error
1 (R/NW)	NEFIFO	Not Empty FIFO. The `USB_EPI[N]_TXCSR_H.NEFIFO` bit indicates (in host mode) when there is at least one packet in the transmit FIFO. This bit is cleared automatically when a data packet has been transmitted. If the endpoints transmit interrupt is enabled (in the `USB_INTRTXE` register), the USB controller generates an interrupt for this condition. Note that the `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit is also automatically cleared prior to loading a second packet into a double-buffered FIFO.	
		0	FIFO Empty
		1	FIFO Not Empty
0 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EPI[N]_TXCSR_H.TXPKTRDY` bit should be set (in host mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

EPn Transmit Configuration and Status (Peripheral) Register

The USB_EPI[N]_TXCSR_P register provides (in peripheral mode) control and status bits for transfers through the currently selected transmit endpoint.

Figure 27-63: USB_EPI[N]_TXCSR_P Register Diagram

Table 27-39: USB_EPI[N]_TXCSR_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOSET	TxPkRdy Autoset Enable. The USB_EPI[N]_TXCSR_P.AUTOSET bit enables (in peripheral mode) automatic setting of the USB_EPI[N]_TXCSR_P.TXPKTRDY bit when the maximum data packet size (USB_EP[n]_TXMAXP) is loaded into the transmit FIFO. The USB_EP[n]_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EPI[N]_TXCSR_P.TXPKTRDY bit needs to be set manually. For products supporting high-speed operation, this USB_EPI[N]_TXCSR_P.AUTOSET bit should not be set for high-bandwidth endpoints (endpoints with USB_EP[n]_TXMAXP value greater than 1).	
		0	Disable Autoset
		1	Enable Autoset

Table 27-39: USB_EPI[N]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ISO	Isochronous Transfers Enable. The `USB_EPI[N]_TXCSR_P.ISO` bit enables (in peripheral mode) the transmit endpoint for isochronous transfers. This bit should be disabled for bulk or interrupt endpoints.	
		0	Disable Tx EP Isochronous Transfers
		1	Enable Tx EP Isochronous Transfers
12 (R/W)	DMAREQEN	DMA Request Enable Tx EP. The `USB_EPI[N]_TXCSR_P.DMAREQEN` bit enables (in peripheral mode) DMA requests for this transmit endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request
11 (R/W)	FRCDATATGL	Force Data Toggle. The `USB_EPI[N]_TXCSR_P.FRCDATATGL` bit forces (in peripheral mode) the endpoint data toggle to switch and clears the data packet from the FIFO, regardless of whether an ACK was received. This feature can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints.	
		0	No Action
		1	Toggle Endpoint Data
10 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EPI[N]_TXCSR_P.DMAREQMODE` bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared during the cycle before or in the same cycle that the `USB_EPI[N]_TXCSR_P.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
7 (R/W0C)	INCOMPTX	Incomplete Tx. The `USB_EPI[N]_TXCSR_P.INCOMPTX` bit indicates (for high-bandwidth isochronous endpoints in peripheral mode) when a large packet has been split into two or three packets for transmission, but insufficient IN tokens have been received to send all parts.	
		0	No Status
		1	Incomplete Tx (Insufficient IN Tokens)

Table 27-39: USB_EPI[N]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EPI[N]_TXCSR_P.CLRDATATGL` bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
5 (R/W0C)	SENTSTALL	Sent STALL. The `USB_EPI[N]_TXCSR_P.SENTSTALL` bit indicates (in peripheral mode) when the USB controller transmits a STALL handshake. When this condition occurs, the USB controller flushes the FIFO and clears the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit. The processor should clear this bit.	
		0	No Status
		1	STALL Handshake Transmitted
4 (R/W)	SENDSTALL	Send STALL. The `USB_EPI[N]_TXCSR_P.SENDSTALL` bit (in peripheral mode) is set by the processor to issue a STALL handshake to an IN token. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.	
		0	No Request
		1	Request STALL Handshake Transmission
3 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EPI[N]_TXCSR_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit. The `USB_EPI[N]_TXCSR_P.FLUSHFIFO` bit should only be set if the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush endpoint FIFO
2 (R/W0C)	URUNERR	Underrun Error. The `USB_EPI[N]_TXCSR_P.URUNERR` bit indicates (in peripheral mode) when an IN token is received while the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit is not set. The processor should clear this bit.	
		0	No Status
		1	Underrun Error

Table 27-39: USB_EPI[N]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	NEFIFO	Not Empty FIFO. The `USB_EPI[N]_TXCSR_P.NEFIFO` bit indicates (in peripheral mode) when there is at least one packet in the transmit FIFO. This bit is cleared automatically when a data packet has been transmitted. If the endpoints transmit interrupt is enabled (in the `USB_INTRTXE` register), the USB controller generates an interrupt for this condition. Note that the `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit is also automatically cleared prior to loading a second packet into a double-buffered FIFO.	
		0	FIFO Empty
		1	FIFO Not Empty
0 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EPI[N]_TXCSR_P.TXPKTRDY` bit should be set (in peripheral mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

EPn Transmit Polling Interval Register

The `USB_EPI[N]_TXINTERVAL` register defines the polling interval for the currently-selected transmit endpoint for interrupt, isochronous, and bulk transfers. There is a `USB_EPI[N]_TXINTERVAL` register for each configured transmit endpoint, except endpoint 0. The transfer types related to the speed, interval value, and interval operation are as follows:

- Interrupt: Speed = low-speed or full-speed, `USB_EPI[N]_TXINTERVAL` = 1-255, and Operation = polling interval is m frames.
- Interrupt: Speed = high-speed, `USB_EPI[N]_TXINTERVAL` = 1-16, and Operation = polling interval is $2^{(m-1)}$ micro-frames.
- Isochronous: Speed = full-speed or high-speed, `USB_EPI[N]_TXINTERVAL` = 1-16, and Operation = polling interval is $2^{(m-1)}$ frames or micro-frames.
- Bulk: Speed = full-speed or high-speed, `USB_EPI[N]_TXINTERVAL` = 2-16, and Operation = NAK limit is $2^{(m-1)}$ frames or micro-frames.

Note that a `USB_EPI[N]_TXINTERVAL` value of 0 or 1 disables the NAK timeout function.

Not all products support high-speed operation or micro-frames. These features do not apply for products that only support low/full-speed operation.

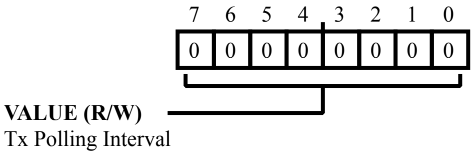

Figure 27-64: USB_EPI[N]_TXINTERVAL Register Diagram

Table 27-40: USB_EPI[N]_TXINTERVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Tx Polling Interval. The `USB_EPI[N]_TXINTERVAL.VALUE` bits define the polling interval value for interrupt and isochronous transfers. The `USB_EPI[N]_TXINTERVAL.VALUE` bits select the number of frames (or micro-frames, if the processor supports high-speed operation) after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.

EPn Transmit Maximum Packet Length Register

The USB_EPI[N]_TXMAXP register defines the maximum amount of data that can be transferred through the selected transmit endpoint in a single frame. When setting this value, consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. The USB_EPI[N]_TXMAXP register provides indexed access to the maximum packet length register for each Tx endpoint, except endpoint 0.

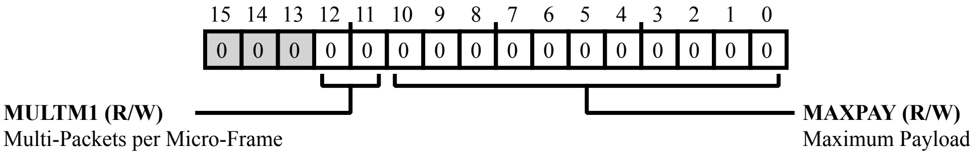

Figure 27-65: USB_EPI[N]_TXMAXP Register Diagram

Table 27-41: USB_EPI[N]_TXMAXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:11 (R/W)	MULTM1	Multi-Packets per Micro-Frame. The USB_EPI[N]_TXMAXP.MULTM1 bits select the number of high-speed, high-bandwidth isochronous or interrupt packets that may be transferred in a micro-frame. The valid number of packets per micro-frame is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller splits the FIFO data into multiple packets less than or equal to the maximum payload size.
10:0 (R/W)	MAXPAY	Maximum Payload. The USB_EPI[N]_TXMAXP.MAXPAY bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024 but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The USB_EPI[N]_TXMAXP.MAXPAY bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1.

EPn Transmit Type Register

The `USB_EPI[N]_TXTYPE` register selects the endpoint number and transaction protocol to use for the currently selected transmit endpoint. There is a `USB_EPI[N]_TXTYPE` register for each transmit endpoint. Note that this register is only used in host mode.

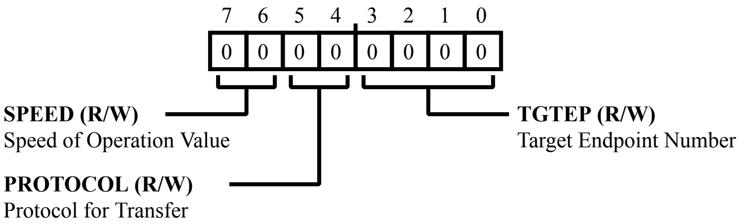

Figure 27-66: USB_EPI[N]_TXTYPE Register Diagram

Table 27-42: USB_EPI[N]_TXTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/W)	SPEED	Speed of Operation Value. The `USB_EPI[N]_TXTYPE.SPEED` bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00.	
		0	Same Speed as the Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed
5:4 (R/W)	PROTOCOL	Protocol for Transfer. The `USB_EPI[N]_TXTYPE.PROTOCOL` bits select the transfer protocol for the endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
3:0 (R/W)	TGTEP	Target Endpoint Number. The `USB_EPI[N]_TXTYPE.TGTEP` bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the transmit endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.)	

Table 27-42: USB_EPI[N]_TXTYPE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Endpoint 0
		1	Endpoint 1
		2	Endpoint 2
		3	Endpoint 3
		4	Endpoint 4
		5	Endpoint 5
		6	Endpoint 6
		7	Endpoint 7
		8	Endpoint 8
		9	Endpoint 9
		10	Endpoint 10
		11	Endpoint 11
		12	Endpoint 12
		13	Endpoint 13
		14	Endpoint 14
		15	Endpoint 15

EPn Number of Bytes Received Register

The `USB_EP[n]_RXCNT` register indicates the number of received data bytes in the endpoint receive FIFO. The value returned changes as the contents of the FIFO change and is only valid while the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit or `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is set.

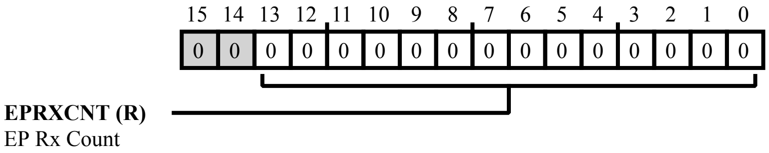

Figure 27-67: USB_EP[n]_RXCNT Register Diagram

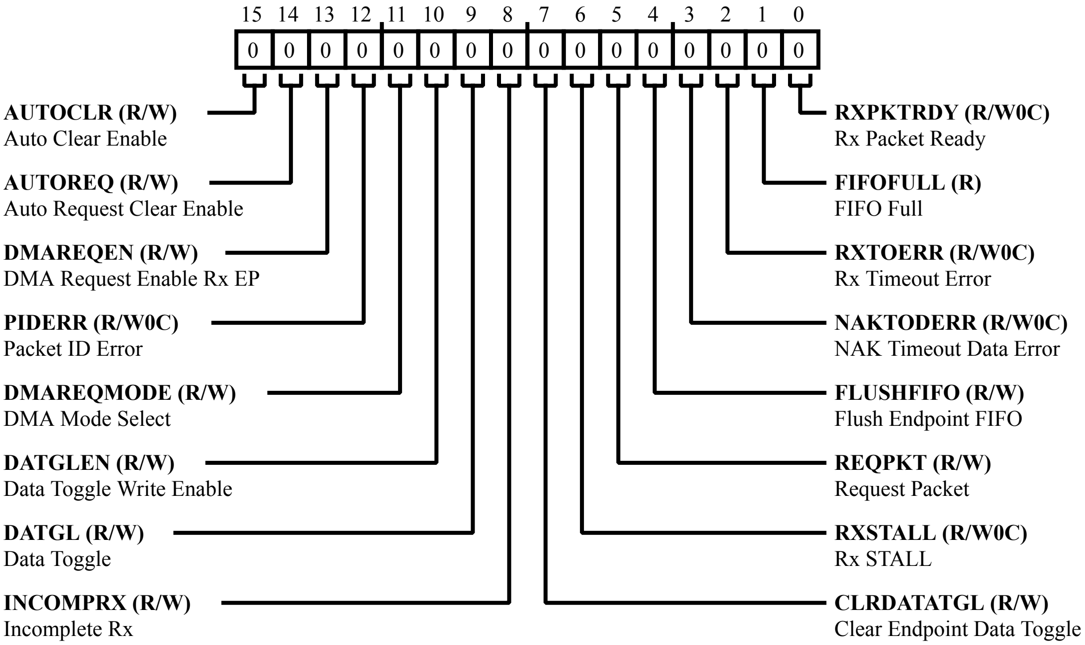
Table 27-43: USB_EP[n]_RXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/NW)	EPRXCNT	EP Rx Count. The `USB_EP[n]_RXCNT.EPRXCNT` bits hold the number of data bytes ready to be read from the receive FIFO.

EPn Receive Configuration and Status (Host) Register

The `USB_EP[n]_RXCSR_H` register provides (in host mode) control and status bits for transfers through the currently selected receive endpoint.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 27-68: USB_EP[n]_RXCSR_H Register Diagram

Table 27-44: USB_EP[n]_RXCSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOCLR	Auto Clear Enable. The `USB_EP[n]_RXCSR_H.AUTOCLR` bit directs (in host mode) the USB controller to automatically clear the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit when a packet of size `USB_EP[n]_RXMAXP` bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear `USB_EP[n]_RXCSR_H.RXPKTRDY` manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the `USB_EP[n]_RXMAXP` value. The USB controller auto clears the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.) • Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3 • Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2 • Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1 • Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP For products supporting high-speed operation, the `USB_EP[n]_RXCSR_H.AUTOCLR` bit should not be set for high-bandwidth isochronous endpoints.	
		0	Disable Auto Clear
		1	Enable Auto Clear
14 (R/W)	AUTOREQ	Auto Request Clear Enable. The `USB_EP[n]_RXCSR_H.AUTOREQ` bit directs (in host mode) the USB controller to automatically clear the `USB_EP[n]_RXCSR_H.REQPKT` bit when `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is cleared. This bit is automatically cleared when a short packet is received.	
		0	Disable Auto Request Clear
		1	Enable Auto Request Clear
13 (R/W)	DMAREQEN	DMA Request Enable Rx EP. The `USB_EP[n]_RXCSR_H.DMAREQEN` bit enables (in host mode) DMA requests for this receive endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 27-44: USB_EP[n]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W0C)	PIDERR	Packet ID Error. The `USB_EP[n]_RXCSR_H.PIDERR` bit indicates (in host mode) when a PID error occurs for isochronous transactions. This bit is ignored in host mode for bulk or interrupt transactions.	
		0	No Status
		1	PID Error
11 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EP[n]_RXCSR_H.DMAREQMODE` bit selects (in host mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the `USB_EP[n]_RXCSR_H.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
10 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EP[n]_RXCSR_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint `USB_EP[n]_RXCSR_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL
9 (R/W)	DATGL	Data Toggle. The `USB_EP[n]_RXCSR_H.DATGL` bit indicates (in host mode) the current state of the endpoint data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is Set
		1	DATA1 is Set
8 (R/W)	INCOMPRX	Incomplete Rx. The `USB_EP[n]_RXCSR_H.INCOMPRX` bit indicates (in host mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when `USB_EP[n]_RXCSR_H.RXPKTRDY` is cleared. For all other modes, this bit is zero.	
		0	No Status
		1	Incomplete Rx

Table 27-44: USB_EP[n]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EP[n]_RXCSR_H.CLRDATATGL` bit is set (in host mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
6 (R/W0C)	RXSTALL	Rx STALL. The `USB_EP[n]_RXCSR_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
5 (R/W)	REQPKT	Request Packet. The `USB_EP[n]_RXCSR_H.REQPKT` bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when `USB_EP[n]_RXCSR_H.RXPKTRDY` is set.	
		0	No Request
		1	Send IN Tokens to Device
4 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP[n]_RXCSR_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit. The `USB_EP[n]_RXCSR_H.FLUSHFIFO` bit should only be set if the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO

Table 27-44: USB_EP[n]_RXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W0C)	NAKTODERR	NAK Timeout Data Error. The `USB_EP[n]_RXCSR_H.NAKTODERR` bit indicates (in host mode for isochronous transfers) a NAK timeout data error when the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when the `USB_EP[n]_RXCSR_H.RXPKTRDY` bit is cleared. The `USB_EP[n]_RXCSR_H.NAKTODERR` bit indicates (in host mod for bulk transfers) when a receive endpoint is halted following the receipt of NAK responses greater than the limit set in the `USB_EP[n]_RXINTERVAL` register. The processor should clear this bit to allow the endpoint to continue. If double packet buffering is enabled, the `USB_EP[n]_RXCSR_H.REQPKT` bit should also be set in the same cycle as this bit is cleared.	
		0	No Status
		1	NAK Timeout Data Error
2 (R/W0C)	RXTOERR	Rx Timeout Error. The `USB_EP[n]_RXCSR_H.RXTOERR` bit indicates (in host mode) when three attempts have been made to receive a packet and no data packet has been received. The USB controller generates an interrupt for this condition. The processor should clear this bit. Note that `USB_EP[n]_RXCSR_H.RXTOERR` is valid only when the endpoint is operating in bulk or interrupt mode.	
		0	No Status
		1	Rx Timeout Error
1 (R/NW)	FIFOFULL	FIFO Full. The `USB_EP[n]_RXCSR_H.FIFOFULL` bit indicates (in host mode) when no more packets can be loaded into the receive FIFO.	
		0	No Status
		1	FIFO Full
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP[n]_RXCSR_H.RXPKTRDY` is set (in host mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EPn Receive Configuration and Status (Peripheral) Register

The `USB_EP[n]_RXCSR_P` register provides (in peripheral mode) control and status bits for transfers through the currently selected receive endpoint.

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOCLR	Auto Clear Enable. The `USB_EP[n]_RXCSR_P.AUTOCLR` bit directs (in peripheral mode) the USB controller to automatically clear the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit when a packet of size `USB_EP[n]_RXMAXP` bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear `USB_EP[n]_RXCSR_P.RXPKTRDY` manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the `USB_EP[n]_RXMAXP` value. The USB controller auto clears the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.) • Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3 • Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2 • Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1 • Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP For products supporting high-speed operation, the `USB_EP[n]_RXCSR_P.AUTOCLR` bit should not be set for high-bandwidth isochronous endpoints.	
		0	Disable Auto Clear
		1	Enable Auto Clear
14 (R/W)	ISO	Isochronous Transfers. The `USB_EP[n]_RXCSR_P.ISO` bit selects (in peripheral mode) between isochronous transfers and bulk/interrupt transfers.	
		0	This bit should be cleared for bulk or interrupt transfers.
		1	This bit should be set for isochronous transfers.
13 (R/W)	DMAREQEN	DMA Request Enable Rx EP. The `USB_EP[n]_RXCSR_P.DMAREQEN` bit enables (in peripheral mode) DMA requests for this receive endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 27-45: USB_EP[n]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	DNYETPERR	Disable NYET Handshake. The `USB_EP[n]_RXCSR_P.DNYETPERR` bit disables (in peripheral mode for high speed bulk/interrupt transactions) NYET handshakes. When this bit is set, all successful receive packets are ACK'd, including the point at which the FIFO becomes full. The `USB_EP[n]_RXCSR_P.DNYETPERR` bit must be set for all interrupt endpoints in high speed mode.	
		0	Enable NYET Handshake
		1	Disable NYET Handshake
11 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EP[n]_RXCSR_P.DMAREQMODE` bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the `USB_EP[n]_RXCSR_P.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
8 (R/W)	INCOMPRX	Incomplete Rx. The `USB_EP[n]_RXCSR_P.INCOMPRX` bit indicates (in peripheral mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when `USB_EP[n]_RXCSR_P.RXPKTRDY` is cleared. For all other modes, this bit is zero.	
		0	No Status
		1	Incomplete Rx
7 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EP[n]_RXCSR_P.CLRDATATGL` bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
6 (R/W0C)	SENTSTALL	Sent STALL. The `USB_EP[n]_RXCSR_P.SENTSTALL` bit indicates (in peripheral mode) when a STALL handshake is transmitted. The processor should clear this bit.	
		0	No Status
		1	STALL Handshake Transmitted

Table 27-45: USB_EP[n]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SENDSTALL	Send STALL. The `USB_EP[n]_RXCSR_P.SENDSTALL` bit is set (in peripheral mode) by the processor to send a STALL handshake. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.	
		0	No Action
		1	Request STALL Handshake
4 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP[n]_RXCSR_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit. The `USB_EP[n]_RXCSR_P.FLUSHFIFO` bit should only be set if the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO
3 (R/NW)	DATAERR	Data Error. The `USB_EP[n]_RXCSR_P.DATAERR` bit indicates (in peripheral mode for isochronous transfers) when the `USB_EP[n]_RXCSR_P.RXPKTRDY` bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when `USB_EP[n]_RXCSR_P.RXPKTRDY` is cleared. The `USB_EP[n]_RXCSR_P.DATAERR` bit is always zero for bulk endpoints in peripheral mode.	
		0	No Status
		1	Data Error
2 (R/W0C)	ORUNERR	OUT Run Error. The `USB_EP[n]_RXCSR_P.ORUNERR` bit indicates (in peripheral mode for isochronous transfers) when an OUT packet cannot be loaded into the receive FIFO. The processor should clear this bit. The `USB_EP[n]_RXCSR_P.ORUNERR` bit always returns zero in bulk mode.	
		0	No Status
		1	OUT Run Error
1 (R/NW)	FIFOFULL	FIFO Full. The `USB_EP[n]_RXCSR_P.FIFOFULL` bit indicates (in peripheral mode) when no more packets can be loaded into the receive FIFO.	
		0	No Status
		1	FIFO Full

Table 27-45: USB_EP[n]_RXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W0C)	RXPKTRDY	Rx Packet Ready. The `USB_EP[n]_RXCSR_P.RXPKTRDY` is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.	
		0	No Rx Packet
		1	Rx Packet in Endpoint FIFO

EPn Receive Polling Interval Register

The `USB_EP[n]_RXINTERVAL` register defines the polling interval for the currently-selected receive endpoint for interrupt, isochronous, and bulk transfers. There is a `USB_EP[n]_RXINTERVAL` register for each configured receive endpoint, except endpoint 0. The transfer types related to speed, interval value, and interval operation are as follows:

- Interrupt: Speed = low-speed or full -speed, `USB_EP[n]_RXINTERVAL` = 1-255, and Operation = polling interval is m frames.
- Interrupt: Speed = high-speed, `USB_EP[n]_RXINTERVAL` = 1-16, and Operation = polling interval is $2^{(m-1)}$ micro-frames.
- Isochronous: Speed = full-speed or high-speed, `USB_EP[n]_RXINTERVAL` = 1-16, and Operation = polling interval is $2^{(m-1)}$ frames or micro-frames.
- Bulk: Speed = full-speed or high-speed, `USB_EP[n]_RXINTERVAL` = 2-16, and Operation = NAK limit is $2^{(m-1)}$ frames or micro-frames.

Note that a `USB_EP[n]_RXINTERVAL` value of 0 or 1 disables the NAK timeout function.

Not all products support high-speed operation or micro-frames. These features do not apply for products that only support low/full-speed operation.

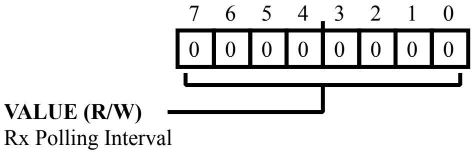

Figure 27-70: USB_EP[n]_RXINTERVAL Register Diagram

Table 27-46: USB_EP[n]_RXINTERVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Rx Polling Interval. The `USB_EP[n]_RXINTERVAL.VALUE` bits define the polling interval value for interrupt and isochronous transfers and select the number of frames (or microframes, if the processor supports high-speed operation) after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.

EPn Receive Maximum Packet Length Register

The `USB_EP[n]_RXMAXP` register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single frame.

Note that a value greater than the maximum allowed of 1023 for full-speed USB operation produces unpredictable results. Also, note that the total amount of data represented by the value written to this register must not exceed the receive FIFO size, and should not exceed half the FIFO size if double-buffering is required.

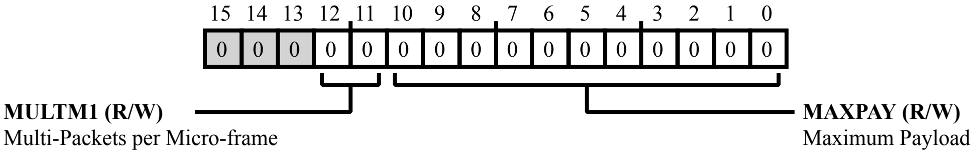

Figure 27-71: USB_EP[n]_RXMAXP Register Diagram

Table 27-47: USB_EP[n]_RXMAXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:11 (R/W)	MULTM1	Multi-Packets per Micro-frame. The `USB_EP[n]_RXMAXP.MULTM1` bits select the number of high-speed, high-bandwidth isochronous or interrupt packets that may be transferred in a micro-frame. The valid number of packets per micro-frame is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller combines multiple packets received within a micro-frame into a single packet in the FIFO.
10:0 (R/W)	MAXPAY	Maximum Payload. The `USB_EP[n]_RXMAXP.MAXPAY` bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024, but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The `USB_EP[n]_RXMAXP.MAXPAY` bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1.

EPn Receive Type Register

The `USB_EP[n]_RXTYPE` register selects the endpoint number and transaction protocol to use for the currently selected receive endpoint. There is a `USB_EP[n]_RXTYPE` register for each receive endpoint. Note that this register is only used in host mode.

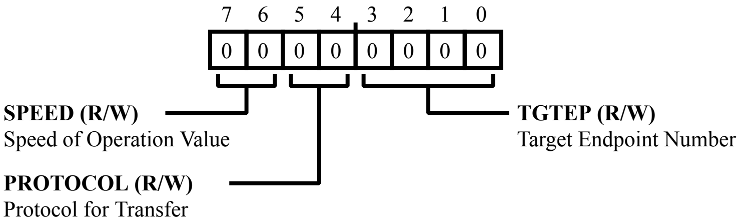

Figure 27-72: USB_EP[n]_RXTYPE Register Diagram

Table 27-48: USB_EP[n]_RXTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/W)	SPEED	Speed of Operation Value. The `USB_EP[n]_RXTYPE.SPEED` bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When it is not connected to devices through a hub, program this field with 00.	
		0	Same Speed as the Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed
5:4 (R/W)	PROTOCOL	Protocol for Transfer. The `USB_EP[n]_RXTYPE.PROTOCOL` bits select the transfer protocol for the endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
3:0 (R/W)	TGTEP	Target Endpoint Number. The `USB_EP[n]_RXTYPE.TGTEP` bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the receive endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.)	

Table 27-48: USB_EP[n]_RXTYPE Register Fields (Continued)

Figure 27-73: USB_EP[n]_TXCSR_H Register Diagram

Table 27-49: USB_EP[n]_TXCSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOSET	TxPkRdy Autoset Enable. The `USB_EP[n]_TXCSR_H.AUTOSET` bit enables (in host mode) the automatic setting of the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit when the maximum data packet size (`USB_EP[n]_TXMAXP`) is loaded into the transmit FIFO. The `USB_EP[n]_TXMAXP` value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit needs to be set manually. For products supporting high-speed operation, this `USB_EP[n]_TXCSR_H.AUTOSET` bit should not be set for high-bandwidth endpoints (endpoints with `USB_EP[n]_TXMAXP` value greater than 1).	
		0	Disable Autoset
		1	Enable Autoset
12 (R/W)	DMAREQEN	DMA Request Enable Tx EP. The `USB_EP[n]_TXCSR_H.DMAREQEN` bit enables (in host mode) DMA requests for this transmit endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request

Table 27-49: USB_EP[n]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	FRCDATATGL	Force Data Toggle. The `USB_EP[n]_TXCSR_H.FRCDATATGL` bit forces (in host mode) the endpoint data toggle to switch and clears the data packet from the FIFO, regardless of whether an ACK was received. This feature can be used by interrupt transmit endpoints to communicate rate feedback for isochronous endpoints.	
		0	No Action
		1	Toggle Endpoint Data
10 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EP[n]_TXCSR_H.DMAREQMODE` bit selects (in host mode) between DMA request mode 1 or 0. This bit must not be cleared during the cycle before or the same cycle that the `USB_EP[n]_TXCSR_H.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
9 (R/W)	DATGLEN	Data Toggle Write Enable. The `USB_EP[n]_TXCSR_H.DATGLEN` bit enables (in host mode) the USB controller to write the current state of the endpoint `USB_EP[n]_TXCSR_H.DATGL` bit. This bit is automatically cleared once the new value is written.	
		0	Disable Write to DATGL
		1	Enable Write to DATGL
8 (R/W)	DATGL	Data Toggle. The `USB_EP[n]_TXCSR_H.DATGL` bit indicates (in host mode) the current state of the endpoint data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.	
		0	DATA0 is set
		1	DATA1 is set

Table 27-49: USB_EP[n]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W0C)	NAKTOINCMP	NAK Timeout Incomplete. The `USB_EP[n]_TXCSR_H.NAKTOINCMP` bit indicates (for bulk endpoints in host mode) when the transmit endpoint is halted following the receipt of NAK responses for longer than the time set in the `USB_EP[n]_TXINTERVAL` register. The processor should clear this bit, allowing the endpoint to continue. For products supporting high-speed operation, for high-bandwidth isochronous endpoints in host mode, this bit indicates when no response is received from the device to which the packet is being sent.	
		0	No Status
		1	NAK Timeout Over Maximum
6 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EP[n]_TXCSR_H.CLRDATATGL` bit is set (in host mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
5 (R/W0C)	RXSTALL	Rx STALL. The `USB_EP[n]_TXCSR_H.RXSTALL` bit indicates (in host mode) when a STALL handshake is received. The processor core should clear this bit.	
		0	No Status
		1	Stall Received from Device
4 (R/W)	SETUPPKT	Setup Packet. The `USB_EP[n]_TXCSR_H.SETUPPKT` bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit is set.	
		0	No Request
		1	Send SETUP Token
3 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP[n]_TXCSR_H.FLUSHFIFO` bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit. The `USB_EP[n]_TXCSR_H.FLUSHFIFO` bit should only be set if the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush Endpoint FIFO

Table 27-49: USB_EP[n]_TXCSR_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W0C)	TXTOERR	Tx Timeout Error. The `USB_EP[n]_TXCSR_H.TXTOERR` bit indicates (in host mode) when three attempts have been made to send a packet and no handshake packet has been received. The USB controller generates an interrupt for this condition, clears the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit, and flushes the FIFO. The processor should clear this bit. Note that `USB_EP[n]_TXCSR_H.TXTOERR` is valid only when the endpoint is operating in bulk or interrupt mode.	
		0	No Status
		1	Tx Timeout Error
1 (R/NW)	NEFIFO	Not Empty FIFO. The `USB_EP[n]_TXCSR_H.NEFIFO` bit indicates (in host mode) when there is at least one packet in the transmit FIFO. This bit is cleared automatically when a data packet has been transmitted. If the endpoints transmit interrupt is enabled (in the `USB_INTRTXE` register), the USB controller generates an interrupt for this condition. Note that the `USB_EP[n]_TXCSR_H.TXPKTRDY` bit is also automatically cleared prior to loading a second packet into a double-buffered FIFO.	
		0	FIFO Empty
		1	FIFO Not Empty
0 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP[n]_TXCSR_H.TXPKTRDY` bit should be set (in host mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

EPn Transmit Configuration and Status (Peripheral) Register

The USB_EP[n]_TXCSR_P register provides (in peripheral mode) control and status bits for transfers through the currently selected transmit endpoint.

Figure 27-74: USB_EP[n]_TXCSR_P Register Diagram

Table 27-50: USB_EP[n]_TXCSR_P Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	AUTOSET	TxPkRdy Autoset Enable. The USB_EP[n]_TXCSR_P.AUTOSET bit enables (in peripheral mode) automatic setting of the USB_EP[n]_TXCSR_P.TXPKTRDY bit when the maximum data packet size (USB_EP[n]_TXMAXP) is loaded into the transmit FIFO. The USB_EP[n]_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EP[n]_TXCSR_P.TXPKTRDY bit needs to be set manually. For products supporting high-speed operation, this USB_EP[n]_TXCSR_P.AUTOSET bit should not be set for high-bandwidth endpoints (endpoints with USB_EP[n]_TXMAXP value greater than 1).	
		0	Disable Autoset
		1	Enable Autoset

Table 27-50: USB_EP[n]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ISO	Isochronous Transfers Enable. The `USB_EP[n]_TXCSR_P.ISO` bit enables (in peripheral mode) the transmit endpoint for isochronous transfers. This bit should be disabled for bulk or interrupt endpoints.	
		0	Disable Tx EP Isochronous Transfers
		1	Enable Tx EP Isochronous Transfers
12 (R/W)	DMAREQEN	DMA Request Enable Tx EP. The `USB_EP[n]_TXCSR_P.DMAREQEN` bit enables (in peripheral mode) DMA requests for this transmit endpoint.	
		0	Disable DMA Request
		1	Enable DMA Request
11 (R/W)	FRCDATATGL	Force Data Toggle. The `USB_EP[n]_TXCSR_P.FRCDATATGL` bit forces (in peripheral mode) the endpoint data toggle to switch and clears the data packet from the FIFO, regardless of whether an ACK was received. This feature can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints.	
		0	No Action
		1	Toggle Endpoint Data
10 (R/W)	DMAREQMODE	DMA Mode Select. The `USB_EP[n]_TXCSR_P.DMAREQMODE` bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared during the cycle before or in the same cycle that the `USB_EP[n]_TXCSR_P.DMAREQEN` bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention.	
		0	DMA Request Mode 0
		1	DMA Request Mode 1
7 (R/W0C)	INCOMPTX	Incomplete Tx. The `USB_EP[n]_TXCSR_P.INCOMPTX` bit indicates (for high-bandwidth isochronous endpoints in peripheral mode) when a large packet has been split into two or three packets for transmission, but insufficient IN tokens have been received to send all parts.	
		0	No Status
		1	Incomplete Tx (Insufficient IN Tokens)

Table 27-50: USB_EP[n]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	CLRDATATGL	Clear Endpoint Data Toggle. The `USB_EP[n]_TXCSR_P.CLRDATATGL` bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.	
		0	No Action
		1	Reset EP Data Toggle to 0
5 (R/W0C)	SENTSTALL	Sent STALL. The `USB_EP[n]_TXCSR_P.SENTSTALL` bit indicates (in peripheral mode) when the USB controller transmits a STALL handshake. When this condition occurs, the USB controller flushes the FIFO and clears the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit. The processor should clear this bit.	
		0	No Status
		1	STALL Handshake Transmitted
4 (R/W)	SENDSTALL	Send STALL. The `USB_EP[n]_TXCSR_P.SENDSTALL` bit (in peripheral mode) is set by the processor to issue a STALL handshake to an IN token. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.	
		0	No Request
		1	Request STALL Handshake Transmission
3 (R/W)	FLUSHFIFO	Flush Endpoint FIFO. The `USB_EP[n]_TXCSR_P.FLUSHFIFO` bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit. The `USB_EP[n]_TXCSR_P.FLUSHFIFO` bit should only be set if the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is set. Note that setting this bit at other times may cause data corruption.	
		0	No Flush
		1	Flush endpoint FIFO
2 (R/W0C)	URUNERR	Underrun Error. The `USB_EP[n]_TXCSR_P.URUNERR` bit indicates (in peripheral mode) when an IN token is received while the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is not set. The processor should clear this bit.	
		0	No Status
		1	Underrun Error

Table 27-50: USB_EP[n]_TXCSR_P Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	NEFIFO	Not Empty FIFO. The `USB_EP[n]_TXCSR_P.NEFIFO` bit indicates (in peripheral mode) when there is at least one packet in the transmit FIFO. This bit is cleared automatically when a data packet has been transmitted. If the endpoints transmit interrupt is enabled (in the `USB_INTRTXE` register), the USB controller generates an interrupt for this condition. Note that the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is also automatically cleared prior to loading a second packet into a double-buffered FIFO.	
		0	FIFO Empty
		1	FIFO Not Empty
0 (R/W1S)	TXPKTRDY	Tx Packet Ready. The `USB_EP[n]_TXCSR_P.TXPKTRDY` bit should be set (in peripheral mode) by the processor core after loading a data packet into the FIFO. This bit is cleared automatically when the data packet is transmitted. An interrupt is generated (if enabled) when the bit is cleared.	
		0	No Tx Packet
		1	Tx Packet in Endpoint FIFO

EPn Transmit Polling Interval Register

The `USB_EP[n]_TXINTERVAL` register defines the polling interval for the currently-selected transmit endpoint for interrupt, isochronous, and bulk transfers. There is a `USB_EP[n]_TXINTERVAL` register for each configured transmit endpoint, except endpoint 0. The transfer types related to the speed, interval value, and interval operation are as follows:

- Interrupt: Speed = low-speed or full-speed, `USB_EP[n]_TXINTERVAL` = 1-255, and Operation = polling interval is m frames.
- Interrupt: Speed = high-speed, `USB_EP[n]_TXINTERVAL` = 1-16, and Operation = polling interval is $2^{(m-1)}$ micro-frames.
- Isochronous: Speed = full-speed or high-speed, `USB_EP[n]_TXINTERVAL` = 1-16, and Operation = polling interval is $2^{(m-1)}$ frames or micro-frames.
- Bulk: Speed = full-speed or high-speed, `USB_EP[n]_TXINTERVAL` = 2-16, and Operation = NAK limit is $2^{(m-1)}$ frames or micro-frames.

Note that a `USB_EP[n]_TXINTERVAL` value of 0 or 1 disables the NAK timeout function.

Not all products support high-speed operation or micro-frames. These features do not apply for products that only support low/full-speed operation.

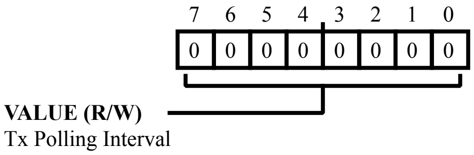

Figure 27-75: USB_EP[n]_TXINTERVAL Register Diagram

Table 27-51: USB_EP[n]_TXINTERVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Tx Polling Interval. The `USB_EP[n]_TXINTERVAL.VALUE` bits define the polling interval value for interrupt and isochronous transfers. The `USB_EP[n]_TXINTERVAL.VALUE` bits select the number of frames (or micro-frames, if the processor supports high-speed operation) after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.

EPn Transmit Maximum Packet Length Register

The USB_EP[n]_TXMAXP register defines the maximum amount of data that can be transferred through the selected transmit endpoint in a single frame. When setting this value, consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. The USB_EP[n]_TXMAXP register provides indexed access to the maximum packet length register for each Tx endpoint, except endpoint 0.

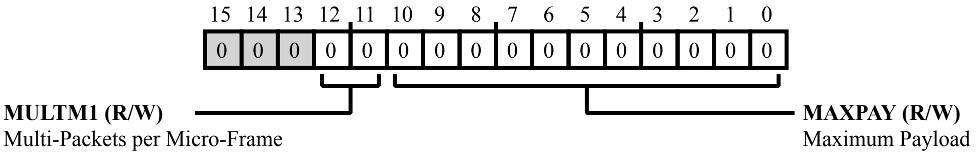

Figure 27-76: USB_EP[n]_TXMAXP Register Diagram

Table 27-52: USB_EP[n]_TXMAXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:11 (R/W)	MULTM1	Multi-Packets per Micro-Frame. The USB_EP[n]_TXMAXP.MULTM1 bits select the number of high-speed, high-bandwidth isochronous or interrupt packets that may be transferred in a micro-frame. The valid number of packets per micro-frame is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller splits the FIFO data into multiple packets less than or equal to the maximum payload size.
10:0 (R/W)	MAXPAY	Maximum Payload. The USB_EP[n]_TXMAXP.MAXPAY bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024 but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The USB_EP[n]_TXMAXP.MAXPAY bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1.

EPn Transmit Type Register

The `USB_EP[n]_TXTYPE` register selects the endpoint number and transaction protocol to use for the currently selected transmit endpoint. There is a `USB_EP[n]_TXTYPE` register for each transmit endpoint. Note that this register is only used in host mode.

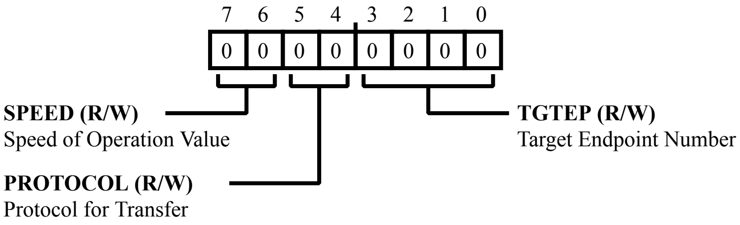

Figure 27-77: USB_EP[n]_TXTYPE Register Diagram

Table 27-53: USB_EP[n]_TXTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/W)	SPEED	Speed of Operation Value. The `USB_EP[n]_TXTYPE.SPEED` bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00.	
		0	Same Speed as the Core
		1	High-Speed
		2	Full-Speed
		3	Low-Speed
5:4 (R/W)	PROTOCOL	Protocol for Transfer. The `USB_EP[n]_TXTYPE.PROTOCOL` bits select the transfer protocol for the endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
3:0 (R/W)	TGTEP	Target Endpoint Number. The `USB_EP[n]_TXTYPE.TGTEP` bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the transmit endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.)	

Table 27-53: USB_EP[n]_TXTYPE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration

		13	Endpoint 13
		14	Endpoint 14
		15	Endpoint 15

Function Address Register

The `USB_FADDR` register contains the device address used in peripheral mode. The processor writes this register with the address received through a SET_ADDRESS command from the host.

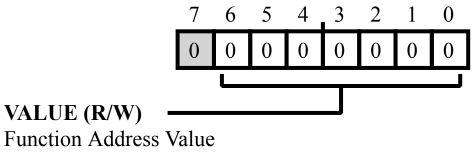

Figure 27-78: USB_FADDR Register Diagram

Table 27-54: USB_FADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Function Address Value. The `USB_FADDR.VALUE` bits contain the address of the peripheral part of the transaction.

FIFO Byte (8-Bit) Register

Writes to the `USB_FIFOB[n]` register go to the endpoint Tx FIFO and reads from the `USB_FIFOB[n]` register come from the endpoint Rx FIFO. The `USB_FIFOB[n]`, `USB_FIFOH[n]`, and `USB_FIFO[n]` registers are the same register. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (`USB_FIFO[n]` register) writes and reads, which are more efficient. If the USB packet is a non-word (4-byte) size, the program should use a half-word (`USB_FIFOH[n]` register) or byte (`USB_FIFOB[n]` register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

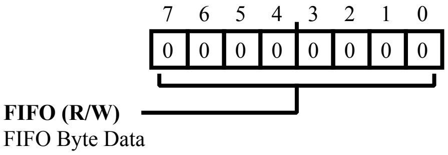

Figure 27-79: USB_FIFOB[n] Register Diagram

Table 27-55: USB_FIFOB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FIFO	FIFO Byte Data. The `USB_FIFOB[n].FIFO` bits provide byte access to the USB Tx and Rx endpoint FIFOs.

FIFO Half-Word (16-Bit) Register

Writes to the `USB_FIFOH[n]` register go to the endpoint Tx FIFO and reads from the `USB_FIFOH[n]` register come from the endpoint Rx FIFO. The `USB_FIFOB[n]`, `USB_FIFOH[n]`, and `USB_FIFO[n]` registers are the same register. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (`USB_FIFO[n]` register) writes and reads, which are more efficient. If the USB packet is a non-word (4-byte) size, programs should use a half-word (`USB_FIFOH[n]` register) or byte (`USB_FIFOB[n]` register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

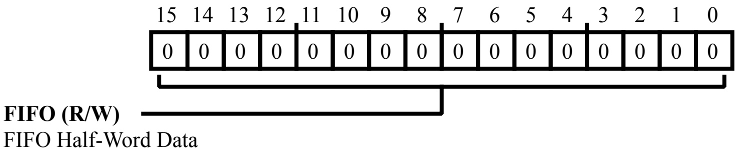

Figure 27-80: USB_FIFOH[n] Register Diagram

Table 27-56: USB_FIFOH[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	FIFO	FIFO Half-Word Data. The `USB_FIFOH[n].FIFO` bits provide half-word access to the USB Tx and Rx endpoint FIFOs.

FIFO Word (32-Bit) Register

Writes to the `USB_FIFO[n]` register go to the endpoint Tx FIFO and reads from the `USB_FIFO[n]` register come from the endpoint Rx FIFO. The `USB_FIFOB[n]`, `USB_FIFOH[n]`, and `USB_FIFO[n]` registers are the same registers. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (`USB_FIFO[n]` register) writes and reads, which are more efficient. If the USB packet is a non-word (4-byte) size, programs should use a half-word (`USB_FIFOH[n]` register) or byte (`USB_FIFOB[n]` register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

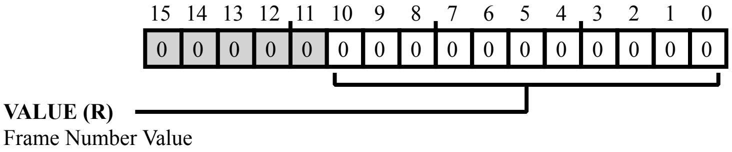
Figure 27-81: USB_FIFO[n] Register Diagram

Table 27-57: USB_FIFO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	FIFO Word Data. The `USB_FIFO[n].VALUE` bits provide word access to the USB Tx and Rx endpoint FIFOs.

Frame Number Register

The `USB_FRAME` register contains the frame number of the last received frame. The data in this register has bit 10 as the MSB and bit 0 as the LSB.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R)
Frame Number Value

Figure 27-82: USB_FRAME Register Diagram

Table 27-58: USB_FRAME Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Frame Number Value. The `USB_FRAME.VALUE` bits contains the frame number of the last received frame. The data in this field has bit 10 as the MSB and bit 0 as the LSB.

Full-Speed EOF 1 Register

The `USB_FS_EOF1` register defines the minimum time gap allowed between the start of the last transaction and the end of frame for full-speed transactions.

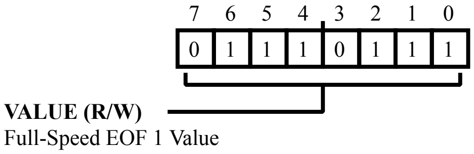


Figure 27-83: USB_FS_EOF1 Register Diagram

Table 27-59: USB_FS_EOF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Full-Speed EOF 1 Value. The `USB_FS_EOF1.VALUE` bits set the time before the end of the frame to stop beginning new transactions (in units of 533.3ns) for full-speed transactions. The default setting corresponds to 63.46us.

High-Speed EOF 1 Register

The `USB_HS_EOF1` register defines the minimum time gap allowed between the start of the last transaction and the end of frame for high-speed transactions.

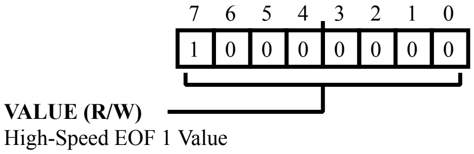

Figure 27-84: USB_HS_EOF1 Register Diagram

Table 27-60: USB_HS_EOF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	High-Speed EOF 1 Value. The `USB_HS_EOF1.VALUE` sets the time before the end of the frame to stop beginning new transactions (in units of 133.3ns) for high-speed transactions. The default setting corresponds to 17.07us.

ID Control

The `USB_IDCTL` register can be used to override the ID pin and force the controller to act as an A-device or B-device.

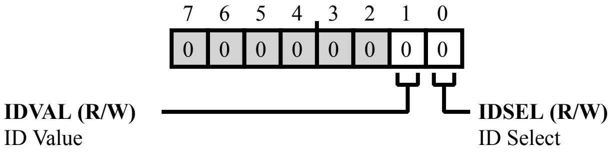

Figure 27-85: USB_IDCTL Register Diagram

Table 27-61: USB_IDCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	IDVAL	ID Value. When the `USB_IDCTL.IDSEL` bit =1, the `USB_IDCTL.IDVAL` bit sets the value of the ID input to the controller. This bit has no effect if `USB_IDCTL.IDSEL`=0.	
		0	A-Device
		1	B-Device
0 (R/W)	IDSEL	ID Select. The `USB_IDCTL.IDSEL` bit selects the source of the ID input to the controller. This can be used to bypass the ID input pin and force the controller to act as an A-device or B-device.	
		0	ID pin selected for controller input
		1	IDCTL[1] selected for controller input

Common Interrupts Enable Register

The `USB_IEN` register enables interrupts for USB controller system sources. Enabling an interrupt in this register directs the USB controller to generate an interrupt if the corresponding interrupt pending bit in the `USB_IRQ` register is set.

Figure 27-86: USB_IEN Register Diagram

Table 27-62: USB_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	VBUSERR	VBUS Threshold Indicator Interrupt Enable. The `USB_IEN.VBUSERR` bit enables the `USB_IRQ.VBUSERR` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
6 (R/W)	SESSREQ	Session Request Indicator Interrupt Enable. The `USB_IEN.SESSREQ` bit enables the `USB_IRQ.SESSREQ` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
5 (R/W)	DISCON	Disconnect Indicator Interrupt Enable. The `USB_IEN.DISCON` bit enables the `USB_IRQ.DISCON` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
4 (R/W)	CON	Connection Indicator Interrupt Enable. The `USB_IEN.CON` bit enables the `USB_IRQ.CON` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt

Table 27-62: USB_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	SOF	Start of Frame Indicator Interrupt Enable. The `USB_IEN.SOF` bit enables the `USB_IRQ.SOF` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
2 (R/W)	RSTBABBLE	Reset/Babble Indicator Interrupt Enable. The `USB_IEN.RSTBABBLE` bit enables the `USB_IRQ.RSTBABBLE` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
1 (R/W)	RESUME	Resume Indicator Interrupt Enable. The `USB_IEN.RESUME` bit enables the `USB_IRQ.RESUME` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt
0 (R/W)	SUSPEND	Suspend Indicator Interrupt Enable. The `USB_IEN.SUSPEND` bit enables the `USB_IRQ.SUSPEND` interrupt.	
		0	Disable Interrupt
		1	Enable Interrupt

Index Register

The `USB_INDEX` register contains an index value for mirrored addressing of USB controller endpoint control and status registers.

There is one set of registers, but they are mirrored at two address locations if the endpoint is selected by the `USB_INDEX` register. An endpoint's register set only appears in the indexed location if the `USB_INDEX` register is written with that endpoint number. You can read/write an endpoint's register in either the directly mapped location which is always visible, or in the indexed location which is only visible if the `USB_INDEX` register is written with the endpoint number. The `USB_INDEX` register and indexed address locations only affect address decoding. For example, loading a 0 into the `USB_INDEX` register selects endpoint 0 access.

The `USB_INDEX` register can be used for indexed access of the directly mapped control/status registers from USB controller address offset 0x100-0x1FF. For products supporting the dynamic FIFO size feature, the endpoint Tx/Rx size and address registers always use the `USB_INDEX` register, there is no direct mapping for these endpoint-specific registers. The multi-point `USB_MP[n]_TXFUNCADDR`, `USB_MP[n]_TXHUBADDR`, `USB_MP[n]_TXHUBPORT`, `USB_MP[n]_RXFUNCADDR`, `USB_MP[n]_RXHUBADDR`, and `USB_MP[n]_RXHUBPORT` registers only have direct mapping, no indexed mapping.

Before accessing an endpoint's control/status registers using the indexed range, write the endpoint number to the `USB_INDEX` register to ensure that the correct control/status registers appear in the indexed range of the memory map.

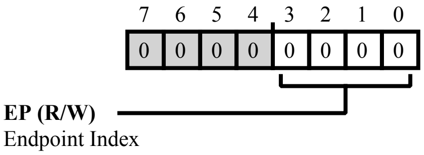

Figure 27-87: USB_INDEX Register Diagram

Table 27-63: USB_INDEX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	EP	Endpoint Index. The `USB_INDEX.EP` bits select mirrored access for an endpoints indexed control and status registers. Valid values for this bit field are 0-11.

Receive Interrupt Register

The `USB_INTRRX` register indicates which interrupts are currently active for the receive (Rx) endpoints. Note that the USB controller automatically clears this register when it is read.

SUSPEND (RC)
Suspend Indicator
RESUME (RC)
Resume Indicator
RSTBABBLE (RC)
Reset/Babble Indicator
SOF (RC)
Start of Frame Indicator

Figure 27-92: USB_IRQ Register Diagram

Table 27-68: USB_IRQ Register Fields

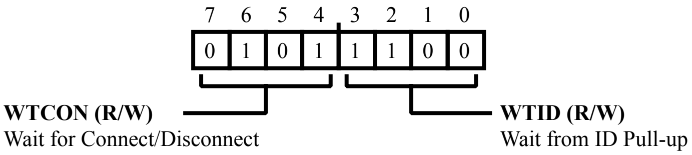
Bit No. (Access)	Bit Name	Description/Enumeration	
7 (RC/NW)	VBUSERR	VBUS Threshold Indicator. The `USB_IRQ.VBUSERR` bit indicates whether the USB controller has detected that the VBUS is below the VBUS valid threshold. This bit is valid only when the USB controller is an A device. Note that the `USB_IRQ.VBUSERR` bit and the `USB_VBUS_CTL.DRVINT` bit share an interrupt source line.	
		0	No Interrupt
		1	Interrupt Pending
6 (RC/NW)	SESSREQ	Session Request Indicator. The `USB_IRQ.SESSREQ` bit indicates whether the USB controller has detected a session request signal. This bit is valid only when the USB controller is an A device.	
		0	No Interrupt
		1	Interrupt Pending
5 (RC/NW)	DISCON	Disconnect Indicator. The `USB_IRQ.DISCON` bit indicates whether the USB controller has detected a device disconnect (host mode) or has detected a session end (peripheral mode).	
		0	No Interrupt
		1	Interrupt Pending

Table 27-68: USB_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (RC/NW)	CON	Connection Indicator. The `USB_IRQ.CON` bit indicates whether the USB controller has detected a device connection. This bit is valid only in host mode.	
		0	No Interrupt
		1	Interrupt Pending
3 (RC/NW)	SOF	Start of Frame Indicator. The `USB_IRQ.SOF` bit indicates whether the USB controller has detected a start of a frame.	
		0	No Interrupt
		1	Interrupt Pending
2 (RC/NW)	RSTBABBLE	Reset/Babble Indicator. The `USB_IRQ.RSTBABBLE` bit indicates whether the USB controller has detected reset signalling on the bus. In host mode, the USB controller also indicates when the USB controller detects babble. Note that the `USB_IRQ.RSTBABBLE` bit is only active after the first SOF has been sent.	
		0	No Interrupt
		1	Interrupt Pending
1 (RC/NW)	RESUME	Resume Indicator. The `USB_IRQ.RESUME` bit indicates whether the USB controller has detected resume signaling on the bus while the USB controller is in suspend mode.	
		0	No Interrupt
		1	Interrupt Pending
0 (RC/NW)	SUSPEND	Suspend Indicator. The `USB_IRQ.SUSPEND` bit indicates whether the USB controller has detected suspend signalling on the bus. This bit is valid only in peripheral mode.	
		0	No Interrupt
		1	Interrupt Pending

Link Information Register

The `USB_LINKINFO` register specifies the PHY-related delays.



7 6 5 4 3 2 1 0
0 1 0 1 1 1 0 0
WTCON (R/W)
Wait for Connect/Disconnect
WTID (R/W)
Wait from ID Pull-up

Figure 27-93: USB_LINKINFO Register Diagram

Table 27-69: USB_LINKINFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/W)	WTCON	Wait for Connect/Disconnect. The `USB_LINKINFO.WTCON` bits set the wait time to be applied to allow the users to connect or disconnect filter.
3:0 (R/W)	WTID	Wait from ID Pull-up. The `USB_LINKINFO.WTID` bits set the delay to be applied from IDPULLUP being asserted to IDDIG being considered valid.

LPM Attribute Register

The USB_LPM_ATTR register defines the link power management (LPM) attributes for LPM transactions and sleep/wake operation. In peripheral mode, the USB_LPM_ATTR register contains values received in the most recent, accepted (ACK'd) LPM transaction. In host mode, the USB_LPM_ATTR register contains values (loaded by software) that set up the next LPM transaction. The USB controller inserts the LPM values within the next LPM transaction.

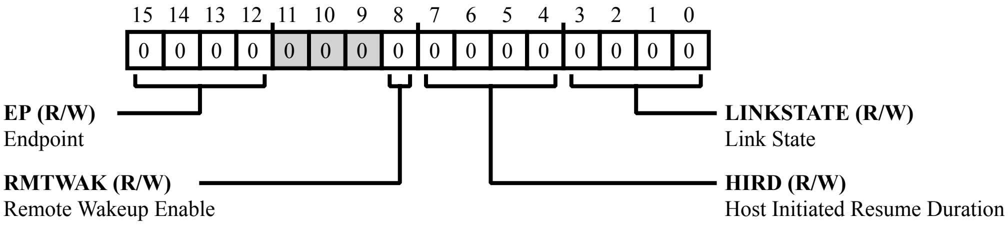


Figure 27-94: USB_LPM_ATTR Register Diagram

Table 27-70: USB_LPM_ATTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:12 (R/W)	EP	Endpoint. The USB_LPM_ATTR.EP bits select the endpoint in the token packet of the LPM transaction.	
8 (R/W)	RMTWAK	Remote Wakeup Enable. The USB_LPM_ATTR.RMTWAK bit enables remote wakeup. This bit is applied on a temporary basis only and is only applied to the current suspend state. After the current suspend cycle, the remote wakeup capability that was negotiated during enumeration applies.	
		0	Disable Remote Wakeup
		1	Enable Remote Wakeup
7:4 (R/W)	HIRD	Host Initiated Resume Duration. The USB_LPM_ATTR.HIRD bits select the host-initiated resume duration. This value is the minimum time that the host drives resume on the bus. The value in this register corresponds to an actual resume time of: Resume Time = 50us + HIRD*75us. This equation produces results in a range of 50us to 1200us.	
3:0 (R/W)	LINKSTATE	Link State. The USB_LPM_ATTR.LINKSTATE bits is value is provided by the host to the peripheral to indicate what state the peripheral must transition to after the receipt and acceptance of a LPM transaction. (Enumerations not shown are reserved.)	
		1	Sleep State (L1)

LPM Control Register

The `USB_LPM_CTL` register controls link power management (LPM) operations, including LPM enable, NAK, resume, and mode transition.

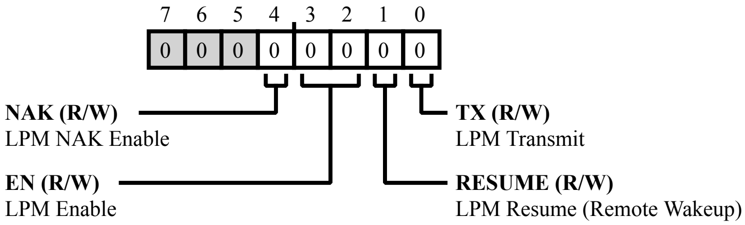

Figure 27-95: USB_LPM_CTL Register Diagram

Table 27-71: USB_LPM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	NAK	LPM NAK Enable. The `USB_LPM_CTL.NAK` bit enables (in peripheral mode) a NAK-all-non-LPM transactions mode for all end points, forcing a NAK response to all transactions other than an LPM transaction. This bit only takes effect after the controller has been LPM suspended. In this case, the USB controller continues to NAK, until this bit has been cleared by software.	
		0	Disable LPM NAK
		1	Enable LPM NAK
3:2 (R/W)	EN	LPM Enable. The `USB_LPM_CTL.EN` bits enable (In peripheral mode) LPM operations. The LPM operation may be enabled at different levels, which determine the response of the USB controller to LPM transactions.	
		0	Disable LPM. LPM and extended transactions are not supported. The USB controller does not respond to LPM transactions, and these transaction timeout.
		1	Disable LPM. LPM and extended transactions are not supported. The USB controller does not respond to LPM transactions, and these transaction timeout.
		2	Enable Extended Transactions. LPM is not supported, but extended transactions are supported. The USB controller responds to an LPM transaction with a STALL.
		3	Enable LPM and Extended Transactions. Both LPM and extended transactions are supported. The USB controller responds with a NYET or an ACK as determined by the value of LPMXMT and other conditions.

Table 27-71: USB_LPM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	RESUME	LPM Resume (Remote Wakeup). The `USB_LPM_CTL.RESUME` bit initiates resume (remote wakeup). The operation of this bit differs from the `USB_POWER.RESUME` bit in that the LPM resume signal timing is controlled by hardware. When set, the USB controller asserts resume signaling for 50us in host mode or asserts resume signaling for the time specified by the `USB_LPM_ATTR.HIRD` field in device mode. The `USB_LPM_CTL.RESUME` bit is self-clearing.
		0 No Action
		1 LPM Resume
0 (R/W)	TX	LPM Transmit. The `USB_LPM_CTL.TX` bit puts the USB controller in LPM transmit mode. But, this mode operates differently in host mode versus peripheral mode. In peripheral mode, this bit is set by software to instruct the controller to transition to the L1 state upon receipt of the next LPM transaction. This bit is only effective if LPM enable (`USB_LPM_CTL.EN`) is set to 0x3. The LPM transmit enable bit can be set in the same cycle as LPM enable. If the `USB_LPM_CTL.TX` and `USB_LPM_CTL.EN` bits are enabled, the USB controller can respond in the following ways: • If no data is pending (all transmit FIFOs are empty), the USB controller responds with an ACK, clears the `USB_LPM_CTL.TX` bit, and generates a software interrupt. • If data is pending (data resides in at least one transmit FIFO), the USB controller responds with a NYET, does not clear the `USB_LPM_CTL.TX` bit, and generates a software interrupt. In host mode, this bit is set by software to transmit an LPM transaction. This bit is self-clearing. The USB controller clears this bit immediately on receipt of any token or after three timeouts have occurred.
		0 Disable LPM Tx
		1 Enable LPM Tx

LPM Function Address Register

The `USB_LPM_FADDR` register selects the link power management (LPM) function address.

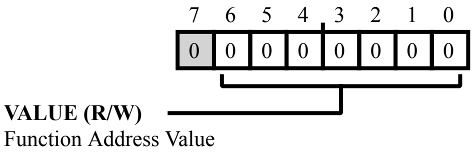

Figure 27-96: USB_LPM_FADDR Register Diagram

Table 27-72: USB_LPM_FADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Function Address Value. The `USB_LPM_FADDR.VALUE` bits hold the LPM function address value that the USB controller places in the LPM payload.

LPM Interrupt Enable Register

The USB_LPM_IEN register enables the link power management (LPM) related interrupts. When an interrupt is enabled in this register and the corresponding interrupt is pending in USB_LPM_IRQ, the USB controller generates the interrupt. When an interrupt is disabled in this register, the corresponding interrupt may be pending in USB_LPM_IRQ, but the USB controller does not generate an interrupt.

Figure 27-98: USB_LPM_IRQ Register Diagram

Table 27-74: USB_LPM_IRQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RC/NW)	LPMERR	LPM Error Interrupt. The `USB_LPM_IRQ.LPMERR` bit indicates an LPM error interrupt condition. This interrupt has differing conditions for host mode versus peripheral mode. In peripheral mode, this bit is set if an LPM transaction is received that has a `USB_LPM_ATTR.LINKSTATE` field that is not supported. The USB controller responds to the transaction with a STALL. Note that the USB controller updates the `USB_LPM_ATTR` register, so software can observe the non-compliant LPM packet payload. In host mode, this bit is set if the response to a LPM transaction is received with a bit stuff or PID error. No suspend occurs and the state of the device is now unknown.	
		0	No Interrupt Pending
		1	Interrupt Pending
4 (RC/NW)	LPMRES	LPM Resume Interrupt. The `USB_LPM_IRQ.LPMRES` bit indicates that the USB controller has been resumed for any reason. This bit is mutually exclusive from the `USB_POWER.RESUME` bit.	
		0	No Interrupt Pending
		1	Interrupt Pending

Table 27-74: USB_LPM_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (RC/NW)	LPMNC	LPM NYET Control Interrupt. The `USB_LPM_IRQ.LPMNC` bit indicates an LPM NYET control interrupt condition. This interrupt has differing conditions for host mode versus peripheral mode. In peripheral mode, this bit is set when an LPM transaction is received, and the USB controller responds with a NYET due to data pending in the transmit FIFOs. This interrupt may only occur when the `USB_LPM_CTL.EN` field is set to 11, the `USB_LPM_CTL.TX` field is set to 1, and there is data pending in the transmit FIFOs. In host mode, this bit is set when an LPM transaction has been transmitted, but has failed to complete. The transaction failure is due to a timeout or bit errors in the response for three attempts. 0 No Interrupt Pending 1 Interrupt Pending
2 (RC/NW)	LPMACK	LPM ACK Interrupt. The `USB_LPM_IRQ.LPMACK` bit indicates an LPM ACK interrupt condition. This interrupt has differing conditions for host mode versus peripheral mode. In peripheral mode, this bit is set when an LPM transaction is received, and the USB controller responds with an ACK. This interrupt may only occur when the `USB_LPM_CTL.EN` field is set to 11, the `USB_LPM_CTL.TX` field is set to 1, and there is no data pending in the controller transmit FIFOs. In host mode, this bit is set when an LPM transaction is transmitted, and the device responds with an ACK. 0 No Interrupt Pending 1 Interrupt Pending
1 (RC/NW)	LPMNY	LPM NYET Interrupt. The `USB_LPM_IRQ.LPMNY` bit indicates an LPM NYET interrupt condition, but this interrupt has differing conditions for host mode versus peripheral mode. In peripheral mode, this bit is set when an LPM transaction is received, and the USB controller responds with a NYET. This interrupt may only occur when the `USB_LPM_CTL.EN` field is set to 11, and the `USB_LPM_CTL.TX` field is set to 0. In host mode, this bit is set when an LPM transaction is transmitted and the device responds with a NYET. 0 No Interrupt Pending 1 Interrupt Pending

Low-Speed EOF 1 Register

The `USB_LS_EOF1` register defines the minimum time gap allowed between the start of the last transaction and the end of frame for low-speed transactions.

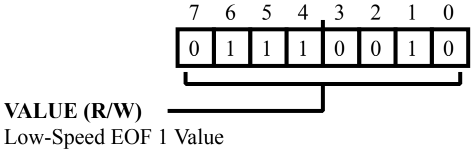

Figure 27-99: USB_LS_EOF1 Register Diagram

Table 27-75: USB_LS_EOF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Low-Speed EOF 1 Value. The `USB_LS_EOF1.VALUE` bits set the time before end of frame to stop beginning new transactions (in units of 1.067us) for low-speed transactions. The default setting corresponds to 121.6us.

MPn Receive Function Address Register

The `USB_MP[n]_RXFUNCADDR` register specifies the receive endpoint's target address in host mode. This register is not used in device mode. Note that the `USB_MP[n]_RXFUNCADDR` register does not exist for EP0.

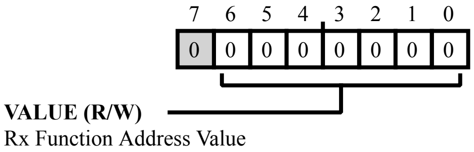

Figure 27-100: USB_MP[n]_RXFUNCADDR Register Diagram

Table 27-76: USB_MP[n]_RXFUNCADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Rx Function Address Value. The `USB_MP[n]_RXFUNCADDR.VALUE` bits hold the address of the target device for this endpoint.

MPn Receive Hub Address Register

The `USB_MP[n]_RXHUBADDR` register specifies the hub address of the endpoint in host mode. This register is not used in device mode. Note that this register only needs to be programmed when a full-speed or low-speed device is connected to a high-speed hub, which carries out the necessary transaction translation. Note that the `USB_MP[n]_RXHUBADDR` register does not exist for EP0.

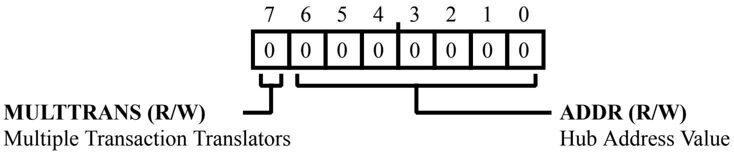

Figure 27-101: USB_MP[n]_RXHUBADDR Register Diagram

Table 27-77: USB_MP[n]_RXHUBADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	MULTTRANS	Multiple Transaction Translators. The `USB_MP[n]_RXHUBADDR.MULTTRANS` bit should be set if the hub has multiple transaction translators.	
		0	Single Transaction Translator
		1	Multiple Transaction Translators
6:0 (R/W)	ADDR	Hub Address Value. The `USB_MP[n]_RXHUBADDR.ADDR` bits hold the address of the hub to which this device is connected.	

MPn Receive Hub Port Register

The `USB_MP[n]_RXHUBPORT` register specifies the hub port for full-speed and low-speed endpoints in host mode. This register is not used in device mode. The `USB_MP[n]_RXHUBPORT` register lets the USB controller support SPLIT transactions. Note that the `USB_MP[n]_RXHUBPORT` register does not exist for EP0.

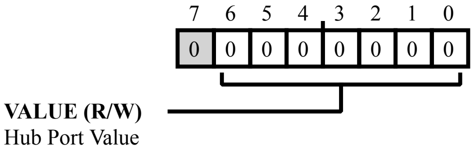

Figure 27-102: USB_MP[n]_RXHUBPORT Register Diagram

Table 27-78: USB_MP[n]_RXHUBPORT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Hub Port Value. The `USB_MP[n]_RXHUBPORT.VALUE` bits hold the hub port value of the target device for this endpoint.

MPn Transmit Function Address Register

The `USB_MP[n]_TXFUNCADDR` register specifies the transmit endpoint's target address in host mode. This register is not used in device mode. Note that the `USB_MP[n]_TXFUNCADDR` register must be setup for EP0. (The `USB_MP[n]_RXFUNCADDR` register does not exist for EP0.)

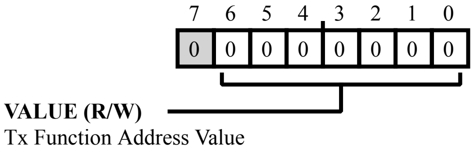

Figure 27-103: USB_MP[n]_TXFUNCADDR Register Diagram

Table 27-79: USB_MP[n]_TXFUNCADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Tx Function Address Value. The `USB_MP[n]_TXFUNCADDR.VALUE` bits hold the address of the target device for this endpoint.

MPn Transmit Hub Address Register

The USB_MP[n]_TXHUBADDR register specifies the hub address of the endpoint in host mode. This register is not used in device mode. Note that this register only needs to be programmed when a full-speed or low-speed device is connected to a high-speed hub, which carries out the necessary transaction translation. Also, note that EP0 only uses the USB_MP[n]_TXHUBADDR register. (The USB_MP[n]_RXHUBADDR register does not exist for EP0.)

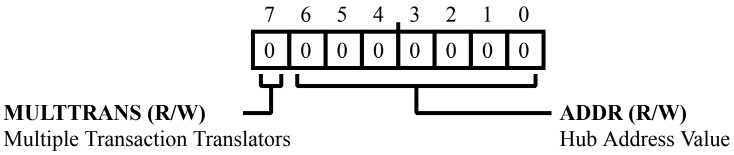

Figure 27-104: USB_MP[n]_TXHUBADDR Register Diagram

Table 27-80: USB_MP[n]_TXHUBADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	MULTTRANS	Multiple Transaction Translators. The USB_MP[n]_TXHUBADDR.MULTTRANS bit should be set if the hub has multiple transaction translators.	
		0	Single Transaction Translator
		1	Multiple Transaction Translators
6:0 (R/W)	ADDR	Hub Address Value. The USB_MP[n]_TXHUBADDR.ADDR bits hold the address of the hub to which this device is connected.	

MPn Transmit Hub Port Register

The `USB_MP[n]_TXHUBPORT` register specifies the hub port for full-speed and low-speed endpoints in host mode. This register is not used in device mode. The `USB_MP[n]_TXHUBPORT` register lets the USB controller support SPLIT transactions. EP0 only uses the `USB_MP[n]_TXHUBPORT` register. (The `USB_MP[n]_RXHUBPORT` register does not exist for EP0.)

Table 27-81: USB_MP[n]_TXHUBPORT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	VALUE	Hub Port Value. The `USB_MP[n]_TXHUBPORT.VALUE` bits hold the hub port value of the target device for this endpoint.

PHY Control Register

The USB_PHY_CTL register provides access to PHY control features.

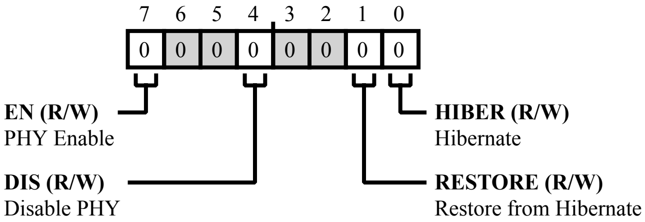

Figure 27-106: USB_PHY_CTL Register Diagram

Table 27-82: USB_PHY_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	EN	PHY Enable. The USB_PHY_CTL.EN bit enables the USB controller PHY. This bit enables the schmitt-trigger inputs on D+ and D- to detect session request protocol. The bit also enables the bias circuits and VBUS comparators to detect when a host is connected. This bit should be set for all USB controller operations.	
4 (R/W)	DIS	Disable PHY. The USB_PHY_CTL.DIS bit disables the PHY, so it draws minimal power.	
		0	Enable USB PHY and 5V protection on USB signals.
		1	Disable USB PHY and 5V protection on USB signals. Caution: When 5V protection is disabled, the absolute max voltage on USB signals is reduced. See the data sheet for details.
1 (R/W)	RESTORE	Restore from Hibernate. The USB_PHY_CTL.RESTORE bit causes the PHY to come out of hibernate and release its latches.	
0 (R/W)	HIBER	Hibernate. The USB_PHY_CTL.HIBER bit causes the PHY to prepare for hibernate. Latches hold the pullup/pulldown state when the core power is removed.	

PLL and Oscillator Control Register

The `USB_PLL_OSC` register provides access to PLL and oscillator-related control features.

Figure 27-107: USB_PLL_OSC Register Diagram

Table 27-83: USB_PLL_OSC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	PLLSTABLE	PLL Stable. The `USB_PLL_OSC.PLLSTABLE` status bit indicates that the oscillator and PLL clock are stable.
7 (R/W)	PLLMSEL	PLL Multiplier Select. The `USB_PLL_OSC.PLLMSEL` bit directs the PLL to use the PLL multiplier value stored in the `USB_PLL_OSC.PLLM` bits.
6:1 (R/W)	PLLM	PLL Multiplier Value. The `USB_PLL_OSC.PLLM` bit field contains the PLL multiplier. This field should be set such that CLKIN * `USB_PLL_OSC.PLLM` value = 480MHz.
0 (R/W)	DIVCLKIN	Divide CLKIN. The `USB_PLL_OSC.DIVCLKIN` bit enables a divide CLKIN by 2 function for the PLL.

Power and Device Control Register

The `USB_POWER` register controls suspend and resume signaling and some operational aspects of the USB controller.

Figure 27-108: USB_POWER Register Diagram

Table 27-84: USB_POWER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	ISOUPDT	ISO Update Enable. The `USB_POWER.ISOUPDT` bit directs the USB controller to waits for an SOF token from the time the `USB_EP[n]_TXCSR_P.TXPKTRDY` bit is set before sending the packet. If an IN token is received before an SOF token, the USB controller send a zero length data packet. This `USB_POWER.ISOUPDT` bit only affects endpoints performing isochronous transfers. This bit only is valid in peripheral mode (`USB_DEV_CTL.HOSTMODE` = 0).	
		0	Disable ISO Update
		1	Enable ISO Update
6 (R/W)	SOFTCONN	Soft Connect/Disconnect Enable. In peripheral mode, the D+/- lines default to disconnected. Setting this bit enables the D+/- termination resistors. This bit is automatically set when the `USB_DEV_CTL.SESSION` bit is written with 1. The `USB_POWER.SOFTCONN` bit enables USB controller soft connect/disconnect, enabling the termination resistors for `USB_DP` (Data +) and `USB_DM` (Data -) pins. When disabled, these pins are three-stated. Note that `USB_POWER.SOFTCONN` only is valid in peripheral mode (`USB_DEV_CTL.HOSTMODE` = 0).	
		0	Disable Soft Connect/Disconnect
		1	Enable Soft Connect/Disconnect

Table 27-84: USB_POWER Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	HSEN	High-Speed Mode Enable. The `USB_POWER.HSEN` bit enables USB controller negotiation for high speed (on devices supporting high-speed mode) when the device is reset by the hub/host. If disabled, the USB controller only operates in full-speed mode. When operating in full-speed mode, this bit should be cleared.	
		0	Disable Negotiation for HS Mode
		1	Enable Negotiation for HS Mode
4 (R/NW)	HSMODE	High-Speed Mode. The `USB_POWER.HSMODE` bit indicates whether or not the USB controller successfully negotiated high-speed mode during a USB controller reset. In peripheral mode (`USB_DEV_CTL.HOSTMODE` = 0), this bit has valid data when the USB controller completes reset. In host mode (`USB_DEV_CTL.HOSTMODE` = 1), this bit has valid data when the `USB_IRQ.RSTBABBLE` bit is cleared, remaining valid for the duration of the session.	
		0	Full-Speed Mode (HS fail during reset)
		1	High-Speed Mode (HS success during reset)
3 (R/W)	RESET	Reset USB. The `USB_POWER.RESET` bit indicates (in both host and peripheral modes) that the USB controller has detected that reset signaling is present on the bus. In peripheral mode (`USB_DEV_CTL.HOSTMODE` = 0), this bit is read only, but in host mode (`USB_DEV_CTL.HOSTMODE` = 1), this bit is read/write, permitting the processor core to set the bit and initiate a USB controller reset.	
		0	No Reset
		1	Reset USB
2 (R/W)	RESUME	Resume Mode. The `USB_POWER.RESUME` bit directs the USB controller to generate resume signaling when the function is in suspend mode (`USB_POWER.SUSPEND` =1). The processor core should clear this bit after 10 ms (a maximum of 15 ms) to end resume signaling. When the USB controller is in host mode (`USB_DEV_CTL.HOSTMODE` = 1), the USB controller automatically sets the `USB_POWER.RESUME` bit when resume signaling from the target is detected while the USB controller is suspended.	
		0	Disable Resume Signaling
		1	Enable Resume Signaling

Table 27-84: USB_POWER Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	SUSPEND	Suspend Mode. When the USB controller is in host mode (`USB_DEV_CTL.HOSTMODE` = 1), the `USB_POWER.SUSPEND` bit enables suspend mode. When the USB controller is in peripheral mode (`USB_DEV_CTL.HOSTMODE` = 0), the USB controller sets the `USB_POWER.SUSPEND` bit on entry to suspend mode and clears the bit when the processor reads the `USB_IRQ` register. Note that the USB controller automatically clears this bit if the `USB_POWER.RESUME` bit is set.	
		0	Disable Suspend Mode (Host)
		1	Enable Suspend Mode (Host)
0 (R/W)	SUSEN	SUSPENDM Output Enable. The `USB_POWER.SUSEN` bit enables the SUSPENDM output (internal USB controller signal). When enabled, the SUSPENDM output signal is used by the USB controller PHY to power-down its drivers when the USB controller is not active.	
		0	Disable SUSPENDM Output
		1	Enable SUSPENDM Output

RAM Information Register

The `USB_RAMINFO` register provides information about the width of the USB controller RAM.

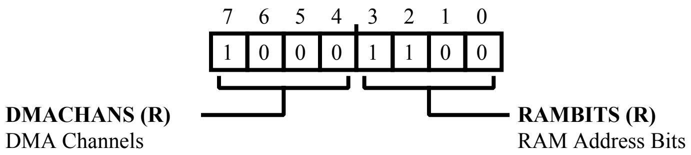

Figure 27-109: USB_RAMINFO Register Diagram

Table 27-85: USB_RAMINFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	DMACHANS	DMA Channels. The `USB_RAMINFO.DMACHANS` bits indicate the number of DMA channels.
3:0 (R/NW)	RAMBITS	RAM Address Bits. The `USB_RAMINFO.RAMBITS` bits indicate the number of RAM address bits. The USB controller FIFO RAM is 32-bits wide. The number of bytes in the FIFO RAM may be calculated from the formula: $RAM\_bytes = 2^{(RAM\_Bits+2)}$

EPn Request Packet Count Register

The `USB_RQPKTCNT[n]` register specifies (in host mode) the number of packets to request in a block transfer of one or more bulk packets of size `USB_EP[n]_RXMAXP` from a receive endpoint. This register only applies for receive endpoints 1 through 11 in host mode.

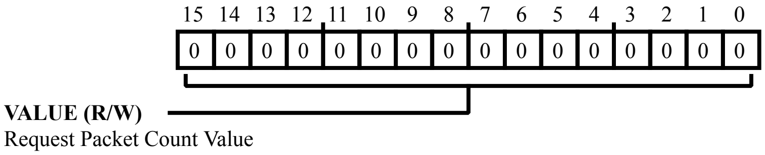

Figure 27-110: USB_RQPKTCNT[n] Register Diagram

Table 27-86: USB_RQPKTCNT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Request Packet Count Value. The `USB_RQPKTCNT[n].VALUE` bits specify the number of bulk packets to request in a block transfer from a receive endpoint. This field is used with the auto request feature (`USB_EP[n]_RXCSR_H.AUTOREQ`).

Receive FIFO Address Register

The `USB_RXFIFOADDR` sets the start address for the selected Rx FIFO for endpoints 1-11. There is one receive FIFO address register for each endpoint, except endpoint 0. The `USB_RXFIFOADDR` register is indexed and selected by the `USB_INDEX` register. Note that the endpoint 0 FIFO has a fixed 64-byte size and is always located at address 0.

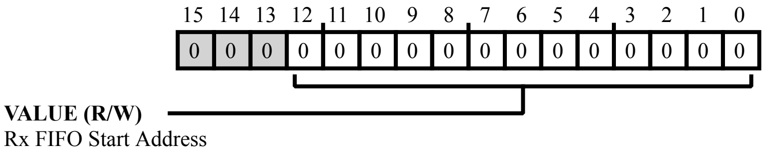

Figure 27-111: USB_RXFIFOADDR Register Diagram

Table 27-87: USB_RXFIFOADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VALUE	Rx FIFO Start Address. The `USB_RXFIFOADDR.VALUE` bits hold the start address of the selected endpoint FIFO (selected with the `USB_INDEX` register) in units of 8 bytes, according to the formula: FIFO address = `USB_RXFIFOADDR.VALUE` * 8

Receive FIFO Size Register

The USB_RXFIFOSZ register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single frame. When setting this value, consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. This register provides indexed-access to the FIFO (packet) size selection for each Rx endpoint (except endpoint 0).

Note that a value greater than the maximum allowed of 1023 for full-speed USB controller operation produces unpredictable results.

Also, note that the value written to this register should match the programmed maximum individual packet size (MaxPktSize) of the standard endpoint descriptor for the associated endpoint. (See the Universal Serial Bus Specification Revision 2.0, Chapter 9). A mismatch could cause unexpected results. The total amount of data represented by the value written to this register must not exceed the Rx FIFO size, and should not exceed half the FIFO size if double-buffering is required.

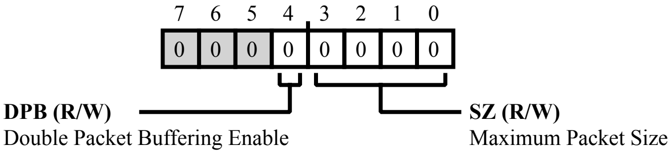

Figure 27-112: USB_RXFIFOSZ Register Diagram

Table 27-88: USB_RXFIFOSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DPB	Double Packet Buffering Enable. The USB_RXFIFOSZ.DPB bit enables double packet buffering, doubling the FIFO (packet) size selected with the USB_RXFIFOSZ.SZ field.	
		0	Single Packet Buffering
		1	Double Packet Buffering
3:0 (R/W)	SZ	Maximum Packet Size. The USB_RXFIFOSZ.SZ bits select the maximum FIFO (packet) size according to the formula: FIFOSZ= $2^{(SZ+3)}$ If the USB_RXFIFOSZ.DPB is cleared, the FIFO size is FIFOSZ from this formula. If the USB_RXFIFOSZ.DPB is set, the FIFO is twice this size. For each enumeration value, the enumerations descriptions show the packet size (PktSz=), the FIFO size if DPB=0 (DPB0=), and the FIFO size if DPB=1 (DPB1=); these values are in bytes.	
		0	PktSz=8, DPB0=8, DPB1=16
		1	PktSz=16, DPB0=16, DPB1=32

Table 27-88: USB_RXFIFOSZ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	PktSz=32, DPB0=32, DPB1=64
		3	PktSz=64, DPB0=64, DPB1=128
		4	PktSz=128, DPB0=128, DPB1=256
		5	PktSz=256, DPB0=256, DPB1=512
		6	PktSz=512, DPB0=512, DPB1=1024
		7	PktSz=1024, DPB0=1024, DPB1=2048
		8	PktSz=2048, DPB0=2048, DPB1=4096
		9	PktSz=4096, DPB0=4096, DPB1=8192

Software Reset Register

The `USB_SOFT_RST` register provides reset controls for the USB controller CLK domain and XCLK domain. The USB controller PHY operates in the controller's XCLK domain, and the USB controller interface to the processor core operates in the controller's CLK domain. Note that for correct operation, both of the reset control bits (`USB_SOFT_RST.RST` and `USB_SOFT_RST.RSTX`) should always be asserted simultaneously.

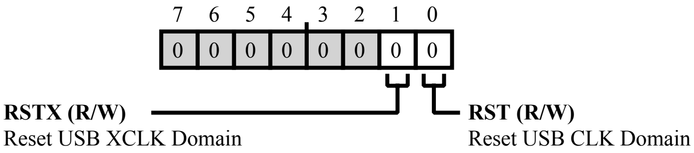

Figure 27-113: USB_SOFT_RST Register Diagram

Table 27-89: USB_SOFT_RST Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	RSTX	Reset USB XCLK Domain. The `USB_SOFT_RST.RSTX` bit resets logic in the USB XCLK domain. This bit is self-clearing. Note that this bit should always be asserted simultaneously with the `USB_SOFT_RST.RST` bit.	
		0	No Reset
		1	Reset USB XCLK Domain
0 (R/W)	RST	Reset USB CLK Domain. The `USB_SOFT_RST.RST` bit resets logic in the USB CLK domain. This bit is self-clearing. Note that this bit should always be asserted simultaneously with the `USB_SOFT_RST.RSTX` bit.	
		0	No Reset
		1	Reset USB CLK Domain

Testmode Register

The `USB_TESTMODE` register places the USB controller into the test mode state and can also put the USB controller into one of the test modes for high-speed operation. For more information about these modes, see the USB 2.0 specification.

Note that the `USB_TESTMODE` register is not used in normal operation. Only one of the test mode (bits 0-6) selection bits may be set at a time.

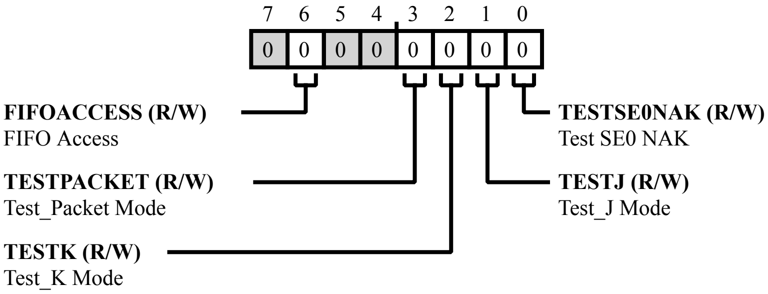

Figure 27-114: USB_TESTMODE Register Diagram

Table 27-90: USB_TESTMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	FIFOACCESS	FIFO Access. The `USB_TESTMODE` bit directs the USB controller to transfer the packet in the endpoint 0 Tx FIFO to the endpoint 0 Rx FIFO. The bit is cleared automatically.
3 (R/W)	TESTPACKET	Test_Packet Mode. The `USB_TESTMODE.TESTPACKET` bit selects Test_Packet test mode, which applies only when the USB controller is in high-speed mode. In this mode, the USB controller repetitively transmits on the bus a 53-byte test packet, whose form is defined in the USB 2.0 Specification, Section 7.1.20. Note that the test packet has a fixed format and must be loaded into the endpoint 0 FIFO before this test mode is entered.
2 (R/W)	TESTK	Test_K Mode. The `USB_TESTMODE.TESTK` bit selects Test_K test mode. In this mode, the USB controller transmits a continuous K on the bus.
1 (R/W)	TESTJ	Test_J Mode. The `USB_TESTMODE.TESTJ` bit selects Test_J test mode. In this mode, the USB controller transmits a continuous J on the bus.
0 (R/W)	TESTSE0NAK	Test SE0 NAK. The `USB_TESTMODE.TESTSE0NAK` bit selects Test_SE0_NAK test mode, which applies only when the USB controller is in high-speed mode. In this mode, the USB controller remains in high-speed mode, but responds to any valid IN token with a NAK.

Transmit FIFO Address Register

The USB_TXFIFOADDR register sets the start address for the selected Tx FIFO for endpoints 1-11. There is one transmit FIFO address register for each endpoint, except endpoint 0. The USB_TXFIFOADDR register is indexed and selected by the USB_INDEX register. Note that the endpoint 0 FIFO has a fixed 64-byte size and is always located at address 0.

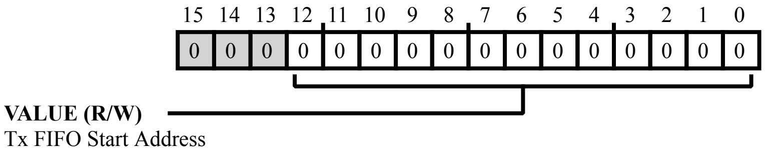

Figure 27-115: USB_TXFIFOADDR Register Diagram

Table 27-91: USB_TXFIFOADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VALUE	Tx FIFO Start Address. The USB_TXFIFOADDR.VALUE bits hold the start address of the selected endpoint FIFO (selected with the USB_INDEX register) in units of 8 bytes, according to the formula: FIFO address = USB_TXFIFOADDR.VALUE * 8

Transmit FIFO Size Register

The `USB_TXFIFOSZ` register defines the maximum amount of data that can be transferred through the selected transmit endpoint in a single frame. When setting this value, consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. This register provides indexed access to the FIFO (packet) size selection for each Tx endpoint (except endpoint 0).

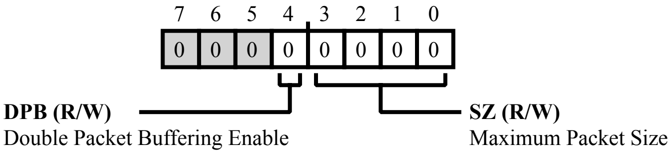

Figure 27-116: USB_TXFIFOSZ Register Diagram

Table 27-92: USB_TXFIFOSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DPB	Double Packet Buffering Enable. The `USB_TXFIFOSZ.DPB` bit enables double packet buffering, doubling the FIFO (packet) size selected with the `USB_TXFIFOSZ.SZ` field.	
		0	Single Packet Buffering
		1	Double Packet Buffering
3:0 (R/W)	SZ	Maximum Packet Size. The `USB_TXFIFOSZ.SZ` bits select the maximum FIFO (packet) size according to the formula: FIFOSZ= $2^{(SZ+3)}$ If the `USB_TXFIFOSZ.DPB` is cleared, the FIFO size is FIFOSZ from this formula. If the `USB_TXFIFOSZ.DPB` is set, the FIFO is twice this size. For each enumeration value, the enumerations descriptions show the packet size (PktSz=), the FIFO size if DPB=0 (DPB0=), and the FIFO size if DPB=1 (DPB1=); these values are in bytes.	
		0	PktSz=8, DPB0=8, DPB1=16
		1	PktSz=16, DPB0=16, DPB1=32
		2	PktSz=32, DPB0=32, DPB1=64
		3	PktSz=64, DPB0=64, DPB1=128
		4	PktSz=128, DPB0=128, DPB1=256
		5	PktSz=256, DPB0=256, DPB1=512
		6	PktSz=512, DPB0=512, DPB1=1024
		7	PktSz=1024, DPB0=1024, DPB1=2048

Table 27-92: USB_TXFIFOSZ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		8	PktSz=2048, DPB0=2048, DPB1=4096
		9	PktSz=4096, DPB0=4096, DPB1=8192

VBUS Control Register

Table 27-93: USB_VBUS_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	DRV	VBUS Drive. The `USB_VBUS_CTL.DRV` bit indicates the state of the UTMI+ DrvVBUS signal from the USB controller.
3 (R/W1C)	DRVINT	VBUS Drive Interrupt. The `USB_VBUS_CTL.DRVINT` bit indicates the state of the DrvVBUSInt interrupt.
2 (R/W)	DRVIEN	VBUS Drive Interrupt Enable. The `USB_VBUS_CTL.DRVIEN` bit enables the DrvVBUS interrupt.
1 (R/W)	DRVOD	VBUS Drive Open Drain. The `USB_VBUS_CTL.DRVOD` selects whether the DrvVBUS output is open drain.
0 (R/W)	INVDRV	VBUS Invert Drive. The `USB_VBUS_CTL.INVDRV` bit selects whether the DrvVBUS output is inverted.

VBUS Pulse Length Register

The `USB_VPLEN` register defines the duration of the VBUS pulsing charge for SRP initiation.

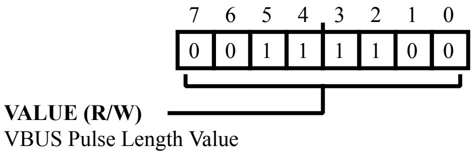

Figure 27-118: USB_VPLEN Register Diagram

Table 27-94: USB_VPLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	VBUS Pulse Length Value. The `USB_VPLEN.VALUE` bits sets the duration of the VBUS pulsing charge in units of 546.1us. The default setting corresponds to 32.77ms. Note that VBUS pulsing was removed in the OTG specification v2.0, section 5.1.4.

28 Media Local Bus (MLB)

Media Local Bus (MediaLB®) is an on-PCB or inter-chip communication bus, which allows an application to access the MOST network data. Media Local Bus supports all the MOST network data transport methods including synchronous stream data, asynchronous packet data, control message data and isochronous data. The MLB topology supports communication among the MLB controller and MLB devices, where the MLB controller is the interface between the MLB devices and the MOST network.

The MLB module serves as an interface between the MediaLB and the processor, implementing the requirements of the physical layer and the link layer outlined in the MediaLB specification. It supports up to 64 logical channels with up to 468 bytes of data per MediaLB frame. Transmit and receive data can be transferred between MediaLB and on-chip memory with DMA block transfers.

The MLB supports the MOST25, MOST50 and MOST150 standards and this document assumes familiarity with these standards. For more information, refer to the Media Local Bus specification version 4.2.

- Copyright 1998-2016 Microchip Technology Inc. All rights reserved. Portions of this chapter are included with permission from Microchip Technology, Inc.

Features

The objective of Media Local Bus (MediaLB) is to map all the MOST Network data types (transport methods) into a single low-cost, scalable, and standardized hardware interface between a MediaLB controller and at least one other MediaLB Device. The adoption of MediaLB simplifies the hardware interface, reduces the pin count, and facilitates the design of modular reusable hardware. From a software development perspective, the use of MediaLB relieves the system developer from the complexity of the MOST network, which simplifies software development and enables the design of reusable software for different applications. This simplified, standardized interface shortens time to market and makes software maintenance effortless.

- Compliant to Media Local Bus specification version 4.2
- Support MOST25, MOST50, MOST150 standards
- Support 3-pin and 6-pin modes
  - 6-pin mode supports a data rate of 2048 × FS
  - 3-pin mode support various data rates of 256 × FS, 512 × FS, 1024 × FS

- Support 64 logic channels
- Dedicated PLL for clock recovery and phase alignment
- Dedicated pins for 6-pin mode (LVDS)
- Shared pins for 3-pin mode
- Dedicated internal RAM for data buffering and channel table
- Recovered clock (after division) available out on a shared pin for DAI

NOTE: Only one MLB interface (3 pin or 6 pin mode) can be active at any given time.

MLB Definitions

The following are standard MLB and MOST terms that are used in this chapter.

AGU

Address Generation Units. To access a particular HBI channel the HC must first configure one of two HBI address generation units. AGUs can be configured by writing the HBI command registers, HCMD0 and HCMD1.

CAT

Channel Allocation Table. The Channel Allocation Table (CAT) is comprised of 16 CTR entries. Each 16-bit CAT entry represents a logical connection to or from a transmit/receive device (for example MediaLB or HBI channel).

CDT

Channel Descriptor Table.

FCE

Flow Control Enable bit. The FCE bit is used by MediaLB isochronous Rx channels only.

HBI

Host Bus Interface. The HBI block provides 16-bit parallel slave access to all MOST channels and data types for the external Host Controller (HC). The HBI supports up to 64 independent channels.

HC

Host Controller (external).

HCMDx

HBI Command registers.

HSTSx

HBI status registers.

MFE

Multi-Frame per sub-buffer enable bit. The MFE bit is used by MediaLB synchronous channels only.

PML

Packet Message Length.

Clocking

The MLB controller provides an external clock pin—the media local bus clock. The MLB controller generates the clock. It is synchronized to the MOST network and provides the timing for the entire MLB interface at FS = 48 kHz.

Functional Description

The ***Media LB Block Diagram*** figure shows the MLB high-level architecture. The MLB core serves as an interface between the MediaLB and the processor, implementing the requirements of the physical layer and the link layer outlined in the MediaLB specification. The MLB core has the following responsibilities.

- Transmit commands and data when functioning as the transmitting device associated with a *Channel Address*
- Receive data and transmit Rx Status responses when functioning as the receiving device associated *Channel Address*
- MLB lock detection
- System channel command handling

The MediaLB device can function as either a MediaLB 3-pin interface (single-ended) or MediaLB 6-pin interface (differential) but only one interface can be active at a time. The MediaLB interfaces are capable of exchanging data at speeds up to 1024 × Fs in 3-pin mode or 2048 × Fs in 6-pin mode.

A set of physical channels for exchanging data over the MediaLB bus is supported. These physical channels (4 bytes in length, or a quadlet) can be grouped into logical channels, where each logical channel is referenced using a channel address and represents a uni-directional datapath between a specific MediaLB device transmitting the data and the MediaLB device(s) receiving the data. The MediaLB 6-pin interface provides support for up to 468 bytes of data per frame. The logical channels, configured by system software, can be any combination of channel types (synchronous, asynchronous, isochronous, or control) and direction (transmit or receive).

ADSP-SC58x MLB Register List

The MediaLB Device Interface Macro 2 (MediaLB DIM 2), also referred to as OS62420, implements the required functionality of a Media Local Bus (MediaLB) device. This logic serves as an interface between the inter-chip MediaLB bus and a customer IC, implementing the physical- and link-layer requirements outlined in the MediaLB Specification.

Media LB Protocol

The MediaLB topology supports communication among all MediaLB devices, including the MediaLB controller. The bus interface consists of a uni-directional line for clock (MLBC), a bidirectional line for signal information (MLBS), and a bidirectional line for data transfer (MLBD). The MediaLB topology supports one controller connected to one or more devices, where the controller is the interface between the MediaLB devices and the MOST network.

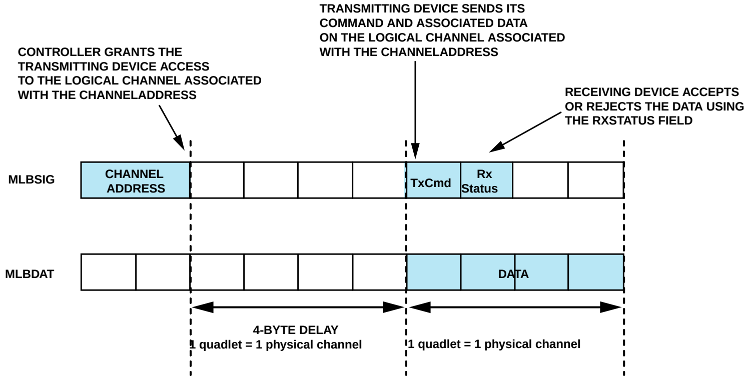
The MediaLB controller includes MediaLB device functionality, and also generates the MediaLB clock (MLBC) that is synchronized to the MOST Network. This generated clock provides the timing for the entire MediaLB interface. The MLBS line is a multiplexed signal which carries channel addresses generated by the MediaLB controller, as well as command and RxStatus bytes from MediaLB devices. The MLBD line is driven by the transmitting MediaLB device and is received by all other MediaLB devices, including the MediaLB controller. The MLBD line carries the actual data (synchronous, asynchronous, control, or isochronous).

Once per MOST network frame, the MLB controller generates a unique frame sync pattern on the `MLB_SIG` line. The end of the frame sync pattern defines the byte boundary and the channel boundary for the `MLB_SIG` and `MLB_DAT` lines of all MLB devices.

The MLB controller manages the arbitration for all the channels on the MLB and grants bandwidth for all the MLB devices. An MLB *physical channel* is defined as four bytes wide, or a quadlet. Physical channels can be grouped into multiple quadlets (which do not have to be consecutive) to form an MLB *logical channel*, which is defined by a unique channel address.

As shown in ***MLB Data Structure***, the MLB controller initiates communication by sending out a channel address on the `MLB_SIG` line for each physical channel. The channel address indicates which MLB device is transmitting and which MLB devices are receiving in the following physical channel. Therefore, four bytes after the controller outputs the channel address on the `MLB_SIG` line, the transmitting device outputs a command byte command on the `MLB_SIG` line and outputs the respective data on the `MLB_DAT` line, concurrently. The MLB command byte contains the type of data currently being transmitted (for example synchronous, asynchronous or control).

The MLB device receiving the channel data outputs a status byte, RxStatus, on the `MLB_SIG` line immediately after the transmitting device outputs the command byte. The status response can indicate that the receiving device is busy and cannot receive the data at present, or the device is ready to receive the data. Since synchronous stream data is sent in a broadcast fashion, receiving devices cannot return a busy status and should not drive RxStatus onto the `MLB_SIG` line.



TRANSMITTING DEVICE SENDS ITS COMMAND AND ASSOCIATED DATA ON THE LOGICAL CHANNEL ASSOCIATED WITH THE CHANNELADDRESS
CONTROLLER GRANTS THE TRANSMITTING DEVICE ACCESS TO THE LOGICAL CHANNEL ASSOCIATED WITH THE CHANNELADDRESS
RECEIVING DEVICE ACCEPTS OR REJECTS THE DATA USING THE RXSTATUS FIELD

MediaLB 3-PIN INTERFACE

Figure 28-2: Media LB Block Diagram

MediaLB Interface

The Media Local Bus (MediaLB) block supports both a MediaLB 3-pin interface and MediaLB 6-pin interface; however, only one MediaLB interface can be active at any given time. Both MediaLB interfaces provide real-time access to all network data types - synchronous, asynchronous, control, and isochronous data.

- MediaLB 3-pin interface – Supports the MediaLB protocol for single-ended 3-pin mode, with a maximum data rate of 1024 FS (49.152 MHz at FS =48 kHz).
- MediaLB 6-pin interface – Supports the MediaLB protocol for high-speed differential 6-pin mode, with a maximum data

  maximum data rate of 2048 FS (98.304 MHz at FS =48 kHz).

MediaLB Channel Address to Logical Channel Mapping

The MediaLB channel addresses are mapped to the logical channels as shown in the ***MediaLB Channel Address to Logical Channel Mapping*** table.

Table 28-3: MediaLB Channel Address to Logical Channel Mapping

Channel Address	Logical Address
0x0002	1
0x0004	2
0x0006	3
...	...

Table 28-3: MediaLB Channel Address to Logical Channel Mapping (Continued)

Channel Address	Logical Address
0x007C	62
0x007E	63
0x01FE	0 (Logical channel 0 is the system channel and is reserved)

Routing Fabric

The Routing Fabric (RF) block manages the flow of data between the MediaLB port and the HBI port. It manages accessing the Channel Table RAM (CTR) and Data Buffer RAM (DBR), which are explained in the following subsections. The routing fabric uses channel descriptors (stored in the CTR) to manage access to dynamic buffers in the DBR.

Data Buffer RAM

The Data Buffer RAM (DBR) is an 8-bit x 16k entries deep, single-port synchronous SRAM and provides dynamic circular buffering between the transmit and receive devices. The size and location of each data buffer is defined by software in the Channel Descriptor Table (CDT), which is located in the Channel Table RAM (CTR), described in following sections.

Channel Table RAM

The Channel Table RAM (CTR) is a 128-bit x 144-entry table that allows system software to dynamically configure channel routing and allocate data buffers in the DBR. The CTR is logically divided into three tables:

- Channel Descriptor Tables
- AHB Descriptor Table (ADT)
- Channel Allocation Table

Address Mapping

The ***CTR Address Mapping*** table shows the address mapping for the CTR.

Table 28-4: CTR Address Mapping

Label	Address	Bits [127:96]	Bits [95:64]	Bits [63:32]	Bits [31:0]

</table>

[*1] A fixed relationship exists between ADT entries and HBI CAT entries. When using HBI channel 0 (CAT64), program ADT0. When using HBI channel 1 (CAT65), program ADT1, and so on.

Channel Allocation Table

The *Channel Allocation Table (CAT)* table is comprised of 16 CTR entries (addresses 0x80 0x8F) as shown in the *CTR Entry Map* table. Each 16-bit CAT entry represents a logical connection to or from a transmit or receive device. (for example, MediaLB channel). All entries are indexed according to a fixed physical address assigned to every RX/TX channel as shown in the *CAT Entry Formats* table. The value stored in a CAT entry includes a 6-bit connection label, which provides a pointer to the CDT. To complete a logical channel and form a routing connection, system software must assign the same connection label to both the RX and TX channels.

Table 28-5: CAT Entry Map

Peripheral	TX Channels	RX Channels	CAT Start Index	CAT End Index	Entries
MediaLB	0 to 64	64 TX Channels	0	63	64
HBI	0 to 64	64 TX Channels	64	127	64

The format of a full CAT entry is shown in the *CAT Entry Formats* table, with field descriptions described in the *CAT Field Definitions* table. All reserved bits of a CAT entry field should be written as zero.

Table 28-6: CAT Entry Formats

Channel Type	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Control	rsvd		MT	RNW	CE	CT[2:0] = 001			rsvd		CL[5:0]					
Synchronous	rsvd	MFE	MT	RNW	CE	CT[2:0] = 000			rsvd		CL[5:0]					

Table 28-7: CAT Field Definitions

Field	Description
CL[5:0]	Connection Label (offset into CDT)
CT[2:0]	Channel Type (others) 111 = Reserved 110 = Reserved 101 = Reserved 100 = Reserved 011 = Isochronous 010 = Asynchronous 001 = Control 000 = Synchronous
CE	Channel Enable. 0 = Disabled, 1 = Enabled
RNW	Read Not Write. 0 = Write, 1 = Read
MT	Mute Enable. 0 = Disabled When set for synchronous channels, the MT bit forces RX channels to write zeros into the channel data buffer, and TX channels to output zeros on the physical interface. When set for asynchronous and control channels, the MT bit causes DMA to halt at a packet boundary. Not valid for isochronous channels.
FCE	Flow Control Enable. 0 = Disabled, 1 = Enabled The FCE bit is used by MediaLB isochronous RX channels only.
MFE	Multi-Frame per sub-buffer enable. 0 = Disabled, 1 = Enabled The MFE bit is used by MediaLB synchronous channels only.
rsvd	Reserved. Software writes a 0 to all reserved bits when the entry is initialized. These bits are read-only after initialization.

Channel Set Up

Data direction is in reference to the DBR. The data direction of CAT entries corresponding to the same channel is reversed for the HBI CAT and the MediaLB CAT.

- For a Tx channel (from the HC to the MediaLB interface):
    - HBI CAT entry: RNW = 0 (write)

  - MediaLB CAT entry: RNW = 1 (read)
- Conversely, for an Rx channel (data from MediaLB to HC):
  - HBI CAT entry: RNW = 1 (read)
  - MediaLB CAT entry: RNW = 0 (write)

Figure 28-3: DBR Directional Relationship

Channel Descriptor Tables

The Channel Descriptor Table (CDT) is comprised of 64 CTR entries (addresses 0x00 - 0x3F), as shown in the Table 28-4 CTR Address Mapping table. Each 128-bit CDT entry (also referred to as a channel descriptor) is referenced by a connection label and contains information about a data buffer in the DBR (for example buffer size, address pointers). The format of each CDT entry is dependent on the channel type (synchronous, isochronous, asynchronous, or control).

NOTE: All reserved channel descriptor bits must be written to 0 by software when initialized.

Synchronous Channel Descriptors

The format and field definitions for a synchronous CDT entry are shown in the *Synchronous CDT Entry Format* and *Synchronous CDT Entry Field Definitions* tables.

Table 28-8: Synchronous CDT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 28-11: Isochronous CDT Entry Field Definitions

Field	Description	Details	Access
BA	Buffer Base Address	Can start at any byte in the 16k DBR.	RW
BD	Buffer Depth	BD = size of buffer in bytes 1. Buffer end address = BA + BD. Isochronous buffers must be large enough to hold at least 3 blocks (packets) of data. BD Must be an integer multiple of blocks.	RW
BF	Buffer Full	Software initializes to 0, hardware updates. DMA write hardware sets BF when the buffer is full. DMA read hardware clears BF when the buffer is empty. BF is valid only when buffer is full or empty, otherwise ignore.	RWU
BS	Block Size	BS defines when to begin the DMA to the data buffer. BS = buffer block size in bytes 1. For RX channels, the DMA writes start when the number of empty bytes in the data buffer the block size. For TX channels, the DMA reads start when the number of valid bytes in the data buffer the block size.	RWU
RPTR	Read Pointer	Software initializes to 0, hardware updates. Counts the read address offset within a buffer. DMA read address = BA + RPTR.	RWU
WPTR	Write Pointer	Software initializes to 0, hardware updates. Counts the write address offset within a buffer. DMA write address = BA + WPTR.	RWU

Table 28-11: Isochronous CDT Entry Field Definitions (Continued)

Field	Description	Details	Access
RSTS	Read Status	Software initializes to 0, hardware updates. RSTS States: xx1 = active xx0 = idle	RWU
WSTS	Write Status	Software initializes to 0, hardware updates. WSTS States: xxx0 =active xxx1 = idle xx0x = command protocol error 1xxx = buffer overflow (FCE = 0 only)	RWU
Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.			RWU

Asynchronous/Control Channel Descriptors

The format and field definitions for an Asynchronous/Control CDT entry are shown in the ***Asynchronous/Control CDT Entry Format*** and ***Asynchronous/Control CDT Entry Field Definitions*** tables.

BD	Buffer Depth	BD = size of buffer in bytes 1. Buffer end address = BA + BD. BD = max packet length 1.	RW

Table 28-13: Asynchronous/Control CDT Entry Field Definitions (Continued)

Field	Description	Details	Access
RPC	Read Packet Count	Software initializes to 0, hardware updates. Used with RPC, RPTR and WPTR to determine if the buffer is empty or full.	RWU
WPC	Write Packet Count	Software initializes to 0, hardware updates. Used with RPC, RPTR and WPTR to determine if the buffer is empty or full.	RWU
RPTR	Read Pointer	Software initializes to 0, hardware updates. Counts the read address offset within a buffer. DMA read address = BA + RPTR.	RWU
WPTR	Write Pointer	Software initializes to 0, hardware updates. Counts the write address offset within a buffer. DMA read address = BA + WPTR.	RWU
RSTS	Read Status	Software initializes to 0, hardware updates. RSTS States: x0x00 = idle xx1xx = *ReceiverProtocolError* response received from RX device 1xxxx = *ReceiverBreak* command received from RX device	RWU
WSTS	Write Status	Software initializes to 0, hardware updates. Status States (only valid for DMA pointers associated with the MLB block, not HBI block pointers): xxx0 = idle xxx1 = command protocol error detected xx0x = *AsyncBreak*/*ControlBreak* command received from TX device	RWU
Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.			RWU

AHB Descriptor Table (ADT)

The AHB block manages data exchange between local channel data buffers within MLB module and the system memory buffer. To support system memory buffering, a ping-pong memory structure is implemented on a per channel basis using 128-bit descriptors for AHB Descriptor Table (ADT) entries. The Table 28-4 CTR Address Mapping table provides a complete address map of the CTR, including the location of the ADT.

Each logical channel is assigned a separate 128-bit descriptor, defining the data buffers in the system memory used by the DMA interface for that channel. The descriptors are stored at fixed addresses in the CTR as described in previous section. The ***ADT Field Definitions*** table provides an overview of field definitions for ADT entries.

Table 28-14: ADT Field Definitions

Field	No. of Bits	Description	Access
CE	1	Channel Enable. 0 = Disabled	RW, U
LE	1	Endianness Select. 0 = Big Endian, 1 = Little Endian	RW
PG	1	Page pointer. Software initializes to 0, hardware writes thereafter. 0 = Ping buffer, 1 = Pong buffer	RW, U
RDY1	1	Buffer Ready bit for ping buffer page. 0 = Not ready, 1 = Ready	RW
RDY2	1	Buffer Ready bit for pong buffer page. 0 = Not ready, 1 = Ready	RW
DNE1	1	Buffer Done bit for ping buffer page. 0 = Not done, 1 = Done	R, U, c0
DNE2	1	Buffer Done bit for pong buffer page. 0 = Not done, 1 = Done	R, U, c0
ERR1	1	Error Response detected for ping buffer page. 0 = No error, 1 = Error	R, U, c0
ERR2	1	Error Response detected for pong buffer page. 0 = No error, 1 = Error	R, U, c0
PS1	1	Packet Start bit for ping buffer page. 0 = No packet start, 1 = Packet start Reserved for synchronous and isochronous channels.	RW, U both TX and RX
PS2	1	Packet Start bit for pong buffer page. 0 = No packet start, 1 = Packet start Reserved for synchronous and isochronous channels.	RW, U both TX and RX
MEP1	1	Most Ethernet Packet indicator for ping buffer page. 0 = Not MEP, 1 = MEP. MEP1 only valid for the first page of a segmented buffer. Reserved for control synchronous and isochronous channels.	Rsvd for TX, R, U, c0 for RX
MEP2	1	Most Ethernet Packet indicator for pong buffer page. 0 = Not MEP, 1 = MEP. MEP2 only valid for the first page of a segmented buffer. Reserved for control synchronous and isochronous channels.	Rsvd for TX, R, U, c0 for RX
BD1	11 to 13	Buffer Depth for ping buffer page. 11 or 12 bits for asynchronous and control channels. 13 bits for synchronous and isochronous channels.	RW
BD2	11 to 13	Buffer Depth for pong buffer page. 11 or 12 bits for asynchronous and control channels. 13 bits for synchronous and isochronous channels.	RW
BA1	32	Buffer Base Address for ping buffer page	RW
BA2	32	Buffer Base Address for pong buffer page.	RW
Reserved	varies	Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.	RW, U

The ***Ping-Pong System Memory Structure*** figure shows that this system memory structure is similar for all channel types and shows the relationship between the BAn, BDn, and PG descriptor fields.

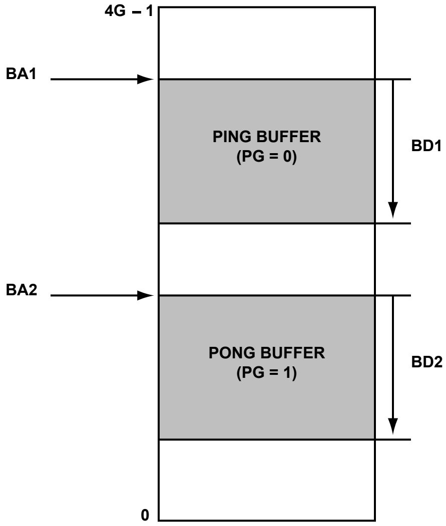

Figure 28-4: Ping-Pong System Memory Structure

Each ADT entry (also referred to as a *Channel Descriptor)* holds a 32-bit BAn field which defines the start of each ping or pong buffer within system memory. The BDn field is used to indicate the size for the respective ping or pong page. The maximum size is 2k entries for asynchronous and control channels and 8k entries for isochronous and synchronous channels.

Synchronous Channel Descriptors

The synchronous buffering scheme allows each ping or pong buffer to contain a single frame or a multiple number of frames. For this reason, the synchronous buffer depth (BDn) must be defined in terms of an integer number (n), frames per sub-buffer (m) and bytes per frame (bpf) of data (for example BDn = n m bpf 1). The ***Synchronous ADT Entry Format*** table shows the format for a synchronous ADT entry. The field definitions are defined in the ***ADT Field Definitions*** table. Each synchronous channel buffer can be up to 8k-bytes deep.

Table 28-15: Synchronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved

48	RDY2	DNE2	ERR2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Isochronous Channel Descriptors

The isochronous buffering scheme allows each ping or pong buffer to contain a single block or a multiple number of blocks. For this reason, the isochronous buffer depth (BDn) must be defined in terms of an integer number (n) and block size (BS) (for example BDn = n (BS + 1) 1).

The ***Isochronous ADT Entry Format*** table shows the format for an isochronous ADT entry. The field definitions are defined in the ***ADT Field Definitions*** table. Each isochronous channel buffer can be up to 8k-bytes deep.

Table 28-16: Isochronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	BD1[12:0]												
48	RDY2	DNE2	ERR2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Asynchronous and Control Channel Descriptors

Every asynchronous and control packet adheres to the Port Message Protocol (PMP), which designates the first two bytes of each packet as the packet length (PML). Each packet must be no more than 2048-bytes (PML 2048).

Software must set the buffer ready bit (RDYn) for each buffer as it programs the DMA. As hardware processes each buffer, it sets the done bit (DNEn) and generates an interrupt to inform HC. When hardware finishes processing a buffer, it can begin processing another buffer if RDYn is set. The application is responsible for setting up and configuring the channel buffer descriptor prior to every DMA access on the channel.

Two packet buffering modes are supported by hardware for programming the DMA, single-packet mode (`MLB_ACTL.MPB` =0) and multiple-packet mode (`MLB_ACTL.MPB` =1). The MPB is written prior to enabling the channel DMA.

Single Packet Mode. The single-packet mode asynchronous and control buffering scheme supports a maximum of one packet per buffer (for example, ping or pong). Both non-segmented and segmented data packets are allowed while using single-packet mode. Non-segmented packets are exchanged when only one buffer (for example, ping or pong) is needed for packet transfer. Segmented packets are exchanged when a single packet is too long for one buffer and the packet must span multiple buffers.

The ***Single-Packet Asynchronous and Control Entry Format*** table shows the format for single-packet mode asynchronous and control ADT entries. The field definitions are defined in the ***ADT Field Definitions*** table.

Table 28-17: Single-Packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1	MEP1	BD1[10:0]										
48	RDY2	DNE2	ERR2	PS2	MEP2	BD2[10:0]										
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Multiple Packet Mode. The multiple-packet mode asynchronous and control buffering scheme supports more than one packet per system memory buffer, as shown in the ***Asynchronous/Control CDT Entry Format*** table. Multiple-packet mode reduces the interrupt rate for packet channels at the cost of increasing buffering and latency.

For TX packet channels in multiple-packet mode, software sets the packet start bit (PSn) for every buffer. Setting PSn informs hardware that the first two bytes of the buffer contains the port message length (PML) of the first packet. After the first packet, hardware keeps track of where packets start and end within the current buffer. Software should not write to PSn while the buffer is active (RDYn = 1 and DNEn = 0). For TX packet channels, the buffer is done (DNEn = 1) when the last byte of the last packet in the buffer is read from system memory. Software should set the buffer depth to contain the exact number of complete packets for that buffer. Segmented buffers are not supported for TX packet channels in multiple-packet mode.

NOTE: The PS1 and PS2 bits are only valid for TX channels. Set PS1 and PS2 = 1 at the start of the buffer.

Table 28-18: Multiple-Packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

48	RDY2	DNE2	ERR2	PS2	BD2[11:0]											
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Interrupt Interface Block

The interrupt interface raises an interrupt when specific changes to HBI channel descriptors occur, including:

- For asynchronous and control read/write channels:
  - a packet is available to read in the channel buffer, or
  - sufficient empty space is available in the channel buffer to accept a requested packet write
- For isochronous read/write channels:
  - the number of valid bytes in the channel buffer exceeds the block size, or
  - the number of empty bytes in the channel buffer exceeds the block size

Operating Modes

The following sections describe the operating modes of the MLB interface. The channel type selection enables the logical channels to operate in synchronous, asynchronous, isochronous, or control channels.

NOTE: The logical channels can be any combination of channel type (for example synchronous, asynchronous, or control) and direction (transmit or receive).

Isochronous Data Exchange

An isochronous HBI channel is initially opened and synchronized with HCMD0.CMD[2:0]= 010. For isochronous channels, no further synchronization is required from the HBI perspective; however, an optional resynchronization command is available for HC flexibility. Setting HCMD0.CMD[2:0]= 011 reinitializes the address pointer within the data buffer, ensuring that subsequent data exchange with the channel is aligned at an isochronous packet boundary. When the HC must close an isochronous channel before it has read or written an entire data packet, setting HCMD0.CMD[2:0]= 000 reopens the channel without synchronizing the address pointer in the buffer. This action allows reading and writing to continue where the HC previously stopped.

For isochronous data transmission, the ***Exchanging Isochronous Data on an HBI Channel*** figure shows the flow control.

Figure 28-5: Exchanging Isochronous Data on an HBI Channel

Asynchronous and Control Data Exchange

An asynchronous or control HBI channel is initially opened using HCMD0.CMD[2:0]= 010. Occasionally, the HC may need to close a packet channel before it has completed writing or reading the current packet of data (for example, the HC needs to use this AGU to service another HBI channel). In this case, the HC can reopen the previous channel with HCMD0.CMD[2:0]= 000. This situation allows the HC to continue writing or reading a packet from the point it left off. In this situation, the PML is already known and the packet length is not reread or rewritten by the HC.

During the reading of a packet, if the HC sets HCMD0.CMD[2:0]= 010 for the channel before the last byte of the packet is read, an internal hardware pointer is reset to the beginning of the packet buffer. This situation requires that the HC reread the PML (from HSTS1) and reread the packet data (from HDATn) from the beginning. In the same manner, if the HC resets HCMD0.CMD[2:0]= 010 for the channel before the last byte of a packet is written, an internal hardware pointer is reset to the beginning of the packet buffer. This situation requires that the HC rewrite the PML (to HCMD1) and rewrite the packet data (to HDATn) from the beginning. Any previous packet data in the buffer is overwritten.

Frame synchronization is not supported for asynchronous channels.

Synchronous Data Exchange

The MLB core provides two modes of operation; standard and multi-frame per sub-buffer which provide flexibility for implementing synchronous channels. Channels configured for standard mode require less buffer space, but have higher interrupt rates and more stringent latency requirements. Channels setup for multi-frame per sub-buffer mode require more buffer space, but have lower interrupt rates and less stringent latency requirements.

To set up a channel in multi-frame per sub-buffer mode:

1. Program the `MLB_CTL0.FCNT` bit field to select the number of frames per sub-buffer.
2. Program the CAT to enable multi-frame sub-buffering (MFE= 1) for each particular channel.
3. Set the buffer depth in the CDT: BD= 4 × m × bpf 1 where: m = frames per sub-buffer, bpf = bytes per frame.
4. Repeat for additional synchronous channels

A sample synchronous data buffer is shown in the ***Synchronous Data Buffer Structure*** figure. Each data buffer contains four sub-buffers and each sub-buffer contains space for 1 to 64 frames of data, determined by the `MLB_CTL0.FCNT` bits.

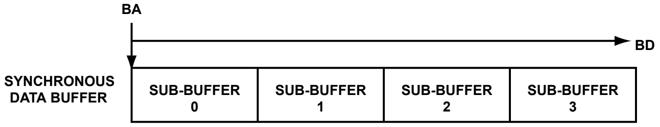

Figure 28-6: Synchronous Data Buffer Structure

Data Transfer

Two modes of operation are supported for transferring channel data between the MLB and internal memory. DMA allows the multi-channel DMA engine to manage data transfers without core intervention. Core driven mode (I/O mode) allows software to manage the transfer of data between MLB and internal memory.

NOTE: All hardware channels must use the same data transfer method. Mixed mode operation where hardware channels operate in both I/O mode and DMA mode is not supported.

DMA

The processor supports DMA mode which uses only INCR8, INCR4 and SINGLE beat bursts. Program the `MLB_ACTL.DMAMODE` = 1 to use DMA mode.

Programming Model

This section provides general guidelines for programming the MediaLB interface.

Channel Initialization

The software flow required to initialize a channel must be performed in order to ensure proper operation.

Configure the Hardware

1. Initialize the CTR and registers.
    a. Set all the CTR (CAT, CDT, and ADT) bits to 0.
    b. Set all bits of all registers to 0.
2. Configure the MediaLB interface.
    a. Select 3-pin or 6-pin MediaLB operation: `MLB_CTL0.PEN` =0 (3-pin), `MLB_CTL0.PEN` =1 (6-pin).
    b. Select MediaLB clock speed via `MLB_CTL0.CLK`.
    c. Set MediaLB enable via `MLB_CTL0.EN`.
3. Configure the HBI interface.
    a. Set `MLB_HCMR0` and `MLB_HCMR1` = 0xFFFFFFFF to activate all channels.
    b. Set the HBI enable bit: `MLB_HCTL.EN` =1.

Program the CAT and the CDT

1. Initialize all bits of the CAT to 0.
2. Select a logical channel: N = 1 – 63.
3. Program the CDT for channel N.
    a. Set the 14-bit base address (BA)
    b. Set the 12-bit or 13-bit buffer depth (BD): BD = buffer depth in bytes 1
    - For synchronous channels: (BD + 1) = 4 frames per sub-buffer (m) bytes-per-frame (bpf)
    - For isochronous channels: (BD + 1) mod (BS + 1) = 0

- For asynchronous channels: (BD + 1) max packet length (1024 for a MOST Data Packet (MDP)
- 1536 for a MOST Ethernet Packet (MEP)
- For control channels: (BD + 1) max packet length (64)

4. Program the CAT for the inbound DMA.
   a. For TX channels (to MediaLB) HBI is the inbound DMA
   b. For RX channels (from MediaLB) MediaLB is the inbound DMA
   c. Set the channel direction: RNW = 0
   d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
   e. Set the connection label: CL[5:0] = N
   f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
   g. Set the channel enable: CE = 1
   h. Set all other bits of the CAT to 0
5. Program the CAT for the outbound DMA.
   a. For TX channels (to MediaLB) HBI is the outbound DMA
   b. For RX channels (from MediaLB) MediaLB is the outbound DMA
   c. Set the channel direction: RNW = 1
   d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
   e. Set the channel label: CL[5:0] = N
   f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
   g. Set the channel enable: CE = 1
   h. Set all other bits of the CAT to 0
6. Repeat steps 2 through 5 to initialize all logical channels.

Program the ADT

1. Initialize all bits of the ADT to 0
2. Select a logical channel: N = 1 – 63
3. Program the AMBA AHB block ping page for channel N
   a. Set the 32-bit base address (BA1)

   b. Set the 11-bit buffer depth (BD1): BD1 = buffer depth in bytes – 1
      - For synchronous channels: (BD1 + 1) = n frames per sub-buffer (m) bytes-per-frame (bpf)
      - For isochronous channels: (BD1 + 1) mod (BS + 1) = 0
      - For asynchronous channels: 5 (BD1 + 1) 4096 (max packet length)
      - For control channels: 5 (BD1 + 1) 4096 (max packet length)
   c. For asynchronous and control Tx channels set the packet start bit (PS1) iff the page contains the start of the packet
   d. Clear the page done bit (DNE1)
   e. Clear the error bit (ERR1)
   f. Set the page ready bit (RDY1)
4. Program the AMBA AHB block pong page for channel N
   a. Set the 32-bit base address (BA2)
   b. Set the 11-bit buffer depth (BD2): BD2 = buffer depth in bytes – 1
      - For synchronous channels: (BD2 + 1) = n frames per sub-buffer (m) bytes-per-frame (bpf)
      - For isochronous channels: (BD2 + 1) mod (BS + 1) = 0
      - For asynchronous channels: 5 (BD2 + 1) 4096 (max packet length)
      - For control channels: 5 (BD2 + 1) 4096 (max packet length)
   c. For asynchronous and control TX channels set the packet start bit (PS2) iff the page contains the start of the packet
   d. Clear the page done bit (DNE2)
   e. Clear the error bit (ERR2)
   f. Set the page ready bit (RDY2)
5. Select Big Endian (LE = 0) or Little Endian (LE = 1)
6. Select the active page: PG = 0 (ping), PG = 1 (pong)
7. Set the channel enable (CE) bit for all active logical channels
8. Repeat steps 2 through 7 for all active logical channels.

Service

After initialization, each channel will require periodic servicing. Use the procedures in the following sections to service DMA and MLB interrupts and to poll for MLB system commands.

Servicing the DMA Channel Interrupts

1. Program the `MLB_ACMR0`/`MLB_ACMR1` registers to enable interrupts from all active DMA channels.
2. Select the status clear method. `MLB_ACTL.SCE` =0 (hardware clears on read), `MLB_ACTL.SCE` = 1 (software writes a 1 to clear).
3. Select 1 or 2 interrupt signals. Configure the `MLB_ACTL.SMX` bit =0 (one interrupt for channels 0 through 31 and another interrupt for channels 32 through 63 on). Configure the `MLB_ACTL.SMX` bit =1 (single interrupt for all channels).
4. Wait for an interrupt.
5. Read the `MLB_ACSR0`/`MLB_ACSR1` registers to determine which channel or channels are causing the interrupt.
6. If the `MLB_ACTL.SCE` bit =1, write the results of step 5 back to the `MLB_ACSR0` and `MLB_ACSR1` registers to clear the interrupt.
7. Select a logical channel (N = 0 – 63) with an interrupt to service.
8. Read the ADT entry for channel N to:
   a. Determine the active page (ping or pong) via the PG bit
   b. Determine which page(s) are done via the DNEn bits
   c. Determine which channels encountered an AHB error via the ERRn bit
   d. Determine which asynchronous and control Rx channel pages contain a packet start via the PSn bit (extract the PML)
9. Repeat steps 6 through 8 for all channels with pending interrupts
10. Repeat steps 4 through 9 while there are active channels.

Servicing the MediaLB Status Interrupts

1. Select the MediaLB channel status register (`MLB_MS0`/`MLB_MS1`) to be cleared by software, writing a 0 to the appropriate bits.
2. Program the `MLB_MIEN` register to enable protocol error interrupts for all active MediaLB channels. (`MLB_MIEN.CTXPE` =1, `MLB_MIEN.CRXPE` =1, `MLB_MIEN.ATXPE` =1, `MLB_MIEN.ARXPE` =1, `MLB_MIEN.SYNCPE` =1, and `MLB_MIEN.ISOCPE` =1).
3. Wait for an interrupt on the `MLB_INT0`/`MLB_INT1` signal.
4. Read the `MLB_MS0`/`MLB_MS1` registers to determine which channel(s) are causing the interrupt.
5. Read the RSTS/WSTS of the appropriate CDT(s) to determine the interrupt type.

6. Clear the RSTS/WSTS errors to ensure that the current status of channel operations is reflected in the register:

Option	Description
For synchronous RX channels	WSTS[3] = 0
For synchronous TX channels	RSTS[3] = 0
For isochronous RX channels	WSTS[2:1] = 00
For isochronous TX channels	RSTS[2:1] = 00
For asynchronous and control RX channels	WSTS[4] = 0 and WSTS[2] = 0
For asynchronous and control TX channels	RSTS[4] = 0 and RSTS[2] = 0

Polling for MediaLB System Commands

The MediaLB System status (`MLB_MSS`) register is used to detect a system command received from the MediaLB controller. The processor's peripheral automatically sends the appropriate system response to the MediaLB controller. The procedure for the application is:

1. The application periodically polls the `MLB_MSS` register.
2. Clear by writing a 0 to the appropriate bit in the `MLB_MSS` register after the application finishes the service.
3. If `MLB_MSS.SWSYSCMD` = 1, read the `MLB_MSD` register to receive the system data sent from MediaLB controller.

ADSP-SC58x MLB Register Descriptions

MediaLB Device Interface Macro 2 (MLB) contains the following registers.

Table 28-19: ADSP-SC58x MLB Register List

Name	Description
`MLB_ACMR0`	Peripheral Channel Mask 0 Register
`MLB_ACMR1`	Peripheral Channel Mask 1 Register

Peripheral Channel Mask 0 Register

The `MLB_ACMR0` register allows control over which channel(s) generate interrupts on MLB_INT[1:0]. All of the bits in this register default to 0 (masked) so the HC must initially write to the `MLB_ACMR0` register to enable interrupts. Each bit of this register is read/write accessible.

		0	Mask interrupt for Channel 63:32 (bitwise; all channels shown)
		4294967295	Unmask interrupt for Channel 63:32 (bitwise; all channels shown)

Peripheral Channel Status 0 Register

The `MLB_ACSR0` register contains interrupt bits for each of the 64 physical channels. When a bit in this register is set, it indicates that the corresponding physical channel has an interrupt pending.

A peripheral interrupt is triggered when either DNEn or ERRn is set within the Bus Channel Descriptor. The HC is notified of the channel interrupt via MLB_INT[1:0]. When an interrupt occurs in ACCUSER (for channels 31 to 0) MLB_INT[0] is set. When an interrupt occurs in `MLB_ACSR1` (for channels 63 to 32) MLB_INT[1] is set.

Interrupts in the `MLB_ACSR0` and `MLB_ACSR1` registers can be optionally multiplexed onto a single interrupt signal, MLB_INT[0], if the `MLB_ACTL.SMX` bit = 1.

If the `MLB_ACTL.SCE` bit =0, hardware automatically clears the interrupt bit(s) after the HC reads the peripheral channel status registers. Alternatively, if the `MLB_ACTL.SCE` bit =1, software must write a 1 to the appropriate bit(s) of the peripheral channel status registers to clear the interrupt(s).

		0	No interrupt on Channel 31:0 (bitwise; all channels shown)
		4294967295	Interrupt on Channel 31:0 (bitwise; all channels shown)

Peripheral Channel Status 1 Register

The MLB_ACSR1 register contains interrupt bits for each of the 64 physical channels. When a bit in this register is set, it indicates that the corresponding physical channel has an interrupt pending.

A peripheral interrupt is triggered when either DNEn or ERRn is set within the Bus Channel Descriptor. The HC is notified of the channel interrupt via MLB_INT[1:0]. When an interrupt occurs in ACCUSER (for channels 31 to 0) MLB_INT[0] is set. When an interrupt occurs in MLB_ACSR1 (for channels 63 to 32) MLB_INT[1] is set.

Interrupts in the MLB_ACSR1 and MLB_ACSR0 registers can be optionally multiplexed onto a single interrupt signal, MLB_INT[0], if the `MLB_ACTL.SMX` bit = 1.

If the `MLB_ACTL.SCE` bit =0, hardware automatically clears the interrupt bit(s) after the HC reads the peripheral channel status registers. Alternatively, if the `MLB_ACTL.SCE` bit =1, software must write a 1 to the appropriate bit(s) of peripheral channel status registers to clear the interrupt(s).

		0	No interrupt on Channel 63:32 (bitwise; all channels shown)
		4294967295	Interrupt on Channel 63:32 (bitwise; all channels shown)

Bus Control Register

The `MLB_ACTL` register is written by the HC to configure the block for channel interrupts. This register contains bits to select the packet buffering mode and the DMA mode. This register also contains bits that are used to multiplex channel interrupts onto a single interrupt signal and to select the method of clearing channel interrupts.

Table 28-24: MLB_ACTL Register Fields

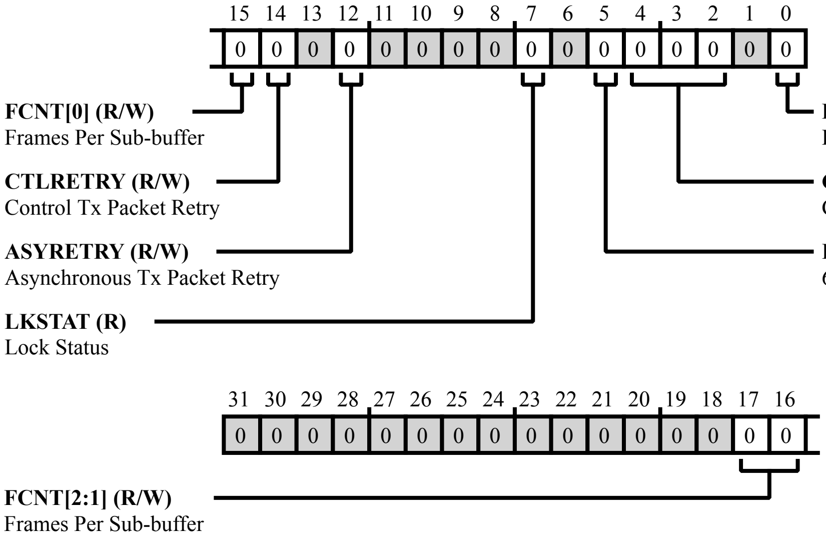
Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	MPB	Packet Buffering Mode. The `MLB_ACTL.MPB` bit selects whether the buffering mode is single-packet or multiple-packet.	
		0	single-packet mode
		1	multiple-packet mode
2 (R/W)	DMAMODE	DMA Mode. The `MLB_ACTL.DMAMODE` bit selects between DMA mode 1 and 0. DMA Mode 0 uses incrementing bursts of an unspecified length. This allows the block to perform single beat transfers as well as an incrementing (INCR) burst of unspecified length up to the maximum specified burst length (8 beats). DMA Mode 1 uses only INCR8, INCR4, and SINGLE beat bursts. The hburst[2:0] signal encodes the burst transfer used for a DMA operation.	
		0	DMA Mode 0
		1	DMA Mode 1

Table 28-24: MLB_ACTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SMX	Interrupt Multiplex Enable. The `MLB_ACTL.SMX` bit selects whether ACSR0 generates an interrupt on MLB_INT[0] and ACSR1 generates an interrupt on MLB_INT[1] or ACSR0 and ACSR1 generate an interrupt on MLB_INT[0] only.	
		0	ACSR0 generates an interrupt on MLB_INT[0]; ACSR1 generates an interrupt on MLB_INT[1]
		1	ACSR0 and ACSR1 generate an interrupts on MLB_INT[0] only
0 (R/W)	SCE	Software Clear Enable. The `MLB_ACTL.SCE` bit selects whether hardware clears the interrupt after a ACSRn register read or software clears the interrupt.	
		0	Hardware clears interrupt after a ACSRn register read
		1	Software clears interrupt

MediaLB Control 0 Register

The `MLB_CTL0` register contains bit that enable the module and provide module status. Note that the maximum speed for ML6-pin mode is 2048 x FS.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
FCNT[2:1] (R/W)
Frames Per Sub-buffer

Figure 28-12: MLB_CTL0 Register Diagram

Table 28-25: MLB_CTL0 Register Fields

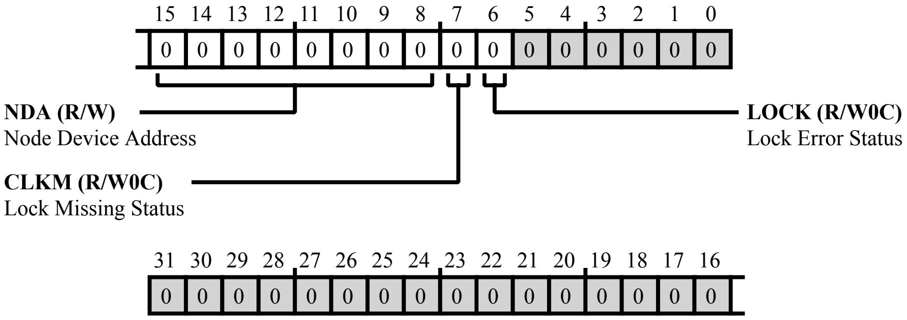
Bit No. (Access)	Bit Name	Description/Enumeration	
17:15 (R/W)	FCNT	Frames Per Sub-buffer. The `MLB_CTL0.FCNT` bit field configures the frames per sub-buffer on synchronous channels.	
		0	1 Frame per sub-buffer (Operation is the same as Standard mode)
		1	2 frames per sub-buffer
		2	4 frames per sub-buffer
		3	8 frames per sub-buffer
		4	16 frames per sub-buffer
		5	32 frames per sub-buffer
		6	64 frames per sub-buffer
14 (R/W)	CTLRETRY	Control Tx Packet Retry. When the `MLB_CTL0.CTLRETRY` bit is set, a control packet that is flagged with a Break or Protocol error by the receiver is retransmitted. When cleared, a control packet that is flagged with a Break or Protocol error by the receiver is skipped.	

Table 28-25: MLB_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W)	ASYRETRY	Asynchronous Tx Packet Retry. When the `MLB_CTL0.ASYRETRY` bit is set, an asynchronous packet that is flagged with a Break or Protocol error by the receiver is retransmitted. When cleared, an asynchronous packet that is flagged with a Break or ProtocolError by the receiver is skipped.
7 (R/NW)	LKSTAT	Lock Status. When the `MLB_CTL0.LKSTAT` bit is set (=0), the MediaLB block is synchronized to the incoming MediaLB frame with the following conditions. • If `MLB_CTL1.LOCK` =0 (unlocked), `MLB_CTL1.LOCK` is set after a FRAMESYNC is detected at the same position for three consecutive frames. • If `MLB_CTL1.LOCK` =1 (locked), `MLB_CTL1.LOCK` is cleared after not receiving a FRAMESYNC at the expected time for two consecutive frames. In this case FRAMESYNC patterns occurring at locations other than the expected one are ignored.
5 (R/W)	PEN	6-pin Enable. The `MLB_CTL0.PEN` bit configures the MLB for 6-pin or 3-pin mode. 0 3-pin interface enabled 1 6-pin interface enabled
4:2 (R/W)	CLK	Clock Speed Select. The `MLB_CTL0.CLK` bit field sets the clock speed. 0 256 x Fs (MLB_CTL.PEN = 0) 1 512 x Fs (MLB_CTL.PEN = 0) 2 1024 x Fs (MLB_CTL.PEN = 0) 3 2048 x Fs (MLB_CTL.PEN = 1) 4 Reserved 5 Reserved 6 Reserved 7 Reserved
0 (R/W)	EN	Enable. When the `MLB_CTL0.EN` bit is set (=1), MediaLB clock, signal, and data are received and transmitted on the appropriate MediaLB pins.

Control 1 Register

The MLB_CTL1 register contains bits that provide lock status and control system commands.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit No. (Access)	Bit Name	Description/Enumeration	
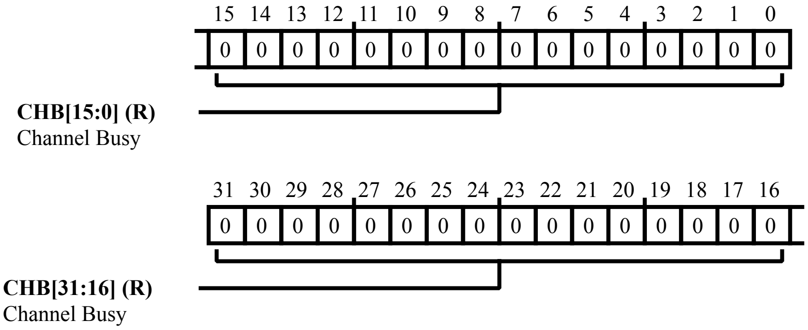
2 (R/W)	CLKOUTSEL	CLKOUT Select. The `MLB_GCTL.CLKOUTSEL` bit selects either the MLB 3 pin clock or the 6 pin clock as MLBCLKOUT.	
		0	MLB 3 pin clock is selected for MLBCLKOUT
		1	MLB 6 pin clock is selected for MLBCLKOUT
1 (R/W)	CLKOUTEN	CLKOUT Enable.	

HBI Channel Busy 0 Register

The HC can determine which channel(s) are busy by reading the `MLB_HCBR0` register. An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of this register is read-only.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

31:0 (R/NW)	CHB	Channel Busy. The `MLB_HCBR0.CHB` bit field contains the bitwise channel busy bit for channels 31:0. When a bit is cleared (=0) the channel is idle. When a bit is set (=1) the channel is busy.

HBI Channel Busy 1 Register

The HC can determine which channel(s) are busy by reading the `MLB_HCBR1` register. An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of this register is read-only.

Table 28-45: MLB_MIEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	CTXBREAK	Control Transmit Break Enable. When the MLB_MIEN.CTXBREAK bit is set, a ReceiverBreak response received from the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
28 (R/W)	CTXPE	Control Transmit Protocol Error Enable. When the MLB_MIEN.CTXPE bit is set, a ProtocolError generated by the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
27 (R/W)	CTXDONE	Control Transmit Packet Done Enable. When the MLB_MIEN.CTXDONE bit is set, a packet transmitted with no errors on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Table 28-45: MLB_MIEN Register Fields (Continued)

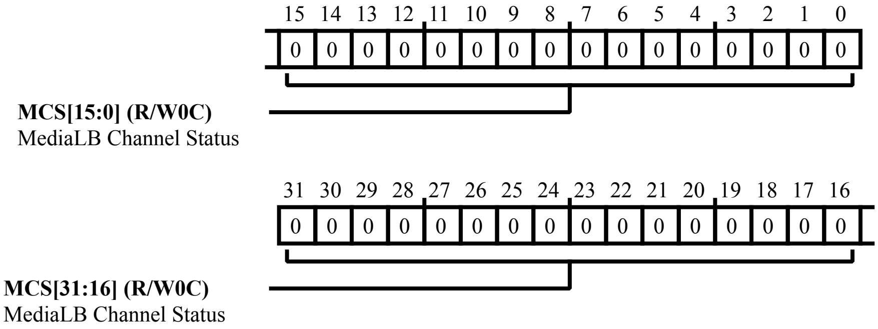
Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	CRXBREAK	Control Receive Break Enable. When the `MLB_MIEN.CRXBREAK` bit is set, a ControlBreak command received from the transmitter on a control Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.
25 (R/W)	CRXPE	Control Receive Protocol Error Enable. When the `MLB_MIEN.CRXPE` bit is set, a ProtocolError detected on a control Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.
24 (R/W)	CRXDONE	Control Receive Packet Done Enable. When the `MLB_MIEN.CRXDONE` bit is set, a packet received with no errors on a control Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.
22 (R/W)	ATXBREAK	Asynchronous Transmit Break Enable. When the `MLB_MIEN.ATXBREAK` bit is set, a ReceiverBreak response received from the receiver on an asynchronous Tx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.
21 (R/W)	ATXPE	Asynchronous Transmit Protocol Error Enable. When the `MLB_MIEN.ATXPE` bit is set, a ProtocolError generated by the receiver on an asynchronous Tx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.
20 (R/W)	ATXDONE	Asynchronous Transmit Done Enable. When the `MLB_MIEN.ATXDONE` bit is set, a packet transmitted with no errors on an asynchronous Tx channel channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.
19 (R/W)	ARXBREAK	Asynchronous Receive Break Enable. When the `MLB_MIEN.ARXBREAK` bit is set, a AsyncBreak command received from the transmitter on an asynchronous Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.
18 (R/W)	ARXPE	Asynchronous Receive Protocol Error Enable. When the `MLB_MIEN.ARXPE` bit is set, a protocol error detected on an asynchronous Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.
17 (R/W)	ARXDONE	Asynchronous Receive Packet Done Enable. When the `MLB_MIEN.ARXDONE` bit is set, a packet received with no errors on an asynchronous Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.

Table 28-45: MLB_MIEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	SYNCPE	Synchronous Protocol Error Enable. When the `MLB_MIEN.SYNCPE` bit is set, a protocol error detected on a synchronous Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set. This occurs only when isochronous flow control is disabled.
1 (R/W)	ISOCBUFO	Isochronous Receive Buffer Overflow Enable. When the `MLB_MIEN.ISOCBUFO` bit is set, a buffer overflow on an isochronous Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set. This occurs only when isochronous flow control is disabled.
0 (R/W)	ISOCPE	Isochronous Receive Protocol Error Enable. When the `MLB_MIEN.ISOCPE` bit is set, a protocol error detected on an isochronous Rx channel causes the appropriate channel bit in the `MLB_MS0` or `MLB_MS1` registers to be set.

Channel Status 0 Register

The `MLB_MS0` register indicates the channel status for MediaLB channels 31 to 0. Channel status bits are set by hardware and cleared by software. Status is only set if the appropriate bits in the `MLB_MIEN` register are set.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

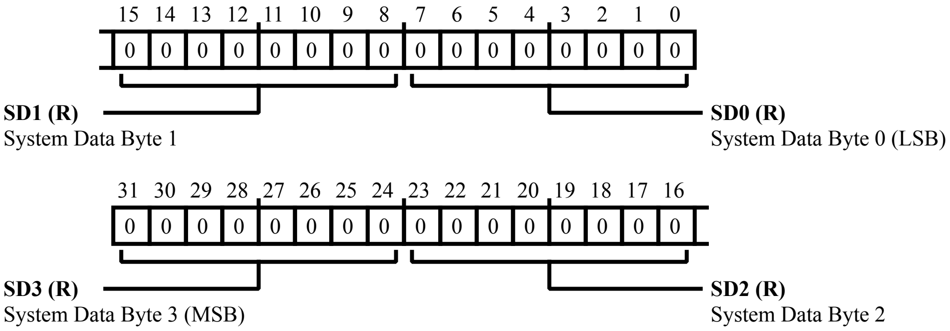
31:0 (R/W0C)	MCS	MediaLB Channel Status. The `MLB_MS1.MCS` bit field indicates the MediaLB channel status for channels 63 to 32.

System Data Register

The `MLB_MSD` register allows system software to receive control information from the MLB controller. The `MLB_MSD` register is updated once per frame by the hardware during the MLB system channel.

The `MLB_MSD` register is loaded with the data from the MLBDAT_IN signal during the system channel quadlet. System software must read this register before the start of the next MLB frame to prevent the current data from being lost.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	SD3	System Data Byte 3 (MSB). The `MLB_MSD.SD3` bits are updated with MediaLB Data [31:24] when a MediaLB software system command is received in the system quadlet. If the `MLB_MSS.SWSYSCMD` bit is already set, then SD3 is not updated.
23:16 (R/NW)	SD2	System Data Byte 2. The `MLB_MSD.SD2` bits are updated with MediaLB Data [23:16] when a MediaLB software system command is received in the system quadlet. If the `MLB_MSS.SWSYSCMD` bit is already set, then SD2 is not updated.
15:8 (R/NW)	SD1	System Data Byte 1. The `MLB_MSD.SD1` bits are updated with MediaLB Data [15:8] when a MediaLB software system command is received in the system quadlet. If the `MLB_MSS.SWSYSCMD` bit is already set, then SD1 is not updated.
7:0 (R/NW)	SD0	System Data Byte 0 (LSB). The `MLB_MSD.SD0` bits are updated with MediaLB Data [7:0] when a MediaLB software system command is received in the system quadlet. If the `MLB_MSS.SWSYSCMD` bit is already set, then SD0 is not updated.

System Status Register

The MLB_MSS register allows system software to monitor and control the status of the MLB network. The register is updated once per frame by hardware during the MLB system channel. The bits of this register are not valid until the processor is locked to the MLB interface (except for the bits associated with MLB lock and unlock, SDMU and SDML). System software must service events before the start of the next MLB frame to prevent the current frame status from being lost.

Table 28-49: MLB_MSS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	SERVREQ	Service Request Enable. When the `MLB_MSS.SERVREQ` bit set, the MediaLB block responds with a device present, request service system response if a matching channel scan system command is detected. When cleared, the MediaLB block responds with a device present system response.
4 (R/W0C)	SWSYSCMD	Software System Command Detected. The `MLB_MSS.SWSYSCMD` bit indicates that a software system command was detected (in the system quadlet). The `MLB_MSS.SWSYSCMD` bit is set by hardware, cleared by software. Data is stored in the MLB_MSD register for this command.
3 (R/W0C)	CSSYSCMD	Channel Scan System Command Detected. The `MLB_MSS.CSSYSCMD` bit indicates that a channel scan system command was detected (in the system quadlet). The `MLB_MSS.CSSYSCMD` bit is set by hardware, cleared by software. If the node address specified in the data quadlet matches the value in the `MLB_CTL1.NDA` bit field, the device responds either device present or device present, request service system response in the next system quadlet.

Table 28-49: MLB_MSS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W0C)	ULKSYSCMD	Network Unlock System Command Detected. The `MLB_MSS.ULKSYSCMD` bit indicates a network unlock system command was detected (in the system quadlet). The `MLB_MSS.ULKSYSCMD` bit is by hardware, cleared by software.
1 (R/W0C)	LKSYSCMD	Network Lock System Command Detected. The `MLB_MSS.LKSYSCMD` bit indicates a network lock system command was detected (in the system quadlet). The `MLB_MSS.LKSYSCMD` bit is set by hardware and cleared by software.
0 (R/W0C)	RSTSYSCMD	Reset System Command Detected. The `MLB_MSS.RSTSYSCMD` bit indicates a reset system command was detected (in the system quadlet). The `MLB_MSS.RSTSYSCMD` bit is set by hardware, cleared by software.

29 PCI Express

Peripheral Component Interconnect Express (PCIe) is a high performance, general purpose I/O interconnect defined for a wide variety of computing and communication platforms.

PCIe retains some desirable attributes of the PCI interface, such as its usage model, load-store architecture, and software interfaces, whereas its parallel bus implementation is replaced by a highly scalable, fully serial interface. PCI Express takes advantage of recent advances in point-to-point interconnects, switch-based technology, and packetized protocol to deliver new levels of performance and features.

The PCIe Dual Mode core implements the three PCI Express protocol layers; the transaction layer, data link layer, and the MAC portion of the physical layer. It also implements the application-dependent functionality of the PCI Express transaction layer for packet transmission, which is located between the application logic and the PCI Express protocol layers. As shown in the ***PCIe Layers*** figure, a complete PCI Express Port solution includes the core, an analog PHY macro, and application logic to source and sink data. The physical layer is split across the PIPE such that the MAC functionality (LTSSM) is in the core and the PHY functionality is implemented in the PIPE-compliant PHY. The PIPE interface is internal to the core, and the external interface for the PHY consists of one transmit and one receive differential pair. Otherwise, the PHY module resides outside of the core, interfacing through the standard PIPE.

The PCIe interface is in compliance with PCI-SIG standards. If you require detailed information on PCIe protocol, refer the corresponding PCI-SIG specifications. The PCIe controller follows the following standards.

- PCI Express Base 3.0 Specification, revision 1.0
- PIPE Specification for PCI Express, Version 4.0, Intel Corporation

PCIe Features

The PCI Express core is compliant with the PCI Express Gen 2 standard. The following features are supported:

- Dual operation mode: Root Complex (RC) and End Point (EP)
- Supports a single bidirectional x1 link interface
- Supports 2.5 Gbps or 5.0 Gbps per lane per direction
- 3.3 V I/O power supply (The PHY can also support a 2.5 V I/O)
- Maximum outbound payload size of 256 bytes
- Maximum inbound payload size of 256 bytes
- Maximum remote read request size of 256 bytes
- Polarity inversion on receive
- Single virtual channel (VC)
- Single traffic class (TC)
- Single function in End Point (EP) mode
- ECRC generation and checking
- PCI device power management
- PCI Express active state power management (ASPM) state L0s and L1

- PCI Express link power management
- PCI Express advanced error reporting
- PCI Express messages for both transmit and receive
- Filtering for posted, non-posted, and completion traffic
- Configurable BAR filtering, I/O filtering, configuration filtering, and completion lookup/timeout
- Access to configuration space registers and external application memory-mapped registers through local bus controller
- Legacy interrupts reception (RC) and generation (EP)
- MSI reception (RC) and generation (EP)
- Tx-to-Rx PIPE loopback
- IEEE 1149.6 (JTAG) boundary scan

Functional Description

The following sections provide information on the function of the PCIe.

ADSP-SC58x PCIE Register List

The following table lists the registers used by the PCIe interface.

Table 29-1: ADSP-SC58x PCIE Register List

Name	Description
PCIE_ACK_ASPMCTL_[n]	Acknowledge Frequency and L0-L1 ASPM Control Register
PCIE_ACK_TMR_[n]	Acknowledge Latency Timer and Replay Timer Register
PCIE_ADVERR_CAPBCTL_[n]	Advanced Error Capabilities and Control Register
PCIE_ADVERR_EXTCAPB_[n]	Advanced Error Reporting Extended Capability Header Register
PCIE_APP_CORERR_MSG	Correctable Error Message Requester ID Register
PCIE_APP_CTL	Application Control Register
PCIE_APP_DIAGCTL	Diagnostic Control Register
PCIE_APP_DIAGSTAT	Diagnostic Status Register
PCIE_APP_FERR_MSG	Fatal Error Message Requester ID Register
PCIE_APP_INTSTAT	Application Interrupts Status Register
PCIE_APP_NFERR_MSG	Non Fatal Error Message Requester ID Register
PCIE_APP_PMACK_MSG	Power Management Acknowledge Message Requester ID Register
PCIE_APP_PMEVT_MSG	Power Management Event Message Requester ID Register

Table 29-1: ADSP-SC58x PCIE Register List (Continued)

Name	Description
PCIE_APP_PMTOFF_MSG	Power Management Turn Off Message Requester ID Register
PCIE_APP_STAT	Application Status Register
PCIE_APP_UNLK_MSG	Unlock Message Requester ID Register
PCIE_APP_VNDR_MSG	Vendor Message Requester ID Register
PCIE_APP_VNDR_MSG_HDR0	Vendor Message Header Bytes 8 to 11 Register
PCIE_APP_VNDR_MSG_HDR1	Vendor Message Header Bytes 12 to 15 Register
PCIE_AUX_CLKFREQ_[n]	Auxiliary Clock Frequency Control Register
PCIE_BERR_RESP_[n]	Peripheral and SCB Bridge Slave Error Response Register
PCIE_BUSMGR_WDOG_[n]	Bus Order Manager Watchdog Off Register
PCIE_BUS_MULOB_DECOMP_[n]	Bus Multiple Outbound Decomposition SubReq Control Register

Figure 29-2: PCIe Interface Block Diagram

Module-level Block Diagrams and Descriptions

The following modules are integrated in the PCIe port:

- Reset clock control and PHY control (RSCKPHY). Controls the PCIe port's clocking and reset functions. It can be accessed by on-chip fabric masters regardless of the dual-mode core and PHY status.
- Application (APP). ADSP-SC58x specific application registers and logic.
- The PCIe core and PCIe PHY. Form the heart of the PCIe interface and implement the PCIe protocol stack, and the physical pins, connected to each other through the PIPE interface.

Registers and memory space are accessed over the following system cross bar (SCB) ports:

- DBI SCB slave interface. PCI, PCIe, port logic and application registers.
- Slave SCB interface. PCIe memory space across the PCIe link.
- Master SCB port. On-chip address space accessed from a PCIe partner over the PCIe link.
- RSCKPHY SCB port. RSCKPHY and PCIe PHY registers.

Reset Clock and PHY Control Module (RSCKPHY)

The RSCKPHY block includes the clock and reset circuitry and PCIe PHYs control and status registers. It also drives the bus to configure the PCIe core to either a Root Complex (RC) or an End Point (EP) port. The whole PCIe port is reset by the `RCU_SYSRES` signal and enabled by software.

While booting through the PCIe port is not one of the default ADSP-SC58x boot modes, applications can choose to implement a second stage boot loader kernel that configures and enables the PCIe port to load a custom application into the ADSP-SC58x memory.

The RSCKPHY block generates all clocks and reset signals for the PCIe core and PCIe PHY.

RSCKPHY System Cross Bar (SCB) Port

On-chip masters can access the RSCKPHY MMRs through a dedicated SCB port in the SYSCLK clock domain.

PCIe Reset

All on-chip modules are reset if a system reset (`RCU_SYSRES` asserted) event occurs. The PCIe APP, Core, PHY and Core's SCB Interface are taken out of reset only by software. After a Hardware or System Reset only the RSCKPHY block is out of reset. The `PCIE_RSCK_CTL.PCIERES` bit controls the assertion and deassertion of the PCIe cold reset signal. When the `PCIE_RSCK_CTL.PCIERES` bit is cleared, the core, application, PHY and the core's SCB interface are brought out of reset and their clocks are enabled. To satisfy the PHYs Power-On-Reset timing, RSCKPHY delays the deassertion of its cold reset output by at least 25000 SYSCLK cycles.

The PCIe core and PCIe PHY mode of operation (Root Complex or End Point) is determined by the value of the `PCIE_RSCK_CTL.DEVTYP` bit field at the time the `PCIE_RSCK_CTL.PCIERES` bit is cleared (both fields can be written at the same time). Writing values other than 0x0 or 0x4 to the `PCIE_RSCK_CTL.DEVTYP` bit field is not allowed.

To reset the PCIe port (warm or hot reset), the PCIe core asserts its Link Reset Request signal to make RSCKPHY assert Reset Request signal. This signal is used as an interrupt. Writing 1 to the `PCIE_RSCK_CTL.DBISLVDIS` bit enables the PCIe port reset. The application software may also decide to assert the Power Reset signals by setting the `PCIE_RSCK_CTL.PCIERES` bit.

Clocking

The PHY uses external reference clock (REFCLK_P and REFCLK_N). These are the external reference 100 MHz differential clocks. If the PHYs input clock has been stable and running for more than 10 µsec, the additional delay can be disabled by clearing the `PCIE_RSCK_CTL.RESDELEN` bit. Software can request to remove the reference clock by setting the `PCIE_RSCK_CTL.RFCKRMREQ` bit. The `PCIE_RSCK_STAT.RFCKRMEN` bit shows when the reference clock can be removed.

PCLK is generated by the PHY TX PLL from the reference clock. Its frequency changes when the PCIe port transitions from one frequency to another. CORE_CLK is the primary clock for the core. It is identical to PCLK.

The SCB interface synchronizes between the SCB buses in the SYSCLK domain and the core in the CORE_CLK domain. From the PCIe perspective there are no restrictions on SYSCLK other than changing frequencies when the interface is idle.

AUX_CLK is the clock source for parts of the Power Management Controller module. It is implemented as a low frequency (f_{SYSCLK}/16) clock derived from SYSCLK.

Power Management

An EP needs to send a Power Management Event (PM_PME) message to the RC to wake up from a power down state. For the message to be sent, the Power Management Controller (PMC) in the PCIe core module needs to wake up and the PCIe link brought to its L0 state. This process is triggered by the application software writing 1 to the `PCIE_RSCK_CTL.PMPMEREQ` bit.

It is the application software responsibility not to write 1 to the `PCIE_RSCK_CTL.PMPMEREQ` bit until the previous message has been transmitted.

Reset

The ***Reset Summary*** table provides descriptions of the PCIe reset states.

Table 29-5: Reset Summary

Reset State	Triggered By	Description
System Reset	Reset Control Unit	This is a full-chip reset state. It is triggered by Hard or System Reset events (See the RCU chapter of the HRM). Resets the Reset Clock and PHY Control, Application, Core, Core's SCB Interface and PHY.
Cold Reset	`PCIE_RSCK_CTL.PCIERES` bit	This state is entered if `PCIE_RSCK_CTL.PCIERES` is set. All the PCIe modules except RSCKPHY are reset. Resets the Application, Core, Core's SCB Interface and PHY. To exit Cold Reset software must clear `PCIE_RSCK_CTL.PCIERES`
Warm Reset	Core	This state is entered if the PCIe core requests a link reset. All the PCIe modules except RSCKPHY and sticky bits and registers are reset. Resets the Application, Core, Core's SCB Interface and PHY except sticky bits.
Hot Reset	PCIe Link	This state is entered if a downstream port needs to reset an upstream port asserting a downstream reset request. All the PCIe modules except RSCKPHY and sticky bits and registers are reset. Resets the Application, Core, Core's SCB Interface and PHY except sticky bits.

Responding to a Warm or Hot Reset

During normal operation when the link has to be reset, the PCIe core asserts the link reset request output. The PCIe core and PHY is not reset until that PHY has had a chance to transmit the EIOS.

When the link reset request signal is asserted, the SCB bridge operates as follows:

System cross bar bridge slave interface (including DBI slave interface):

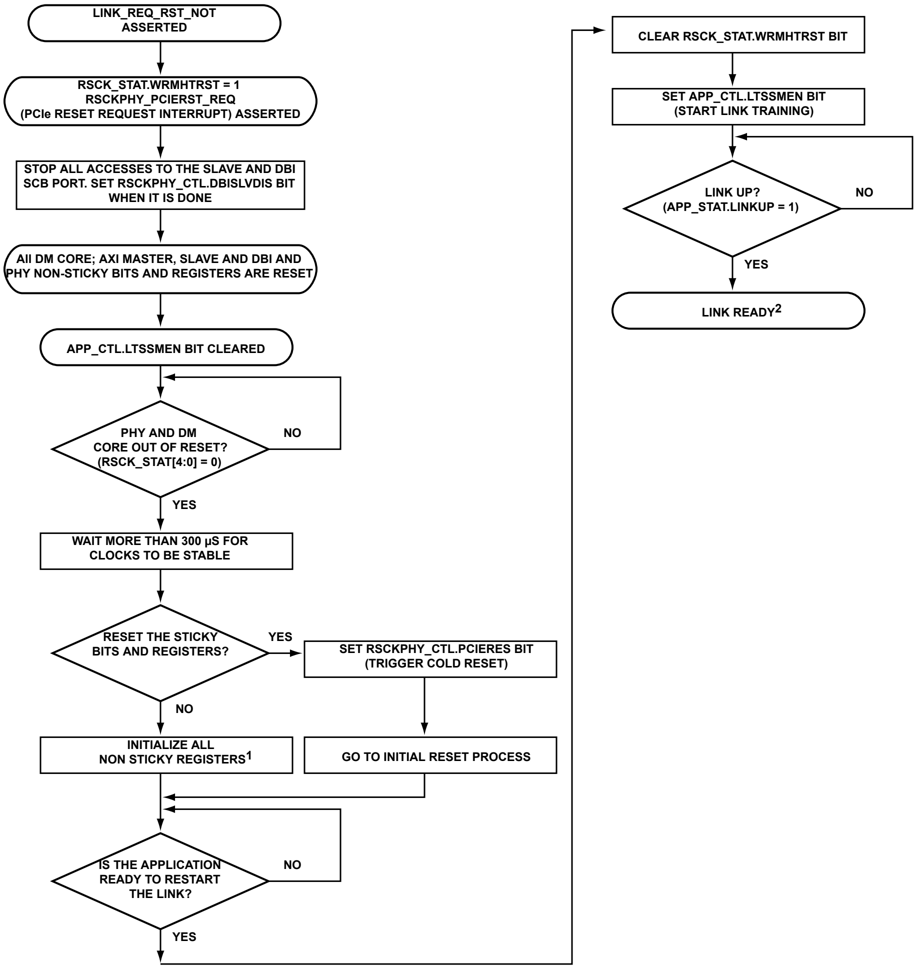
- Keeps accepting any new read/write requests but does not forward them to the PCIe link or application registers.
- For write requests:
  - Allows the application SCB master to complete all write data bursts and dumps data internally in the bridge.
  - On the completion of write data burst, generates a write response with slave error status.
- Generates a slave error response for all SCB beats of read requests.

  For more details, see PCI Express Controller DM Port Core Databook “Generating a Warm Reset (Link Down Reset)” and “Generating and Processing Hot Resets (Training Resets)”.

System cross bar bridge master interface:

- Stops generating any new read and write requests.
- Waits for (and dumps) the completion of all responses from the application for every outstanding command.

The reset request signal is asserted in response to link reset requests assertion. It is the responsibility of the application software to stop all accesses to the slave SCB and DBI SCB ports. Once all accesses are stopped, software must write 1 to the `PCIE_RSCK_CTL.DBISLVDIS` bit to reset the PCIe core. The application software should implement the process shown in the ***Hot Reset Process*** figure.



LINK_REQ_RST_NOT ASSERTED
RSCK_STAT.WRMHTRST = 1 RSCKPHY_PCIERST_REQ (PCIe RESET REQUEST INTERRUPT) ASSERTED
STOP ALL ACCESSES TO THE SLAVE AND DBI SCB PORT. SET RSCKPHY_CTL.DBISLVDIS BIT WHEN IT IS DONE
All DM CORE; AXI MASTER, SLAVE AND DBI AND PHY NON-STICKY BITS AND REGISTERS ARE RESET
APP_CTL.LTSSMEN BIT CLEARED
PHY AND DM CORE OUT OF RESET? (RSCK_STAT[4:0] = 0)
NO
YES
WAIT MORE THAN 300 µS FOR CLOCKS TO BE STABLE
RESET THE STICKY BITS AND REGISTERS?
YES
SET RSCKPHY_CTL.PCIERES BIT (TRIGGER COLD RESET)
NO
INITIALIZE ALL NON STICKY REGISTERS1
GO TO INITIAL RESET PROCESS
IS THE APPLICATION READY TO RESTART THE LINK?
NO
YES
CLEAR RSCK_STAT.WRMHTRST BIT
SET APP_CTL.LTSSMEN BIT (START LINK TRAINING)
LINK UP? (APP_STAT.LINKUP = 1)
NO
YES
LINK READY2

NOTES:
1. Internal Address Translation and Embedded DMA registers have to be reprogrammed, and the custom configuration space setting must be re-written.
2. If configured as an EP, the application logic must wait for the PCIE_EP_STATCMD_n.BME bit to be set in order to access the PCIe address space.
If configured as a RC, the application logic must wait for the PCIE_RC_STATCMD_[n].MSE and the PCIE_RC_STATCMD_[n].IOE bits to be set in order to generate any MEM or I/O requests.

Figure 29-3: Hot Reset Process

The RSCKPHY block resets the PCIe core and PCIe_PHY modules.

Hot reset is similar to a warm reset. The upstream port requests the RSCKPHY to reset the core in response to a reset request sent by the downstream port. If the PCIe core is configured as a root complex port, the application may request the core to reset upstream devices by writing 1 (across the DBI port) to the `PCIE_APP_CTL.INITDSRST` bit. Writing one to this bit makes the APP module assert its APP_INIT_RST to the PCIe core.

In this case, the process involves the RC and EP devices on both sides of the PCIe link. Writing to the `PCIE_APP_CTL.INITDSRST` bit occurs in the RC device. The reset request is transmitted over the PCIe link to the EP device. Then the EP core starts the hot reset sequence.

The application can send new requests to the core only after verifying that the link is up again.

Application Module (APP)

The APP module implements the application-specific control and status logic and registers. Registers are mapped to the PCIe core configuration space. The SCB master accesses these registers across the DBI bus. When the port is configured as an End Point (EP), the remote PCIe device can also access registers across the PCIe link.

This module enables the application software running on the local core to handle PCIe interrupts and messages, and to access general link information. This entire module resides in the PCIe core and is reset when the PCIe core is reset.

APP Registers Access

Application registers are mapped to the upper DBI address or configuration space. Local cores can access these registers regardless of the PCIe core configuration. In EP mode, these registers can also be accessed from the PCIe wire using CFG requests or with BAR matched MEM requests.

The following limitations apply to SCB accesses:

- SCB transfers to the APP address space must be 32-bits wide. Errors are not reported when the size is not equal to 32 bits
- Byte access within a 32-bit double word is not supported
- Zero-byte writes should not be issued

Accessing the ADI-specific PCIe registers enables software to control PCIe features such as Message Signaled Interrupts (MSI) and power management messages, and to debug the PCIe core.

Interrupts When Configured as a PCIe End Point (EP)

The APP enables the application software to signal an interrupt to the RC over the PCIe serial link. Interrupts are asserted in one of two ways, as message signaled interrupts or as an INTA assert message. Accessing APP registers is enabled as long as the core is out of reset, regardless of the PCIe core configuration. The application software should not trigger an interrupt when the PCIe core is configured as RC.

The `PCIE_APP_STAT.MSIEN` `PCIE_APP_STAT.MSIEN` bit reflects the state of the MSI enable bit in the MSI control register. If `PCIE_APP_STAT.MSIEN` is set, the interrupt request is converted into an MSI message. The `PCIE_APP_STAT.OUTSTMSI` bit reflects the status of the previous Interrupt request when the `PCIE_APP_STAT.MSIEN` bit is set.

The `PCIE_APP_STAT.OUTSTMSI` bit signals that an MSI interrupt has been requested but the PCIe core has not accepted it.

The PCIe core grants the MSI request by asserting MSI_GRANT. The `PCIE_APP_STAT.OUTSTMSI` bit and `PCIE_APP_STAT.MSIGRANT` bits are cleared and set, respectively.

If `PCIE_APP_STAT.MSIEN` is cleared, the interrupt request is converted into a PCI legacy INTA assert message. The `PCIE_APP_STAT.OUTSTINTA` bit reflects the status of the previous interrupt request when `PCIE_APP_STAT.MSIEN` is cleared.

The `PCIE_APP_STAT.OUTSTINTA` bit signals that an INTA interrupt has been requested. The `PCIE_APP_STAT.OUTSTINTA` bit does not indicate that the RC device is processing the interrupt.

Interrupts when Configured as an RC

An MSI can be received in two ways. If the SCB MSI controller is enabled, MSIs do not reach the master SCB port and generate a PCIe interrupt instead. MSI status and control registers are part of the port logic registers. If the SCB MSI controller is disabled, MSIs reach the master SCB port as a write transaction to a predetermined address.

When configured as an RC, the PCIe core accepts Assert_INTx and Deassert_INTx messages from the downstream component and signal the APP module to trigger a PCIe interrupt. Incoming interrupts are registered in the `PCIE_APP_INTSTAT` (legacy interrupts status) register. The RC can also write directly to the APP registers to trigger an interrupt deassert message on the EP device.

Inbound Messages

Inbound messages are dropped and not forwarded to the master SCB interface. Instead, these messages are registered and a PCIe interrupt triggered to report the reception of a message. Message interrupts can be individually enabled by setting the appropriate interrupt enable bit in the `PCIE_APP_CTL` register. Each type of message has a corresponding bit in the `PCIE_APP_INTSTAT` register. These bits are set to signal the reception of a message and must be cleared to receive a new message of the same type.

Table 29-6: Inbound Messages Support

Message Type	Interrupt Enable **`PCIE_APP_CTL`** Register	Interrupt Status **`PCIE_APP_INTSTAT`** Register	Header 4th Double Word	Header 3rd Double Word	Requester ID (BDF)
Vendor	VENIEN	VENDMSG	APP_VNDR_MSG_HDR0	APP_VNDR_MSG_HDR1	APP_VNDR _MSG
Unlock	UNLKIEN	UNLK	Not Applicable	Not Applicable	APP_UNLK _MSG
Correctable Error	CORERRIEN	CORERR	Not Applicable	Not Applicable	APP_CORERR _MSG
Non Fatal Error	NFTLERRIEN	NFTLERR	Not Applicable	Not Applicable	APP_NFERR_MSG
Fatal Error	FERRIEN	FTLERR	Not Applicable	Not Applicable	APP_FERR _MSG
Power Management Event	PMEIEN	PME	Not Applicable	Not Applicable	APP_PMEVT_MSG
Power Management Acknowledge	PMTOACKIEN	PMTOACK	Not Applicable	Not Applicable	APP_PMACK_MSG
Power Management Turn Off	PMTOFFIEN	PMTOFF	Not Applicable	Not Applicable	APP_PMTOFF _MSG

Outbound Messages

In addition to MSI and PCI legacy interrupts, the transmission of power management turn-off or unlock messages is triggered by writing 1 to the corresponding `PCIE_APP_CTL.PMOFFREQ` or `PCIE_APP_CTL.UNLKREQ` bits. Power management enable messages are triggered by writing 1 to the `PCIE_RSCK_CTL.PMPMEREQ` bit. These two messages can be triggered when the PCIe core is configured as an RC. It is the responsibility of the application software to not start a new message until the previous message has been transmitted. The core does not return an acknowledgment or grant signal.

Diagnostics

APP also includes a diagnostic feature that enables the application software to inject LCRC and ECRC errors into the datapath of the core.

To inject an LCRC error, the application software must write a 1 to the `PCIE_APP_DIAGCTL.LCRCGEN` bit and initiate a packet transmission. To inject an ECRC error, the application software must write a 1 to the `PCIE_APP_DIAGCTL.ECRCERR` bit and initiate a packet transmission. The `PCIE_APP_DIAGSTAT.LCRC` bit is set when LCRC error packets are transmitted. The `PCIE_APP_DIAGSTAT.ECRC` bit is set when ECRC error packets are transmitted.

This handshake between control and status allows the application to control a specific packet injection with a CRC or ECRC error. Inverting the last bit of an LCRC or ECRC value generates the LCRC and ECRC errors.

Architectural Concepts

The following sections describe PCIe architectural features supporting register and address space accesses, configuration, and PHY control.

Register Accesses (PCIe Link and SCB DBI Port)

The PCIe registers are used to configure and control the PCIe port. The registers are accessed:

- across the DBI SCB interface or over the PCIe link using memory read or write requests, or
- using CFG requests when the DM core is configured as an EP

Accesses over the DBI SCB port must be 32 bits wide with addresses aligned to the data width (address [1:0] = 00).

These registers are divided into two groups. The first group of registers is implemented inside the PCIe core. It includes the PCI configuration header, PCI standard capability structures, PCIe extended capability structures and port logic. The second group of registers is implemented inside the APP module. It includes the application-specific registers.

PCIe link configuration transfers access the PCIe core registers when the registers address is less than 0xC00. It transfers using APP registers when the address is greater than or equal to 0xC00. The PCI configuration header, PCI standard capability structures, PCIe are PCIe core configuration registers specified by the PCI Express specification revision 3.0. The PCI Express 3.0 specification does not specify the port logic registers. These registers are accessed as memory-mapped registers or normally using CFG requests. A PCIe master can also access the PCIe registers using memory accesses to the local DBI SCB address space.

On-chip SCB masters have no concept of MEM, I/O, or CFG transfers. The PCIe core registers are mapped to the lower 4 KB addresses of the PCIe DBI region (DBI address [13:12] = 00). To enable writes to some read-only and shadow registers, PCIe registers are also mapped onto the 4 KB region (DBI write address [13:12] = 01). APP registers are mapped to the higher 4 KB addresses of the PCIe DBI region (address [13:12] = 1x).

SOC Address Space Accesses

The SCB master interface enables a remote PCIe device to read and write to a slave connected to the on-chip fabric. The ***PCIe Address Space*** table provides details on the address space for the processor.

Table 29-7: PCIe Address Space

Name	Base Address	End Address
PCIE-DBI*1	0x310B_8000	0x310B_AFFF
PCIE-RSCKPHY	0x310B_B000	0x310B_BFFF

*1 In the ADSP-SC58x, the PCIe and application registers are mapped as follows:

PCIe core registers 0x310B_8000 to 0x310B_8FFF

PCIe core write enabled registers 0x310B_9000 to 0x310B_9FFF

APP registers 0x310B_A000 to 0x310B_AFFF

System Cross Bar (SCB) Master Features

- Address bus width is 32-bit
- Data bus width is 32-bit
- Only incremental bursts are supported
- Maximum allowable burst length is 16 Beats
- Graceful flush and reset when link is down
- No exclusive access support
- Only posted writes are expected, therefore the master SCB port ignores the write response from the SCB slave.
- PCIe Advanced Error Reporting (AER) is not supported. AER is only supported with respect to the native PCIe core. Errors detected by the bridge are not reported as part of AER.
- Read requests above the 256 bytes limit are not supported

PCIe Address Space Accesses

The System Cross Bar slave interface enables a master on the on-chip fabric to read and write through the System Cross Bar bridge to a remote PCIe device. (In the ADSP-SC58x processor, the PCIe address space size is 256 MB mapped to addresses 0x5000_0000 to 0x5FFF_FFFF). The Internal Address Translation Unit (iATU) enables the mapping of these 256 MB to anywhere in the PCIe memory space.

Table 29-8: ADSP-SC58x System Component Memory Address Map

ADSP-SC58x System Component Memory Address Map			ARM View	System View	SHARC View			
			All Accesses	All Accesses	Data Accesses		Code Execution	
			Byte	Byte	Byte	NW	VISA	Non-VISA
Memory	Sub-division	Group range -->	0000_0000- FFFF_FFFF	2000_0000- FFFF_FFFF	2000_0000- FFF_FFFF	100_0000- 1FFF_FFFF	80_0000- FF_FFFF	40_0000- 7F_FFFF
PCIe Data	256MB	5000_0000	5007_FFFF	5000_0000	5007_FFFF	5000_0000	5007_FFFF	200_0000
		5008_0000	5017_FFFF	5008_0000	5017_FFFF	5008_0000	5017_FFFF	202_0000
		5018_0000	57FF_FFFF	5018_0000	57FF_FFFF	5018_0000	57FF_FFFF	206_0000
		5800_0000	5FFF_FFFF	5800_0000	5FFF_FFFF	5800_0000	5FFF_FFFF	N/A

SCB Slave Port Features

- Address bus width is 32-bit
- Data bus width is 32-bit
- Only incremental bursts are supported
- Maximum allowable burst length is 16 Beats
- Graceful flush and reset when link is down
- No exclusive access support
- No write interleaving with reads
- No write interleaving with writes of different AWIDs
- Outbound write burst with zero or partial (but contiguous) write strobes set is only supported for the first and last beats of a burst.
- All accesses are memory accesses (always posted)
- Write responses are generated by the PCIe core after the write request and are received
- PCIe Advanced Error Reporting (AER) is not supported. AER is only supported with respect to the native PCIe core. Errors detected by the bridge are not reported as part of AER.
- Read requests above the 256 Bytes limit are not supported

Message Signaled Interrupts (MSI) Controller

The SCB Interface block provides an optional programmable MSI controller to detect and terminate inbound MSI requests. Rather than propagating MSI MWr TLPs onto the SCB bus through the master interface; the MSI packets are captured and terminated in the SCB Interface block and an interrupt is signaled locally.

The MSI Controller is programmed with an address that is used as the system MSI address. When an inbound (received) MWr request is passed to the SCB interface and matches the specified MSI address, as well as the conditions specified for an MSI memory write request, then an MSI interrupt is detected. This memory write request is not driven onto the SCB master interface. The MSI Controller decodes the MSI MWr data payload to determine which endpoint device (EP) sent the MSI and which interrupt vector the MSI corresponds to. When a valid interrupt has been decoded, the `PCIE_APP_INTSTAT.MSI` bit is set. This bit remains set when any MSI interrupt is pending. It is only de-asserted when there is no MSI interrupt pending. The controller has a full set of MSI registers.

Features

- MSI interrupt controller only enabled in RC mode when the `PCIE_RSCK_CTL.DEVTYP` bit field =0x4. It is inactive in EP mode.
- The MSI interrupt controller provides support for up to eight EPs. Each supported EP has a set of interrupt enable, mask, and status registers.
- Guarantees correct SCB ordering with respect to other inbound posted writes by generating the MSI interrupt only after an SCB slave acknowledges responses of previous posted TLPs.
- A maximum of 32 interrupts are supported per EP.

MSI Request Detection Criteria

An MSI interrupt request is detected when the core receives a MWr TLP that satisfies the following conditions:

- Header attributes bits are zero. No snoop (NS) and relaxed ordering (RO) must be zero.
- Length field is 0x01 to indicate a payload of one double word.
- First byte enable (FBE) must be such that it is enabling the first two bytes (16 bits) of the payload.
- Last byte enable (LBE) is 4b0000.
- TLP address corresponds to systems chosen MSI address as programmed in the MSI Controller Address register (`PCIE_MSI_CTL_LADDR_[n]` and `PCIE_MSI_CTL_UADDR_[n]`). This register is not the MSI Lower 32 Bits Address Register which is part of the PCI Express MSI capability register structure In addition to these criteria the MWr must also pass the receive filtering rules.

The following table shows the MSI Controller software register map. The tables show the address's offset. The MSI Controller registers base address is 0x310B8700.

Table 29-9: MSI Controller Software Registers

Byte Offset	Name	Description	Reset	Access
+0x120	PCIE_MSI_CTL_LADDR_[n]	MSI Controller Address Register.	0x00000000	R/W
	PCIE_MSI_CTL_UADDR_[n]	MSI Controller Upper Address Register.	0x00000000	R/W

	PCIE_MSI_IMSK7_[n]	MSI Controller Interrupt#7 Mask Register.	0x00000000	R/W

Table 29-9: MSI Controller Software Registers (Continued)

Byte Offset	Name	Description	Reset	Access
	PCIE_MSI_ISTAT7_[n]	MSI Controller Interrupt#7 Status Register.	0x00000000	R/W
	PCIE_MSI_GPIO_IO_[n]	MSI Controller General Purpose IO Register.	0x00000000	R/W

Internal Address Translation (iATU)

The Address Translation Unit is used for mapping internal/external memory regions to external/internal memory regions. If an outbound transaction falls into one of the enabled iATU regions, TLP headers are created replacing the default values by the corresponding fields in the regions iATU registers. Without address translation, application addresses are passed straight through to the SCB master/slave interfaces.

Inbound Address Translation Features

- Match mode operation for MEM, I/O, CFG, and MSG TLPs. No translation for completions.
- Selectable BAR Match mode operation for I/O and MEM TLPs.
-
    - TLPs destined for PCIe or APP registers in an upstream port are not translated.
    - TLPs that are not error-free (ECRC, malformed and so on) are not translated.
- Programmable TLP header field matching.
- Up to 5 address regions programmable for location and size.
- Programmable enable/disable per region.
- Automatic FMT field translation between three DWORDS and four DWORDS for 64-bit addresses.
- Invert Address Matching mode to translate accesses outside of a successful address match.
- ECAM Configuration Shift mode to allow a 256 MB CFG1 space to be located anywhere in the 64-bit address space.
- The minimum region size is 64 kB.

Outbound Address Translation Features

- Address Match mode operation for MEM and I/O, CFG, and MSG TLPs. No translation for completions.
- Supports type translation through TLP type header field replacement for MEM or I/O types to MSG/CFG types.
    - Includes posted to non-posted translation (for example, MWr to CfgWr0)
    - No translation from completions
- Programmable TLP header field replacement.

- Up to 4 address regions programmable for location and size.
- Programmable enable/disable per region.
- Automatic FMT field translation between three DWORDS and four DWORDS for 64-bit addresses.
- Invert Address Matching mode to translate accesses outside of a successful address match.
- Response code which defines the completion status to return for accesses matching a region.
- The minimum region size is 64 kB.
- DMA bypass mode to allow TLPs which are initiated by the embedded DMA engine, to pass through the iATU un-translated.

Configuration and Programming

The ***iATU Configuration*** table provides the basic values for configuring the iATU.

Table 29-10: iATU Configuration Summary

Parameter	Value	Notes
Maximum Number of Outbound Address Translation Regions	4	Enables the SCB to PCIe address mapping. The PCIe space is defined as 256 Mbytes.
Maximum Number of Inbound Address Translation Regions	5	Enables PCIe to SCB address mapping. Assuming one region dedicated to System L2, one to L1s in multiprocessing space, one to MMRs, one to ASYNC memory and one DDR memory.
Minimum size of an Address Translation Region	64 Kbytes	

The following table shows the iATU software register map. The table shows the address's offset. The iATU registers Base Address is 0x310B8700.

Table 29-11: iATU Software Registers

Byte Offset	Name	Description	Reset	Access

Embedded DMA Controller (eDMA)

The Embedded DMA Controller implements single DMA write and DMA read channels. It can simultaneously perform the following types of memory transactions.

- DMA Write. Copy a block of data in local memory to remote memory over the PCIe link.
- DMA Read. Copy a block of data in remote memory to local memory over the SCB fabric.

Read and write transfers are processed at the same time, and in parallel with normal (non-DMA) traffic. When a DMA transfer completes or an error occurs, the DMA optionally interrupts the local CPU or sends an interrupt MWr (IMWr) to the remote CPU. The DMA is highly configurable and can be programmed using the local DBI or over the PCIe wire. The channels are named *read channel 0* and *write channel 0*. There are a set of registers associated with each DMA channel that are used for programming the DMA channel to create a correct set of header fields for any TLP that it generates. To access some of these registers (DMA channel context registers), indirect addressing through an index register needs to be used.

The following tables show the DMA software register map. The tables show the address's offset. The eDMA registers base address is 0x310B8700.

Table 29-12: DMA Software Registers

Byte Offset	Description
+0x278	Number of DMA Channels
+0x27C	DMA Write Engine Enable
+0x280	DMA Write Doorbell
+0x288	DMA Write Engine Channel Arbitration Weight Low
+0x28C	DMA Write Engine Channel Arbitration Weight High

+0x314	Not used (RsvdP).
+0x318	DMA Read Interrupt Mask
+0x31C	DMA Read Interrupt Clear
+0x320	Not used (RsvdP)
+0x324	DMA Read Error Status Low
+0x328	DMA Read Error Status High
up to +0x330	Not used (RsvdP)
+0x334	DMA Read Linked List Error Enable
+0x338	Not used (RsvdP)

Table 29-13: DMA Interrupt Registers (Continued)

Byte Offset	Description
+0x33C	DMA Read Done IMWr Address Low
+0x340	DMA Read Done IMWr Address High
+0x344	DMA Read Abort IMWr Address Low
+0x348	DMA Read Abort IMWr Address High
+0x34C	DMA Read Channels 1 and 0 IMWr Data
+0x350	DMA Read Channels 3 and 2 IMWr Data
+0x354	DMA Read Channels 5 and 4 IMWr Data
+0x358	DMA Read Channels 7 and 6 IMWr Data

Operations

The following sections provide information about PCIe operations including initialization, reading and writing memory and DMA.

Initialization

Initialization involves two main tasks:

- Configuring the PCIe port. This is accomplished by the application software immediately after taking the PCIe port out of reset.
- Initializing the PCIe. This is accomplished by the PCIe core as a result of the previous step or as a result of configuration writes received across the PCIe link.

Port Configuration

Clearing the `PCIE_RSCK_CTL.PCIERES` bit starts the reset exit sequence of the PCIe port. The `PCIE_RSCK_CTL.DEVTYP` bit determines if the PCIe core is configured as an End Point or a Root Complex port. The `PCIE_RSCK_CTL.DEVTYP` bit has to be stable before taking the PCIe core out of reset. The application software should check that all reset bits in the `PCIE_RSCK_STAT` register are cleared before accessing the local PCIe core and the APP registers. Initialize all relevant PCIe registers along with any address translation mapping before setting the `PCIE_APP_CTL.LTSSMEN` bit. Once asserted, the APP block and the LTSSM begin link training.

PCI configuration header space, PCIe standard and extended capability structures and port logic and application registers are accessed by a SOC fabric master over the DBI SCB port.

The PCIe specification requires components to enter the LTSSM detect state within 20 ms of the end of reset. The specification does not ask components on the same link to exit reset at the same time. The PCIe specification also notes that the only transition out of detect is polling. The LTSSM is kept in the detect state as long as the

`PCIE_APP_CTL.LTSSMEN` bit is low and transitions to polling when the `PCIE_APP_CTL.LTSSMEN` bit is set. Polling makes the PCIe link exit electrical idle and send TS1 ordered set.

If the PCIe core is configured as a RC, software must wait a minimum of 100 ms before sending a configuration request to the device immediately below that port. The PCIe specification allows downstream devices that receive a configuration request to respond with a configuration request retry status (CRS) completion status to terminate the request. The request stalls until the local initialization is completed and the local device is ready to communicate with the host.

BARs Disable Example

Five BAR registers are enabled by default. As a result of that the amount of memory space advertised by the EP may be too large. The following example shows how to disable all BARs except BAR0.

1. Verify that the `PCIE_MISC_CTL1_[n].RODBIWREN` bit is set (enables DBI write accesses to read only registers).
2. Clear the `PCIE_EP_BAR0_MASK[n].ENABLED`/`PCIE_EP_BAR1_MASK[n].ENABLED` bits (1 ≥ n ≥ 4) registers.

   The `PCIE_EP_BAR0_MASK[n].ENABLED`/`PCIE_EP_BAR1_MASK[n].ENABLED` bits are sticky and they do not need to be modified after a warm or hot reset event.

Using the iATU's address match mode, it is also possible to map multiple SCB slaves (for example L1, L2, SMMR, DMC0, DMC1) to a single BAR address range.

For example, to allocate various SCB slaves (L1, L2, SMMR, DMC0, DMC1) to BAR0 in the following way.

Table 29-14: iATU SCB Slave Address Mapping

iATU Region	SCB Slave	SCB Slave Start Address	Size Required	BAR0 address range
0	L1	0x380000	64K bytes	0x10000000-0x1000FFFF
1	L2	0x20080000	256K bytes	0x10010000-0x1004FFFF
2	SMMR	0x31024180	64K bytes	0x10050000-0x1005FFFF
3	DMC0	0x80000000	63M bytes	0x10200000-0x140FFFFF
4	DMC1	0xC0000000	63M bytes	0x14100000-0x17FFFFFF

The following example code can be used to configure the iATU to achieve the address mapping shown in the table.

```
//L1 iATU map
*pREG_PCIE0_IATU_VWPRT_0          =    0x80000000;
*pREG_PCIE0_IATU_LBADDR_INB_0     = 0x10000000;
*pREG_PCIE0_IATU_UBADDR_INB_0     = 0x0;
*pREG_PCIE0_IATU_LMTADDR_OUTB_0   = 0x1000FFFF;
*pREG_PCIE0_IATU_LTADDR_INB_0     =    0x380000|0x28800000;
*pREG_PCIE0_IATU_UTADDR_INB_0     =    0x0;
*pREG_PCIE0_IATU_CTL1_INB_0       =    0x0;
```

```
*pREG_PCIE0_IATU_CTL2_INB_0        =    0x80000000;

//L2 iATU map
*pREG_PCIE0_IATU_VWPRT_0           =    0x80000001;
*pREG_PCIE0_IATU_LBADDR_INB_0      = 0x10010000;
*pREG_PCIE0_IATU_UBADDR_INB_0      = 0x0;
*pREG_PCIE0_IATU_LMTADDR_OUTB_0    = 0x1004FFFF;
*pREG_PCIE0_IATU_LTADDR_INB_0      =    0x20080000;
*pREG_PCIE0_IATU_UTADDR_INB_0      =    0x0;
*pREG_PCIE0_IATU_CTL1_INB_0        =    0x0;
*pREG_PCIE0_IATU_CTL2_INB_0        =    0x80000000;

//SMMR iATU map
*pREG_PCIE0_IATU_VWPRT_0           =    0x80000002;
*pREG_PCIE0_IATU_LBADDR_INB_0      = 0x10050000;
*pREG_PCIE0_IATU_UBADDR_INB_0      = 0x0;
*pREG_PCIE0_IATU_LMTADDR_OUTB_0    = 0x1005FFFF;
*pREG_PCIE0_IATU_LTADDR_INB_0      =    0x31024180;
*pREG_PCIE0_IATU_UTADDR_INB_0      =    0x0;
*pREG_PCIE0_IATU_CTL1_INB_0        =    0x0;
*pREG_PCIE0_IATU_CTL2_INB_0        =    0x80000000;

//DMC0 iATU map
*pREG_PCIE0_IATU_VWPRT_0           =    0x80000003;
*pREG_PCIE0_IATU_LBADDR_INB_0      = 0x10200000;
*pREG_PCIE0_IATU_UBADDR_INB_0      = 0x0;
*pREG_PCIE0_IATU_LMTADDR_OUTB_0    = 0x140FFFFF;
*pREG_PCIE0_IATU_LTADDR_INB_0      =    0x80000000;
*pREG_PCIE0_IATU_UTADDR_INB_0      =    0x0;
*pREG_PCIE0_IATU_CTL1_INB_0        =    0x0;
*pREG_PCIE0_IATU_CTL2_INB_0        =    0x80000000;

//DMC1 iATU map
*pREG_PCIE0_IATU_VWPRT_0           =    0x80000004;
*pREG_PCIE0_IATU_LBADDR_INB_0      = 0x14100000;
*pREG_PCIE0_IATU_UBADDR_INB_0      = 0x0;
*pREG_PCIE0_IATU_LMTADDR_OUTB_0    = 0x17FFFFFF;
*pREG_PCIE0_IATU_LTADDR_INB_0      =    0xC0000000;
*pREG_PCIE0_IATU_UTADDR_INB_0      =    0x0;
*pREG_PCIE0_IATU_CTL1_INB_0        =    0x0;
*pREG_PCIE0_IATU_CTL2_INB_0        =    0x80000000;
```

Link Training and Establishment

The PCIe core implements the LTSSM function according to the *PCI Express Base 3.0 Specification*, revision 1.0.

Downstream Device Enumeration by Root Complex

Before issuing any request to the device across the PCIe link, the application software must initialize the iATU register to correctly translate the SCB read or write transactions into PCIe TLPs. All PCIe configuration registers may be accessed by an SOC fabric master over the DBI SCB.

When the PHY link is up and running the `PCIE_APP_STAT.LNKUP` bit is set.

The PCIe software:

- Scans the PCIe fabric to discover its topology and learn how the fabric is populated
- Programs the base and limit registers of switch ports to reflect the BAR range of the devices enumerated downstream
- Programs the BARs of endpoints

Host Software Writes to Bus Master Enable (BME), Memory Space Enable (MSE), and I/O Space Enable (ISE) Bits in PCI-Compatible Command Register

End Point

The EP application logic must not generate any MEM or I/O requests until the host software has set the `PCIE_EP_STATCMD_[n].BME` bit in the PCI-compatible command register. This bit is not checked before transmitting requests. Therefore the application software must monitor the status of the `PCIE_EP_STATCMD_[n].BME` bit by reading the register over the DBI SCB interface.

Root Complex

The RC application logic must not generate any MEM or I/O requests until the host has enabled the Memory Space Enable bit (`PCIE_RC_STATCMD_[n].MSE`) and the I/O Space Enable bits (`PCIE_RC_STATCMD_[n].IOE`) in the PCI-compatible command register. The RC port core does not check these bits before transmitting requests. Therefore the application can monitor the status of these bits by reading the register over the DBI SCB.

Configuration for Memory Read and Write Transactions

The following sections provides procedures for configuring memory reads and writes.

NOTE: Do not configure the IATU when inbound or outbound transactions are in progress. The ***Inbound Transactions*** and ***Outbound Transactions*** figures show the respective data transfers.

Inbound Programming Example (BAR Match Mode)

Define Inbound Region n (4 ≥ n ≥ 0) as the memory region matching BAR4 mapping to 0x8000 0000 in the processor's address space using the following equation. In BAR Match mode the region size is set by the BAR mask of the matched BAR.

Refer to IATU Register section and the ***iATU Address Region Mapping: Inbound 64-bit (BAR Match Mode)*** figure below. Set up the `PCIE_IATU_VWPRT_[n]` register to region n to access the IATU configuration registers of this region.

1. Configure the Index register to the set inbound region n as the current region.
2. Write n to the `PCIE_IATU_VWPRT_[n].REGNINDX` bit field and 1 to the `PCIE_IATU_VWPRT_[n].REGNDIR` bit.

3. Configure the target address registers.
4. Write 0x8000 0000 to the `PCIE_IATU_LTADDR_INB_[n]` register to set the lower target address.
5. Write 0x0000 0000 to the `PCIE_IATU_UTADDR_INB_[n]` register to set the upper target address.
6. Configure the region through the region control 1 inbound register.
7. Write 0x0000 0000 to the `PCIE_IATU_CTL1_INB_[n]` register to define the type of the region to be MEM.
8. Enable the region for BAR match mode.
9. Write 0xC000 0400 to the `PCIE_IATU_CTL2_INB_[n]` register to enable the region for BAR match for BAR#4.

NOTE:
1. Setting the destination address for the BAR match is tied closely to the BAR mask. For example BAR0 has a BAR mask of 0xF0000000 meaning it can be assigned any address with bits [31:28] between 0x1 and 0xF and bits [27:0] always 0x0000000. The BAR match address translation mode also uses this mask. PCIe's target address should provide the correct [27:0] bits

Figure 29-6: iATU Address Region Mapping: Inbound 64-bit (BAR Match Mode)

Inbound Programming Example (Address Match Mode)

Define Inbound Region n (4 ≥ n ≥ 0) as MEM region matching TLPs with address in the range (see also the ***iATU Address Region Mapping: 64-bit Address Outbound and Inbound (Address Match Mode*** figure):

- From {PCIE_MSTARTH, PCIE_MSTARTHL} to {PCIE_MSTARTH, PCIE_MSTARTHL} + 0xFF_FFFF
- SOC MEM Region
- From 0x8000_0000 to 0x80FF_FFFF

Configure the `PCIE_IATU_VWPRT_[n]` register to region n to access the IATU configuration registers of this region.

1. Configure the `PCIE_IATU_VWPRT_[n].REGNINDX`Index Register to set inbound region n as the current region.
2. Write n to the `PCIE_IATU_VWPRT_[n].REGNINDX` bit field and write 1 to the `PCIE_IATU_VWPRT_[n].REGNDIR` bit.
3. Setup the region base and limit address registers.
4. Write PCIE_MSTARTL to the `PCIE_IATU_LBADDR_INB_[n]` register to set the lower base address.
5. Write PCIE_MSTARTH to the `PCIE_IATU_UBADDR_INB_[n]` register to set the upper base address.
6. Write 0xFF_FFFF to the `PCIE_IATU_LMTADDR_INB_[n]` register to set the limit address.
7. Setup the target address registers.
8. Write 0x8000_0000 to the `PCIE_IATU_LTADDR_INB_[n]` register to set the lower target address.
9. Write 0x0000_0000 `PCIE_IATU_LTADDR_INB_[n]` register to set the upper target address
10. Configure the region through the region control 1 register.
11. Write 0x0000_0000 to the `PCIE_IATU_CTL1_INB_[n]` register to define the type of the region to be MEM.
12. Enable the region.
13. Write 0x8000_0000 to the `PCIE_IATU_CTL1_INB_[n]` register to enable the region.

Figure 29-7: iATU Address Region Mapping: 64-bit Address Outbound and Inbound (Address Match Mode)

Outbound Programming Example

Define Outbound Region n (3 ≥ n ≥ 0) as:

- SOC MEM Region

  - From MSTART (0x5000_0000 ≥ MSTART ≥ 0x5FFF_0000)
  - To MEND (0x5000_FFFF ≥ MSTART ≥ 0x5FFF_FFFF)
- Mapped to PCIe IO Space
  - From PCIE_MSTART
  - To PCIE_MEND

Refer to iATU Register section. Set up the port logic registers (`PCIE_IATU_VWPRT_[n]`) to region n to access the iATU configuration registers of this region.

1. Setup the Index Register to set outbound region n as the current region.
2. Write n to the `PCIE_IATU_VWPRT_[n].REGNINDX` bit field and write 1 to the `PCIE_IATU_VWPRT_[n].REGNDIR` bit.
3. Setup the region base and limit address registers.
4. Write MSTART to the `PCIE_IATU_LBADDR_OUTB_[n]` register to set the lower base address.
5. Write 0x0000 0000 to the `PCIE_IATU_LBADDR_OUTB_[n]` register to set the upper base address.
6. Write MEND to the `PCIE_IATU_LMTADDR_OUTB_[n]` register to set the limit address.
7. Setup the target address registers.
8. Write PCIE_MSTART to the `PCIE_IATU_LTADDR_OUTB_[n]` register to set the lower target address.
9. Write 0x0000 0000 to the `PCIE_IATU_UTADDR_OUTB_[n]` register to set the upper target address.
10. Configure the region through the region control 1 register.
11. Write 0x0000 0002 to the `PCIE_IATU_CTL1_OUTB_[n]` register to define the region type as I/O.
12. Enable the region.
13. Write 0x8000 0000 to the `PCIE_IATU_CTL2_OUTB_[n]` register to enable the region.

Non DMA Transfers

Non DMA transfers are transfers triggered by a local System Cross Bar fabric master (transmit) or by a remote partner (receive).

Transmit Transaction Layer Packets (TLP)

Data is transmitted to a PCIe link partner by writing to the slave system cross bar port. Data is read from a PCIe partner by reading from the slave SCB port. The slave system cross bar buses are directly connected to PCIe core's corresponding inputs and outputs. The iATU is used to map outbound system cross bar transactions from different system cross bar address regions to PCIe address regions and to determine their TLP types.

The address field of each request is checked to see if it falls into any of the enabled regions. When an address match is found, the TLP address field, TYPE, TLP digest field present (TD) and attributes (ATTR) header fields are replaced with the corresponding fields in the `PCIE_IATU_CTL1_OUTB_[n]` register.

Receive Transaction Layer Packets (TLP)

The writes addresses of the PCIe partners are translated into master SCB write transactions to the SOC address space. PCIe partners' reads from the processor's assigned address are translated into master system cross bar read transactions from SOC address space. The master system cross bar buses are directly connected to PCIe core corresponding inputs and outputs.

Inbound address translation operates in one of two modes as determined by the `PCIE_IATU_CTL2_INB_[n].MAT` bit field.

- Address Match Mode. Normally used by a RC, but may be useful in mapping sections of an EP memory region into noncontiguous sections. The address field of each request TLP is checked to see if it falls into any of the enabled address regions. When an address match is found the TLP address is modified.
- BAR Match Mode. Normally used by an EP. Looking for an address match is a two step process.
    1. The standard internal PCI Express BAR matching mechanism checks if the address field of any MEM and IO request TLP falls into any address region defined by the enabled BAR address and masks.
    2. When a matched BAR is found, the iATU compares the BAR ID to the `PCIE_IATU_CTL2_INB_[n].BARNUM` bit field for all enabled regions.

The `PCIE_APP_STAT.RXQNEMPTY` bit signals that the receive queues are not empty.

DMA Transfers

These are transfers triggered by the DMA write channel (local to remote memory) or by the DMA read channel (remote to local memory).

The presence of the DMA controller does not affect:

- Normal filtering rules for inbound TLPs (for example, BAR checking in end points)
- The operation of any internal or external address translation. To prevent the iATU from translating inbound or outbound requests that are generated by the internal DMA module one of the following approaches can be implemented:
    - Ensure that the combination of DMA channel programming and iATU control register programming, causes no translation of DMA traffic to occur in the iATU.
    - Activate the DMA bypass mode to allow request TLPs which are initiated by the DMA controller to pass through the iATU untranslated.

Initialize all registers except `PCIE_DMA_VWPRT_SEL_[n]`. Initialize reserved bits to 0x0.

Read Transfer

The DMA issues a read request to the PCIe link (1 and 2 in the ***DMA Read Transfers*** figure). When the read data is received (3 in the figure), the DMA issues a write request to the local memory (4 and 5 in the figure). Once the write completes, the local memory issues a write response to the PCIe core (6 in the figure).

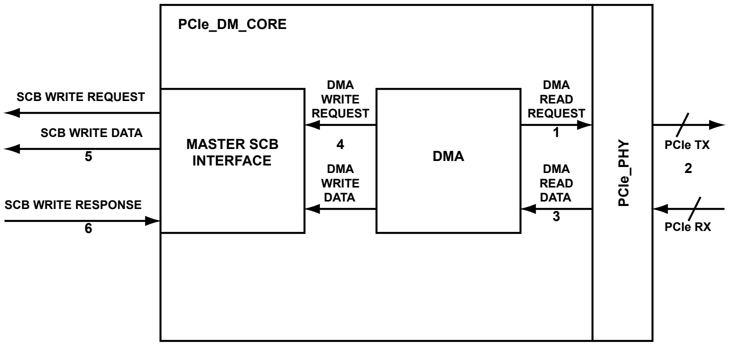

Figure 29-8: DMA Read Transfers

To access the read channel registers, set the `PCIE_DMA_VWPRT_SEL_[n].DIR` bit and clear the `PCIE_DMA_VWPRT_SEL_[n].NUM` bit field.

The address of the remote buffer is programmed using the `PCIE_DMARD_SAR_LO_[n]` register and the address of the local buffer is programmed using the `PCIE_DMARD_DAR_LO_[n]` register.

The DMA transfer size is programmed using the `PCIE_DMARD_XFRSZ_[n]` register. The DMA decrements the value in this register as the DMA transfer progresses. This register can be read at any time to determine the number of bytes remaining to be transferred. When all bytes are successfully transferred, the result is zero. The DMA transfer size can be of any value from one byte, up to a maximum of 4 GB.

Program bits [31:12] in the `PCIE_DMARD_CTL1_[n]` register to set the TC, TD, RO, NS, AT and FN TLP header fields for any TLP it generates. Once all the DMA controller registers are programmed, a DMA read transfer is started by writing 0x0 to the `PCIE_DMARD_DRBL_[n].NUM` bit field.

The normal end of a DMA read transfer is detected by any of the following methods:

- The assertion of the RSCKPHY_EDMA_INT interrupt and setting the `PCIE_DMARD_IMSK_[n].DONE` bit.
- The reception of a Done remote interrupt
- When the CS (Channel Status) field in the `PCIE_DMARD_CTL1_[n].CS` is stopped, and the `PCIE_DMARD_XFRSZ_[n]` register = 0x0.
- Polling the `PCIE_DMARD_ISTAT_[n]` register.

The abnormal end of a DMA read transfer is detected by any of the following methods:

- The assertion of a RSCKPHY_EDMA_INT interrupt and setting the `PCIE_DMARD_ISTAT_[n].ABRT` bit.

- The reception of an abort remote interrupt
- When the `PCIE_DMARD_CTL1_[n].CS` (channel status) field halts. The `PCIE_DMARD_XFRSZ_[n]` register indicates the remaining number bytes to be transferred except when there is a system cross bar write error.
- Polling the `PCIE_DMARD_ISTAT_[n]` register.

The application software can stop DMA read transfers by writing to the `PCIE_DMARD_DRBL_[n].STOP` bit. This action also sets the `PCIE_DMARD_ISTAT_[n].ABRT` bit.

Write Transfer

The DMA issues a read request to the local memory (1 and 2 in the ***DMA Write Transfers*** figure). When the read data is received (3 and 4 in the figure), the DMA sends the data to the PCIe link (5 and 6 in the figure).

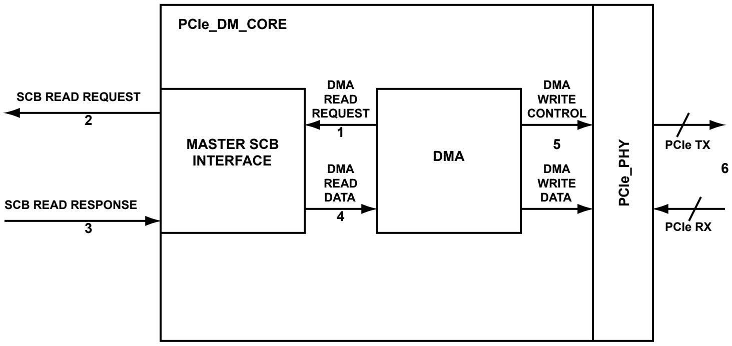

Figure 29-9: DMA Write Transfers

To access the write channel registers, clear the `PCIE_DMA_VWPRT_SEL_[n].DIR` bit and the `PCIE_DMA_VWPRT_SEL_[n].NUM` bit field.

The address of the local buffer is programmed using the DMASAR_WR_LOn register and the address of the remote buffer is programmed using the `PCIE_DMAWR_DAR_LO_[n]` register.

The DMA transfer size is programmed using the `PCIE_DMAWR_XFRSZ_0[n]` register. The DMA decrements the value in this register as the DMA transfer progresses. This register can be read at any time to determine the number of bytes remaining to be transferred. When all bytes are successfully transferred, the result is zero. The DMA transfer size can be of any value from one byte, up to a maximum of 4 GB. Program bits [31:12] in the `PCIE_DMAWR_CTL1_[n]` register to set the TC, TD, RO, NS, AT and FN TLP header fields for any TLP it generates.

Once all the DMA controller registers are programmed, a DMA write transfer is started by writing 0x0 to the `PCIE_DMAWR_DRBL_[n].NUM` bit field.

The normal end of a DMA write transfer is detected by any of the following methods:

- The assertion of RSCKPHY_EDMA_INT interrupt and setting the `PCIE_DMAWR_IMSK_[n].DONE` bit.
- The reception of a DONE remote interrupt.

- When the `PCIE_DMAWR_CTL1_[n].CS` bit field (Channel Status) is stopped and the `PCIE_DMAWR_XFRSZ_0[n]` register =0x0
- Polling the `PCIE_DMAWR_ISTAT_[n]` register.

The abnormal end of a DMA write transfer is detected by any of the following methods:

- The RSCKPHY_EDMA_INT interrupt is asserted and the`PCIE_DMAWR_IMSK_[n].ABRT` bit is set.
- The reception of a ABORT remote interrupt.
- When the `PCIE_DMAWR_CTL1_[n].CS` bit field halts. The `PCIE_DMAWR_XFRSZ_0[n]` register indicates the remaining number of bytes to be transferred.
- Polling the `PCIE_DMAWR_ISTAT_[n]` register.

The application software can stop DMA write transfers by writing to the `PCIE_DMARD_DRBL_[n].STOP` bit. This action also sets the `PCIE_DMAWR_ISTAT_[n].ABRT` bit.

Flow Control

The flow control mechanism is divided into two phases: initialization and update. The PCIe core automatically performs both of these phases with minimal support required from the application.

EP to EP Transactions

An EP does not know the actual address of other EPs in the PCIe system. To enable transfers between EPs or between an EP and other memory-mapped components, the iATU needs to be programmed. To do this the PCIe upstream device can access the iATU directly over the PCIe link or can “ask” an EP local master to do so.

Gen2 5.0 GT/s Operation

The PCIe core supports all non-optional Gen2 5.0 GT/s features defined in the PCI Express Base 3.0 Specification, revision 1.0. The interface between the core and the PHY is compliant with the PIPE Specification for PCI Express, Version 4.0. The number of active symbols on the PIPE interface is constant and the frequency of the core doubles each time as the core transitions from the Gen1 to the Gen2 rate.

Power Management

The power management (PM) state of a PCIe link is determined by the D-state of the upstream port (USP, PCIe core configured as an EP). Power is managed in two ways, by software running on the host or locally by the Active State Power Management (ASPM) hardware.

Power Management Software

The Power Management Control and Status registers should be set to the desired default values, the NO_SOFT_RST should be set as software Reset is not supported. The PM software running on the upstream device can direct the PCIe core to enter any of the D1 or D3 low-power states. It does this by writing to the Power Management Control and Status Register (PMCSR) in the PCI-PM capability structure. Link states L0 and L1 are not visible to the PM software and are derived from PM D-state connected to the link. The action of changing the D-state in the PMCSR indirectly causes the USP to change the link power state. The L1 state is entered when the USP on a link is programmed to a D-state other than D0.

The following table shows the relationship between Device State (Dx), Link State (Sx) and PHY state (Px) and summarizes the state of clock and power sources for the supported Power States.

Table 29-15: Device State (Dx), Link State (Sx) and PHY state (Px)

D-State	Link State Change Trigger[*1]	Permissible Quiescent[*2] Link States	Active Power Supplies[*3]	Active Clock Supplies[*4]	PIPE_CLK CORE_CLK	PHY State
D0$_{\text{unitialized}}$	n/a	L0	VDDINT	PCIeCLK SYSCLK	ON	P0, P0S
D0$_{\text{active}}$	ASPM[*5]	L0				
		L0S				
		L1				P1
D1, D3$_{\text{hot}}$	PCI-PM[*6]	L1				

*1 The ***Port Type Link States*** table shows what link state each port type can trigger.

*2 V_{DDINT} is connected to the PCIe core V_{AUX} and V_{MAIN}. V_{AUX} is the power supply for the Power Management Controller (PMC) and Configuration Dependent Module (CDM) modules. V_{MAIN} is the power supply for the rest of the core.

*3 V_{DDINT} is connected to the PCIe core V_{AUX} and V_{MAIN}. V_{AUX} is the power supply for the Power Management Controller (PMC) and Configuration Dependent Module (CDM) modules. V_{MAIN} is the power supply for the rest of the core.

*4 The PCIeCLK or REFCLK is connected to the PCIe PHY which is the platform reference clock (REFCLK) for the PHY TX PLL. The platform low-power clock (CLK_RST's AUXCLK input) is derived from *SYSCLK*.

*5 ASPM is the Active State Power Management (Autonomous Link Power Management) hardware.

*6 By executing a PMCSR write. PMCSR is the power management control and status register (`PCIE_PMT_CTLSTAT_[n]`) in the PCI Compatible Power Management structure (PCI-PM).

Table 29-16: Port Type Link States

Port	Triggers L0/L0s Entry	Triggers L1 Entry
USP	Yes	Yes, on any of these triggers: Software programs non-D0 state (PCI-PM) USP's idle timer expires (ASPM)
DSP	No	Indirectly by writing non-D0 value to PMCSR of the USP link partner.

If the USP device needs to transition back to D0 it can send a PME message to the host. The PM software can put the USP into D0 by writing to the Power Management Control and Status Register (`PCIE_PMT_CTLSTAT_[n]`) in the PCI-PM capability structure.

Active State Power Management (ASPM)

ASPM is enabled through the ASPM control field in the link control register (`PCIE_LNK_CAPB_[n].ASPM`). When the USP is in L0 and detects idle on the link for a specific amount of time (determined by the `PCIE_ACK_ASPMCTL_[n].FREQ` and `PCIE_LNK_CAPB_[n].L0SELAT` L0s entrance latency field2 in the (Ack Frequency and L0-L1 ASPM Control Register), it automatically transitions the link to the L0 or L1 power state. Each link direction (transmit and receive) is processed separately. The core exits L0s when there is traffic waiting to be sent.

Completion Timeout Ranges

Timeout ranges are supported as defined in the PCI Express Base 3.0 Specification, revision 1.0.

PHY Registers Access

PHY registers can be accessed in the following ways:

- As memory-mapped registers across the ADI_RCCKPHY and PHY parallel interface
- Across the JTAG port

RCCKPHY

See Reset Clock and PHY Control Module (RSCKPHY).

Event Control

The following sections provide information about PCIe errors, messages, and interrupts.

Error Handling and Debug

The following sections provide information on errors and debugging the PCIe module.

System Cross Bar Master Interface to PCIe Link Error Mapping

PCIe masters can access the ADSP-SC58x address space across the master system cross bar interface. The system cross bar slave responds to posted or non-posted requests issuing write or read response transactions.

Memory read transactions are non-posted and require the PCIe port to create a completion packet, including error information if needed.

Error Mapping:

- System cross bar SLVERR Slave Error, means that the slave wishes to return an error condition to the master is mapped to a CA (Completer Abort) error.
- System cross bar DECERR Decode Error, means that there is no slave at the transaction address is mapped to an UR (Unsupported Request) error.

Memory writes are posted transactions and do not require a completion packet to be generated. The application can send a message to the root to inform the PCIe software about the error, but the error is not seen by the requester. The system cross bar master interface does not forward information about the requester to the target of the write transaction, the write ID is always 0. The write response is dropped by the system cross bar bridge and not forwarded to the PCIe link.

PCIe Link Error Mapping to SCB Slave Interface

PCIe slaves can access PCIe's address space across the slave system cross bar interface. All accesses are treated as memory ones. System cross bar slave accesses can be used to create different type of packets if the iATU is enabled and configured as needed. The PCIe slave responds to non-posted requests (read requests) sending completion packets. Completion packets including error information, if needed.

Error mapping:

- PCIe completion time-out is mapped to system cross bar DECERR (decode error).
- ECRC error is mapped to system cross bar SLVERR (slave error).
- Poisoned error (data in TLP is known to be corrupted) is mapped to system cross bar SLVERR
- CA (completer abort) error is mapped to system cross bar SLVERR
- CRS (configuration request retry status) error is mapped to system cross bar SLVERR
- UR (unsupported request) is mapped to system cross bar DECERR

Completion packets are not generated for PCIe posted transactions, therefore responses to slave memory write transactions are generated locally.

Messages

Messages are generated from memory write transactions using the Internal Address Translation Unit. To ensure that the iATU does not translate MSI or power management messages, the third and fourth double words of these messages do not match any programmed iATU address region.

When there is a successful address match on an outbound MEM TLP, and the translated TLP type field is MSG, then the message code field of the TLP is set to the value in the *Message Code* field of the `PCIE_IATU_CTL2_OUTB_[n]` register. A MWr (memory write transaction) with an effective length of 0" (taking into account SLV_AWSTRB) is converted to Msg and all other MWr TLPs are converted to MsgD.

PCIe Interrupts

The following sections provide information on interrupts associated with the PCIe module.

PCIe Interrupt Request

The following interrupts can trigger a PCIe interrupt request:

- Message signaled interrupt

- Legacy interrupts
- Incoming message interrupts
- Link up
- Receive overflow

These interrupts can be individually enabled by the application software, as needed. To determine the source of the interrupt, read the `PCIE_APP_INTSTAT` register and write a 1 to the interrupt status bit to clear it.

Configuration

To enable end points to generate MSIs, MSI capabilities register `PCIE_MSI_CAPB_NPTR_[n]`,`PCIE_MSI_CAPB_OFF4_[n]`, `PCIE_MSI_CAPB_OFF8_[n]` and `PCIE_MSI_CAPB_OFFC_[n]` (See section 10) need to be programmed.

The local core or the PCIe host configures the MSI interrupt controller.

- The local core or the PCIe host programs the common MSI address used for the EPs into the `PCIE_MSI_CTL_LADDR_[n]` and `PCIE_MSI_CTL_UADDR_[n]` registers.
- The PCIe host reads the MSI capability of each EP to determine the number of vectors enabled in each EP and use this information to program the interrupt enable registers in the MSI interrupt controller.
- The local core or the PCIe host programs all interrupt enable registers (for example `PCIE_MSI_IEN0_[n]`) and all interrupt mask registers (for example `PCIE_MSI_IMSK0_[n]`).

MSI Generation by the EP Local Core

The local EP core provides the following.

- Verify that the `PCIE_APP_STAT.OUTSTMSI` bit is cleared.
- Write 1 to the `PCIE_APP_CTL.INTREQ` bit.
- If the PCIe core is multiple message capable, set the `PCIE_APP_CTL.MSIVECT` bit field to identify the MSI source.
- Poll the `PCIE_APP_STAT.MSIGRANT` bit to check if the MSI request has been granted.
- Clear the `PCIE_APP_STAT.MSIGRANT` bit before issuing a new MSI request.

MSI Reception by the RC port

MSI packets are captured and terminated in the system cross bar bridge, the packet's payload is decoded, the corresponding interrupt status register (for example `PCIE_MSI_ISTAT0_[n]`) is updated and an interrupt is signaled asserting the PCIe interrupt request. The interrupt routine running on the local RC core should:

- Read the interrupt status registers if MSIs from EPn are enabled.
- Write to the interrupt status registers to clear the bit that triggered the interrupt.

Configuration

Only INTA can be generated. To enable end points to generate INTA, disable MSIs `PCIE_MSI_CAPB_NPTR_[n]` bit 16 =0). The local core or any other system cross bar master in the RC enables each specific interrupt.

- The local core or any other system cross bar master sets the `PCIE_APP_CTL.AIEN`, `PCIE_APP_CTL.BIEN`, `PCIE_APP_CTL.CIEN` or `PCIE_APP_CTL.DIEN` bits.

Interrupt Assert Generation by the EP Local Core (INTA only)

The local EP core should:

- Verify that the `PCIE_APP_STAT.OUTSTMSI` bit is cleared
- Write 1 to the `PCIE_APP_CTL.INTREQ` bit

Interrupt De-assert Generation by the EP Local Core (INTA only)

The application software or any system cross bar master can trigger an INTA deassert message and clear the `PCIE_APP_STAT.OUTSTINTA` bit. It should:

- Write 1 to the `PCIE_APP_CTL.INTACLR` bit. Two cases can be considered:
  - The device that receives the interrupt understands a sequence of assert INTA message and deassert INTA message as an interrupt pulse that has to be serviced if enabled.
  - The device that receives the interrupt needs to acknowledge its reception to the interrupt source to clear it. In this case the interrupt routine on the PCIe Host can either write to the EP's `PCIE_APP_CTL` register or send a message (write) to the EP to acknowledge the reception of the interrupt.

Writing to the `PCIE_APP_CTL.INTACLR` bit when the `PCIE_APP_STAT.MSIEN` bit is set has no effect.

Interrupt Reception by the RC Port (INTA, INTB, INTC or INTD)

The reception of an enabled interrupt sets the corresponding bit in the `PCIE_APP_INTSTAT` register. These interrupts are treated as level. The interrupt service routine should:

- Test the `PCIE_APP_INTSTAT.INTA`, `PCIE_APP_INTSTAT.INTB`, `PCIE_APP_INTSTAT.INTC` and `PCIE_APP_INTSTAT.INTD` bits to determine which interrupt to service.
- If necessary, write to the EP to acknowledge that the interrupt is being serviced. The interrupt service routine can only clear the above interrupt bits by writing to EP's APP_CTL register.
- Wait for the INTiASSTD to clear to exit.

Incoming Messages Interrupts

The following Inbound messages trigger a PCIe interrupt:

- Vendor Defined
- Unlock Transaction (RC Mode)
- Error Signaling (EP Mode)
    - Correctable
    - Non-Fatal
    - Fatal
- Power Management
    - Event (RC Mode)
    - Turn Off Acknowledge (RC Mode)
    - Turn Off (EP Mode)

Configuration

Enabling interrupts that cannot be received in EP or RC modes is meaningless.

The local core or any other system cross bar master in the RC enables each specific interrupt.

- Write 1 to the appropriate interrupt enable bit in the `PCIE_APP_CTL` register.

Interrupt Reception

Applies to the reception of an enabled interrupt. The corresponding bit in the `PCIE_APP_INTSTAT` register is set. The interrupt routine should:

- Test the `PCIE_APP_INTSTAT.CORERR`, `PCIE_APP_INTSTAT.FTLERR`, `PCIE_APP_INTSTAT.NFTLERR`, `PCIE_APP_INTSTAT.PME` `PCIE_APP_INTSTAT.PMTOACK`, `PCIE_APP_INTSTAT.PMTOFF`, `PCIE_APP_INTSTAT.UNLK`, and `PCIE_APP_INTSTAT.VENDMSG` bits to determine which interrupt to serve.
- Read the corresponding APP_<message name>_MSG registers (xxxMSGRQID) to discover the source of the xxx message.
- If a Vendor message is received, reading the `PCIE_APP_VNDR_MSG_HDR1` and `PCIE_APP_VNDR_MSG_HDR0` registers provide
- Once the interrupt is serviced, clear the status bit by writing 1 to the corresponding bit in the `PCIE_APP_INTSTAT` register.

Link Up- and Receive-Overflow Interrupts

These interrupts can be enabled in both EP as well as RC modes of operation.

Configuration

The Local core or any other system cross bar master in the RC has to enable the Receive Overflow interrupt. The Link Up interrupt is enabled by default but can be disabled by software.

- Write 1 to the `PCIE_APP_CTL.RXQOVFIEN` bits to enable the Receive Overflow interrupt.
- Write 1 to the `PCIE_APP_CTL.LNKUPINTDIS` bits to disable the Link Up interrupt.

The `PCIE_APP_STAT.LNKUP` bit reflects the status of the Links Data and MAC/PHY layers.

Interrupt Reception

Applies to the reception of an enabled interrupt. The corresponding bit in the `PCIE_APP_INTSTAT` register is set. The interrupt routine should:

- Test the `PCIE_APP_INTSTAT.LNKUP` and `PCIE_APP_INTSTAT.RXQOVF` bits to determine which interrupt to serve.
- Once the interrupt is serviced, clear the status bit by writing 1 to the corresponding bit in the `PCIE_APP_INTSTAT` register.

End Point

If the PCIe core is configured as an EP, the application software can send the upstream device either MSI (Message Signaled Interrupts) or virtual legacy INTA messages.

MSI Generation

See section 4.5.3.2.1 Interrupts in EP mode.

INTA Assert and INTA Deassert Generation

See section 4.5.3.2.1 Interrupts in EP mode.

The application software needs to deassert the virtual interrupt when the system software has disabled interrupts or if the PCI Express link has been placed in a low power state. The PCIe core does automatically send a deassert interrupt message when software disables interrupts. The application software must deassert the virtual interrupt before it can send a new interrupt because the PCIe core requires a rising edge on the virtual interrupt signal to generate a new Assert interrupt message. The core does not automatically send a deassert interrupt message when the power state changes.

Root Complex

If the PCIe core is configured as an RC, it can receive either MSI or Legacy Interrupt messages but cannot generate them. These messages make the RSCKPHY_PCIEINT_REQ interrupt signal to become active. If the MSI controller is disabled, MSIs do not make RSCKPHY_PCIEINT_REQ interrupt signal assert, instead MSI are forwarded as Write Transactions to the SCB master port. See section 4.5.3.2.2. for more information.

MSI Reception in the SCB Bridge

When an inbound (received) MWr request is passed to the peripheral or system cross bar bridge and matches the specified MSI address, as well as the conditions specified for an MSI memory write request, then an MSI interrupt is detected and RSCKPHY_PCIEINT_REQ interrupt signal asserted. The MSI write request never appears on the SCB master bus.

Programming and Using the MSI Controller in the SCB Bridge

The host CPU configures the MSI capabilities of all endpoints through CFG requests across the link or accessing the DBI address space.

- Program the "MSI Data Register" `PCIE_MSI_CAPB_OFF8_[n]` (which is part of the PCI Express MSI capability register structure of each EP) as follows to allow the MSI interrupt controller to decode the interrupt source.
- Program the "MSI Lower 32 Bits Address Register" `PCIE_MSI_CAPB_OFF4_[n]` (which is part of the PCI Express MSI capability register structure) of every EP with one common MSI address.

Table 29-17: MSI Data Register Programming

15:8	7:5	4:0
Not Used	EP Number Allows each EP to be identified within the system, For example, EP#5 is programmed with 3'b101	Interrupt Vector Number • Identifies the interrupt source within each EP • Programmed to 5'b00000. • Set by MSI generation logic to identify each interrupt source in real time • Supports up to 32 Vectors

The host CPU configures the MSI interrupt controller through CFG requests across the link or accessing the DBI address space.

- Program the common MSI address that you used for the EPs into the interrupt controller's MSI Controller Address register (`PCIE_MSI_CTL_LADDR_[n]`)
- Read the MSI capability of each EP to determine the number of vectors enabled in each EP and uses this information to program the interrupt enable registers in the MSI interrupt controller. The interrupt enable register allows up to 32 MSI interrupt vectors to be enabled within the MSI interrupt controller for a given EP. It is the responsibility of the host CPU to read the contents of the "Multiple Message Enable" field in an EP's MSI capability structure and program that EP's Interrupt Enable register in the interrupt controller appropriately. For example when the "Multiple Message Enable" is 0b100 for endpoint N (which corresponds to 16 enabled interrupt vectors), then the host CPU should program interrupt enable register #N in the interrupt controller with 0x0000FFFF.

Legacy Interrupts Reception

The PCIe core can receive INTA, INTB, INTC and INTD interrupt messages. Each interrupt can be individually enabled by setting the corresponding bit in the `PCIE_APP_CTL` register. If any of the enabled interrupts is detected, the corresponding bit in the `PCIE_APP_INTSTAT` register is set and RSCKPHY_PCIEINT_REQ asserted.

Local Interrupts

In addition to the PCIe Interrupts that are always generated by EP ports and received by RC ports, messages, and local events can also make RSCKPHY_PCIEINT_REQ assert. These interrupts may be generated in any of the PCIe core configurations.

Inbound Messages

The following Inbound Messages are registered:

- Vendor Defined
- Unlock Transaction (RC Mode)
- Error Signaling (EP Mode)
  - Correctable
  - Non-Fatal
  - Fatal
- Power Management
  - Event (RC Mode)
  - Turn Off Acknowledge (RC Mode)
  - Turn Off (EP Mode)

The information related to vendor messages is registered in a set of three registers:

- (If applicable) `PCIE_APP_VNDR_MSG_HDR0` message request header bytes 8 to 11
- (If applicable) `PCIE_APP_VNDR_MSG_HDR1` message request header bytes 12 to 15
- `PCIE_APP_VNDR_MSG` message request header requester ID field (bytes 4 and 5)

All other messages have only an APP_*Message Name*_MSG register. Each register holds the coresponding message request header ID field The message header information and requester ID are registered if the corresponding interrupt bit in the `PCIE_APP_INTSTAT` is not set.

Link Up

This Interrupt is triggered when the `PCIE_APP_STAT.LNKUP` bit transitions from 0 to 1. It tells the system that the link is up and ready to transfer data or messages. The `PCIE_APP_STAT.LNKUP` bit is read only. When the Link Up interrupt is asserted the `PCIE_APP_INTSTAT.LNKUP` bit is set.

Receive Overflow Interrupt

If an overflow occurs in any of the receive queues, the `PCIE_APP_INTSTAT.RXQOVF` bit is set and RSCKPHY_PCIEINT_REQ is asserted. This bit stays set and the interrupt asserted until the application software writes 1 to it.

Reset Interrupt Request

The Reset Interrupt Request is triggered only by the PCIe core warm or hot link reset request. This interrupt has to be enabled if the PCIe port is enabled. A warm or hot reset event sets the `PCIE_RSCK_STAT.WRMHTRST` bit.

In response to the RSCKPHY_PCIERST_REQ the interrupt service routine performs the following tasks.

- Allows the PCIe master accesses to complete normally.
- Stops all system cross bar bus masters from accessing PCIe core slave system cross bar port.
- Allows the slave system cross bar transactions in progress complete. The response is bus error.
- Stops the system cross bar bus masters from accessing the PCIe core DBI SCB port.
- Allows the slave DBI SCB transactions in progress to complete. The response is bus error.
- Two actions may follow.
  - Write 1 to the `PCIE_RSCK_CTL.DBISLVDIS` bit to let CLK_RST reset the PCIe core, non sticky registers and PCIe PHY.
  - Set the `PCIE_RSCK_CTL.PCIERES` bit to reset the whole PCIe port (similar to cold reset).
- If set, clear the `PCIE_RSCK_CTL.PCIERES` bit.
- Write 1 to the `PCIE_RSCK_STAT.WRMHTRST` bit to clear the interrupt request.

The core reset, PHY reset system cross bar master interface, system cross bar slave interface and system cross bar DBI interface reset status can be monitored by software by checking the `PCIE_RSCK_STAT.CORERST`, `PCIE_RSCK_STAT.PHYRST`, `PCIE_RSCK_STAT.MSTRST`, `PCIE_RSCK_STAT.SLVRST` and `PCIE_RSCK_STAT.DBIRST` bits. These bits are implemented for debug purposes and should be treated as asynchronous.

DMA Interrupts

RSCKPHY_EDMAINT_REQ is an interrupt request signal dedicated to the Embedded DMA controller.

Programming Model

The following sections provide general programming information for the PCIe module.

Enumeration

Enumeration is the first step in the system discovery and configuration process run by the PCIe CPU.

Enumeration Driver Example

The processor's PCIe port does not check configuration requests (at the application transmit interface) for valid target Bus-Device-Function (BDF) numbers before it transmits them. It does not check that the *target bus number* > *secondary bus number* and that *target bus number* ≤ *subordinate bus number*. Software running on the local core provides only legal requests to the PCIe core. Only one PCIe port is implemented, therefore bus 0 has only a single device on it. This device may be an EP or a switch. If the device is an EP the number of functions (F) is determined and the only valid BDF numbers are 00F. If the device is a switch the search on the secondary bus and down continues normally until the last EP is discovered.

The following ***CfgRd0 or CfgRd1 Example*** example requires the use and configuration of the iATU (See section 4.6.4. Internal Address Translation). Enumeration uses configuration requests, therefore the iATU has to be configured to translate slave system cross bar reads into CfgRd0 or CfgRd1 and slave system cross bar writes into CfgWr0 or CfgWr1 outbound transactions. To determine what Device 0 on bus 0 is, the RC can issue a CfgRd1 request from the device's 0 Vendor ID register. If the response is 0xFFFF (unsupported request), device 0 is an End Point and the PCIe software continues issuing CfgRd0 to determine the number of functions. If the response is different than 0xFFFF, device 0 is a bridge and the Enumeration process continues using configuration requests as required by the PCIe system topology.

Define Outbound Region n (3 ≥ n ≥ 0) as:

- MSIZE = 64 Kbytes
- SOC MEM Region
  - From MSTART (0x5000_0000 ≥ MSTART ≥ 0x5FFF_0000)
  - To MEND (0x5000_FFFF ≥ MSTART ≥ 0x5FFF_FFFF)
- Mapped to PCIe Configuration Space
  - CFG Space[31:16] = BDF
  - CFG Space[15:12] = 0x0
  - CFG Space[11:8] = Extended Register Number
  - CFG Space[7:2] = Configuration Register Number
  - CFG Space[1:0] = 0x0

Define Outbound Transaction as Cfg

- TYPE = CfgRd0 or CfgRd1
- TC = 0x0
- TD = 0
- ATTR = 0x0
- AT = 0x0

Port Logic Registers. Configure the `PCIE_IATU_VWPRT_[n]` register to access the region n IATU configuration registers.

1. Setup the Index Register to set outbound region n as the current region.
   a. Write n to `PCIE_IATU_VWPRT_[n].REGNINDX` and 0 to `PCIE_IATU_VWPRT_[n].REGNDIR` register address.
2. Setup the Region Base and Limit Address registers.
   a. Write “MSTART” to the `PCIE_IATU_LBADDR_OUTB_[n]` register to set the lower base address.
   b. Write 0x0000_0000 to the `PCIE_IATU_UBADDR_OUTB_[n]` register to set the upper base address.
   c. Write “MEND” to `PCIE_IATU_LMTADDR_OUTB_[n]` register to set the limit address.
3. Setup the Target Address Registers.
   a. Write “CFG Space” to the `PCIE_IATU_LTADDR_OUTB_[n]` register to set the lower target address.
   b. Write 0x0000_0000 to the `PCIE_IATU_UTADDR_OUTB_[n]` register to set the upper target address.
4. Configure the region through the Region Control 1 register.
   a. Write to the `PCIE_IATU_CTL1_OUTB_[n].TYPE`, `PCIE_IATU_CTL1_OUTB_[n].TC`, `PCIE_IATU_CTL1_OUTB_[n].TD`, `PCIE_IATU_CTL1_OUTB_[n].ATTR` and `PCIE_IATU_CTL1_OUTB_[n].AT` bits and 0 to all the other bits.
5. Enable the region.
   a. Write 0x8000_0000 to the `PCIE_IATU_CTL2_OUTB_[n]` register to enable the region.

Configuration write transactions are implemented in the same way as configuration read transactions. Configure the `PCIE_IATU_CTL1_OUTB_[n].TYPE` bit field to CfgWr0 or CfgWr1.

DMA Transfers

The order in which the DMA Controller’s registers are programmed is not important except for the `PCIE_DMAWR_DRBL_[n]` or `PCIE_DMARD_DRBL_[n]` registers, which initiates the DMA transfer.

DMA Write Transfer Example

Transfer 1MB from local L2 (0x2400 0000) to PCIe memory space (0x5000 0000)

1. Write 0x0 to the `PCIE_DMA_VWPRT_SEL_[n]` register to select channel 0 write registers.
2. Write 0x1 to the `PCIE_DMAWR_EN_[n].EN` bit.
3. Write 0x0 to the `PCIE_DMAWR_IMSK_[n]` register.

4. Clear the PCIE_DMAWR_CTL1_[n].AT, PCIE_DMAWR_CTL1_[n].RO, PCIE_DMAWR_CTL1_[n].NS, PCIE_DMAWR_CTL1_[n].TC, PCIE_DMAWR_CTL1_[n].FNUM and PCIE_DMAWR_CTL1_[n].RIE bit fields.
5. Set the PCIE_DMAWR_CTL1_[n].LIE and the PCIE_DMAWR_CTL1_[n].TD bits.
6. Set the PCIE_DMAWR_XFRSZ_0[n] register to 0x0010 0000 (1 MB).
7. Set the PCIE_DMAWR_SAR_LO_[n] register to 0x2400 0000.
8. Set the PCIE_DMAWR_SAR_HI_[n] register to 0x0000 0000.
9. Set the PCIE_DMAWR_DAR_LO_[n] register to 0x5000 0000.
10. Set the PCIE_DMAWR_DAR_HI_[n] register to 0x0000 0000.
11. Write 0x0 to the PCIE_DMAWR_DRBL_[n] register.

DMA Read Transfer Example

Transfer 1MB from remote PCIe memory space (0x5000 0000) to local L2 (0x2400 0000)

1. Write 0x8000_0000 to the PCIE_DMA_VWPRT_SEL_[n] register to select channel 0 read registers.
2. Write 0x1 to the PCIE_DMARD_EN_[n].EN bit.
3. Write 0x0 to the PCIE_DMARD_IMSK_[n] register.
4. Clear the PCIE_DMARD_CTL1_[n].AT, PCIE_DMARD_CTL1_[n].RO, PCIE_DMARD_CTL1_[n].NS, PCIE_DMARD_CTL1_[n].TC, PCIE_DMARD_CTL1_[n].FNUM and PCIE_DMARD_CTL1_[n].RIE bit fields.
5. Set the PCIE_DMARD_CTL1_[n].LIE and the PCIE_DMARD_CTL1_[n].TD bits.
6. Set the PCIE_DMARD_XFRSZ_[n] register to 0x0010 0000 (1 MB).
7. Set the PCIE_DMARD_SAR_LO_[n] register to 0x2400 0000.
8. Set the PCIE_DMARD_SAR_LO_[n] register to 0x0000 0000.
9. Set the PCIE_DMARD_DAR_LO_[n] register to 0x5000 0000.
10. Set the PCIE_DMARD_DAR_HI_[n] register to 0x0000 0000.
11. Write 0x0 to the PCIE_DMARD_DRBL_[n] register.

Device Reset

There are two reset types for the ADI PCIe core. The first is initial power-up and is only reached from chip initialization. This has been referred to as Cold reset in prior descriptions. The key to this step is making sure the Physical layer is correctly out of reset and setting the device into the proper operating mode, either Root Complex or End point. The second type of reset is one initiated from an upstream port, referred to as a hot reset request. The hot reset does not require resetting of the physical layer but does require re-training the link and setup of all configuration registers, address translation and DMA engines. The cold reset sequence always proceeds to a hot reset.

Cold Reset

The cold reset is entered via power up or a system reset. This is also referred to as a fundamental reset. The PERST# signal is not connected to the system reset by default. The following steps prepare the hardware to enter the Hot reset sequence.

1. Take the core out of reset and configure as Root complex or Endpoint.

```
if (*pREG_RSCK_CTL & 0x01)  // check if it is reset.
         {
*pREG_RSCK_CTL = 0x00000002; //take core out of reset. set to end point
 delay(256);
          }
```

2. Wait for the core to come out of rest.

```
While (*pREG_RSCK_STAT & 0x1);
```

Hot Reset

The hot reset is entered via the upstream port PCIe TSI ordered sets. This is typically a software driven event. The ADI PCIe core intercepts this bit and when detected sets a bit in the `PCIE_RSCK_STAT` register. Additionally, this bit can trigger an interrupt via the APP_STAT interrupt. The reception of the Hot Reset command indicates the link must re-enter detect state. All configuration registers and address mapping must be re-initialized.

1. Either detect the hot reset request (via the APP_STAT interrupt or polling the `PCIE_RSCK_STAT` register) or enter from the fundamental reset.
2. Clear the reset events and verify

```
if (*pREG_RSCK_STAT & 0x20000)  // lock write error bit is set
{
*pREG_RSCK_STAT = 0x20000;    // clear lock write error bit
 }
 if (*pREG_RSCK_STAT & 0x20)  // reset bit is set
 {
 *pREG_RSCK_STAT = 0x20;  // clear  Hot reset request
 }
 // wait for device to come out of reset
 while ( (*pREG_RSCK_STAT & 0x1F) !=0 );
```

3. Setup the configuration registers, including BAR address size, MSIs and custom device id. Finally, enable the IO and command register space. The program must enable the DBI registers in order to access the configuration space.

```
*pREG_PCIE0_MISC_CONTROL_1_REG0 = 0x1; //Write enable for DBI Read register

*pREG_PCIE0_BAR0_REG0    = 0x08;        // 32 bit address
*pREG_PCIE0_BAR1_CS    = 0x00000000;    //  disable bar1-4
*pREG_PCIE0_BAR2_CS    = 0x00000000;
*pREG_PCIE0_BAR3_CS    = 0x00000000;
*pREG_PCIE0_BAR4_CS    = 0x00000000;

*pREG_PCIE0_TYPE1_DEV_ID_VEND_ID_REG0 =   ((DEV_ID << 16) |VEND_ID);;
*pREG_PCIE0_TYPE1_SUBSYS_ID_VEND_REG0 =   ( (EP_SS_ID << 16) | SSVID_ID );
*pREG_PCIE0_TYPE1_STATUS_COMMAND_REG0   |= 3;
```

4. Setup the address translation. This example matches the incoming BAR0 and translates to L2RAM at 0x2xxxxxxx.

```
*pREG_PCIE0_IATU_VIEWPORT_REG0 =   0x80000000;        // inbound region 0
*pREG_PCIE0_PL_IATU_LWR_TARGET_ADDR_REG_OUTBOUND_00   =   0x20000000;
*pREG_PCIE0_PL_IATU_UPPER_TARGET_ADDR_REG_OUTBOUND_00 =   0x0;
*pREG_PCIE0_PL_IATU_REGION_CTRL_REG_1_OUTBOUND_00     =    0x0;    // MEMr/w
*pREG_PCIE0_PL_IATU_REGION_CTRL_REG_2_OUTBOUND_00   =   0xC0000000;  // BAR0
```

5. Enter link training and wait for link establishment. Link establishment can be detected by polling the `PCIE_APP_STAT` register or via interrupt.

```
// bits[3:0]link speed 1 = 2.5G, 2=5G
*pREG_PCIE_USP0_LINK_CAPABILITIES = 0x0040AC11;
*pREG_APP_CTL = 0x1;                 // start training process
While  (!(*pREG_APP_STAT & 0x01) );       // wait for link to train
```

6. If the device is configured as an endpoint, wait for the upstream port to configure the bus enable bit. If the device is a Root complex begin configuration of endpoint.

```
while ( !(*pREG_PCIE0_TYPE1_STATUS_COMMAND_REG0 & 0x04 ) ); //endpoint
```

7. Begin normal processing while monitoring link status.

ADSP-SC58x Product Specific Information

The following information is specific to PCIe operation on the ADSP-SC58x processors.

PHY Parameter Control

Several signals set static or programmable values that are used by the PHY. Some of these parameters are package-dependent and their programmability is advantageous. Systems drive these from a register with a default value set.

The values for transmit de-emphasis and amplitude are derived from the following equations.

$$\text{TX de-emphasis (dB)} = 20 \times \log_{10}\left[\frac{128 - 2 \times \text{pcs\_tx\_deemph}}{128}\right]$$

$$\text{TX amplitude (V)} = \text{vptx} \times \left[\frac{\text{pcs\_tx\_swing} + 1}{128}\right]$$

Using these relationships, the default settings for 1.0-V launch amplitude and transmit equalization are:

Transmit de-emphasis for PCI Express:

- pcs_tx_deemph: PHY_TXDEEMPH.GEN1 = 24 (0x18) (Typical setting for 2.5 Gb/s operation)

  PHY_TXDEEMPH.GEN2_35 = 24 (0x18) (Typical setting for 5.0 Gb/s operation, 3.5 dB)

  PHY_TXDEEMPH.GEN2_6 = 33 (0x21) (Typical setting for 5.0 Gb/s operation, 6 dB)

Transmit launch amplitude:

- pcs_tx_swing: PHY_TXSWING.FULL = 115 (0x73) (For the default 1.0 V launch amplitude)

  PHY_TXSWING.LOW = 115 (0x73) (To support Mobile mode)

ADSP-SC58x PCIE Register Descriptions

(PCIE) contains the following registers.

Table 29-18: ADSP-SC58x PCIE Register List

Name	Description
PCIE_ACK_ASPMCTL_[n]	Acknowledge Frequency and L0-L1 ASPM Control Register
PCIE_ACK_TMR_[n]	Acknowledge Latency Timer and Replay Timer Register
PCIE_ADVERR_CAPBCTL_[n]	Advanced Error Capabilities and Control Register
PCIE_ADVERR_EXTCAPB_[n]	Advanced Error Reporting Extended Capability Header Register
PCIE_APP_CORERR_MSG	Correctable Error Message Requester ID Register
PCIE_APP_CTL	Application Control Register
PCIE_APP_DIAGCTL	Diagnostic Control Register
PCIE_APP_DIAGSTAT	Diagnostic Status Register
PCIE_APP_FERR_MSG	Fatal Error Message Requester ID Register
PCIE_APP_INTSTAT	Application Interrupts Status Register
PCIE_APP_NFERR_MSG	Non Fatal Error Message Requester ID Register
PCIE_APP_PMACK_MSG	Power Management Acknowledge Message Requester ID Register
PCIE_APP_PMEVT_MSG	Power Management Event Message Requester ID Register
PCIE_APP_PMTOFF_MSG	Power Management Turn Off Message Requester ID Register
PCIE_APP_STAT	Application Status Register

Table 29-18: ADSP-SC58x PCIE Register List (Continued)

Name	Description
PCIE_APP_UNLK_MSG	Unlock Message Requester ID Register
PCIE_APP_VNDR_MSG	Vendor Message Requester ID Register
PCIE_APP_VNDR_MSG_HDR0	Vendor Message Header Bytes 8 to 11 Register
PCIE_APP_VNDR_MSG_HDR1	Vendor Message Header Bytes 12 to 15 Register
PCIE_AUX_CLKFREQ_[n]	Auxiliary Clock Frequency Control Register
PCIE_BERR_RESP_[n]	Peripheral and SCB Bridge Slave Error Response Register
PCIE_BUSMGR_WDOG_[n]	Bus Order Manager Watchdog Off Register
PCIE_BUS_MULOB_DECOMP_[n]	Bus Multiple Outbound Decomposition SubReq Control Register
PCIE_CACHE_CTL1_[n]	ACE Cache Coherency Control Register 1
PCIE_CACHE_CTL3_[n]	ACE Cache Coherency Control Register 3
PCIE_CAPB_NPTR_[n]	PCIe Capabilities, ID, Next Pointer Register
PCIE_CORERR_MSK_[n]	Correctable Error Mask Register
PCIE_CORERR_STAT_[n]	Correctable Error Status Register
PCIE_DEV_CAPB2_[n]	Device Capabilities 2 Register
PCIE_DEV_CTLSTAT2_[n]	Device Control 2 and Status 2 Register
PCIE_DEV_CTLSTAT_[n]	Device Control and Status Register
PCIE_DMARD_ARBWGT_LO_[n]	DMA Read Arbitration Weight Low Off Register
PCIE_DMARD_CH01_IMWR_[n]	DMA Read Channel 1 and 0 IMWr Data Register
PCIE_DMARD_CTL1_[n]	DMA Control 1 Read Channel Register
PCIE_DMARD_DAR_HI_[n]	DMA Destination Address High Read Channel Register
PCIE_DMARD_DAR_LO_[n]	DMA Destination Address Low Read Channel Register
PCIE_DMARD_DONE_IMWR_HI_[n]	DMA Read Done IMWr Address High Register
PCIE_DMARD_DONE_IMWR_LO_[n]	DMA Read Done IMWr Address Low Register
PCIE_DMARD_DRBL_[n]	DMA Read Doorbell Register
PCIE_DMARD_EN_[n]	DMA Read Engine Enable Register
PCIE_DMARD_ERRSTAT_HI_[n]	DMA Read Error Status High Register
PCIE_DMARD_ERRSTAT_LO_[n]	DMA Read Error Status Low Register

Table 29-19: PCIE_ACK_ASPMCTL_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	ENTER	Enter ASPM. The `PCIE_ACK_ASPMCTL_[n].ENTER` bit allows the core to enter ASPM L1 even when link partner did not go to L0s (receive is not in L0s). When cleared (=0), the core goes to ASPM L1 only after an idle period during which both receive and transmit are in L0s. This register field is sticky.	
29:27 (R/W)	L1ENTLAT	L1 Entrance Latency. The `PCIE_ACK_ASPMCTL_[n].L1ENTLAT` bit field specifies the L1 Entrance Latency. Programming this timer with a value greater that 32 us has no effect unless extended sync is used, or all of the credits are infinite. This register field is sticky.	
		0	1 us
		1	2 us
		2	4 us
		3	8 us
		4	16 us
		5	32 us
		6	64 us
		7	64 us

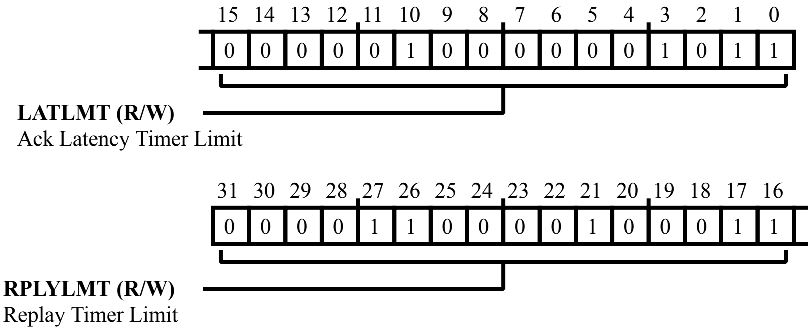
</table>

Table 29-19: PCIE_ACK_ASPMCTL_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FREQ	Frequency. The `PCIE_ACK_ASPMCTL_[n].FREQ` bit field specifies the number of pending Acks the core accumulates (up to 255) before sending an Ack DLLP. Zero indicates that this Ack frequency control feature is turned off and that the core accumulates 255 received TLPs before sending an Ack DLLP. Other values indicate that the core Acks every received TLP.

Acknowledge Latency Timer and Replay Timer Register

The `PCIE_ACK_TMR_[n]` register controls Ack latency timer limits and replay timer limits.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 1 0 0 0 0 0 0 1 0 1 1

Table 29-20: PCIE_ACK_TMR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	RPLYLMT	Replay Timer Limit. The `PCIE_ACK_TMR_[n].RPLYLMT` bit field specifies the replay timer expiration limit. The core initiates a replay on reception of a Nak or when the replay timer expires. For more details, see "Transmit Retry". Programs can modify the effective timer limit with the `PCIE_TMRCTL_MFN_[n].RLMT` bit field. After reset, the core updates the default according to the Negotiated Link Width and Max_Payload_Size. When operating at 5 Gb/s, then an additional 153/CX_NB is added for additional internal processing for received TLPs and transmitted DLLPs.
15:0 (R/W)	LATLMT	Ack Latency Timer Limit. The `PCIE_ACK_TMR_[n].LATLMT` bit field specifies the Ack latency timer expire limit. Programs can modify the effective timer limit with the `PCIE_TMRCTL_MFN_[n].RLMT` bit field. After reset, the core updates the default according to the Negotiated Link Width and Max_Payload_Size. When operating at 5 Gb/s, an additional 51/CX_NB is added for additional internal processing for received TLPs and transmitted DLLPs.

Advanced Error Capabilities and Control Register

The PCIE_ADVERR_CAPBCTL_[n] register controls some ECRC capabilities and their function.

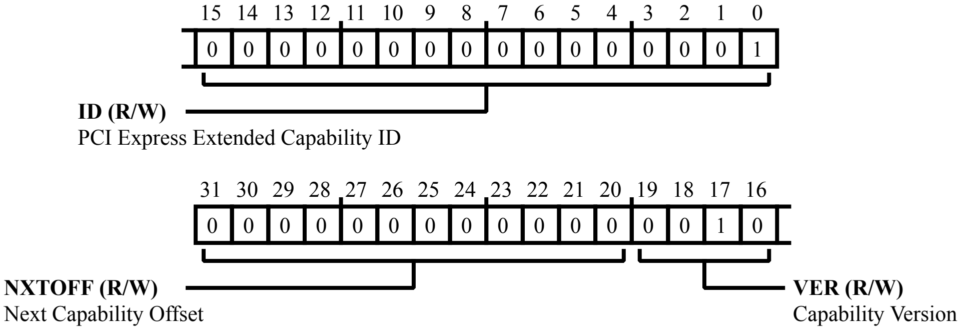
Table 29-21: PCIE_ADVERR_CAPBCTL_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8 (R/W)	CHKEN	ECRC Check Enable. The PCIE_ADVERR_CAPBCTL_[n].CHKEN bit enables ECRC checking. Functions that do not implement the associated mechanism are permitted to set this bit to 0. The default value of this bit is 0 (disabled).
7 (R/NW)	CHKCAPB	Ecrc Check Capability. The PCIE_ADVERR_CAPBCTL_[n].CHKCAPB bit indicates that the Function is capable of checking ECRC.
6 (R/W)	GENEN	ECRC Generation Enable. The PCIE_ADVERR_CAPBCTL_[n].GENEN bit enables ECRC. Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0. The default value of this bit is 0 (disabled).
5 (R/NW)	GENCAPB	Ecrc Gen Capability. If set, the PCIE_ADVERR_CAPBCTL_[n].GENCAPB bit indicates that the Function is capable of generating an ECRC.
4:0 (R/NW)	FEPTR	First Error Pointer. The PCIE_ADVERR_CAPBCTL_[n].FEPTR bit field identifies the bit position of the first error reported in the PCIE_UNCOR_ERRSTAT_[n] register.

Advanced Error Reporting Extended Capability Header Register

The `PCIE_ADVERR_EXTCAPB_[n]` register provides optional extended error reporting capability. It implemented by PCI Express device Functions that support advanced error control and reporting.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1
ID (R/W)
PCI Express Extended Capability ID
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0
NXTOFF (R/W)
Next Capability Offset
VER (R/W)
Capability Version

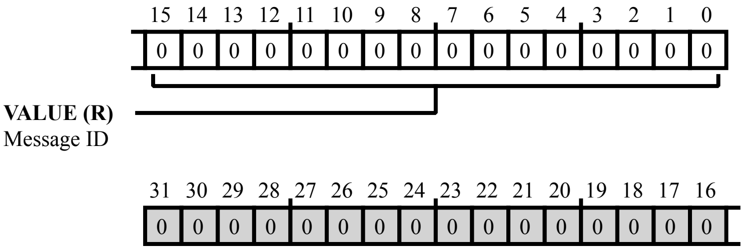
Figure 29-13: PCIE_ADVERR_EXTCAPB_[n] Register Diagram

Table 29-22: PCIE_ADVERR_EXTCAPB_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:20 (R/W)	NXTOFF	Next Capability Offset. The `PCIE_ADVERR_EXTCAPB_[n].NXTOFF` bit field contains the offset to the next PCI Express capability structure or 0x0 if no other items exist in the linked list of capabilities. For extended capabilities implemented in configuration space, this offset is relative to the beginning of PCI compatible configuration space and thus must always be either 0x0 (for terminating list of capabilities) or greater than 0xFF.
19:16 (R/W)	VER	Capability Version. The `PCIE_ADVERR_EXTCAPB_[n].VER` bit field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field must be 0x2 if the End-End TLP Prefix Supported bit is set and must be 0x1 or 0x2 otherwise.
15:0 (R/W)	ID	PCI Express Extended Capability ID. The `PCIE_ADVERR_EXTCAPB_[n].ID` bit field is read-only and reports the PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Advanced Error Reporting Capability is 0x001.

Correctable Error Message Requester ID Register

The `PCIE_APP_CORERR_MSG` register contains the requester ID of the latest received Correctable Error Message. It is advised to read this register when the `PCIE_APP_INTSTAT.CORERR` bit is set.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE (R)
Message ID

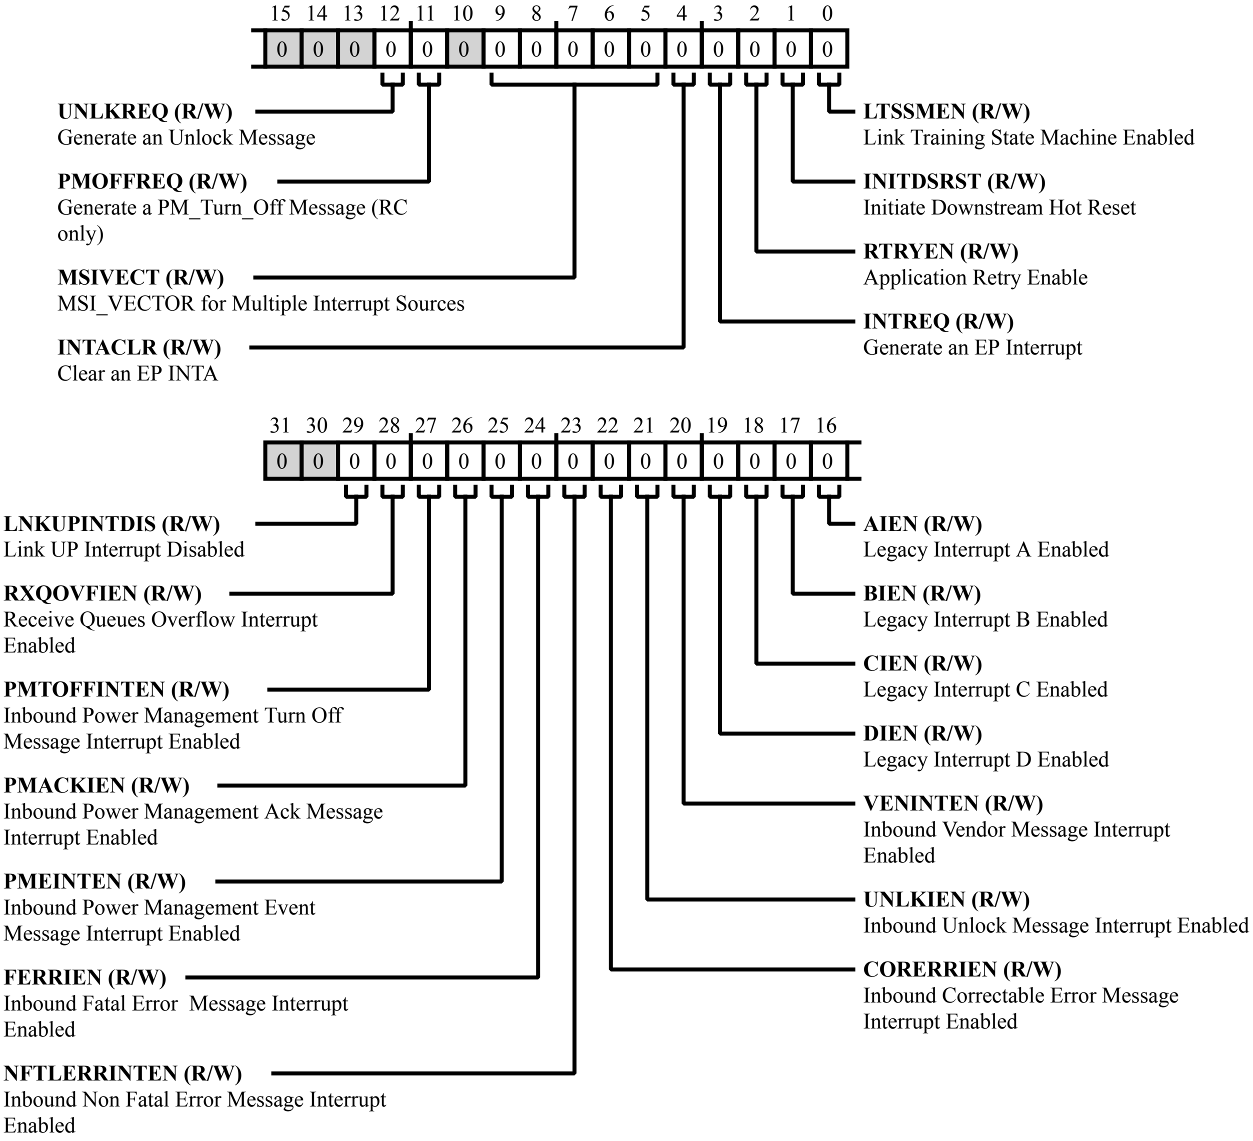
Table 29-23: PCIE_APP_CORERR_MSG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Message ID. The `PCIE_APP_CORERR_MSG.VALUE` bit field contains the requester ID of the latest received Correctable Error Message.

Application Control Register

The `PCIE_APP_CTL` register contains bits that control various PCIE functions. This register also reports whether interrupts are enabled.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
UNLKREQ (R/W)
Generate an Unlock Message
PMOFFREQ (R/W)
Generate a PM_Turn_Off Message (RC only)
MSIVECT (R/W)
MSI_VECTOR for Multiple Interrupt Sources
INTACLR (R/W)
Clear an EP INTA
LTSSMEN (R/W)
Link Training State Machine Enabled
INITDSRST (R/W)
Initiate Downstream Hot Reset
RTRYEN (R/W)
Application Retry Enable
INTREQ (R/W)
Generate an EP Interrupt

Table 29-24: PCIE_APP_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	LNKUPINTDIS	Link UP Interrupt Disabled.	
		0	Interrupt Enabled
		1	Interrupt Disabled
28 (R/W)	RXQOVFIEN	Receive Queues Overflow Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
27 (R/W)	PMTOFFINTEN	Inbound Power Management Turn Off Message Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
26 (R/W)	PMACKIEN	Inbound Power Management Ack Message Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
25 (R/W)	PMEINTEN	Inbound Power Management Event Message Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
24 (R/W)	FERRIEN	Inbound Fatal Error Message Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
23 (R/W)	NFTLERRINTEN	Inbound Non Fatal Error Message Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
22 (R/W)	CORERRIEN	Inbound Correctable Error Message Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
21 (R/W)	UNLKIEN	Inbound Unlock Message Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
20 (R/W)	VENINTEN	Inbound Vendor Message Interrupt Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled

Table 29-24: PCIE_APP_CTL Register Fields (Continued)

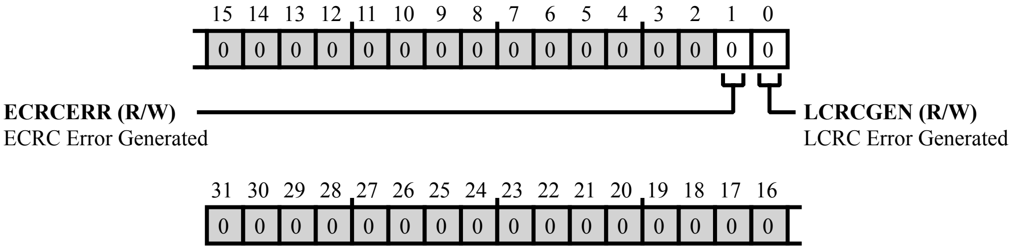
Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	DIEN	Legacy Interrupt D Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
18 (R/W)	CIEN	Legacy Interrupt C Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
17 (R/W)	BIEN	Legacy Interrupt B Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
16 (R/W)	AIEN	Legacy Interrupt A Enabled.	
		0	Interrupt Disabled
		1	Interrupt Enabled
12 (R/W)	UNLKREQ	Generate an Unlock Message.	
11 (R/W)	PMOFFREQ	Generate a PM_Turn_Off Message (RC only).	
9:5 (R/W)	MSIVECT	MSI_VECTOR for Multiple Interrupt Sources.	
4 (R/W)	INTACLR	Clear an EP INTA.	
3 (R/W)	INTREQ	Generate an EP Interrupt.	
2 (R/W)	RTRYEN	Application Retry Enable. The `PCIE_APP_CTL.RTRYEN` bit determines whether the core completes incoming configuration requests with or without a configuration request retry status.	
		0	The core completes incoming configuration requests without a configuration request retry status.
		1	The core completes incoming configuration requests with a configuration request retry status.
1 (R/W)	INITDSRST	Initiate Downstream Hot Reset.	

Table 29-24: PCIE_APP_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	LTSSMEN	Link Training State Machine Enabled. The `PCIE_APP_CTL.LTSSMEN` bit reports the state of the link training state machine.	
		0	The LTSSM is held in the Detect state
		1	Core Configuration Registers are initialized

Diagnostic Control Register

The `PCIE_APP_DIAGCTL` register provides CRC diagnostic message control.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ECRCERR (R/W)
ECRC Error Generated
LCRCGEN (R/W)
LCRC Error Generated
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

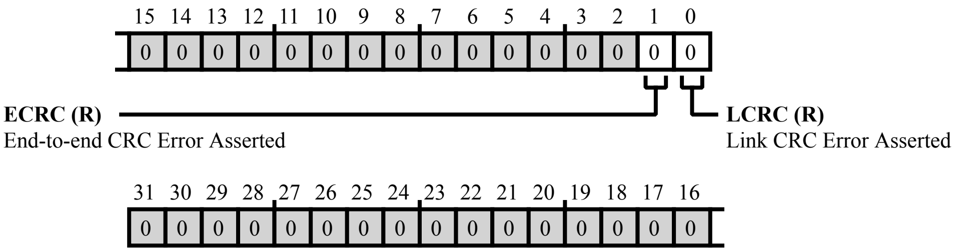
Figure 29-16: PCIE_APP_DIAGCTL Register Diagram

Table 29-25: PCIE_APP_DIAGCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	ECRCERR	ECRC Error Generated. The `PCIE_APP_DIAGCTL.ECRCERR` bit enables ECRC error generation.	
		0	Interrupt not enabled
		1	Interrupt enabled
0 (R/W)	LCRCGEN	LCRC Error Generated. The `PCIE_APP_DIAGCTL.LCRCGEN` bit enables the LCRC error.	
		0	Interrupt not enabled
		1	Interrupt enabled

Diagnostic Status Register

The `PCIE_APP_DIAGSTAT` register reports LCRC and ECRC status.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ECRC (R)
End-to-end CRC Error Asserted
LCRC (R)
Link CRC Error Asserted
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 29-17: PCIE_APP_DIAGSTAT Register Diagram

Table 29-26: PCIE_APP_DIAGSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	ECRC	End-to-end CRC Error Asserted. The `PCIE_APP_DIAGSTAT.ECRC` bit reports the status of the ECRC.	
		0	End-to-end CRC is not corrupted
		1	End-to-end CRC Error injected by writing 1 to DBGCTL.LCRCERR
0 (R/NW)	LCRC	Link CRC Error Asserted. The `PCIE_APP_DIAGSTAT.LCRC` bit reports the status of the LCRC.	
		0	Link CRC is not corrupted
		1	Link CRC Error injected by writing 1 to DBGCTL.LCRCERR

Fatal Error Message Requester ID Register

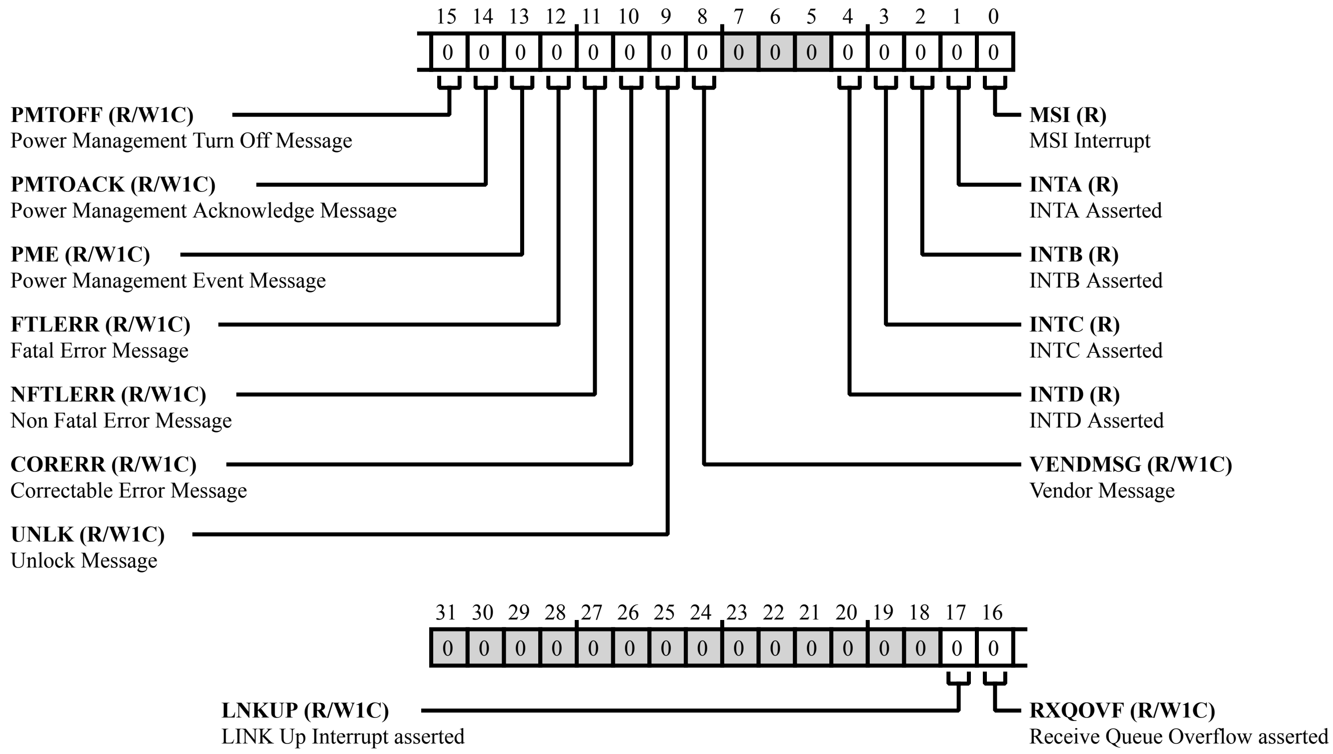
Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Message ID.

Application Interrupts Status Register

The `PCIE_APP_INTSTAT` register reports the status of various interrupts and messages.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PMTOFF (R/W1C)
Power Management Turn Off Message
PMTOACK (R/W1C)
Power Management Acknowledge Message
PME (R/W1C)
Power Management Event Message
FTLERR (R/W1C)
Fatal Error Message
NFTLERR (R/W1C)
Non Fatal Error Message
CORERR (R/W1C)
Correctable Error Message
UNLK (R/W1C)
Unlock Message
MSI (R)
MSI Interrupt
INTA (R)
INTA Asserted
INTB (R)
INTB Asserted
INTC (R)
INTC Asserted
INTD (R)
INTD Asserted
VENDMSG (R/W1C)
Vendor Message
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LNKUP (R/W1C)
LINK Up Interrupt asserted
RXQOVF (R/W1C)
Receive Queue Overflow asserted

Figure 29-19: PCIE_APP_INTSTAT Register Diagram

Table 29-28: PCIE_APP_INTSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LNKUP	LINK Up Interrupt asserted. The `PCIE_APP_INTSTAT.LNKUP` bit reports the status of the link up interrupt.	
		0	Link Up Interrupt was not asserted since the last time this bit was cleared
		1	Link Up Interrupt was asserted since the last time this bit cleared

Table 29-28: PCIE_APP_INTSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	RXQOVF	Receive Queue Overflow asserted. The `PCIE_APP_INTSTAT.RXQOVF` bit reports the status of the receive queue overflow interrupt.	
		0	Receive Queue Overflow Interrupt was not asserted since the last time this bit was cleared
		1	Receive Queue Overflow Interrupt was not asserted since the last time this bit was cleared
15 (R/W1C)	PMTOFF	Power Management Turn Off Message. The `PCIE_APP_INTSTAT.PMTOFF` bit reports the status of the power management turn off message.	
		0	No Message
		1	Message Received
14 (R/W1C)	PMTOACK	Power Management Acknowledge Message. The `PCIE_APP_INTSTAT.PMTOACK` bit reports the status of the power management acknowledge message.	
		0	No Message
		1	Message Received
13 (R/W1C)	PME	Power Management Event Message. The `PCIE_APP_INTSTAT.PME` bit reports the status of the power management event message.	
		0	No Message
		1	Message Received
12 (R/W1C)	FTLERR	Fatal Error Message. The `PCIE_APP_INTSTAT.FTLERR` bit reports the status of the fatal error message.	
		0	No Message
		1	Message Received
11 (R/W1C)	NFTLERR	Non Fatal Error Message. The `PCIE_APP_INTSTAT.NFTLERR` bit reports the status of the non-fatal error message.	
		0	No Message
		1	Message Received

Table 29-28: PCIE_APP_INTSTAT Register Fields (Continued)

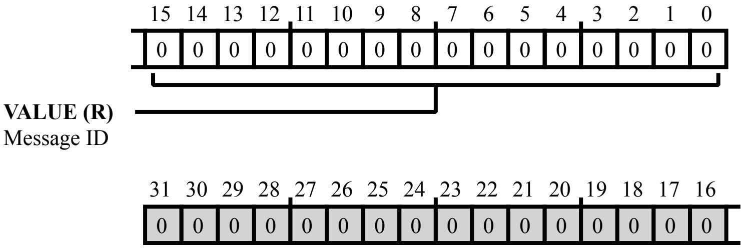
Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W1C)	CORERR	Correctable Error Message. The `PCIE_APP_INTSTAT.CORERR` bit reports the status of the correctable error message.	
		0	No Message
		1	Message Received
9 (R/W1C)	UNLK	Unlock Message. The `PCIE_APP_INTSTAT.UNLK` bit reports the status of the unlock message.	
		0	No Message
		1	Message Received
8 (R/W1C)	VENDMSG	Vendor Message. The `PCIE_APP_INTSTAT.VENDMSG` bit reports the status of the vendor message.	
		0	No Message
		1	Message Received
4 (R/NW)	INTD	INTD Asserted. The `PCIE_APP_INTSTAT.INTD` bit reports the status of the legacy D interrupt.	
		0	INTD De-asserted
		1	INTD Asserted
3 (R/NW)	INTC	INTC Asserted. The `PCIE_APP_INTSTAT.INTC` bit reports the status of the legacy C interrupt.	
		0	INTC De-asserted
		1	INTC Asserted
2 (R/NW)	INTB	INTB Asserted. The `PCIE_APP_INTSTAT.INTB` bit reports the status of the legacy B interrupt.	
		0	INTB De-asserted
		1	INTB Asserted
1 (R/NW)	INTA	INTA Asserted. The `PCIE_APP_INTSTAT.INTA` bit reports the status of the legacy A interrupt.	
		0	INTA De-asserted
		1	INTA Asserted

Table 29-28: PCIE_APP_INTSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	MSI	MSI Interrupt. The `PCIE_APP_INTSTAT.MSI` bit reports the status of the message signaled interrupt.	
		0	MSI Interrupt Not Asserted
		1	MSI Interrupt Asserted

Non Fatal Error Message Requester ID Register

The `PCIE_APP_NFERR_MSG` register contains the requester ID of the latest received Non Fatal Error Message. It is advised to read this register when the `PCIE_APP_INTSTAT.NFTLERR` bit in APP_INTSTAT register is set.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

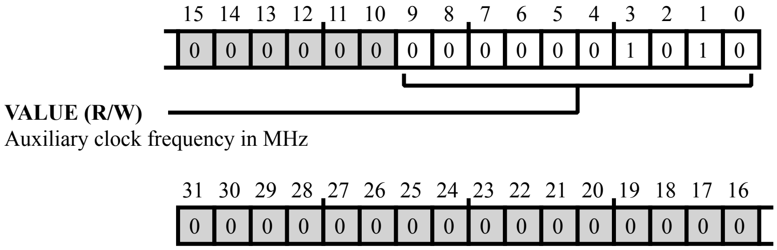
Auxiliary Clock Frequency Control Register

The PCIE_AUX_CLKFREQ_[n] register is used to provide a 1 us reference for counting time during low-power states with aux_clk when the PHY has removed the pipe_clk.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 1 0 1 0
VALUE (R/W)
Auxiliary clock frequency in MHz
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

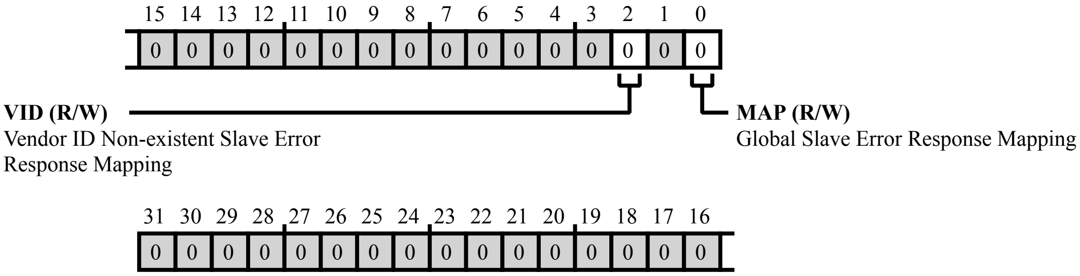
Figure 29-29: PCIE_AUX_CLKFREQ_[n] Register Diagram

Table 29-38: PCIE_AUX_CLKFREQ_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	VALUE	Auxiliary clock frequency in MHz. The `PCIE_AUX_CLKFREQ_[n].VALUE` bit field is used to provide a 1 us reference for counting time during low-power states with aux_clk when the PHY has removed the pipe_clk. Frequencies lower than 1 MHz are possible but with a loss of accuracy in the time counted. If the actual frequency (f) of aux_clk does not exactly match the programmed frequency (f_prog), then an error in the time counted by the core that can be expressed in percentage as: err% = (f_prog/f-1)*100. For example if f=2.5 MHz and f_prog=3 MHz, then err% =(3/2.5-1)*100 =20%, meaning that the time counted by the core on aux_clk will be 20% greater than the time in us programmed in the corresponding time register (for example T_POWER_ON). This bit field is sticky.

Peripheral and SCB Bridge Slave Error Response Register

The `PCIE_BERR_RESP_[n]` register controls the mapping of errors for received inbound completions (of non-posted requests), and the Slave Port response to the SCB master.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VID (R/W)

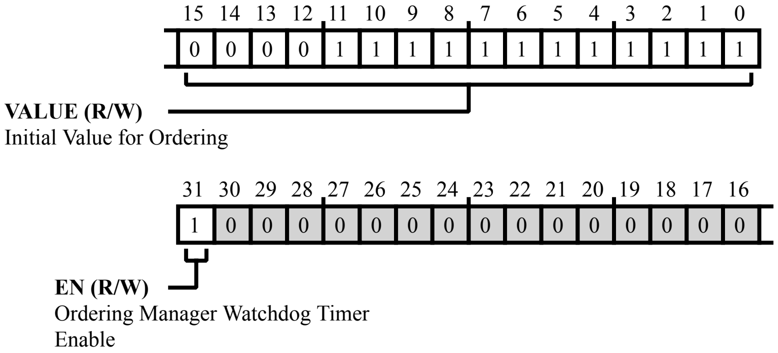
Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	VID	Vendor ID Non-existent Slave Error Response Mapping. Vendor ID Non-existent Slave Error Response Mapping. The `PCIE_BERR_RESP_[n].VID` bit determines the peripheral/SCB slave response for errors on reads to non-existent Vendor ID register. The core ignores the setting in the bit when bit 0 of this register is 0. Note: This register field is sticky.	
		0	OKAY (with FFFF data for non-posted requests)
		1	Error
0 (R/W)	MAP	Global Slave Error Response Mapping. Global Slave Error Response Mapping. The `PCIE_BERR_RESP_[n].MAP` bit determines the peripheral/SCB slave response for all error scenarios on non-posted requests. For more details see "PCIe Link Error Mapping to SCB Slave Interface." Note: This register field is sticky.	
		0	OKAY (with FFFF data for non-posted requests) and ignore the settings in bit [3:2] of this register
		1	ERROR for normal link (data) accesses and Error for normal link data accesses and look at bits [3:2] for other scenarios

Bus Order Manager Watchdog Off Register

The `PCIE_BUSMGR_WDOG_[n]` register contains the initial load value for the bus ordering manager watchdog timer. It has a resolution of 2 us.

The bridge dequeue controller checks (per VC) that there are no outstanding posted transactions on the bus master interface before it takes a completion from the native core receive queue; to prevent violation of rule (5). If necessary it will halt the completion queue and start the watchdog timer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 1 1 1 1 1 1 1 1 1 1 1 1

0 X X X X 0 0 0 0 X X X X 0 0 0
AWVAL (R/W)
Master Write CACHE Signal Value
ARVAL (R/W)
Master Read CACHE Signal Value

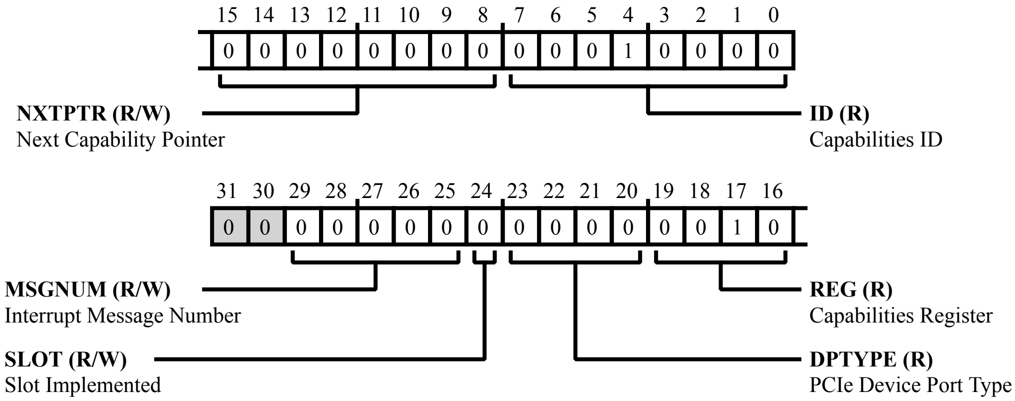
Figure 29-34: PCIE_CACHE_CTL3_[n] Register Diagram

Table 29-43: PCIE_CACHE_CTL3_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:27 (R/W)	AWVAL	Master Write CACHE Signal Value. The `PCIE_CACHE_CTL3_[n].AWVAL` bit field is the value of the individual bits in mstr_awcache when CFG_MSTR_AWCACHE_MODE is 1. This is not applicable to message requests; for message requests the value of mstr_awcache is always 0000. The `PCIE_CACHE_CTL3_[n].AWVAL` bit field is sticky.	
22:19 (R/W)	ARVAL	Master Read CACHE Signal Value. The `PCIE_CACHE_CTL3_[n].ARVAL` bit field is the value of the individual bits in mstr_arcache when CFG_MSTR_ARCACHE_MODE is 1. The `PCIE_CACHE_CTL3_[n].ARVAL` bit field is sticky.	
14:11 (R/W)	AWMD	Master Write CACHE Signal Behavior. The `PCIE_CACHE_CTL3_[n].AWMD` bit field defines how the individual bits in mstr_awcache are controlled. For message requests the value of mstr_awcache is always 0000 regardless of the value of this bit field. The `PCIE_CACHE_CTL3_[n].AWMD` bit field is sticky.	
		0	Set automatically by the SCB master
		1	Set automatically by the SCB master
6:3 (R/W)	ARMD	Master Read CACHE Signal Behavior. The `PCIE_CACHE_CTL3_[n].ARMD` bit field defines how the individual bits in mstr_arcache are controlled. The `PCIE_CACHE_CTL3_[n].ARMD` bit field is sticky.	
		0	Set automatically by the SCB master
		1	Set by the value of the corresponding bit of the CFG_MSTR_ARCACHE_VALUE field

PCIe Capabilities, ID, Next Pointer Register

The `PCIE_CAPB_NPTR_[n]` register configures PCI Express capabilities, identifies the capability structure version number, identifies which MSI/MSI-X vector is used for the interrupt message, and the offset to the next PCI Capability structure Next Pointer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0

Figure 29-35: PCIE_CAPB_NPTR_[n] Register Diagram

Table 29-44: PCIE_CAPB_NPTR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	MSGNUM	Interrupt Message Number. The `PCIE_CAPB_NPTR_[n].MSGNUM` bit field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this Capability structure. For MSI, the value in this field indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the MSI Message Control register. For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined.

The PCIE_CAPB_NPTR_[n].ID read-only bit indicates PCI-SIG defined PCI Express Capability structure version number. A version of the specification that changes the PCI Express Capability structure in a way that is not otherwise identifiable (e.g., through a new Capability field) is permitted to increment this field. All such changes to the PCI Express Capability structure must be software-compatible.
Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as Functions reporting any such Capability Version numbers will contain a PCI Express Capability structure that is compatible with that piece of software. Must be hardwired to 0x2 for Functions compliant to this specification.</td></tr>
</table>

Correctable Error Mask Register

The `PCIE_CORERR_MSK_[n]` register controls reporting of individual correctable errors by this Function to the PCI Express Root Complex via a PCI Express error Message. A masked error (respective bit Set in the mask register) is not reported to the PCI Express Root Complex by this Function. There is a mask bit per error bit in the Correctable Error Status register. Register fields for bits not implemented by the Function are set to 0.

Correctable Error Status Register

The `PCIE_CORERR_STAT_[n]` register reports error status of individual correctable error sources on a PCI Express device Function. When an individual error status bit is Set, it indicates that a particular error occurred; software may clear an error status by writing a 1 to the respective bit. Register bits not implemented by the Function are hardwired to 0.

OBFF (R)
Cap OBFF Support

Figure 29-38: PCIE_DEV_CAPB2_[n] Register Diagram

Table 29-47: PCIE_DEV_CAPB2_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:18 (R/NW)	OBFF	Cap OBFF Support. The `PCIE_DEV_CAPB2_[n].OBFF` bit field indicates if OBFF (Optimized Buffer Flush/Fill) is supported and, if so, what signaling mechanism is used. The value reported in this field must indicate support for WAKE# signaling only if: • For a Downstream Port, driving the WAKE# signal for OBFF is supported and the connector or component connected Downstream is known to receive that same WAKE# signal • For an Upstream Port, receiving the WAKE# signal for OBFF is supported and, if the component is on an add-in-card, that the component is connected to the WAKE# signal on the connector. Root Ports, Switch Ports, and Endpoints are permitted to implement this capability. For Bridges and Ports that do not implement this capability, this field must be set to 00.
		0 Not supported
		1 Supported using Message signaling only
		2 Supported using WAKE# signaling only
		3 Supported using WAKE# and Message signaling
13 (R/NW)	TC1	TLP Processing Hints Complete Support 1. The `PCIE_DEV_CAPB2_[n].TC1` bit indicates Completer support for TPH or Extended TPH. Applicable only to Root Ports and Endpoints. For all other Functions, this field is Reserved.
12 (R/NW)	TC0	TLP Processing Hints Complete Support 0. The `PCIE_DEV_CAPB2_[n].TC0` bit indicates Completer support for TPH or Extended TPH. Applicable only to Root Ports and Endpoints. For all other Functions, this field is Reserved.
11 (R/NW)	LTR	Latency Tolerance Reporting. The `PCIE_DEV_CAPB2_[n].LTR` bit indicates indicates support for the optional Latency Tolerance Reporting (LTR) mechanism. Root Ports, Switches and Endpoints are permitted to implement this capability. For Bridges and other Functions that do not implement this capability, this bit must be set to 0.
10 (R/NW)	NRENP2P	No Routing Element peer-to-peer. If the `PCIE_DEV_CAPB2_[n].NRENP2P` bit is set, the routing element never carries out the passing that is associated with the Relaxed Ordering Attribute field being Set. This bit applies only for Switches and RCs that support peer-to-peer traffic between Root Ports. The `PCIE_DEV_CAPB2_[n].NRENP2P` bit applies only to Posted Requests being forwarded through the Switch or Root-Complex and does not apply to traffic originating or terminating within the Switch or Root-Complex itself. All Ports on a Switch or Root-Complex must report the same value for this bit. For all other functions, this bit must be 0.

Table 29-47: PCIE_DEV_CAPB2_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/NW)	CAS128	Compare and Swap 128 Support. Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0 otherwise. The `PCIE_DEV_CAPB2_[n].CAS128` bit must be set to 1 if the Function supports this optional capability.
8 (R/NW)	CPL64A	CPL 64 Atomic Support. The `PCIE_DEV_CAPB2_[n].CPL64A` bit applies to Functions with Memory Space BARs as well as all Root Ports; must be 0 otherwise. Includes FetchAdd, Swap, and CAS AtomicOps. This bit must be set to 1 if the Function supports this optional capability.
7 (R/NW)	CPL32A	CPL 32 Atomic Support. The `PCIE_DEV_CAPB2_[n].CPL32A` bit applies to Functions with Memory Space BARs as well as all Root Ports; must be 0 otherwise. Includes FetchAdd, Swap, and CAS AtomicOps. This bit must be set to 1 if the Function supports this optional capability.
6 (R/NW)	AR	Atomic Routing Support. The `PCIE_DEV_CAPB2_[n].AR` bit applies only to Switch Upstream Ports, Switch Downstream Ports, and Root Ports; must be 0 for other Function types. This bit must be set to 1 if the Port supports this optional capability.
5 (R/NW)	AF	Alternative Routing ID Forward Support. The `PCIE_DEV_CAPB2_[n].AF` bit applies only to Switch Downstream Ports and Root Ports; must be 0 for other Function types. This bit must be set to 1 if a Switch Downstream Port or Root Port supports this optional capability.
4 (R/NW)	CTD	CPL Timeout Disable Support. A value of 1 in the `PCIE_DEV_CAPB2_[n].CTD` bit indicates support for the Completion Timeout Disable mechanism. The Completion Timeout Disable mechanism is required for Endpoints that issue Requests on their own behalf and PCI Express to PCI/PCI-X Bridges that take ownership of Requests issued on PCI Express. This mechanism is optional for Root Ports. For all other Functions this field is Reserved and must be set to 0.

Table 29-47: PCIE_DEV_CAPB2_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/NW)	CTR	CPL Timeout Range. The `PCIE_DEV_CAPB2_[n].CTR` bit field indicates device Function support for the optional Completion Timeout programmability mechanism. This mechanism allows system software to modify the Completion Timeout value. This field is applicable only to Root Ports, Endpoints that issue Requests on their own behalf, and PCI Express to PCI/PCI-X Bridges that take ownership of Requests issued on PCI Express. For all other Functions this field is Reserved and must be set to 0000. Four time value ranges are defined: • Range A: 50 s to 10 ms • Range B: 10 ms to 250 ms • Range C: 250 ms to 4 s • Range D: 4 s to 64 s All other values are Reserved. It is strongly recommended that the Completion Timeout mechanism not expire in less than 10 ms.	
		0	Completion Timeout programming not supported the Function must implement a timeout value in the range 50 s to 50 ms
		1	Range A
		2	Range B
		3	Ranges A and B
		4	Ranges B and C
		5	Ranges A, B and C
		6	Ranges B, C and D
		7	Ranges A, B, C and D

Device Control 2 and Status 2 Register

The `PCIE_DEV_CTLSTAT2_[n]` register configures the Completion Timeout mechanism and allows the Downstream Port to disable its traditional Device Number field.

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/NW)	ARIFWD	ARI Forward Support. When the `PCIE_DEV_CTLSTAT2_[n].ARIFWD` bit is set, the Downstream Port disables its traditional Device Number field = 0 enforcement when turning a Type 1 Configuration Request into a Type 0 Configuration Request. This permits access to Extended Functions in an ARI Device immediately below the Port. Must be set to 0 if the ARI Forwarding Supported bit is 0.
4 (R/W)	CPLTMODIS	Completion Timeout Disable. When set, the `PCIE_DEV_CTLSTAT2_[n].CPLTMODIS` bit disables the Completion Timeout mechanism.

Device Control and Status Register

Figure 29-40: PCIE_DEV_CTLSTAT_[n] Register Diagram

Table 29-49: PCIE_DEV_CTLSTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/NW)	TPND	Transactions Pending. When the `PCIE_DEV_CTLSTAT_[n].TPND` bit is set for endpoints, it indicates that the Function has issued Non-Posted Requests that have not been completed. A Function reports this bit cleared only when all outstanding Non-Posted Requests have completed or have been terminated by the Completion Timeout mechanism. This bit must also be cleared upon the completion of an FLR. For Root Complex and Switch Ports, when this bit is set, it indicates that a Port has issued Non-Posted Requests on its own behalf (using the Ports own Requester ID) which have not been completed. The Port reports this bit cleared only when all such outstanding Non- Posted Requests have completed or have been terminated by the Completion Timeout mechanism. Note that Root and Switch Ports implementing only the functionality required by this document do not issue Non-Posted Requests on their own behalf, and therefore are not subject to this case. Root and Switch Ports that do not issue Non-Posted Requests on their own behalf hardwire this bit to 0.
20 (R/NW)	AUXPWRDET	AUX Power Detected. The `PCIE_DEV_CTLSTAT_[n].AUXPWRDET` is read-only. Functions that require Aux power report this bit as set if Aux power is detected by the Function.
19 (R/W)	UREQDET	Unsupported Request Detected. The `PCIE_DEV_CTLSTAT_[n].UREQDET` bit indicates that the Function received an Unsupported Request. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For a multi-Function device, each Function indicates status of errors as perceived by the respective Function. Default value of this bit is 0.
18 (R/W)	FERR_DET	Fatal Error Detected. The `PCIE_DEV_CTLSTAT_[n].FERR_DET` bit indicates status of Fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For a multi-Function device, each Function indicates status of errors as perceived by the respective Function. For Functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Uncorrectable Error Mask register. Default value of this bit is 0.
17 (R/W)	NFERRDET	Non-Fatal Error Detected. The `PCIE_DEV_CTLSTAT_[n].NFERRDET` bit indicates status of Nonfatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For a multi-Function device, each Function indicates status of errors as perceived by the respective Function. For Functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Uncorrectable Error Mask register. Default value of this bit is 0.

</table>

Table 29-49: PCIE_DEV_CTLSTAT_[n] Register Fields (Continued)

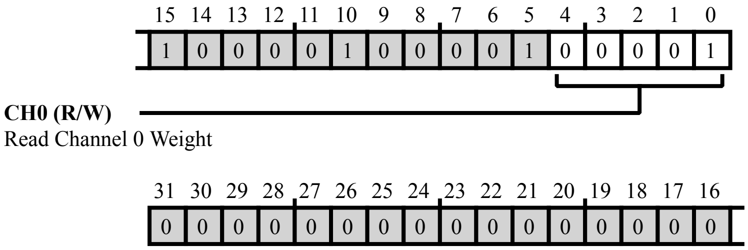
Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	UREQEN	Unsupported Request Reporting Enable. The `PCIE_DEV_CTLSTAT_[n].UREQEN` bit, in conjunction with other bits, controls the signaling of Unsupported Request Errors by sending error Messages. For a multi-Function device, this bit controls error reporting for each Function from point-of-view of the respective Function. A Root Complex Integrated Endpoint that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0. Default value of this bit is 0.
2 (R/W)	FERR_EN	Fatal Error Reporting Enable. The `PCIE_DEV_CTLSTAT_[n].FERR_EN` bit, in conjunction with other bits, controls sending fatal error Messages. For a multi-Function device, this bit controls error reporting for each Function from point-of-view of the respective Function. For a Root Port, the reporting of Fatal errors is internal to the root. No external fatal error Message is generated. A Root Complex Integrated Endpoint that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0b. Default value of this bit is 0.
1 (R/W)	NFERREN	Non-Fatal Error Reporting Enable. The `PCIE_DEV_CTLSTAT_[n].NFERREN` bit, in conjunction with other bits, controls sending non-fatal error Messages. For a multi-Function device, this bit controls error reporting for each Function from point-of-view of the respective Function. For a Root Port, the reporting of Non-fatal errors is internal to the root. No external non-fatal error Message is generated. A Root Complex Integrated Endpoint that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0. Default value of this bit is 0.
0 (R/W)	CERREN	Correctable Error Reporting Enable. The `PCIE_DEV_CTLSTAT_[n].CERREN` bit, in conjunction with other bits, controls sending correctable error messages. For a multi-Function device, this bit controls error reporting for each Function from point-of-view of the respective Function. For a Root Port, the reporting of correctable errors is internal to the root. No external ERR_COR Message is generated. A Root Complex Integrated Endpoint that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0. Default value of this bit is 0.

DMA Read Arbitration Weight Low Off Register

The `PCIE_DMARD_ARBWGT_LO_[n]` register for 5-bit channel weight (for read channels 0-3) specifies the number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. Value range is (0-0x1F) corresponding to (1-32) transactions.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

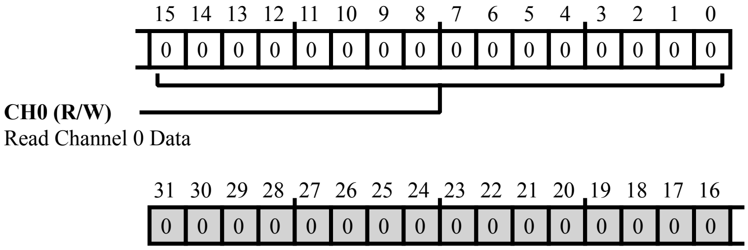
Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	CH0	Read Channel 0 Weight. The `PCIE_DMARD_ARBWGT_LO_[n].CH0` bit field value is used by the channel weighted round robin arbiter to select the next channel read request. The weight is initialized by software before ringing the doorbell.

DMA Read Channel 1 and 0 IMWr Data Register

The `PCIE_DMARD_CH01_IMWR_[n]` register is implemented in RAM whose contents are uninitialized after power on. This register must always have an initialized value because the default is undefined. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 29-43: PCIE_DMARD_CTL1_[n] Register Diagram

Table 29-52: PCIE_DMARD_CTL1_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:30 (R/W)	AT	Address Translation TLP Header. The DMA uses the `PCIE_DMARD_CTL1_[n].AT` bit field when generating MRd/MWr (not IMWr) TLPs.
29:27 (R/W)	TC	Traffic Class TLP Header. The DMA uses the `PCIE_DMARD_CTL1_[n].TC` bit field when generating MRd/MWr (not IMWr) TLPs.
26 (R/W)	TD	Traffic Digest TLP Header. The PCIe core adds the ECRC field and sets the `PCIE_DMARD_CTL1_[n].TD` bit in the TLP header. The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs.

Table 29-52: PCIE_DMARD_CTL1_[n] Register Fields (Continued)

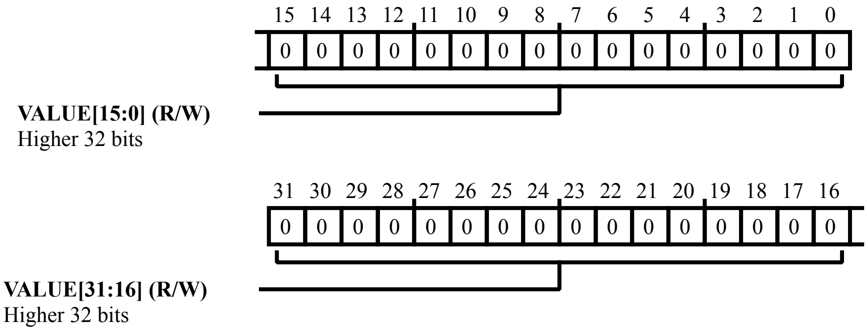
Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	RO	Relaxed Ordering TLP Header. The DMA uses the `PCIE_DMARD_CTL1_[n].RO` bit field when generating MRd/MWr (not IMWr) TLPs.	
24 (R/W)	NS	No Snoop TLP Header. The `PCIE_DMARD_CTL1_[n].NS` bit is used by DMA when generating MRd/MWr (not IMWr) TLPs.	
16:12 (R/W)	FNUM	DMA Function Number. The core uses the `PCIE_DMARD_CTL1_[n].FNUM` bit field when generating the requester ID for the MRd/MWr DMA TLP. When SR-IOV is enabled, this field is ignored if the VFE field in the DMA Write Channel Control 2 Register is set.	
9 (R/W)	LLE	Linked List Enable. The `PCIE_DMARD_CTL1_[n].LLE` bit enables linked list operation.	
		0	Disable Linked Lists
		1	Enable Linked Lists
8 (R/W)	CCS	Consumer Cycle State. The `PCIE_DMARD_CTL1_[n].CCS` bit is used to synchronize the producer (software) and the consumer (DMA). This bit must be initialized. The DMA updates the `PCIE_DMARD_CTL1_[n].CCS` bit during linked list operation. Used in linked list mode only.	
6:5 (R/W)	CS	Channel Status. The `PCIE_DMARD_CTL1_[n].CS` status bits identify the current operational state of the DMA channel.	
		0	Reserved
		1	Running. This channel is active and transferring data.
		2	Halted. An error condition has been detected, and the DMA has stopped this channel.
		3	Stopped. DMA transferred all data for this channel, or channel prematurely stopped by writing to the Stop field of the DMA Write Doorbell Register or DMA Read Doorbell Register.
4 (R/W)	RIE	Remote Interrupt Enable. Programs must set the `PCIE_DMARD_CTL1_[n].RIE` bit to enable the generation of the Done or Abort Remote interrupts. In LL mode, the DMA overwrites this with the RIE of the LL element. The `PCIE_DMARD_CTL1_[n].RIE` bit in a LL element only enables the Done interrupt. In non-LL mode, this bit enables the Done and Abort interrupts. This field is not defined in a link LL element.	

Table 29-52: PCIE_DMARD_CTL1_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	LIE	Local Interrupt Enable. Programs must set the `PCIE_DMARD_CTL1_[n].LIE` bit to enable the generation of the Done or Abort Local interrupts. In LL mode, the DMA overwrites the `PCIE_DMARD_CTL1_[n].LIE` bit with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element.
2 (R/W)	LLP	Load Link Pointer. The `PCIE_DMARD_CTL1_[n].LLP` bit indicates that this linked list element is a link element, and its LL element pointer dwords point to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Used in linked list mode only.
1 (R/W)	TCB	Toggle Cycle Bit. The `PCIE_DMARD_CTL1_[n].TCB` bit indicates to the DMA to toggle its interpretation of the CB. It is used to synchronize the producer (software) and the consumer (DMA). The DMA loads this field with the TCB of the linked list element. This field is not defined in a data LL element and is used in linked list mode only.
0 (R/W)	CB	Cycle Bit. The `PCIE_DMARD_CTL1_[n].CB` bit is used to synchronize the producer (software) and the consumer (DMA). The DMA loads this field with the CB of the linked list element. Used in linked list mode only.

DMA Destination Address High Read Channel Register

The `PCIE_DMARD_DAR_HI_[n]` register is implemented in RAM whose contents are uninitialized after power-on. All fields marked "Reserved" MUST be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Lower 32 bits

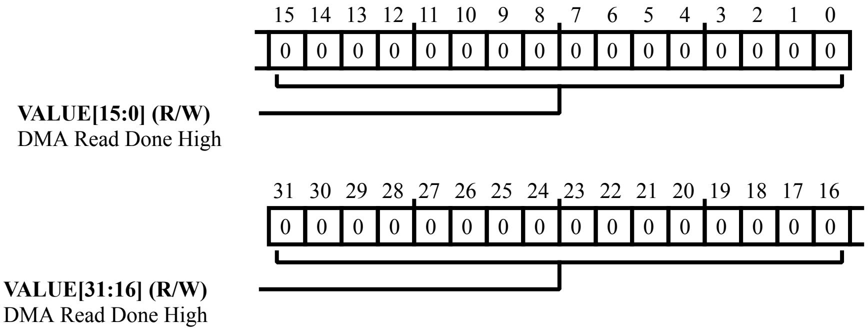
Figure 29-45: PCIE_DMARD_DAR_LO_[n] Register Diagram

Table 29-54: PCIE_DMARD_DAR_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Lower 32 bits. The `PCIE_DMARD_DAR_LO_[n].VALUE` bit field indicates the next address to be written to. The DMA increments the DAR as the DMA transfer progresses. The DAR is always dword aligned even if the transfer size is byte aligned. In LL mode, the DMA overwrites this bit field with the corresponding dword of the LL element. he DAR is the address of the local memory.

DMA Read Done IMWr Address High Register

The `PCIE_DMARD_DONE_IMWR_HI_[n]` register is implemented in RAM whose contents are uninitialized after power on. Therefore, you must always initialize this register value because the default is undefined. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

VALUE[31:16] (R/W)
DMA Read Done Low

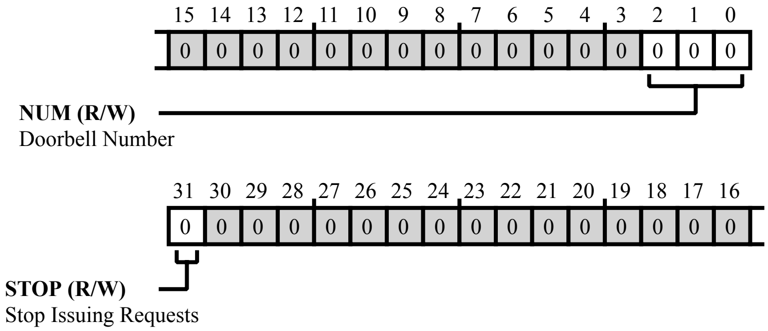
Figure 29-47: PCIE_DMARD_DONE_IMWR_LO_[n] Register Diagram

Table 29-56: PCIE_DMARD_DONE_IMWR_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Read Done Low. The DMA uses the `PCIE_DMARD_DONE_IMWR_LO_[n].VALUE` bit field to generate bits [31:0] of the address field for the Done IMWr TLP. Bits [1:0] must be 00 as this address must be dword aligned.

DMA Read Doorbell Register

The `PCIE_DMARD_DRBL_[n]` bit register provides the doorbell number and stops issuing requests.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
NUM (R/W)
Doorbell Number
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
STOP (R/W)
Stop Issuing Requests

Figure 29-48: PCIE_DMARD_DRBL_[n] Register Diagram

Table 29-57: PCIE_DMARD_DRBL_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	STOP	Stop Issuing Requests. The `PCIE_DMARD_DRBL_[n].STOP` bit is set in conjunction with the doorbell number field. The DMA read channel stops issuing requests, sets the channel status to Stopped, and asserts the Abort interrupt (if enabled). Before setting the `PCIE_DMARD_DRBL_[n].STOP` bit, programs must read the `PCIE_DMARD_CTL1_[n].CS` (channel status) to ensure that the read channel is running (transferring data).
2:0 (R/W)	NUM	Doorbell Number. The `PCIE_DMARD_DRBL_[n].NUM` bit field is the doorbell number. Programs must write 0x0 to this bit field to start the DMA read transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. The range of this field is 0x0 to 0x7, and 0x0 corresponds to channel 0.

DMA Read Engine Enable Register

The `PCIE_DMARD_EN_[n]` register enables the DMA read engine. Programs must initially enable the the DMA read engine (=1) for normal operation, before any other software setup. The enable bit in this register does not need to be toggled or rewritten during normal operation. To soft reset the DMA controller read logic this bit should be cleared (=0). There are three possible reasons for resetting the DMA controller read logic.

- The `PCIE_DMARD_ISTAT_[n].ABRT` bit is set and any of the bits in the `PCIE_DMARD_ERRSTAT_LO_[n]` register are set. Resetting the DMA controller read logic re-initializes the control logic, ensuring that the next DMA read transfer is executed successfully.
- The procedure outlined in "Stop Bit" has been executed, after which, the `PCIE_DMARD_ISTAT_[n].ABRT` bit is set and the `PCIE_DMARD_CTL1_[n].CS` is set to "Stopped". Resetting the DMA controller read logic re-initializes the control logic ensuring that the next DMA read transfer is executed successfully.
- If the DMA engine is incorrectly programmed during software development.

To Soft Reset the DMA controller read logic:

- De-assert the DMA read engine enable bit.
- Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA read engine enable bit returns a 0.
- Assert the DMA read engine enable bit.

This Soft Reset does not clear the DMA configuration registers. The DMA read transfer does not start until you write to the `PCIE_DMARD_DRBL_[n].STOP` bit.

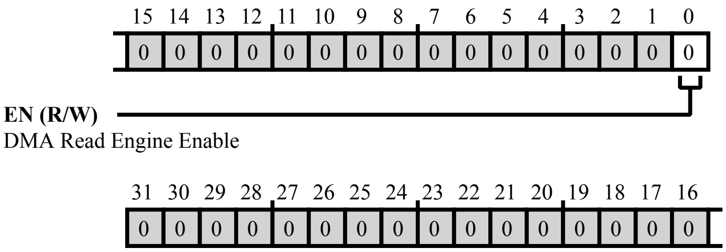


Figure 29-49: PCIE_DMARD_EN_[n] Register Diagram

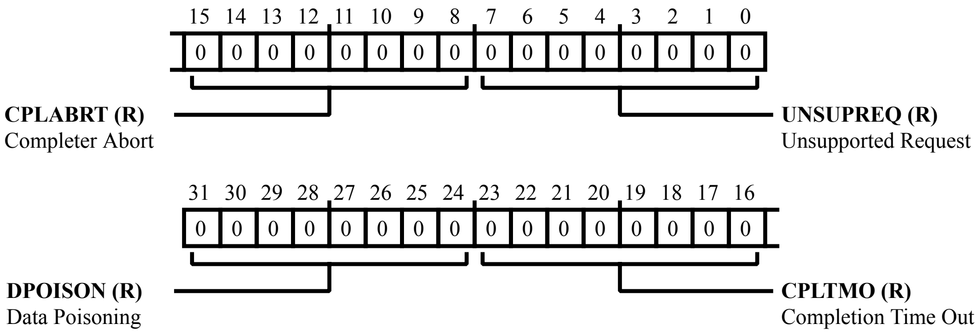
Table 29-58: PCIE_DMARD_EN_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	DMA Read Engine Enable. The `PCIE_DMARD_EN_[n].EN` bit enables or disables the DMA read engine.	
		0	Disable engine (soft reset)
		1	Enable engine

DMA Read Error Status High Register

The PCIE_DMARD_ERRSTAT_HI_[n] register reports errors for read channels 4-7.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

DPOISON (R)
Data Poisoning
CPLTMO (R)
Completion Time Out

Figure 29-50: PCIE_DMARD_ERRSTAT_HI_[n] Register Diagram

Table 29-59: PCIE_DMARD_ERRSTAT_HI_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	DPOISON	Data Poisoning. The PCIE_DMARD_ERRSTAT_HI_[n].DPOISON bit field reports that the DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel drops the completion and then halts. The CX_FLT_MSK_UR_POIS filter rule does not affect this behavior. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enable. For details, see "Interrupts and Error Handling". • Mask. The DMA read interrupt Mask register has no effect on this register. • Clear. Programs must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the (PCIE_DMARD_ICLR_[n]) register to clear this error bit. Note that this action also clears the other error bits for the same channel in this register and in the PCIE_DMARD_ERRSTAT_LO_[n] register.
23:16 (R/NW)	CPLTMO	Completion Time Out. The PCIE_DMARD_ERRSTAT_HI_[n].CPLTMO bit field reports that the DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enable. For details, see "Interrupts and Error Handling". • Mask. The DMA read interrupt Mask register has no effect on this register. • Clear. Programs must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the (PCIE_DMARD_ICLR_[n]) register to clear this error bit. Note that this action also clears the other error bits for the same channel in this register and in the PCIE_DMARD_ERRSTAT_LO_[n] register.

Table 29-59: PCIE_DMARD_ERRSTAT_HI_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	CPLABRT	Completer Abort. The `PCIE_DMARD_ERRSTAT_HI_[n].CPLABRT` bit field reports that the DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enable. For details, see "Interrupts and Error Handling". • Mask. The DMA read interrupt Mask register has no effect on this register. • Clear. Programs must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the (`PCIE_DMARD_ICLR_[n]`) register to clear this error bit. Note that this action also clears the other error bits for the same channel in this register and in the `PCIE_DMARD_ERRSTAT_LO_[n]` register.
7:0 (R/NW)	UNSUPREQ	Unsupported Request. The `PCIE_DMARD_ERRSTAT_HI_[n].UNSUPREQ` bit field reports that the DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_RD_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.

DMA Read Error Status Low Register

The `PCIE_DMARD_ERRSTAT_LO_[n]` register reports errors for read channels 0-3.

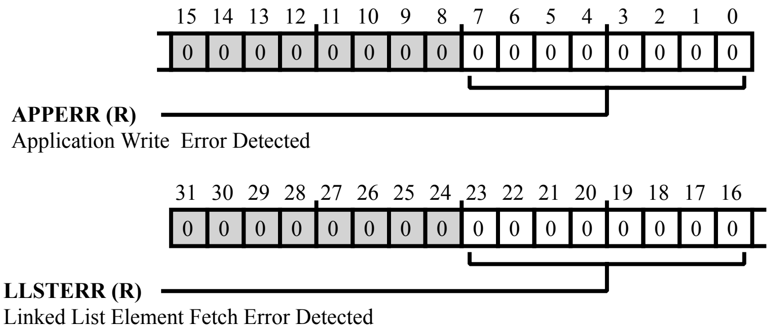

Figure 29-51: PCIE_DMARD_ERRSTAT_LO_[n] Register Diagram

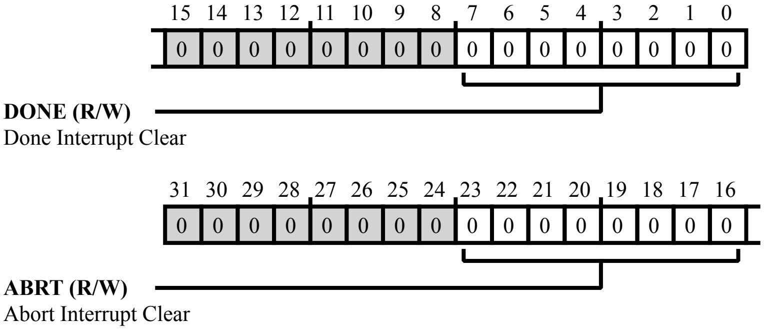
Table 29-60: PCIE_DMARD_ERRSTAT_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/NW)	LLSTERR	Linked List Element Fetch Error Detected. The `PCIE_DMARD_ERRSTAT_LO_[n].LLSTERR` bit field reports that the DMA read channel has received an error response from the AHB/AXI bus while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enable. For details, see "Interrupts and Error Handling". • Mask. The DMA read interrupt Mask register has no effect on this register. • Clear. Programs must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the (`PCIE_DMARD_ICLR_[n]`) register to clear this error bit. Note that this action also clears the other error bits for the same channel in this register and in the `PCIE_DMARD_ERRSTAT_HI_[n]` register.
7:0 (R/NW)	APPERR	Application Write Error Detected. The `PCIE_DMARD_ERRSTAT_LO_[n].APPERR` bit field reports that the DMA read channel has received an error response from the peripheral/core bus (or RTRGT1 interface when the AHB/AXI Bridge is not used) while writing data to it. This error is fatal. The data transfer must be restarted from the beginning, as the channel context is corrupted, and the transfer is not rolled back. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enable. For details, see "Interrupts and Error Handling". • Mask. The DMA read interrupt Mask register has no effect on this register. • Clear. Programs must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the (`PCIE_DMARD_ICLR_[n]`) register to clear this error bit. Note that this action also clears the other error bits for the same channel in this register and in the `PCIE_DMARD_ERRSTAT_HI_[n]` register.

DMA Read Interrupt Clear Register

The `PCIE_DMARD_ICLR_[n]` register is used to clear corresponding bits in the `PCIE_DMARD_ISTAT_[n]` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

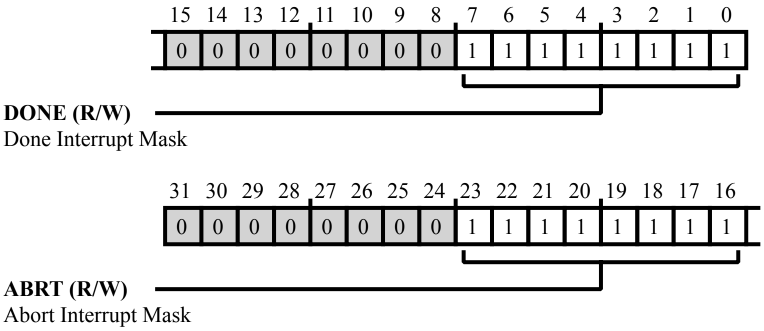
Table 29-61: PCIE_DMARD_ICLR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	ABRT	Abort Interrupt Clear. Writing 1'b1 to the `PCIE_DMARD_ICLR_[n].ABRT` bit field clears the corresponding bit in the `PCIE_DMARD_ISTAT_[n].ABRT` bit field. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Reading from this self-clearing register field always returns 0.
7:0 (R/W)	DONE	Done Interrupt Clear. Writing 1'b1 to the `PCIE_DMARD_ICLR_[n].DONE` bit field clears the corresponding bit in the `PCIE_DMARD_ISTAT_[n].DONE` bit field. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Reading from this self-clearing register field always returns 0.

DMA Read Interrupt Mask Register

The `PCIE_DMARD_IMSK_[n]` register is used to mask interrupts in the `PCIE_DMARD_ISTAT_[n]` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1

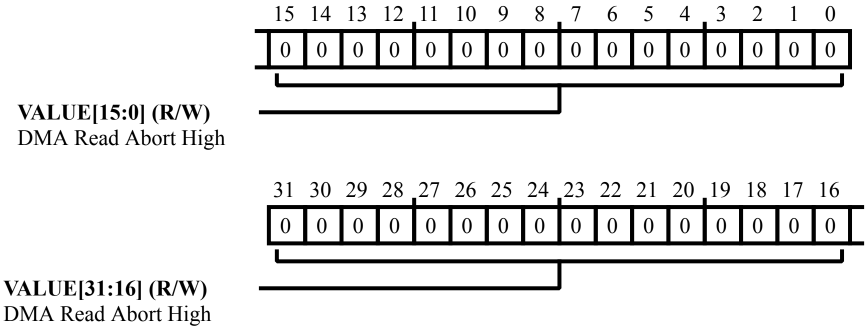
Table 29-62: PCIE_DMARD_IMSK_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	ABRT	Abort Interrupt Mask. The `PCIE_DMARD_IMSK_[n].ABRT` bit field prevents the `PCIE_DMARD_ISTAT_[n].ABRT` status field in the DMA from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.
7:0 (R/W)	DONE	Done Interrupt Mask. The `PCIE_DMARD_IMSK_[n].DONE` bit field prevents the `PCIE_DMARD_ISTAT_[n].DONE` status field in the DMA from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.

DMA Read Abort IMWr Address High Register

The `PCIE_DMARD_IMWRABRT_HI_[n]` register is implemented in RAM whose contents are uninitialized after power on. Programs must always initialize this register value because the default is undefined. All fields marked Reserved MUST be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
DMA Read Abort High

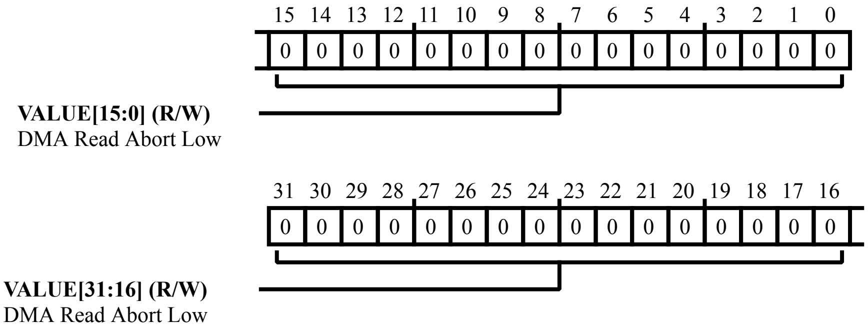
Figure 29-54: PCIE_DMARD_IMWRABRT_HI_[n] Register Diagram

Table 29-63: PCIE_DMARD_IMWRABRT_HI_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Read Abort High. The `PCIE_DMARD_IMWRABRT_HI_[n].VALUE` bit field is used by the DMA to generate bits [63:32] of the address field for the Abort IMWr TLP.

DMA Read Abort IMWr Address Low Register

The `PCIE_DMARD_IMWRABRT_LO_[n]` register is implemented in RAM whose contents are uninitialized after power on. Therefore, you must always initialize this register value because the default is undefined. All fields marked Reserved MUST be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
DMA Read Abort Low

Figure 29-55: PCIE_DMARD_IMWRABRT_LO_[n] Register Diagram

Table 29-64: PCIE_DMARD_IMWRABRT_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Read Abort Low. The `PCIE_DMARD_IMWRABRT_LO_[n].VALUE` bit field is used by the DMA to generate bits [31:0] of the address field for the Abort IMWr TLP. Bits [1:0] must be 00 as this address must be dword aligned.

DMA Read Interrupt Status Register

The `PCIE_DMARD_ISTAT_[n]` register provides status information on DMA reads.

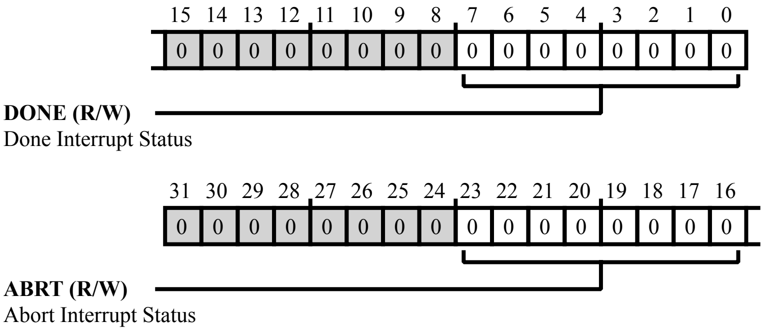

Figure 29-56: PCIE_DMARD_ISTAT_[n] Register Diagram

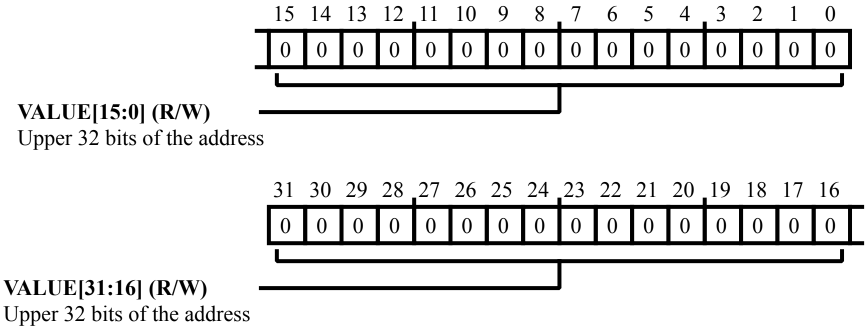
Table 29-65: PCIE_DMARD_ISTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	ABRT	Abort Interrupt Status. The `PCIE_DMARD_ISTAT_[n].ABRT` indicates the DMA read channel has detected an error or the transfer was stopped manually. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Programs can read the DMA Read Error Status Low Register and DMA Read Error Status High Register to determine the source of the error. The DMA read interrupt Mask register has no effect on this bit field. Programs must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit. Programs can write to this bit field to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this bit field.
7:0 (R/W)	DONE	Done Interrupt Status. The `PCIE_DMARD_ISTAT_[n].DONE` indicates the DMA read channel has successfully completed the DMA read transfer. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. The DMA read interrupt Mask register has no effect on this bit field. Programs must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit. Programs can write to this bit field to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this bit field.

DMA LLP High Read Channel Register

The `PCIE_DMARD_LLP_HI_[n]` register is implemented in RAM whose contents are uninitialized after power on. This register value must always be initialized because the default is undefined. All fields marked Reserved must be programmed to 1'b0. All fields marked Reserved MUST be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Upper 32 bits of the address
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Upper 32 bits of the address

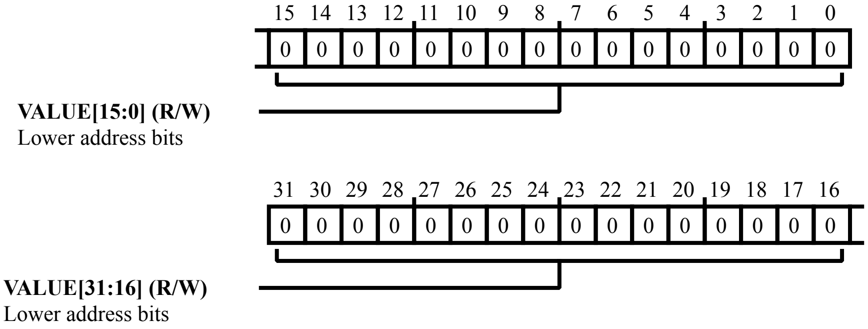
Figure 29-57: PCIE_DMARD_LLP_HI_[n] Register Diagram

Table 29-66: PCIE_DMARD_LLP_HI_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Upper 32 bits of the address. The `PCIE_DMARD_LLP_HI_[n].VALUE` bit field contains the upper 32 bits of the address of the linked list transfer list in local memory. Used in linked list mode only. The `PCIE_DMARD_LLP_HI_[n].VALUE` bit field is updated by the DMA to point to the next element in the transfer list as elements are consumed.

DMA LLP Low Read Channel Register

The `PCIE_DMARD_LLP_LO_[n]` register is implemented in RAM whose contents are uninitialized after power on. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Lower address bits
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Lower address bits

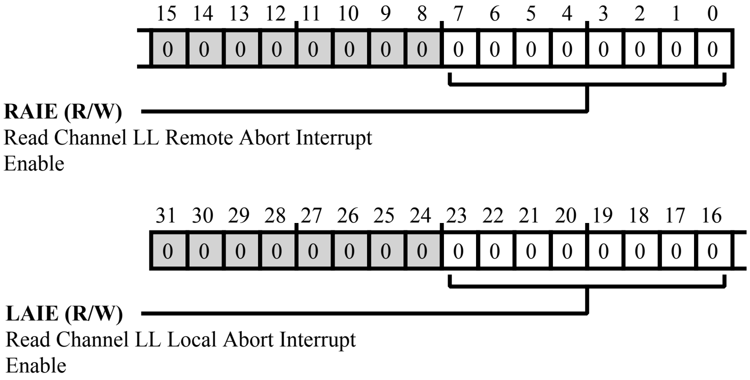
Figure 29-58: PCIE_DMARD_LLP_LO_[n] Register Diagram

Table 29-67: PCIE_DMARD_LLP_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Lower address bits. The `PCIE_DMARD_LLP_LO_[n].VALUE` bit field contains the lower bits of the address of the linked list transfer list in local memory. Used in linked list mode only. The `PCIE_DMARD_LLP_LO_[n].VALUE` bit field is updated by the DMA to point to the next element in the transfer list after the previous element is consumed. • When the current element is a data element; this field is incremented by 6. • When the current element is a link element; this field is overwritten by the LL Element Pointer of the element.

DMA Read Linked List Error Enable Register

The `PCIE_DMARD_LLSTERR_EN_[n]` register provides bits in the LL element that enable the channel done and abort interrupts (local and remote).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Lower 32 bits

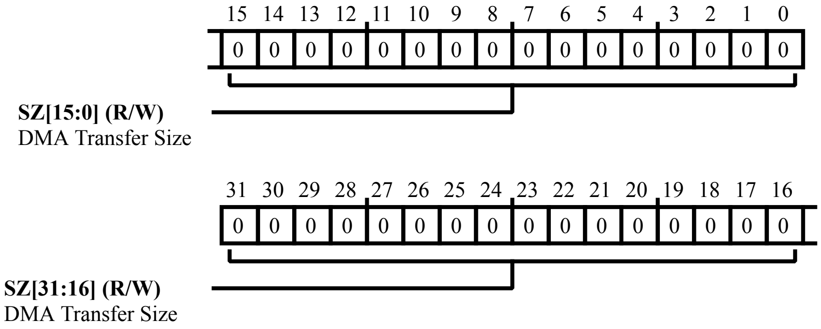
Figure 29-61: PCIE_DMARD_SAR_LO_[n] Register Diagram

Table 29-70: PCIE_DMARD_SAR_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Lower 32 bits. The `PCIE_DMARD_SAR_LO_[n].VALUE` bit field indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. The SAR is the address of the remote memory.

DMA Transfer Size Read Channel Register

The PCIE_DMARD_XFRSZ_[n] register is implemented in RAM whose contents are uninitialized after power-on. All fields marked Reserved MUST be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SZ[15:0] (R/W)
DMA Transfer Size

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SZ[31:16] (R/W)
DMA Transfer Size

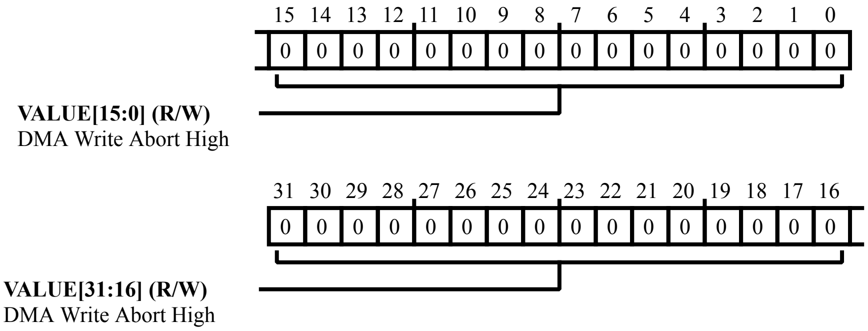
Figure 29-62: PCIE_DMARD_XFRSZ_[n] Register Diagram

Table 29-71: PCIE_DMARD_XFRSZ_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SZ	DMA Transfer Size. The `PCIE_DMARD_XFRSZ_[n].SZ` bit field configures the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA write and read channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites the `PCIE_DMARD_XFRSZ_[n].SZ` bit field with the corresponding dword of the LL element.

DMA Write Abort IMWr Address High Register

The `PCIE_DMAWR_ABRT_IMWR_HI[n]` register is implemented in RAM whose contents are uninitialized after power on. Therefore, you must program and initialize every field as the default is undefined. All fields marked Reserved MUST be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
DMA Write Abort High

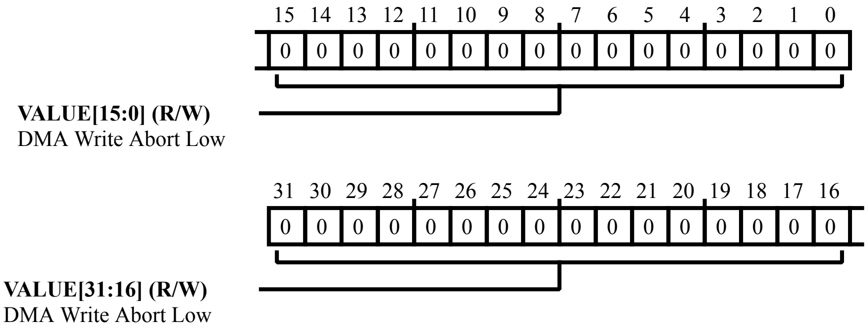
Figure 29-63: PCIE_DMAWR_ABRT_IMWR_HI[n] Register Diagram

Table 29-72: PCIE_DMAWR_ABRT_IMWR_HI[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Write Abort High. The DMA uses the `PCIE_DMAWR_ABRT_IMWR_HI[n].VALUE` bit field to generate bits [63:32] of the address field for the Abort IMWr TLP.

DMA Write Abort IMWr Address Low Register

The `PCIE_DMAWR_ABRT_IMWR_LO[n]` register is implemented in RAM whose contents are uninitialized after power on. Therefore, you must program and initialize every field as the default is undefined. All fields marked Reserved MUST be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 29-73: PCIE_DMAWR_ABRT_IMWR_LO[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Write Abort Low. The DMA uses the `PCIE_DMAWR_ABRT_IMWR_LO[n].VALUE` bit field to generate bits [31:0] of the address field for the Abort IMWr TLP it generates. Bits [1:0] must be 00 as this address must be dword aligned.

DMA Write Channel Arbitration Weight Low Off Register

The `PCIE_DMAWR_ARBWGT_LO_[n]` register specifies the number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. It does this for the 5-bit channel weight (for write channels 0-3). When the channel weight count is reached, the WWR arbiter selects the next channel to be processed. The software must initialize this register before ringing the doorbell. The value range is (0x00-0x1F) corresponding to (1-32) transactions.

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	CH0	Channel 0 Weight. The `PCIE_DMAWR_ARBWGT_LO_[n].CH0` bit field value is used by the channel weighted round robin arbiter to select the next channel read request. The weight is initialized by software before ringing the doorbell.

DMA Write Channel 1 and 0 IMWr Data Register

The `PCIE_DMAWR_CH01_IMWR_[n]` register is implemented in RAM whose contents are uninitialized after power on. Therefore, you must program and initialize every field as the default is undefined. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.

Figure 29-67: PCIE_DMAWR_CTL1_[n] Register Diagram

Table 29-76: PCIE_DMAWR_CTL1_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:30 (R/W)	AT	Address Translation. The DMA uses the `PCIE_DMAWR_CTL1_[n].AT` TLP header field when generating memory read and memory write (not IMWr) TLPs.
29:27 (R/W)	TC	Traffic Class TLP Header Bit. The DMA uses the `PCIE_DMAWR_CTL1_[n].TC` bit TLP header field when generating memory read and memory write (not IMWr) TLPs.
26 (R/W)	TD	Traffic Digest. The PCIe core adds the ECRC field and sets the `PCIE_DMAWR_CTL1_[n].TD` bit in the TLP header. The DMA uses the `PCIE_DMAWR_CTL1_[n].TD` TLP header field when generating memory read and memory write (not IMWr) TLPs.

Table 29-76: PCIE_DMAWR_CTL1_[n] Register Fields (Continued)

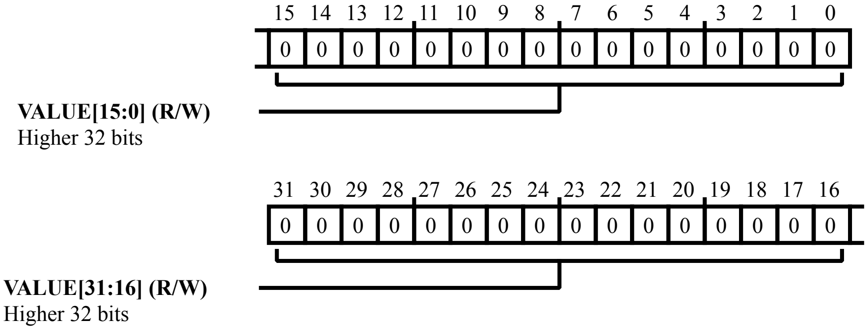
Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	RO	Relaxed Ordering. The DMA uses the `PCIE_DMAWR_CTL1_[n].RO` TLP header field when generating memory read and memory write (not IMWr) TLPs.
24 (R/W)	NS	No Snoop TLP Header. The DMA uses the `PCIE_DMAWR_CTL1_[n].NS` TLP header field when generating memory read and memory write (not IMWr) TLPs.
16:12 (R/W)	FNUM	DMA Function Number. The core uses the `PCIE_DMAWR_CTL1_[n].FNUM` bit field when generating the requester ID for the memory read, memory write DMA TLP.
9 (R/W)	LLE	Linked List Enable. The `PCIE_DMAWR_CTL1_[n].LLE` bit enables (=1) and disables (=0) linked list operation.
8 (R/W)	CCS	Consumer Cycle State. The `PCIE_DMAWR_CTL1_[n].CCS` bit is used in linked list mode to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". This bit must be initialized. The DMA updates this bit during linked list operation.
6:5 (R/W)	CS	Channel Status. The `PCIE_DMAWR_CTL1_[n].CS` bit field identifies the current operational state of the DMA channel. In the case of 2'b11 (Stopped) this means the DMA has transferred all data for this channel, or the program has prematurely stopped this channel by writing to the `PCIE_DMAWR_DRBL_[n].STOP` bit field.
		0 Reserved
		1 Running (channel active and transferring data)
		2 Halted (an error condition has been detected, and the DMA has stopped this channel)
		3 Stopped
4 (R/W)	RIE	Remote Interrupt Enable. Programs must set the `PCIE_DMAWR_CTL1_[n].RIE` bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The `PCIE_DMAWR_CTL1_[n].RIE` bit in a LL element only enables the Done interrupt. In non-LL mode, this bit enables the Done and Abort interrupts. This field is not defined in a link LL element.

Table 29-76: PCIE_DMAWR_CTL1_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	LIE	Local Interrupt Enable. Programs must set the `PCIE_DMAWR_CTL1_[n].LIE` bit to enable generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The `PCIE_DMAWR_CTL1_[n].LIE` bit in a LL element only enables the Done interrupt. In non-LL mode, this bit enables the Done and Abort interrupts. This field is not defined in a link LL element.
2 (R/W)	LLP	Load Link Pointer. The `PCIE_DMAWR_CTL1_[n].LLP` bit is used in linked list mode only. This bit indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element.
1 (R/W)	TCB	Toggle Cycle Bit. The `PCIE_DMAWR_CTL1_[n].TCB` bit indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element.
0 (R/W)	CB	Cycle Bit. The `PCIE_DMAWR_CTL1_[n].CB` bit is used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element.

DMA Dar High Write Channel Register

The `PCIE_DMAWR_DAR_HI_[n]` register is implemented in RAM whose contents are uninitialized after power-on. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Higher 32 bits
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Higher 32 bits

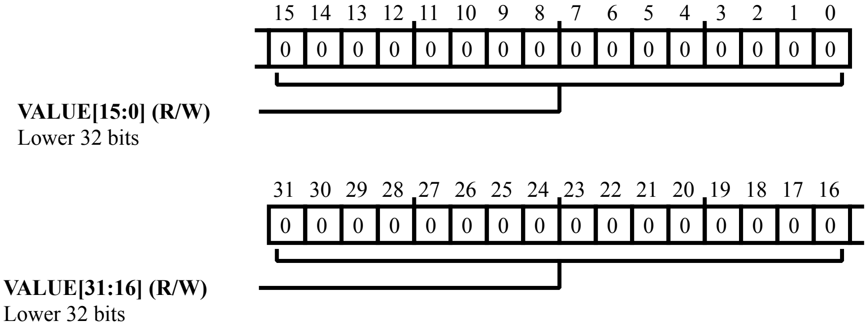
Figure 29-68: PCIE_DMAWR_DAR_HI_[n] Register Diagram

Table 29-77: PCIE_DMAWR_DAR_HI_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Higher 32 bits. In LL mode, the DMA overwrites the `PCIE_DMAWR_DAR_HI_[n].VALUE` bit field with the corresponding dword of the LL element.

DMA DAR Low Write Channel Register

The `PCIE_DMAWR_DAR_LO_[n]` register is implemented in RAM whose contents are uninitialized after power-on. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
Lower 32 bits

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Lower 32 bits

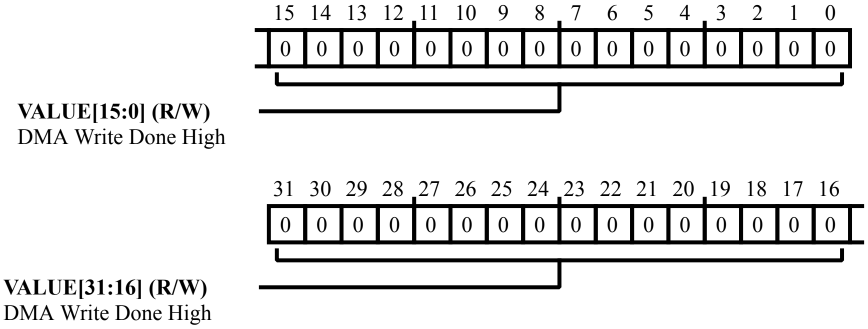
Figure 29-69: PCIE_DMAWR_DAR_LO_[n] Register Diagram

Table 29-78: PCIE_DMAWR_DAR_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Lower 32 bits. The `PCIE_DMAWR_DAR_LO_[n].VALUE` bit field indicates the next address to be written to. The DMA increments the DAR as the DMA transfer progresses. The DAR is always dword aligned even if the transfer size is byte aligned. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. The DAR is the address of the remote memory.

DMA Write Done IMWr Interrupt Address High Register

The `PCIE_DMAWR_DONE_IMWR_HI_[n]` register is implemented in RAM whose contents are uninitialized after power on. Programs must initialize every field as the default is undefined. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
DMA Write Done High

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
DMA Write Done High

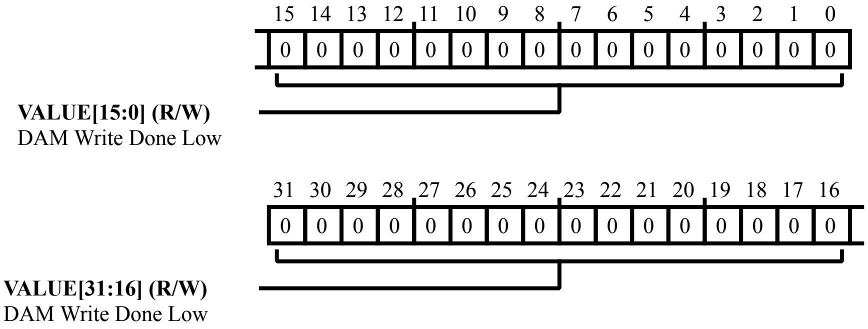
Figure 29-70: PCIE_DMAWR_DONE_IMWR_HI_[n] Register Diagram

Table 29-79: PCIE_DMAWR_DONE_IMWR_HI_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Write Done High. The DMA uses the `PCIE_DMAWR_DONE_IMWR_HI_[n].VALUE` bit field to generate bits [63:32] of the address field for the Done IMWr TLP.

DMA Write Done IMWr Address Low Register

The `PCIE_DMAWR_DONE_IMWR_LO_[n]` register is implemented in RAM whose contents are uninitialized after power on. Therefore, you must program and initialize every field as the default is undefined. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
DAM Write Done Low

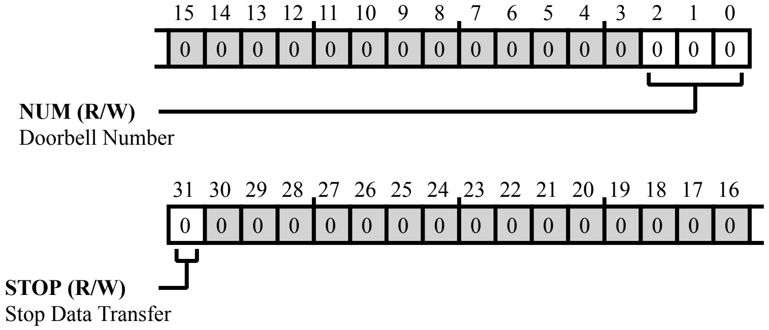
Figure 29-71: PCIE_DMAWR_DONE_IMWR_LO_[n] Register Diagram

Table 29-80: PCIE_DMAWR_DONE_IMWR_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DAM Write Done Low. The DMA uses the `PCIE_DMAWR_DONE_IMWR_LO_[n].VALUE` bit field to generate bits [31:0] of the address field for the Done IMWr TLP. Bits [1:0] must be 00 as this address must be dword aligned.

DMA Write Doorbell Register

The `PCIE_DMAWR_DRBL_[n]` register contains bits that set a channel number to start the DMA write transfer for that channel and to stop a DMA transfer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
NUM (R/W)
Doorbell Number
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
STOP (R/W)
Stop Data Transfer

Figure 29-72: PCIE_DMAWR_DRBL_[n] Register Diagram

Table 29-81: PCIE_DMAWR_DRBL_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	STOP	Stop Data Transfer. The `PCIE_DMAWR_DRBL_[n].STOP` bit is set in conjunction with the `PCIE_DMAWR_DRBL_[n].NUM` field. The DMA write channel stops issuing requests, sets the channel status to Stopped, and asserts the Abort interrupt if it is enabled. Before setting this bit, the program must read the `PCIE_DMAWR_CTL1_[n].CS` bit field to ensure that the write channel is Running (transferring data).
2:0 (R/W)	NUM	Doorbell Number. The `PCIE_DMAWR_DRBL_[n].NUM` bit field provides the channel number to this register to start the DMA write transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. Programs do not need to toggle or write any other value to this register to start a new transfer. The range of this field is 0x0 to 0x7, and 0x0 corresponds to channel 0.

DMA Write Engine Enable Register

The `PCIE_DMAWR_EN_[n]` register enables the DMA write engine.

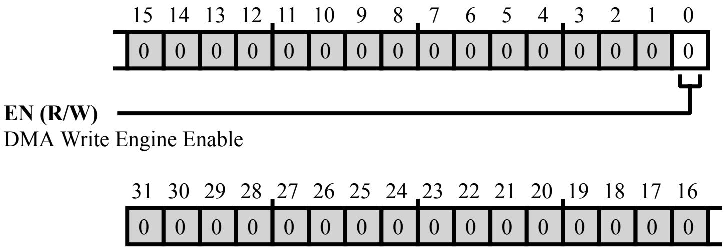


Figure 29-73: PCIE_DMAWR_EN_[n] Register Diagram

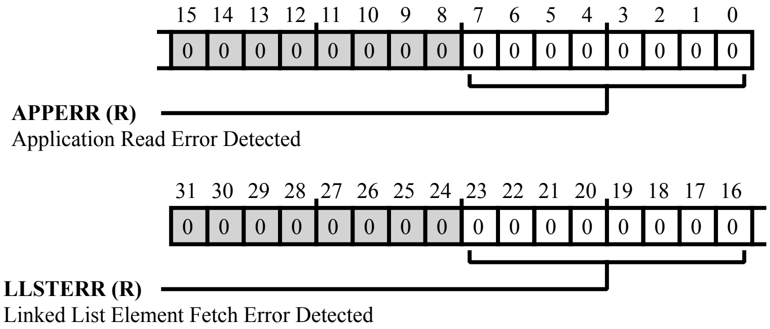
Table 29-82: PCIE_DMAWR_EN_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	EN	DMA Write Engine Enable. When set (=1) the `PCIE_DMAWR_EN_[n].EN` bit enables the DMA write engine. For normal operation, set this bit to 1 before performing any other software setup actions. Programs do not need to toggle or rewrite to this bit during normal operation. Programs should set the `PCIE_DMAWR_EN_[n].EN` bit to 0 to perform a soft reset the DMA controller write logic. There are three reasons for resetting the DMA controller write logic • The `PCIE_DMAWR_ISTAT_[n].ABRT` bit is set, and any of the bits is in the `PCIE_DMAWR_ERRSTAT_[n]` register are set. Resetting the DMA controller write logic re-initializes the control logic, ensuring that the next DMA write transfer is executed successfully. • The program has executed the procedure outlined in the `PCIE_DMAWR_DRBL_[n].STOP` bit description, after which, the `PCIE_DMAWR_ISTAT_[n].ABRT` bit is set and the `PCIE_DMAWR_CTL1_[n].CS` bit field is set to Stopped. Resetting the DMA controller write logic re-initializes the control logic ensuring that the next DMA write transfer is executed successfully. • During software development, when the DMA write engine is programmed incorrectly. To perform a soft reset the DMA controller write logic: • De-assert the DMA write engine enable bit. • Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA write engine enable bit returns a 0. • Assert the DMA write engine enable bit. This soft reset does not clear the DMA configuration registers. The DMA write transfer does not start until you write to the `PCIE_DMAWR_DRBL_[n].STOP` bit.

DMA Write Error Status Register

The `PCIE_DMAWR_ERRSTAT_[n]` register reports various write errors.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
APPERR (R)
Application Read Error Detected
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LLSTERR (R)
Linked List Element Fetch Error Detected

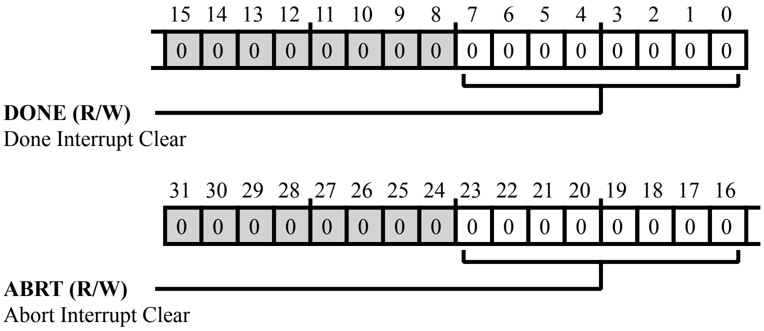
Figure 29-74: PCIE_DMAWR_ERRSTAT_[n] Register Diagram

Table 29-83: PCIE_DMAWR_ERRSTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/NW)	LLSTERR	Linked List Element Fetch Error Detected. The `PCIE_DMAWR_ERRSTAT_[n].LLSTERR` bit provides notice that the DMA write channel has received an error response. This response comes from the peripheral or SCB bus (or the RTRGT1 interface when the peripheral or SCB Bridge is not used) while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For details, see "Interrupts and Error Handling". • Masking: The DMA write interrupt Mask register has no effect on this register. • Clearing: Programs must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Write Interrupt Clear Register" (DMA_WR_INT_CLEAR_OFF) to clear this error bit.
7:0 (R/NW)	APPERR	Application Read Error Detected. The `PCIE_DMAWR_ERRSTAT_[n].APPERR` bit provides notice that the DMA write channel has received an error response. This response comes from the peripheral or SCB bus (or the RTRGT1 interface when the peripheral or SCB Bridge is not used) while reading data from it. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For details, see "Interrupts and Error Handling". • Masking: The DMA write interrupt Mask register has no effect on this register. • Clearing: Programs must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Write Interrupt Clear Register" (DMA_WR_INT_CLEAR_OFF) to clear this error bit.

DMA Write Interrupt Clear Register

The `PCIE_DMAWR_ICLR_[n]` register provides bits that all the program to clear interrupts from the `PCIE_DMAWR_ISTAT_[n].DONE` and `PCIE_DMAWR_ISTAT_[n].DONE` fields. Each bit corresponds to a DMA channel.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Done Interrupt Clear
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ABRT (R/W)
Abort Interrupt Clear

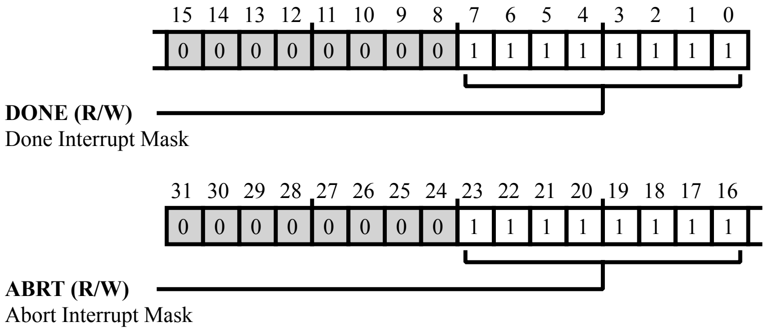
Figure 29-75: PCIE_DMAWR_ICLR_[n] Register Diagram

Table 29-84: PCIE_DMAWR_ICLR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	ABRT	Abort Interrupt Clear. Programs must write a 1'b1 to the `PCIE_DMAWR_ICLR_[n].ABRT` bit field clear the corresponding bit in the `PCIE_DMAWR_ISTAT_[n].ABRT` field of the DMA write interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Reading from this self-clearing register field always returns a 0.
7:0 (R/W)	DONE	Done Interrupt Clear. Programs must write a 1'b1 to the `PCIE_DMAWR_ICLR_[n].DONE` bit field clear the corresponding bit in the `PCIE_DMAWR_ISTAT_[n].DONE` field of the DMA write interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Reading from this self-clearing register field always returns a 0.

DMA Write Interrupt Mask Register

The `PCIE_DMAWR_IMSK_[n]` register is used to mask interrupts in the `PCIE_DMAWR_ISTAT_[n]` register.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1
DONE (R/W)
Done Interrupt Mask
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1
ABRT (R/W)
Abort Interrupt Mask

Figure 29-76: PCIE_DMAWR_IMSK_[n] Register Diagram

Table 29-85: PCIE_DMAWR_IMSK_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	ABRT	Abort Interrupt Mask. The `PCIE_DMAWR_IMSK_[n].ABRT` bit field prevents the `PCIE_DMAWR_ISTAT_[n].ABRT` status field in the DMA from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.
7:0 (R/W)	DONE	Done Interrupt Mask. The `PCIE_DMAWR_IMSK_[n].DONE` bit field prevents the `PCIE_DMAWR_ISTAT_[n].DONE` status field in the DMA from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0.

DMA Write Interrupt Status Register

The PCIE_DMAWR_ISTAT_[n] register provides status information on DMA writes.

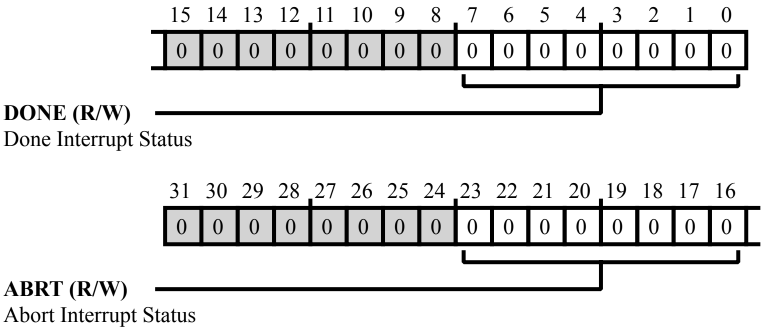


Figure 29-77: PCIE_DMAWR_ISTAT_[n] Register Diagram

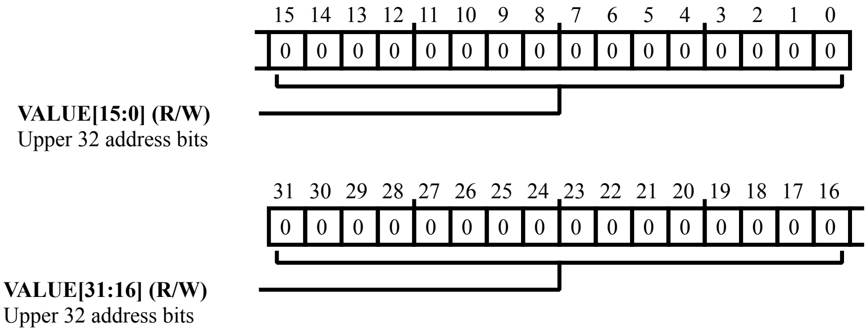
Table 29-86: PCIE_DMAWR_ISTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	ABRT	Abort Interrupt Status. The `PCIE_DMAWR_ISTAT_[n].ABRT` indicates the DMA write channel has detected an error or the transfer was stopped manually. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Programs can read the DMA Read Error Status Low Register and DMA Read Error Status High Register to determine the source of the error. The DMA read interrupt Mask register has no effect on this bit field. Programs must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit. Programs can write to this bit field to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this bit field.
7:0 (R/W)	DONE	Done Interrupt Status. The `PCIE_DMAWR_ISTAT_[n].DONE` bit field indicates the DMA write channel has successfully completed the DMA transfer. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA write interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register.

DMA LLP High Write Channel Register

The `PCIE_DMAWR_LLP_HI_[n]` register is implemented in RAM whose contents are uninitialized after power on. This register value must always be initialized because the default is undefined. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Upper 32 address bits

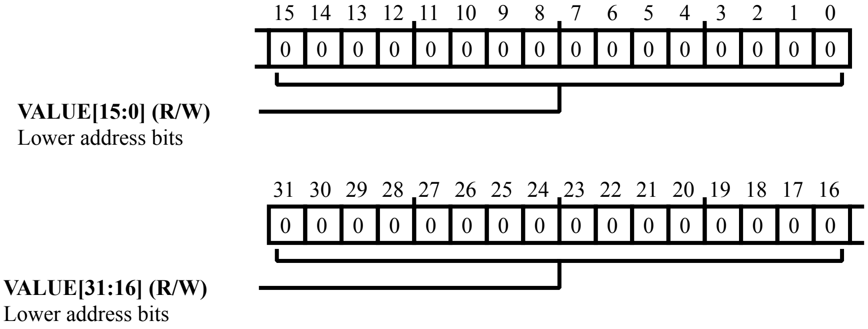
Figure 29-78: PCIE_DMAWR_LLP_HI_[n] Register Diagram

Table 29-87: PCIE_DMAWR_LLP_HI_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Upper 32 address bits. The `PCIE_DMAWR_LLP_HI_[n].VALUE` bit field contains the upper 32 bits of the address of the linked list transfer list in local memory. Used in linked list mode only. The `PCIE_DMAWR_LLP_HI_[n].VALUE` bit field is updated by the DMA to point to the next element in the transfer list as elements are consumed.

DMA LLP Low Write Channel Register

The `PCIE_DMAWR_LLP_LO_[n]` register is implemented in RAM whose contents are uninitialized after power on. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Lower address bits

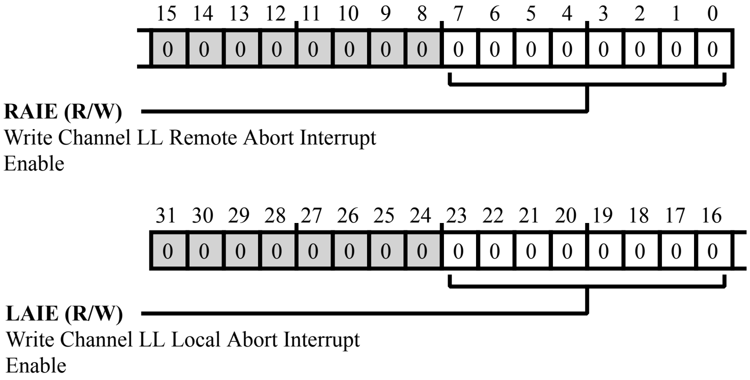
Figure 29-79: PCIE_DMAWR_LLP_LO_[n] Register Diagram

Table 29-88: PCIE_DMAWR_LLP_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Lower address bits. The `PCIE_DMAWR_LLP_LO_[n].VALUE` bit field contains the lower bits of the address of the linked list transfer list in local memory. Used in linked list mode only. The `PCIE_DMAWR_LLP_LO_[n].VALUE` bit field is updated by the DMA to point to the next element in the transfer list after the previous element is consumed. • When the current element is a data element; this field is incremented by 6. • When the current element is a link element; this field is overwritten by the LL Element Pointer of the element.

DMA Write Linked List Error Enable Register

The `PCIE_DMAWR_LLSTERR_EN_[n]` register provides bits in the LL element that enable the channel done and abort interrupts (local and remote).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 29-89: PCIE_DMAWR_LLSTERR_EN_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	LAIE	Write Channel LL Local Abort Interrupt Enable. The `PCIE_DMAWR_LLSTERR_EN_[n].LAIE` bit field enables the write channel local abort interrupt. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only.
7:0 (R/W)	RAIE	Write Channel LL Remote Abort Interrupt Enable. The `PCIE_DMAWR_LLSTERR_EN_[n].RAIE` bit field enables the write channel remote abort interrupt. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only.

DMA Write Posted Request Deadlock Timer Register

The `PCIE_DMAWR_PREQ_TMR_[n]` register sets the time-out value for the write channel DMA transmit write posted request deadlock timer. This timer is only enabled if there is a pending TX non-DMA completion blocked behind the DMA posted request. When the timer expires, the core pulls back the pending DMA posted request and allows non-DMA completions to pass. When all completions have been transmitted, the SCB bridge replays the DMA posted requests. If the DMA posted TLPs are not making progress and posted credits have not been returned within this time frame, then is safe to assume that the DMA posted TLPs are blocked.

The timeout value increments in steps of 2 usec. The default value is 30 usec based on the PCIe specification's maximum latency between posted credit updates from the remote link partner. The timeout value must be less than the remote link partner's completion timeout value to avoid the remote link partner timing out its non-posted requests. The minimum completion timeout value is 50 usec but is typically in the order of tens of milliseconds. If the deadlock timeout value is too close to the completion timeout value then you can reprogram this timer and decrease the timeout value.

To allow sufficient time for posted credits to be updated and avoid unnecessary flushing of DMA posted requests, the recommended minimum timer value is 10 usec.

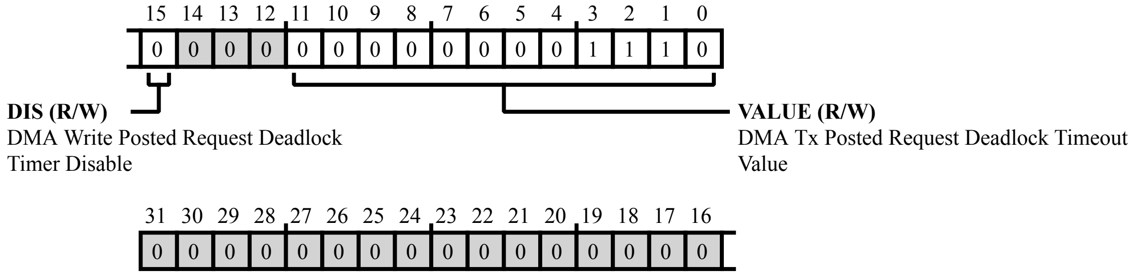

Figure 29-81: PCIE_DMAWR_PREQ_TMR_[n] Register Diagram

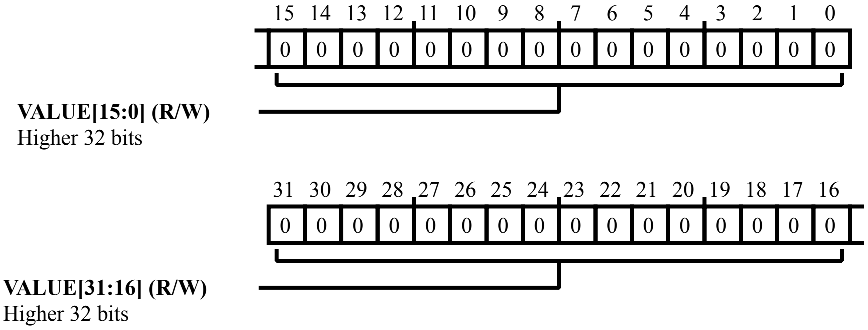
Table 29-90: PCIE_DMAWR_PREQ_TMR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	DIS	DMA Write Posted Request Deadlock Timer Disable. The `PCIE_DMAWR_PREQ_TMR_[n].DIS` bit disables the deadlock timer.
11:0 (R/W)	VALUE	DMA Tx Posted Request Deadlock Timeout Value. The `PCIE_DMAWR_PREQ_TMR_[n].VALUE` bit field sets the DMA Tx posted request deadlock timeout value. In normal operation the receiver must process a posted request within 10 usec. The default value is 30 usec and encoding is 0 = 2us, 1 = 4us, ..., 4095 = 8192us.

DMA SAR High Write Channel Register

The `PCIE_DMAWR_SAR_HI_[n]` register is implemented in RAM whose contents are uninitialized after power-on. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

VALUE[31:16] (R/W)
Lower 32 bits

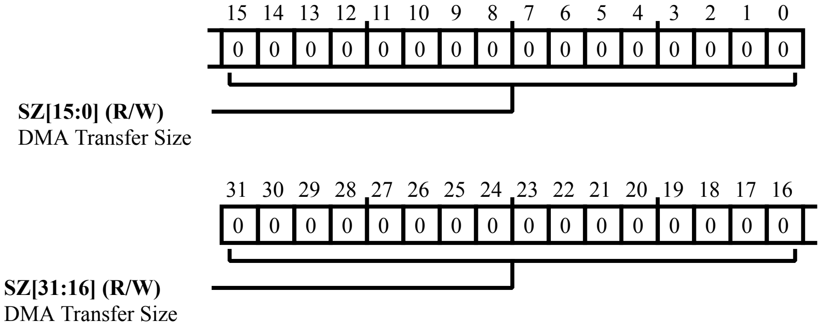
Figure 29-83: PCIE_DMAWR_SAR_LO_[n] Register Diagram

Table 29-92: PCIE_DMAWR_SAR_LO_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Lower 32 bits. The `PCIE_DMAWR_SAR_LO_[n].VALUE` register indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. The SAR is the address of the local memory.

DMA Transfer Size Write Channel Register

The `PCIE_DMAWR_XFRSZ_0[n]` register is implemented in RAM whose contents are uninitialized after power-on. All fields marked Reserved must be programmed to 1'b0. This register is not affected by any of the reset signals.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SZ[31:16] (R/W)
DMA Transfer Size

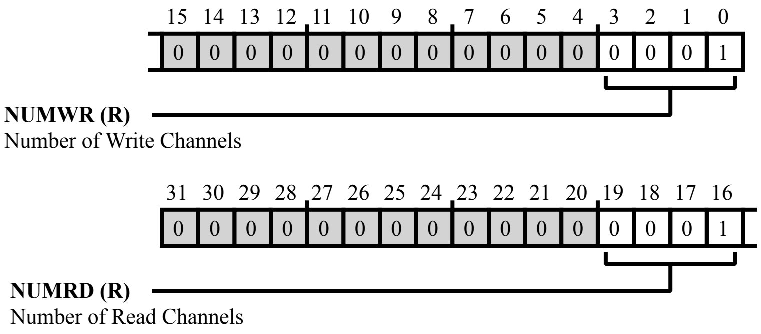
Figure 29-84: PCIE_DMAWR_XFRSZ_0[n] Register Diagram

Table 29-93: PCIE_DMAWR_XFRSZ_0[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SZ	DMA Transfer Size. The `PCIE_DMAWR_XFRSZ_0[n].SZ` bit field configures the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA write and read channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites the `PCIE_DMAWR_XFRSZ_0[n].SZ` bit field with the corresponding dword of the LL element.

DMA Number of Channels Register

The `PCIE_DMA_CTL_[n]` register reports the number of read and write channels that are configured.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1

		0	Locate anywhere in 32-bit access space
		1	Reserved
		2	Locate anywhere in 62-bit access space
		3	Reserved
0 (R/W)	MIO	Memory I/O. The `PCIE_EP_BAR3_[n].MIO` bit indicates memory space.	
		0	Memory space
		1	I/O space

Endpoint Base Address Mask Register 4

The mask for this BAR exists as a shadow register at this address. The `PCIE_EP_BAR0_[n]` register cannot be disabled but but this register (`PCIE_EP_BAR4_MASK[n]`) can be modified to change the size of memory advertised by `PCIE_EP_BAR0_[n]` to the host processor. Writing to this register is enabled if the `PCIE_MISC_CTL1_[n].RODBIWREN` bit is set.

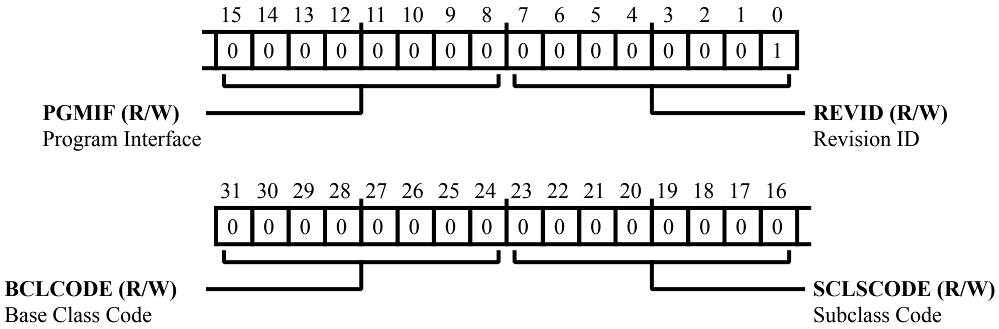
Figure 29-99: PCIE_EP_CAPBPTR_[n] Register Diagram

Table 29-108: PCIE_EP_CAPBPTR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Capabilities Pointer. The `PCIE_EP_CAPBPTR_[n].VALUE` bit field points to the first item in the list of capabilities. Each capability in the list consists of an 8-bit ID field assigned by the PCI SIG, an 8 bit pointer in configuration space to the next capability, and some number of additional registers immediately following the pointer to implement that capability. Each capability must be DWORD aligned. The bottom two bits of all pointers (including the initial pointer at 0x34) are reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits. A pointer value of 0x00 is used to indicate the last capability in the list

Class Code and Revision ID Register

The `PCIE_EP_CCRID_[n]` register identifies the function of a device.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BCLCODE (R/W)
Base Class Code
SCLSCODE (R/W)
Subclass Code

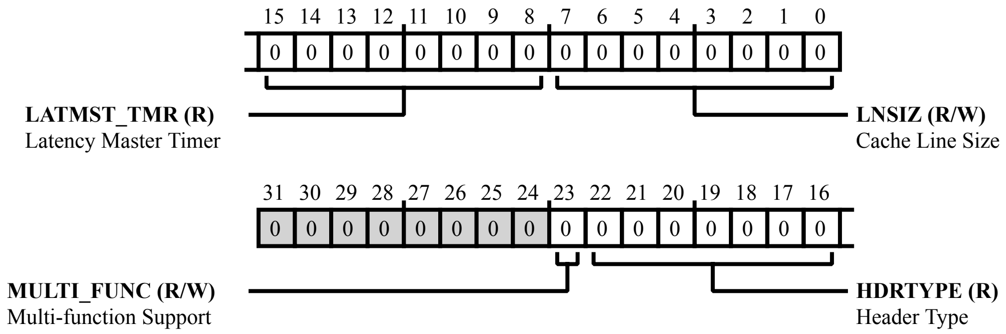
Figure 29-100: PCIE_EP_CCRID_[n] Register Diagram

Table 29-109: PCIE_EP_CCRID_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BCLCODE	Base Class Code. The `PCIE_EP_CCRID_[n].BCLCODE` bit field broadly classifies the type of function the device performs.
23:16 (R/W)	SCLSCODE	Subclass Code. The `PCIE_EP_CCRID_[n].SCLSCODE` bit field identifies more specifically the function of the device.
15:8 (R/W)	PGMIF	Program Interface. The `PCIE_EP_CCRID_[n].PGMIF` bit field identifies a specific register-level programming interface (if any) so that device independent software can interact with the device.
7:0 (R/W)	REVID	Revision ID. The `PCIE_EP_CCRID_[n].REVID` bit field is the device-specific revision identifier.

End Point Configuration Register

The `PCIE_EP_CFG_[n]` register configures the header type, cache line size, and latency timer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LATMST_TMR (R)
Latency Master Timer
LNSIZ (R/W)
Cache Line Size
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
MULTI_FUNC (R/W)
Multi-function Support
HDRTYPE (R)
Header Type

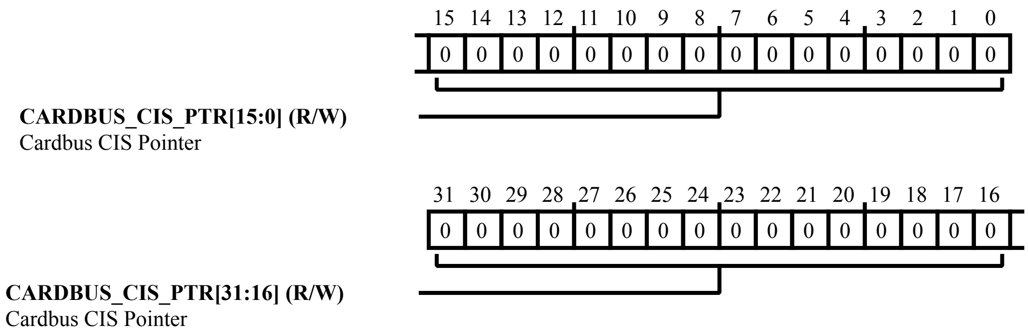
Figure 29-101: PCIE_EP_CFG_[n] Register Diagram

Table 29-110: PCIE_EP_CFG_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/W)	MULTI_FUNC	Multi-function Support. The `PCIE_EP_CFG_[n].MULTI_FUNC` bit must be set to zero.
22:16 (R/NW)	HDRTYPE	Header Type. The `PCIE_EP_CFG_[n].HDRTYPE` bit field identifies the layout of the second part of the predefined header and also whether or not the device contains multiple functions. Bit 7 in this register is used to identify a multifunction device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. Bits 6 through 0 identify the layout of the second part of the predefined header.
15:8 (R/NW)	LATMST_TMR	Latency Master Timer. The `PCIE_EP_CFG_[n].LATMST_TMR` bit field specifies the value of the latency timer in units of PCI bus clocks.
7:0 (R/W)	LNSIZ	Cache Line Size. The `PCIE_EP_CFG_[n].LNSIZ` bit field specifies the system cache line size in units of DWORDS.

CardBus CIS Pointer Register

The `PCIE_EP_CRDBPTR_[n]` register is optionally used by devices that want to share silicon between CardBus and PCI.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CARDBUS_CIS_PTR[31:16] (R/W)
Cardbus CIS Pointer

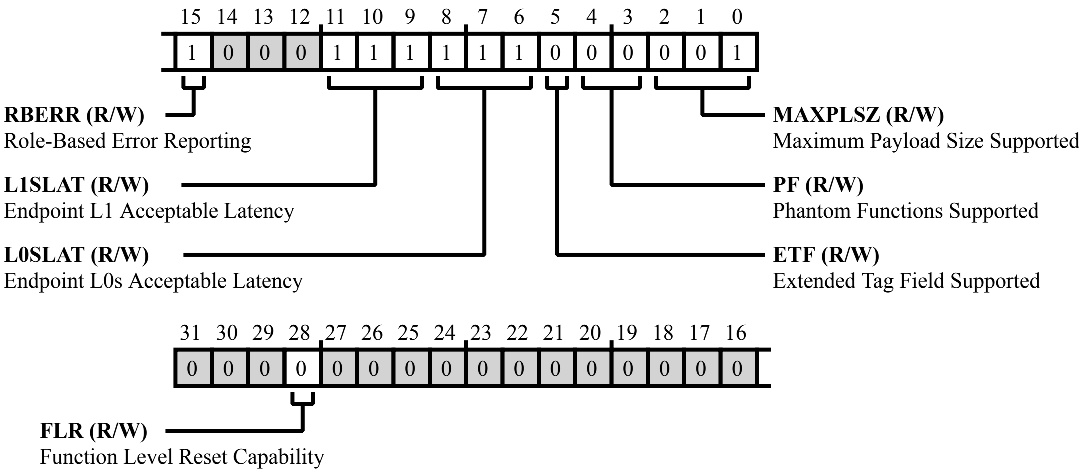
Figure 29-102: PCIE_EP_CRDBPTR_[n] Register Diagram

Table 29-111: PCIE_EP_CRDBPTR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CARDBUS_CIS_PTR	Cardbus CIS Pointer. The `PCIE_EP_CRDBPTR_[n].CARDBUS_CIS_PTR` bit field is used to point to the Card Information Structure (CIS) for the CardBus card. For a detailed explanation of the CIS, refer to the PCMCIA v2.10 specification.

Device Capabilities Register

The `PCIE_EP_DEVCAPB_[n]` register identifies PCI Express device Function specific capabilities.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 0 0 0 1 1 1 1 1 1 0 0 0 0 0 1
RBERR (R/W)
Role-Based Error Reporting
L1SLAT (R/W)
Endpoint L1 Acceptable Latency
L0SLAT (R/W)
Endpoint L0s Acceptable Latency
MAXPLSZ (R/W)
Maximum Payload Size Supported
PF (R/W)
Phantom Functions Supported
ETF (R/W)
Extended Tag Field Supported
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
FLR (R/W)
Function Level Reset Capability

Figure 29-103: PCIE_EP_DEVCAPB_[n] Register Diagram

Table 29-112: PCIE_EP_DEVCAPB_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	FLR	Function Level Reset Capability. A value of 1 in the `PCIE_EP_DEVCAPB_[n].FLR` bit indicates that a Function supports the optional Function Level Reset mechanism. This bit applies to Endpoints only. For all other Function types this bit must be set to 0.	
15 (R/W)	RBERR	Role-Based Error Reporting. When set, the `PCIE_EP_DEVCAPB_[n].RBERR` bit indicates that the Function implements the functionality originally defined in the PCI Express Base Specification. This bit is read-only and always set to 1.	
11:9 (R/W)	L1SLAT	Endpoint L1 Acceptable Latency. The `PCIE_EP_DEVCAPB_[n].L1SLAT` bit field indicates the acceptable latency that an Endpoint can withstand due to the transition from L1 state to the L0 state. It is essentially an indirect measure of the Endpoints internal buffering. For Functions other than Endpoints, this field is Reserved and must be hardwired to 000.	
		0	Maximum of 1 us
		1	Maximum of 2 us
		2	Maximum of 4 us
		3	Maximum of 8 us
		4	Maximum of 16 us
		5	Maximum of 32 us

Table 29-112: PCIE_EP_DEVCAPB_[n] Register Fields (Continued)

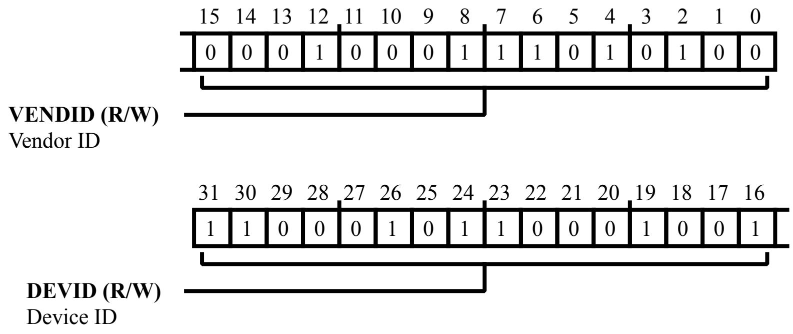
Bit No. (Access)	Bit Name	Description/Enumeration	
		6	Maximum of 64 us
		7	No limit
8:6 (R/W)	L0SLAT	Endpoint L0s Acceptable Latency. The `PCIE_EP_DEVCAPB_[n].L0SLAT` bit field indicates the acceptable total latency that an Endpoint can withstand due to the transition from L0s state to the L0 state. It is essentially an indirect measure of the Endpoints internal buffering. For Functions other than Endpoints, this field is Reserved and must be hardwired to 000.	
		0	Maximum of 64 ns
		1	Maximum of 128 ns
		2	Maximum of 256 ns
		3	Maximum of 512 ns
		4	Maximum of 1 us
		5	Maximum of 2 us
		6	Maximum of 4 us
		7	No limit
5 (R/W)	ETF	Extended Tag Field Supported. The `PCIE_EP_DEVCAPB_[n].ETF` bit indicates the maximum supported size of the Tag field as a Requester. Note that 8-bit Tag field generation must be enabled by the Extended Tag Field Enable bit in the Device Control register of the Requester Function before 8-bit Tags can be generated by the Requester.	
		0	5-bit Tag field supported
		1	8-bit Tag field supported
4:3 (R/W)	PF	Phantom Functions Supported. The `PCIE_EP_DEVCAPB_[n].PF` bit field indicates the support for use of unclaimed Function Numbers to extend the number of outstanding transactions allowed by logically combining unclaimed Function Numbers (called Phantom Functions) with the Tag identifier.	
2:0 (R/W)	MAXPLSZ	Maximum Payload Size Supported. The `PCIE_EP_DEVCAPB_[n].MAXPLSZ` bit field indicates the maximum payload size that the Function can support for TLPs. The Functions of a multi-Function device are permitted to report different values for this field.	
		0	128 bytes max payload size
		1	256 bytes max payload size
		2	512 bytes max payload size

Table 29-112: PCIE_EP_DEVCAPB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	1024 bytes max payload size
		4	2048 bytes max payload size
		5	4096 bytes max payload size
		6	Reserved
		7	Reserved

Device ID and Vendor ID Register

The `PCIE_EP_ID_[n]` register indicates the assigned IDs.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 1 0 0 0 1 1 1 0 1 0 1 0 0
VENDID (R/W)
Vendor ID
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
1 1 0 0 0 1 0 1 1 0 0 0 1 0 0 1
DEVID (R/W)
Device ID

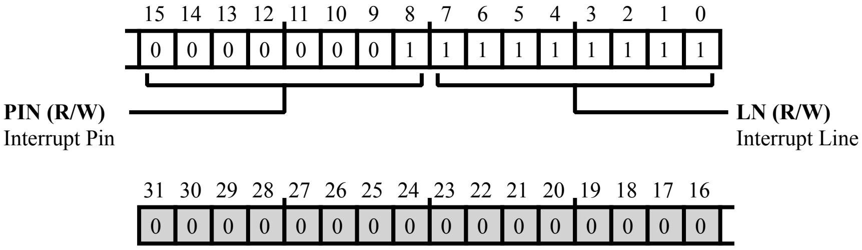
Figure 29-104: PCIE_EP_ID_[n] Register Diagram

Table 29-113: PCIE_EP_ID_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DEVID	Device ID. The `PCIE_EP_ID_[n].DEVID` bit field indicates the vendor assigned field that provides a means for a vendor to classify a particular RCRB.
15:0 (R/W)	VENDID	Vendor ID. The `PCIE_EP_ID_[n].VENDID` bit field indicates the PCI-SIG assigned field that provides a means to associate an RCRB (root complex register block) with a particular vendor.

Interrupt Line and Pin Register

The `PCIE_EP_PINLN_INT_[n]` register provides interrupt and line routing information.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 1 1 1 1 1 1 1 1 1
PIN (R/W)
Interrupt Pin
LN (R/W)
Interrupt Line
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

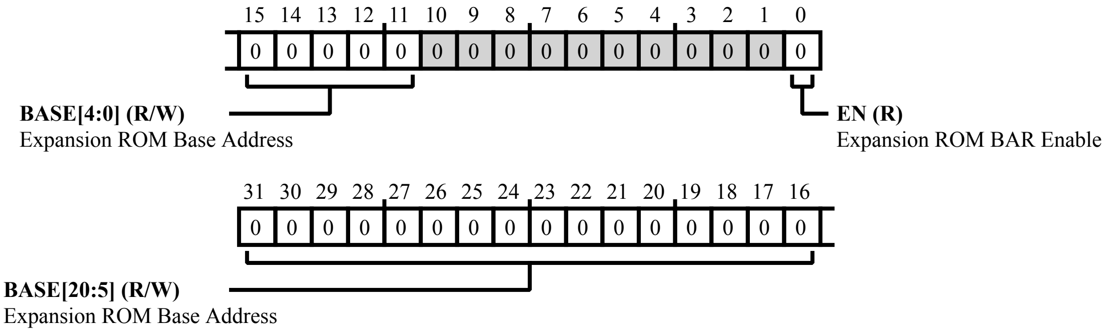
Figure 29-105: PCIE_EP_PINLN_INT_[n] Register Diagram

Table 29-114: PCIE_EP_PINLN_INT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	PIN	Interrupt Pin. The `PCIE_EP_PINLN_INT_[n].PIN` bit field identifies the legacy interrupt Message(s) the Function uses. Valid values are 0x1, 0x2, 0x3, and 0x4 that map to legacy interrupt Messages for INTA, INTB, INTC, and INTD respectively. A value of 0x0 indicates that the Function uses no legacy interrupt Message(s).
7:0 (R/W)	LN	Interrupt Line. The `PCIE_EP_PINLN_INT_[n].LN` bit field communicates interrupt line routing information. The field is read/write and must be implemented by any Function that uses an interrupt pin. Values in this bit field are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this field is used by device drivers and operating systems.

End Point Expansion ROM Base Address Register

The `PCIE_EP_ROMCFG_[n]` register contains bits that indicate the upper 21 bits of the Expansion ROM base address and bits that control whether or not the device accepts accesses to its expansion ROM.



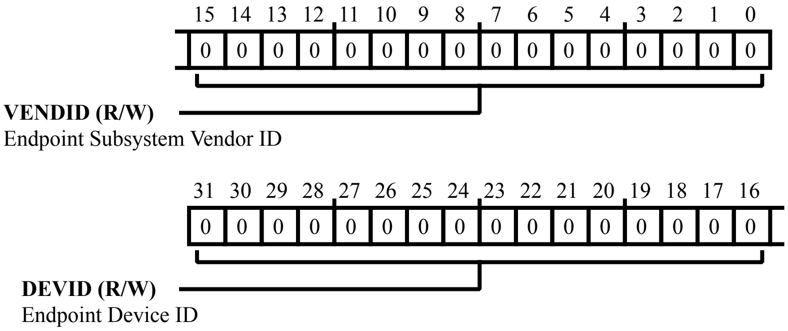
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BASE[4:0] (R/W)
Expansion ROM Base Address
EN (R)
Expansion ROM BAR Enable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BASE[20:5] (R/W)
Expansion ROM Base Address

Figure 29-106: PCIE_EP_ROMCFG_[n] Register Diagram

Table 29-115: PCIE_EP_ROMCFG_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:11 (R/W)	BASE	Expansion ROM Base Address. The `PCIE_EP_ROMCFG_[n].BASE` bit field correspond to the upper 21 bits of the Expansion ROM base address. The number of bits (out of these 21) that a device actually implements depends on how much address space the device requires. For instance, a device that requires a 64 KB area to map its expansion ROM would implement the top 16 bits in the register, leaving the bottom 5 (out of these 21) hardwired to 0. Devices that support an expansion ROM must implement this register.
0 (R/NW)	EN	Expansion ROM BAR Enable. The `PCIE_EP_ROMCFG_[n].EN` bit controls whether or not the device accepts accesses to its expansion ROM. When this bit is 0, the devices expansion ROM address space is disabled. When the bit is 1, address decoding is enabled using the parameters in the other part of the base register. This allows a device to be used with or without an expansion ROM depending on system configuration.

Subsystem ID and Subsystem Vendor ID Register



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 29-108: PCIE_EP_STATCMD_[n] Register Diagram

Table 29-117: PCIE_EP_STATCMD_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	DETPERR	Detected Parity Error. The `PCIE_EP_STATCMD_[n].DETPERR` bit is set by a function whenever it receives a poisoned TLP, regardless of the state of the `PCIE_EP_STATCMD_[n].PERREN` bit. On a function with a Type 1 Configuration header, the bit is set when the poisoned TLP is received by its primary side. The default value of this bit is 0.

Table 29-117: PCIE_EP_STATCMD_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	SSYSERR	Signaled System Error. The `PCIE_EP_STATCMD_[n].SSYSERR` bit is set when a function sends an ERR_FATAL or ERR_NONFATAL message, and the `PCIE_EP_STATCMD_[n].SERREN` bit is set to 1. The default value of this bit is 0.
29 (R/W)	RXMABRT	Received Master Abort. The `PCIE_EP_STATCMD_[n].RXMABRT` bit is set when a Requester receives a completion with unsupported request completion status. On a function with a Type 1 Configuration header, the `PCIE_EP_STATCMD_[n].RXMABRT` bit is set when the unsupported request is received by its Primary side. The default value of this bit is 0.
28 (R/W)	RXTABRT	Received Target Abort. The `PCIE_EP_STATCMD_[n].RXTABRT` bit is set when a requester receives a completion with completer abort completion status. On a function with a Type 1 Configuration header, the `PCIE_EP_STATCMD_[n].RXTABRT` bit is set when the completer abort is received by its primary side. The default value of this bit is 0.
27 (R/W)	STABRT	Signaled Target Abort. The `PCIE_EP_STATCMD_[n].STABRT` bit is set when a function completes a posted or non-posted request as a Completer Abort error. This applies to a function with a Type 1 Configuration header when the completer abort was generated by its primary side. The default value of this bit is 0.
26:25 (R/NW)	DEVSELTMG	Device Select Timing. Does not apply to PCI Express and must be set to 0.
24 (R/W)	MSTDPERR	Master Data Parity Error. The `PCIE_EP_STATCMD_[n].MSTDPERR` bit is set by a Root port, Switch Upstream port, or Switch Downstream port if the `PCIE_EP_STATCMD_[n].PERREN` bit in the command register is set to 1 and either of the following two conditions occurs. • A port receives a poisoned completion going downstream • A port transmits a poisoned request upstream If the `PCIE_EP_STATCMD_[n].PERREN` bit is cleared (=0), the `PCIE_EP_STATCMD_[n].MSTDPERR` bit is never set. The default value of this bit is 0.
23 (R/NW)	FASTB2B	Fast back-to-back transactions enable. Does not apply to PCI Express and must be set to 0.
21 (R/NW)	FAST66	66 MHz Capable. Does not apply to PCI Express and must be set to 0.

Table 29-117: PCIE_EP_STATCMD_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/NW)	CAPBLIST	Capabilities List. The `PCIE_EP_STATCMD_[n].CAPBLIST` bit indicates the presence of an Extended Capability list item. Since all PCI Express device functions are required to implement the PCI Express Capability structure, this bit is always set to 1.
19 (R/W)	ISTAT	Interrupt Status. When the `PCIE_EP_STATCMD_[n].ISTAT` bit is set, an INTx emulation interrupt is pending internally in the function. INTx emulation interrupts forwarded by Root and Switch ports from devices downstream of the Root or Switch port are not reflected in this bit. The default value of this bit is 0.
10 (R/W)	IEN	Interrupt Enable. The `PCIE_EP_STATCMD_[n].IEN` bit controls the ability of a PCI Express Function to generate INTx interrupts. When set, functions are prevented from asserting INTx interrupts. Any INTx emulation interrupts already asserted by the function must be de-asserted when this bit is set. When the `PCIE_EP_STATCMD_[n].IEN` bit is set, INTx interrupts use virtual wires that must, if asserted, be de-asserted using the appropriate Deassert_INTx message(s). Only the INTx virtual wire interrupt(s) associated with the function(s) for which this bit is set are affected. For Endpoints that generate INTx interrupts, this bit is required. For Endpoints that generate INTx interrupts, this bit is required. For Endpoints that do not generate INTx interrupts this bit is optional. If not implemented, this bit must be set to 0.
8 (R/W)	SERREN	Non-fatal and fatal Error reporting Enable. When the `PCIE_EP_STATCMD_[n].SERREN` bit is set, reports of non-fatal and fatal errors detected by the function to the root complex are issued. Errors are reported either through this bit or through the PCI Express specific bits in the `PCIE_EP_CCRID_[n]` register. In addition, for functions with Type 1 Configuration Space headers, this bit controls transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error messages forwarded from the secondary interface. The `PCIE_EP_STATCMD_[n].SERREN` bit does not affect the transmission of forwarded ERR_COR messages. A Root Complex Integrated Endpoint that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0. The default value of this bit is 0.
7 (R/NW)	IDSELSTEP	IDSEL Stepping/Wait Cycle Control. Does not apply to PCI Express and must be set to 0.

Table 29-117: PCIE_EP_STATCMD_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	PERREN	Parity Error Response. The `PCIE_EP_STATCMD_[n].PERREN` bit controls the logging of poisoned TLPs in the `PCIE_EP_STATCMD_[n].MSTDPERR` bit. A Root Complex Integrated Endpoint that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0. The default value of this bit is 0.
5 (R/NW)	VGAPS	VGA Palette Snoop. Does not apply to PCI Express and must be set to 0.
4 (R/NW)	MWIE	Memory Write and Invalidate Enable. Does not apply to PCI Express and must be set to 0.
3 (R/NW)	SCO	Special Cycle Operation. Does not apply to PCI Express and must be set to 0.
2 (R/W)	BME	Bus Master Enable. The `PCIE_EP_STATCMD_[n].BME` bit controls the ability of a PCI Express Endpoint to issue memory and I/O read/write requests, and the ability of a Root or Switch Port to forward memory and I/O read/write requests in the upstream direction. For end points, when the `PCIE_EP_STATCMD_[n].BME` bit is set, the PCI Express function is allowed to issue memory or I/O requests. When this bit is cleared, the PCI Express function is not allowed to issue any memory or I/O requests. MSI/MSI-X interrupt messages are in-band memory writes and setting this bit to 0 also disables MSI/MSI-X interrupt messages. Requests other than memory or I/O requests are not controlled by this bit. The default value of this bit is 0.
1 (R/W)	MSE	Memory Space Enable. The `PCIE_EP_STATCMD_[n].MSE` bit enables memory space.
0 (R/W)	IOE	I/O Space Enable. The `PCIE_EP_STATCMD_[n].IOE` bit enables I/O space.

Error Source Identification Register

The PCIE_ERRSRC_ID_[n] register identifies the source (Requester ID) of first correctable and uncorrectable (Non- Fatal/Fatal) errors reported in the Root Error Status register. This register is updated regardless of the settings of the Root Control register and the Root Error Command register.

Figure 29-111: PCIE_GEN2_CTL_[n] Register Diagram

Table 29-120: PCIE_GEN2_CTL_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	GEN1EIINF	Gen1 Electrical Idle Inference Mode Rate. The `PCIE_GEN2_CTL_[n].GEN1EIINF` bit is used to determine inferred electrical idle (EI) in recovery. This bit does this by looking at the speed or Loopback.Active (as slave) state at Gen1 speed by looking for a 1 value on RxElecIdle instead of looking for a 0 on RxValid. If the PHY fails to deassert the RxValid signal in Recovery.Speed or Loopback.Active (because of corrupted EIOS for example), then electrical idle cannot be inferred successfully in the core by just detecting the condition RxValid=0. This bit is sticky.	
		0	Use RxElecIdle signal to infer Electrical Idle
		1	Use RxValid signal to infer Electrical Idle
20 (R/W)	DEMPH	De-emphasis Level for Upstream Ports. The `PCIE_GEN2_CTL_[n].DEMPH` bit is used to set the de-emphasis level for upstream ports. This bit is sticky.	
		0	-6 dB
		1	-3.5 dB
19 (R/W)	TXCMPRX	Transmit Compliance Receive. When the `PCIE_GEN2_CTL_[n].TXCMPRX` bit is set (=1), it signals the LTSSM to transmit TS ordered sets with the compliance receive bit assert (equal to 1). This bit sticky.	

Table 29-120: PCIE_GEN2_CTL_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	PHYTXCHG	Config PHY Tx Swing. The `PCIE_GEN2_CTL_[n].PHYTXCHG` bit controls the PHY transmitter voltage swing level. The core drives the mac_phy_txswing output from this bit. This bit is sticky.	
		0	Full swing
		1	Low swing
17 (R/W)	DIRSPDCHG	Directed Speed Change. Setting (=1) the `PCIE_GEN2_CTL_[n].DIRSPDCHG` bit instructs the LTSSM to initiate a speed change to Gen2 or Gen3 after the link is initialized at Gen1 speed. The speed change is initiated automatically after link up, and the core clears the contents of this field. To prevent this automatic speed change, write a lower speed value to the `PCIE_LNK_CTLSTAT2_[n].TRGSPD` bit field through the DBI before link up. When the speed change occurs, the core clears the contents of this field. When the program reads this bit it returns 0. To manually initiate the speed change: • Write to `PCIE_LNK_CTLSTAT2_[n].TRGSPD` in the local device • Deassert the `PCIE_GEN2_CTL_[n].DIRSPDCHG` bit • Assert the `PCIE_GEN2_CTL_[n].DIRSPDCHG` bit	
16:8 (R/W)	NUMLANES	Predetermined Number of Lanes. The `PCIE_GEN2_CTL_[n].NUMLANES` bit field defines the number of lanes which are connected and not bad. This value is used to limit the effective link width to ignore broken or unused lanes that detect a receiver. Indicates the number of lanes to check for exit from Electrical Idle in Polling. Active and L2.Idle. It is possible that the LTSSM might detect a receiver on a bad or broken lane during the detect substate. However, it is also possible that such a lane might also fail to exit Electrical Idle and therefore prevent a valid link from being configured. This value is referred to as the "Predetermined Number of Lanes" in section 4.2.6.2.1 of the PCI Express Base 3.0 Specification, revision 1.0. Encoding is as follows: 0x01: 1 lane 0x02: 2 lanes 0x03: 3 lanes ... When there are unused lanes in the system, then the value in this register must change to reflect the number of lanes. The value in the Link Mode Enable field of the Port Link Control Register must also be changed. The value in this register is normally the same as the encoded value in the Port Link Control Register. If one of the used lanes is bad then the value in this register must be reduced. This register field is sticky.	

Table 29-120: PCIE_GEN2_CTL_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FSTTRSEQ	Fast Training Sequences. The `PCIE_GEN2_CTL_[n].FSTTRSEQ` bit field configures the number of Fast Training Sequences (N_FTS) that the core advertises as its N_FTS during Gen2 or Gen3 link training. This value is used to inform the link partner about the PHY"s ability to recover synchronization after a low power state. This value is provided by the PHY vendor. Do not set N_FTS to zero; doing so can cause the LTSSM to go into the recovery state when exiting from L0s. This register field is sticky.

Header Log Register 0

The `PCIE_HDRLOG0_[n]` register contains bytes 0-3 of the Header of the TLP associated with an error.

Bit No. (Access)	Bit Name	Description/Enumeration
24:20 (R/W)	FUNCNUM	Function Number. The `PCIE_IATU_CTL1_INB_[n].FUNCNUM` bit field is used for MEM-I/O and CFG0/CFG1 transactions as described below. • MEM-I/O - EP. When the Address and BAR matching logic in the core indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the `PCIE_IATU_CTL2_INB_[n].FNM` bit is set. • CFG0/CFG1 - EP. When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the `PCIE_IATU_CTL2_INB_[n].FNM` bit is set. • For RC this field is reserved and must be set to 0.
17:16 (R/W)	AT	Address Translation AT Value. When the value in the `PCIE_IATU_CTL1_INB_[n].AT` bit field matches the AT field of an inbound TLP, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the `PCIE_IATU_CTL2_INB_[n].MAT` bit is set. Not valid, ATS is not supported.

Table 29-125: PCIE_IATU_CTL1_INB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10:9 (R/W)	ATTR	Address Translation ATTR Value. When the value in the `PCIE_IATU_CTL1_INB_[n].ATTR` bit field matches the ATTR field of an inbound TLP, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the `PCIE_IATU_CTL2_INB_[n].ATTRM` bit is set.
8 (R/W)	TD	Address Translation TD Value. When the value in the `PCIE_IATU_CTL1_INB_[n].TD` bit field matches the TD field of an inbound TLP, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the `PCIE_IATU_CTL2_INB_[n].TDM` bit is set.
7:5 (R/W)	TC	Address Translation TC Value. When the value in the `PCIE_IATU_CTL1_INB_[n].TC` bit field matches the TC field of an inbound TLP, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the `PCIE_IATU_CTL2_INB_[n].TCM` bit is set.
4:0 (R/W)	TYPE	Address Translation TYPE Value. When the value in the `PCIE_IATU_CTL1_INB_[n].TYPE` bit field matches the TYPE field of an inbound TLP, then address translation proceeds (when all other enable field-matches are successful).

iATU Region Control 1 Outbound Register

The `PCIE_IATU_CTL1_OUTB_[n]` register controls several aspects of outbound address translation used for mapping different address ranges to different memory spaces.

Table 29-126: PCIE_IATU_CTL1_OUTB_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:20 (R/W)	FUNCNUM	Function Number. For an EP: When the value in the `PCIE_IATU_CTL1_OUTB_[n].FUNCNUM` bit field is matched to the address of an outbound TLP and the `PCIE_IATU_CTL2_OUTB_[n].FUNCBYP` bit field =0, then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. The value in this register must be 0x0. For a RC: The `PCIE_IATU_CTL1_OUTB_[n].FUNCNUM` bit field is swapped before SCB decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used.
17:16 (R/W)	AT	Address Translation AT Value. When the value in the `PCIE_IATU_CTL1_OUTB_[n].AT` bit field matches the address of an outbound TLP, then the AT field of the TLP is changed to the value in this register. Not valid. ATS is not supported.
10:9 (R/W)	ATTR	Address Translation ATTR Value. When the value in the `PCIE_IATU_CTL1_OUTB_[n].ATTR` bit field matches the address of an outbound TLP, then the ATTR field of the TLP is changed to the value in this register.
8 (R/W)	TD	Address Translation TD Value. When the value in the `PCIE_IATU_CTL1_OUTB_[n].TD` bit field matches the address of an outbound TLP, then the TD field of the TLP is changed to the value in this register.

Figure 29-118: PCIE_IATU_CTL2_INB_[n] Register Diagram

Table 29-127: PCIE_IATU_CTL2_INB_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	REGEN	Region En. The `PCIE_IATU_CTL2_INB_[n].REGEN` bit must be set to 1 for address translation to take place.

Table 29-127: PCIE_IATU_CTL2_INB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	MAT	Match Mode. The `PCIE_IATU_CTL2_INB_[n].MAT` bit determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received. For MEM-I/O TLPs, this field is interpreted as: • 0=Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. • 1=BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as: • 0=Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. • 1=Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as: • 0=Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. • 1=Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header.
29 (R/W)	INV	Invert Mode. When the `PCIE_IATU_CTL2_INB_[n].INV` bit is set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address).
28 (R/W)	CFGSHFT	CFG Shift Mode. The `PCIE_IATU_CTL2_INB_[n].CFGSHFT` bit is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of the application memory space using a 28-bit effective address.Shifts bits [27:12] of the untranslated address to form bits [31:16] of the translated address.

Table 29-127: PCIE_IATU_CTL2_INB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	FTMMODE	Fuzzy Type Match Mode. When the `PCIE_IATU_CTL2_INB_[n].FTMMODE` bit is set, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that CfgRd0/CfgRd1 and CfgWr0/CfgWr1 and MRd/MRdLk TLPs are seen as identical. The Routing field of Msg/MsgD TLPs is ignored. For example, CFG0 in the `PCIE_IATU_CTL1_INB_[n].TYPE` field matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP.	
25:24 (R/W)	RCODE	Response Code. The `PCIE_IATU_CTL2_INB_[n].RCODE` bit field defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response.	
		0	Normal RADM filter response is used
		1	Unsupported request (UR)
		2	Completer abort (CA)
		3	Reserved
20 (R/W)	VFM	Virtual Function Number Match Enable. For an EP the `PCIE_IATU_CTL2_INB_[n].VFM` bit ensures that a successful Virtual Function Number TLP field comparison match (see `PCIE_IATU_CTL1_INB_[n].FUNCNUM`) occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. For RC the `PCIE_IATU_CTL2_INB_[n].VFM` bit is reserved and must be set to 0.	
19 (R/W)	FNM	Function Number Match Enable. For an EP the `PCIE_IATU_CTL2_INB_[n].FNM` bit ensures that a successful Function Number TLP field comparison match (see `PCIE_IATU_CTL1_INB_[n].FUNCNUM`) occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. For RC the `PCIE_IATU_CTL2_INB_[n].FNM` bit is reserved and must be set to 0.	
16 (R/W)	ATTRM	ATTR Match Enable. The `PCIE_IATU_CTL2_INB_[n].ATTRM` bit ensures that a successful ATTR TLP field comparison match (see `PCIE_IATU_CTL1_INB_[n].ATTR`) occurs for address translation to proceed.	
15 (R/W)	TDM	TD Match Enable. The `PCIE_IATU_CTL2_INB_[n].TDM` bit ensures that a successful TD TLP field comparison match (see `PCIE_IATU_CTL1_INB_[n].TD`) occurs for address translation to proceed.

FUNCBYP (R/W)
Function Number Translation Bypass
DMA_BYP (R/W)
DMA Bypass Mode

Figure 29-119: PCIE_IATU_CTL2_OUTB_[n] Register Diagram

Table 29-128: PCIE_IATU_CTL2_OUTB_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	REGEN	Region Enable. The `PCIE_IATU_CTL2_OUTB_[n].REGEN` bit must be set to 1 for address translation to take place.
29 (R/W)	INV	Invert Mode. When the `PCIE_IATU_CTL2_OUTB_[n].INV` bit is set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address).
28 (R/W)	CFGSHFT	Cfg Shift Mode. The `PCIE_IATU_CTL2_OUTB_[n].CFGSHFT` bit is used for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of the application memory space using a 28-bit effective address. Shifts bits [27:12] of the untranslated address to form bits [31:16] of the translated address.
27 (R/W)	DMA_BYP	DMA Bypass Mode. The `PCIE_IATU_CTL2_OUTB_[n].DMA_BYP` bit allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated.

Table 29-128: PCIE_IATU_CTL2_OUTB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	FUNCBYP	Function Number Translation Bypass. The `PCIE_IATU_CTL2_OUTB_[n].FUNCBYP` bit field configures the iATU to use the function number of the translated TLP from the Slave SCB interface and not from the `PCIE_IATU_CTL1_OUTB_[n].FUNCNUM` or the `PCIE_IATU_CTL3_OUTB_[n].VFNUM` field.
7:0 (R/W)	MSGCODE	Message Code for Address Translation. When the address of an inbound TLP is matched to the `PCIE_IATU_CTL2_OUTB_[n].MSGCODE` bit field, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register.

iATU Region Control 3 Register

The `PCIE_IATU_CTL3_INB_[n]` register controls virtual function of inbound address translation used for mapping different address ranges to different memory spaces.

Table 29-131: PCIE_IATU_LBADDR_INB_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	VAR	Upper 16 bits of Address. The `PCIE_IATU_LBADDR_INB_[n].VAR` bit field forms bits [31:16] of the start address of the address region to be translated. This bit field is writeable.
15:0 (R/NW)	FIXED	Lower 16-bits of Address. The `PCIE_IATU_LBADDR_INB_[n].FIXED` bit field forms bits [15:0] of the start address of the address region to be translated. The start address must be aligned to 64 KB, so these bits are always 0. A write to this location is ignored by the PCIe core. This field is read-only.

IATU Lower Base Outbound Address Register

The `PCIE_IATU_LBADDR_OUTB_[n]` register contains the minimum size of an address translation region to 64 KB. The lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 KB boundaries. More precisely, the lower 16 bits are zero.

Table 29-140: PCIE_IATU_UTADDR_OUTB_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VAR	Upper Target Address. The `PCIE_IATU_UTADDR_OUTB_[n].VAR` bit field forms bits [63:32] of the start address of the new address of the translated region.

IATU View Port Register

The `PCIE_IATU_VWPRT_[n]` register programs the iATU registers through an indirect addressing scheme to reduce the address footprint in the PCI Express extended configuration space. The size of the required port logic space does not depend on the number of regions defined as the index register is used to select which memory region is being accessed.

There are 28 bytes of register space implemented per address region per direction. The number of address regions that are remapped by the iATU is configurable in each direction from 0 (none) to 256. However, only 32 bytes of the PCIe extended configuration space address map is used.

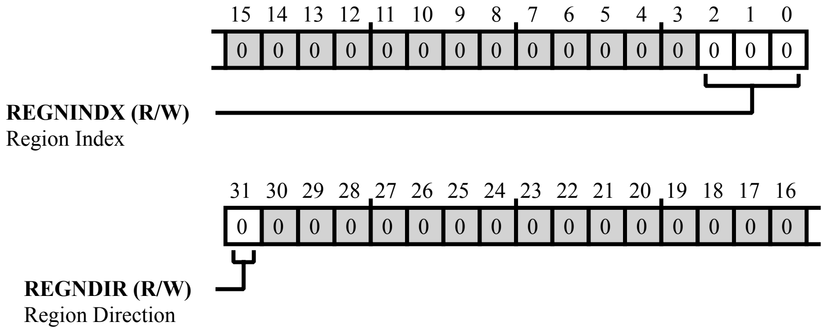

Figure 29-132: PCIE_IATU_VWPRT_[n] Register Diagram

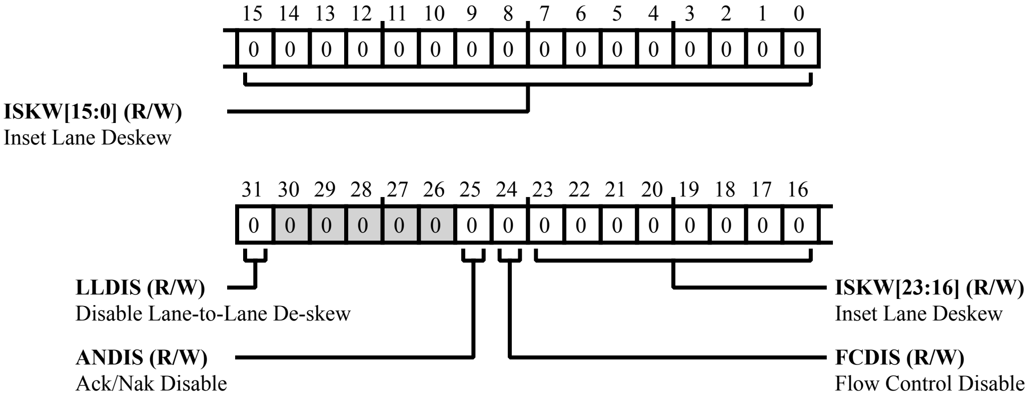
Table 29-141: PCIE_IATU_VWPRT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	REGNDIR	Region Direction. The `PCIE_IATU_VWPRT_[n].REGNDIR` bit defines the region being accessed as either inbound or outbound. 0: Outbound 1: Inbound
2:0 (R/W)	REGNINDX	Region Index. The `PCIE_IATU_VWPRT_[n].REGNINDX` bit field defines which region is being accessed when writing to the control, base, limit and target registers. The value must not be set to a number greater than 3 when an outbound region is being accessed or a value greater than 5 when an inbound region is being accessed. X = is log2(CX_ATU_NUM_INBOUND_REGIONS and CX_ATU_NUM_OUTBOUND_REGIONS).

Lane Skew Register

The `PCIE_LANE_SKEW_[n]` register contains bits that control lane skew and Data Link Layer Packet operations.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ISKW[15:0] (R/W)
Inset Lane Deskew

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LLDIS (R/W)
Disable Lane-to-Lane De-skew
ISKW[23:16] (R/W)
Inset Lane Deskew
ANDIS (R/W)
Ack/Nak Disable
FCDIS (R/W)
Flow Control Disable

Figure 29-133: PCIE_LANE_SKEW_[n] Register Diagram

Table 29-142: PCIE_LANE_SKEW_[n] Register Fields

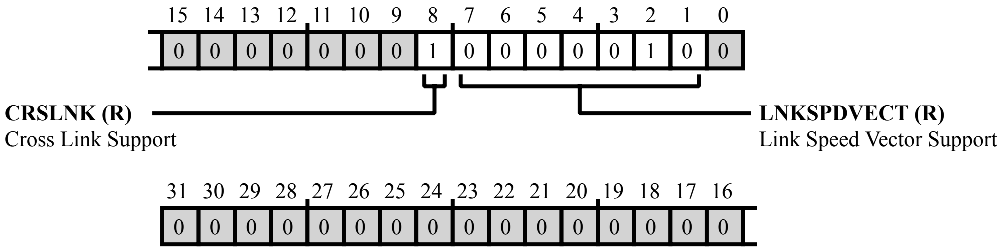
Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LLDIS	Disable Lane-to-Lane De-skew. The `PCIE_LANE_SKEW_[n].LLDIS` bit causes the core to disable the internal Lane-to-Lane de-skew logic. This register field is sticky.	
		0	Lane-to-Lane De-skew enabled
		1	Lane-to-Lane De-skew disabled
25 (R/W)	ANDIS	Ack/Nak Disable. The `PCIE_LANE_SKEW_[n].ANDIS` bit prevents the core from sending Ack and Nak DLLPs. This register field is sticky.	
		0	Do not send Ack and Nak DLLP
		1	Send Ack and Nak DLLP
24 (R/W)	FCDIS	Flow Control Disable. The `PCIE_LANE_SKEW_[n].FCDIS` bit prevents the core from sending FC Data Link Layer Packets (DLLPs). This register field is sticky.	
		0	Do not send FC DLLP
		1	Send FC DLLP

Table 29-142: PCIE_LANE_SKEW_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/W)	ISKW	Inset Lane Deskew. The `PCIE_LANE_SKEW_[n]` bit field configures the optional feature that causes the core to insert skew between lanes for test purposes. There are three bits per lane. The value is in units of one symbol time. For example, the value 010b for a lane forces a skew of two symbol times for that Lane. The maximum skew value for any lane is 5 symbol times. This register field is sticky.

Link Capabilities 2 Register

The PCIE_LNK_CAPB2_[n] register contains bits that indicate the link speed vector and port cross link status.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 1 0 0 0 0 0 1 0 0
CRSLNK (R)
Cross Link Support
LNKSPDVECT (R)
Link Speed Vector Support

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

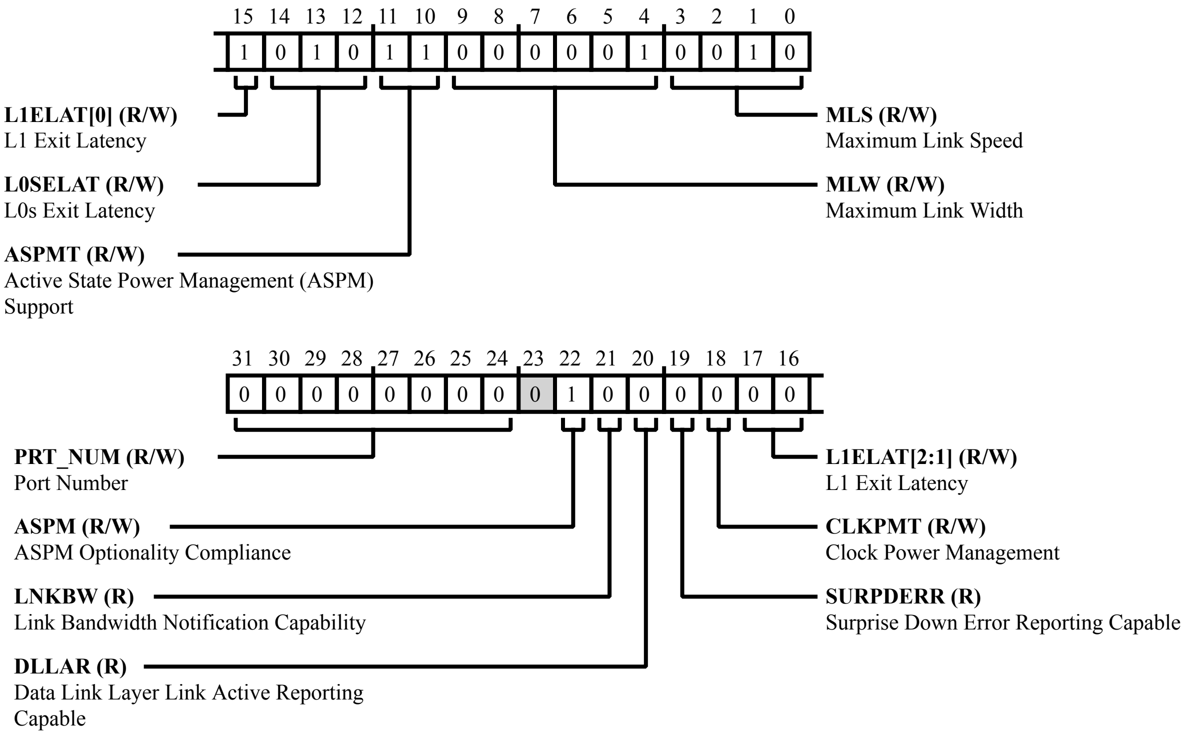
Figure 29-134: PCIE_LNK_CAPB2_[n] Register Diagram

Table 29-143: PCIE_LNK_CAPB2_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	CRSLNK	Cross Link Support. When set to 1, the PCIE_LNK_CAPB2_[n].CRSLNK bit indicates that the associated port supports cross links. When set to 0 on a port that supports link speeds of 8.0 GT/s or higher, this bit indicates that the associated port does not support cross links. When cleared (=0) on a port that only supports link speeds of 2.5 GT/s or 5.0 GT/s, this bit provides no information regarding the ports level of cross link support.	
7:1 (R/NW)	LNKSPDVECT	Link Speed Vector Support. The PCIE_LNK_CAPB2_[n].LNKSPDVECT bit field indicates the supported link speed(s) of the associated port. For each bit, a value of 1 indicates that the corresponding link speed is supported; otherwise, the link speed is not supported.	
		0	2.5 GT/sec
		1	5.0 GT/sec
		2	8.0 GT/sec

Link Capabilities Register

The PCIE_LNK_CAPB_[n] register contains bits that indicate the status of links and various link capabilities.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 0 1 0 1 1 0 0 0 0 0 1 0 0 1 0

L1 Exit Latency
L0SELAT (R/W)
L0s Exit Latency
ASPMT (R/W)
Active State Power Management (ASPM) Support
MLS (R/W)
Maximum Link Speed
MLW (R/W)
Maximum Link Width
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 1 0 0 0 0 0 0
PRT_NUM (R/W)
Port Number
ASPM (R/W)
ASPM Optionality Compliance
LNKBW (R)
Link Bandwidth Notification Capability
DLLAR (R)
Data Link Layer Link Active Reporting Capable
L1ELAT[2:1] (R/W)
L1 Exit Latency
CLKPMT (R/W)
Clock Power Management
SURPDERR (R)
Surprise Down Error Reporting Capable

Figure 29-135: PCIE_LNK_CAPB_[n] Register Diagram

Table 29-144: PCIE_LNK_CAPB_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PRT_NUM	Port Number. The PCIE_LNK_CAPB_[n].PRT_NUM bit field indicates the PCI Express Port number for the given PCI Express Link. Multi-function devices associated with an upstream port must report the same value in this field for all functions.
22 (R/W)	ASPM	ASPM Optionality Compliance. The PCIE_LNK_CAPB_[n].ASPM bit must be set to 1 in all functions. Components implemented against certain earlier versions of this specification will have this bit set to 0. Software is permitted to use the value of this bit to help determine whether to enable ASPM or whether to run ASPM compliance tests.

Table 29-144: PCIE_LNK_CAPB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/NW)	LNKBW	Link Bandwidth Notification Capability. A value of 1 in the `PCIE_LNK_CAPB_[n].LNKBW` bit indicates support for the Link Bandwidth Notification status and interrupt mechanisms. This capability is required for all Root Ports and Switch Downstream Ports supporting links wider than x1 and/or multiple Link speeds. This bit is not applicable and is Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and upstream ports of switches. Functions that do not implement the Link Bandwidth Notification Capability must hardwire this bit to 0.
20 (R/NW)	DLLAR	Data Link Layer Link Active Reporting Capable. For a downstream port, the `PCIE_LNK_CAPB_[n].DLLAR` bit must be hardwired to 1 if the component supports the optional capability of reporting the DL_Active state of the Data Link Control and Management State Machine. For a hot-plug capable downstream port (as indicated by the Hot-Plug Capable bit of the Slot Capabilities register) or a downstream port that supports Link speeds greater than 5.0 GT/s, this bit must be hardwired to 1. For upstream ports and components that do not support this optional capability, this bit must be hardwired to 0.
19 (R/NW)	SURPDERR	Surprise Down Error Reporting Capable. For a downstream port, the `PCIE_LNK_CAPB_[n].SURPDERR` bit must be set (=1) if the component supports the optional capability of detecting and reporting a Surprise Down error condition. For upstream ports and components that do not support this optional capability, this bit must be hardwired to 0.
18 (R/W)	CLKPMT	Clock Power Management. For upstream ports, a 1 the `PCIE_LNK_CAPB_[n].CLKPMT` bit indicates that the component tolerates the removal of any reference clock(s) via the clock request (CLKREQ#) mechanism when the Link is in the L1 and L2/L3 Ready Link states. A value of 0 indicates the component does not have this capability and that reference clock(s) must not be removed in these Link states. This capability is applicable only in form factors that support clock request (CLKREQ#) capability. For a multi-Function device associated with an upstream port, each function indicates its capability independently. Power Management configuration software must only permit reference clock removal if all functions of the multi-function device indicate a 1b in this bit. For ARI devices, all functions must indicate the same value in this bit. For downstream ports, this bit must be set to 0.

Table 29-144: PCIE_LNK_CAPB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17:15 (R/W)	L1ELAT	L1 Exit Latency. The `PCIE_LNK_CAPB_[n].L1ELAT` bit field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from ASPM L1 to L0. If ASPM L1 is not supported, the value is undefined. Note that exit latencies may be influenced by PCI Express reference clock configuration depending upon whether a component uses a common or separate reference clock. Multi-Function devices associated with an Upstream Port must report the same value in this field for all Functions.	
		0	Less than 1s
		1	1 s to less than 2 s
		2	2 s to less than 4 s
		3	4 s to less than 8 s
		4	8 s to less than 16 s
		5	16 s to less than 32 s
		6	32 s-64 s
		7	More than 64 s
14:12 (R/W)	L0SELAT	L0s Exit Latency. The `PCIE_LNK_CAPB_[n].L0SELAT` bit field indicates the L0s exit latency for the given PCI Express Link. The value reported indicates the length of time this port requires to complete transition from L0s to L0. If L0s is not supported, the value is undefined. Note that exit latencies may be influenced by PCI Express reference clock configuration depending upon whether a component uses a common or separate reference clock. Multi-Function devices associated with an upstream port must report the same value in this field for all functions.	
		0	Less than 64 ns
		1	64 ns to less than 128 ns
		2	128 ns to less than 256 ns
		3	256 ns to less than 512 ns
		4	512 ns to less than 1 s
		5	1 s to less than 2 s
		6	2 s-4 s
		7	More than 4 s

Table 29-144: PCIE_LNK_CAPB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	ASPMT	Active State Power Management (ASPM) Support. The `PCIE_LNK_CAPB_[n].ASPMT` bit field indicates the level of ASPM supported on the given PCI Express Link. Multi-function devices associated with an Upstream Port must report the same value in this field for all Functions.	
		0	No ASPM support
		1	0s support
		2	L1 supported
		3	L0s and L1 supported
9:4 (R/W)	MLW	Maximum Link Width. The `PCIE_LNK_CAPB_[n].MLW` bit field indicates the maximum link width (xN corresponding to N Lanes) implemented by the component. This value is permitted to exceed the number of lanes routed to the slot (downstream port), adapter connector (upstream port), or in the case of component-to- component connections, the actual wired connection width. Multi-Function devices associated with an upstream port must report the same value in this field for all Functions.	
		0	Reserved
		1	x1
		2	x2
		3	x4
		4	x8
		5	x12
		6	x16
		7	x32
3:0 (R/W)	MLS	Maximum Link Speed. The `PCIE_LNK_CAPB_[n].MLS` bit field indicates the maximum link speed of the associated port. The encoded value specifies a bit location in the supported link speeds vector (in the `PCIE_LNK_CAPB2_[n]` register) that corresponds to the maximum link speed. All encodings not listed below are reserved. Multi-Function devices associated with an Upstream Port must report the same value in this field for all Functions.	
		0	Supported Link Speeds Vector field bit 0
		1	Supported Link Speeds Vector field bit 1
		2	Supported Link Speeds Vector field bit 2

Figure 29-136: PCIE_LNK_CTLSTAT2_[n] Register Diagram

Table 29-145: PCIE_LNK_CTLSTAT2_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	EQREQ	Link Equalization Request. The `PCIE_LNK_CTLSTAT2_[n].EQREQ` bit is set by hardware to request the link equalization process to be performed on the link.
20 (R/NW)	EQP3DONE	Equalization Phase 3 Successful. When set (=1), the `PCIE_LNK_CTLSTAT2_[n].EQP3DONE` bit indicates that Phase 3 of the Transmitter Equalization procedure has successfully completed.
19 (R/NW)	EQP2DONE	Equalization Phase 2 Successful. When set (=1), the `PCIE_LNK_CTLSTAT2_[n].EQP2DONE` bit indicates that Phase 2 of the Transmitter Equalization procedure has successfully completed.
18 (R/NW)	EQP1DONE	Equalization Phase 1 Successful. When set (=1), the `PCIE_LNK_CTLSTAT2_[n].EQP1DONE` bit indicates that Phase 1 of the Transmitter Equalization procedure has successfully completed.

Table 29-145: PCIE_LNK_CTLSTAT2_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/NW)	EQDONE	Equalization Complete. For a description of this standard PCIe register field, see the PCI Express Base Specification 3.0. This register field is sticky.
16 (R/NW)	CURDEMPH	Current De-emphasis level. When the link is operating at 5.0 GT/sec speed, this bit reflects the level of de-emphasis. The value in this bit is undefined when the link is not operating at 5.0 GT/sec speed. Components that support only the 2.5 GT/sec speed are permitted to set this bit to 0. 0 -6.0 dB 1 -3.5 dB
15:12 (R/W)	PRSTCMPLI	Compliance Preset/De-emphasis. The `PCIE_LNK_CTLSTAT2_[n].PRSTCMPLI` bit field sets the de-emphasis level in Polling for 5.0 GT/sec data rate. Compliance state if the entry occurred due to the Enter Compliance bit being 1. Defined Encodings are 0001=3.5 dB and 0000=6 dB. When the Link is operating at 2.5 GT/sec, this field has no effect. Components that support only 2.5 GT/sec speed are permitted to set this field to 0000. This field is intended for debug and compliance testing purposes. System firmware and software is allowed to modify this field only during debug or compliance testing. In all other cases, the system must ensure that this field is set to the default value.
11 (R/W)	SOSCMPLI	Compliance SOS. When the `PCIE_LNK_CTLSTAT2_[n].SOSCMPLI` bit is set (=1), the LTSSM is required to send SKP Ordered Sets between sequences when sending the Compliance Pattern or Modified Compliance Pattern. For a Multi-Function device associated with an Upstream Port, the bit in Function 0 is of type RWS, and only Function 0 controls the components link behavior. In all other Functions of that device, this bit is of type RsvdP. The default value of this bit is 0. The `PCIE_LNK_CTLSTAT2_[n].SOSCMPLI` bit is applicable when the Link is operating at 2.5 GT/sec or 5.0 GT/sec data rates only. Components that support only the 2.5 GT/sec speed are permitted to hardwire this bit to 0.
10 (R/W)	EMCMPLI	Enter Modified Compliance. When the `PCIE_LNK_CTLSTAT2_[n].EMCMPLI` bit is set (=1), the device transmits Modified Compliance Pattern if the LTSSM enters Polling Compliance state. Components that support only the 2.5 GT/sec speed are permitted to set this bit to 0. The `PCIE_LNK_CTLSTAT2_[n].EMCMPLI` bit is intended for debug and compliance testing purposes. System firmware and software is allowed to modify this bit only during debug or compliance testing. In all other cases, the system must ensure that this bit is set to the default value.

(R/W)</td><td>TXM</td><td colspan="2">Transmit Margin.
The `PCIE_LNK_CTLSTAT2_[n].TXM` bit field controls the value of the non-de-emphasized voltage level at the transmitter pins. This field is reset to 0x0 on entry to the LTSSM Polling.</td></tr>
<tr><td rowspan="3">6
(R/W)</td><td rowspan="3">SELDEMPH</td><td colspan="2">Selectable De-emphasis.
The `PCIE_LNK_CTLSTAT2_[n].SELDEMPH` bit is used to control the transmit deemphasis of the link in specific situations when the link is operating at 5.0 GT/sec.
When the link is not operating at 5.0 GT/sec speed, the setting of this bit has no effect. Components that support only the 2.5 GT/sec speed are permitted to hardwire this bit to 0. This bit is not applicable and reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and upstream ports of switches.</td></tr>
<tr><td>0</td><td>-6 dB</td></tr>
<tr><td>1</td><td>-3.5 dB</td></tr>
<tr><td>5
(R/W)</td><td>HWASDIS</td><td colspan="2">Hardware Autonomous Speed Disable.
When the `PCIE_LNK_CTLSTAT2_[n].HWASDIS` bit is set (=1), hardware cannot change the link speed for device-specific reasons other than attempting to correct unreliable link operation. Initial transition to the highest supported common link speed is not blocked by this bit.</td></tr>
<tr><td>4
(R/W)</td><td>ECMPLI</td><td colspan="2">Enter Compliance.
When set (=1) the `PCIE_LNK_CTLSTAT2_[n].ECMPLI` bit allows software to force a link to enter Compliance mode (at the speed indicated in the Target Link Speed field and the de-emphasis/preset level indicated by the Compliance Preset/De-emphasis field) in both components on a link and then initiating a hot reset on the link.</td></tr>
</table>

Table 29-145: PCIE_LNK_CTLSTAT2_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W)	TRGSPD	Target Link Speed. For downstream ports, the `PCIE_LNK_CTLSTAT2_[n].TRGSPD` bit field sets an upper limit on Link operational speed by restricting the values advertised by the Upstream component in its training sequences. The encoded value specifies a bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the desired target Link speed. All encodings not listed below are reserved. If a value is written to the `PCIE_LNK_CTLSTAT2_[n].TRGSPD` bit field that does not correspond to a supported speed (as indicated by the Supported Link Speeds Vector), the result is undefined. If either of the Enter Compliance or Enter Modified Compliance bits are implemented, then this field must also be implemented. The default value of this field is the highest Link speed supported by the component (as reported in the `PCIE_LNK_CAPB_[n].MLS` bit field) unless the corresponding platform/form factor requires a different default value. For both upstream and downstream ports, this field is used to set the target compliance mode speed when software is using the Enter Compliance bit to force a Link into compliance mode. Components that support only the 2.5 GT/s speed are permitted to set this field to 0000.	
		0	Supported Link Speeds Vector field bit 0

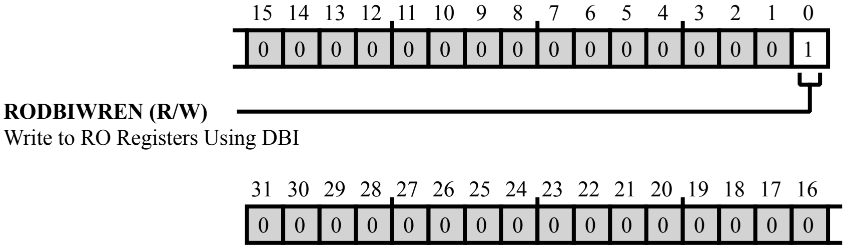
7 (R/W)	EXT_SYNC	Extended Synchronization. For a description of the PCIe standard `PCIE_LNK_CTLSTAT_[n].EXT_SYNC` bit, see the PCI Express Base Specification 3.0.
6 (R/W)	COMCLKCFG	Common Clock Configuration. For a description of the PCIe standard `PCIE_LNK_CTLSTAT_[n].COMCLKCFG` bit, see the PCI Express Base Specification 3.0.
5 (R/W)	RETRAIN	Retrain Link. For a description of the PCIe standard `PCIE_LNK_CTLSTAT_[n].RETRAIN` bit, see the PCI Express Base Specification 3.0.

Table 29-146: PCIE_LNK_CTLSTAT_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	DIS	Link Disable. The `PCIE_LNK_CTLSTAT_[n].DIS` bit disables the link by directing the LTSSM to the disabled state. This bit is reserved on Endpoints, PCI Express to PCI/PCI-X bridges, and upstream ports of switches. Writes to this bit are immediately reflected in the value read from the bit, regardless of actual link state.	
3 (R/W)	RCB	Read Completion Boundary. The `PCIE_LNK_CTLSTAT_[n].RCB` bit indicates the RCB value for the Root Port.	
		0	64-byte
		1	128-byte
1:0 (R/W)	ASPM	Active State Power Management (ASPM) Control. The `PCIE_LNK_CTLSTAT_[n].ASPM` bit field controls the level of ASPM enabled on the given PCI Express Link.	
		0	Disabled
		1	L0s entry enabled
		2	L1 entry enabled
		3	L0s and L1 entry enabled

DBI Read-Only Write Enable Register

The `PCIE_MISC_CTL1_[n]` register allows programs to write applicable hardware init and read-only bits from the local application through the DBI.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1
RODBIWREN (R/W)
Write to RO Registers Using DBI
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

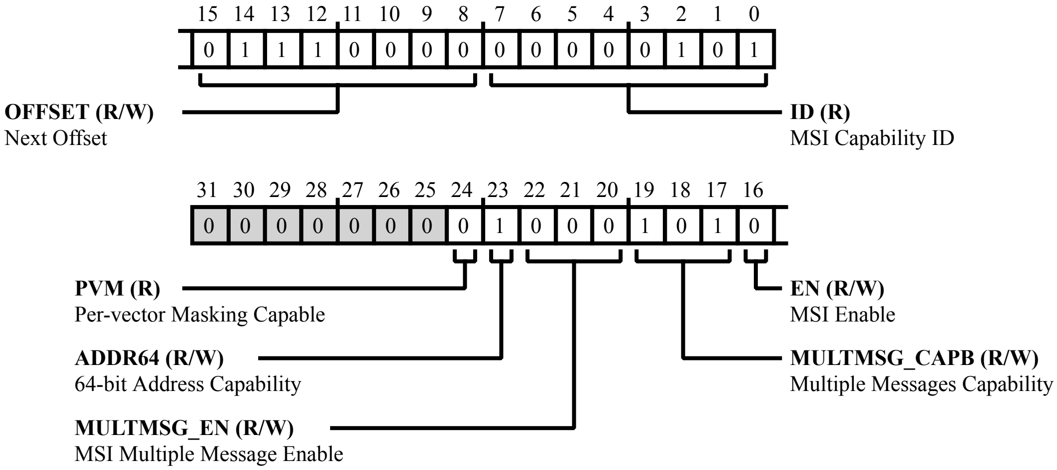
Figure 29-138: PCIE_MISC_CTL1_[n] Register Diagram

Table 29-147: PCIE_MISC_CTL1_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	RODBIWREN	Write to RO Registers Using DBI. The `PCIE_MISC_CTL1_[n].RODBIWREN` bit, when set (=1), allows programs to write applicable hardware init and read-only bits from the local application through the DBI.

MSI Capability ID, Next Pointer and Control Register

The `PCIE_MSI_CAPB_NPTR_[n]` register controls MSI capability.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 1 1 0 0 0 0 0 0 0 0 0 1 0 1
OFFSET (R/W)
Next Offset
ID (R)
MSI Capability ID
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 1 0 0 0 1 0 1 0
PVM (R)
Per-vector Masking Capable
ADDR64 (R/W)
64-bit Address Capability
MULTMSG_EN (R/W)
MSI Multiple Message Enable
EN (R/W)
MSI Enable
MULTMSG_CAPB (R/W)
Multiple Messages Capability

Figure 29-139: PCIE_MSI_CAPB_NPTR_[n] Register Diagram

Table 29-148: PCIE_MSI_CAPB_NPTR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	PVM	Per-vector Masking Capable. The `PCIE_MSI_CAPB_NPTR_[n].PVM` bit determines whether software has the ability to mask individual interrupts with the PVM capability structure (=1) or does not implement PVM (=0).	
23 (R/W)	ADDR64	64-bit Address Capability. The `PCIE_MSI_CAPB_NPTR_[n].ADDR64` bit indicates if the function is capable (=1) or is not capable (=0) of generating a 64-bit message address. This bit is read only.	
22:20 (R/W)	MULTMSG_EN	MSI Multiple Message Enable. System software writes to the `PCIE_MSI_CAPB_NPTR_[n].MULTMSG_EN` bit field to indicate the number of allocated messages (equal to or less than the number of requested messages). The number of allocated messages is aligned to a power of two. If a function requests four messages (indicated by a Multiple Message Capable encoding of 010), system software can allocate either four, two, or one message by writing a 010, 001, or 000 to this field, respectively. When MSI is enabled, a device is allocated at least 1 message. This fields state after reset is 000. This field is read/write.	
		0	1
		1	2
		2	4
		3	8

Table 29-148: PCIE_MSI_CAPB_NPTR_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	16
		5	32
		6	Reserved
		7	Reserved
19:17 (R/W)	MULTMSG_CAPB	Multiple Messages Capability. System software reads the `PCIE_MSI_CAPB_NPTR_[n].MULTMSG_CAPB` bit field to determine the number of requested messages. The number of requested messages must be aligned to a power of two (if a function requires three messages, it requests four by initializing this field to 010). This field is read only.	
		0	1
		1	2
		2	4
		3	8
		4	16
		5	32
		6	Reserved
		7	Reserved
16 (R/W)	EN	MSI Enable. If the `PCIE_MSI_CAPB_NPTR_[n].EN` bit =1, the function is permitted to use MSI to request service and is prohibited from using its INTx# pin (if implemented). System configuration software sets this bit to enable MSI. A device driver is prohibited from writing this bit to mask a functions service request. This bits state after reset is 0 (MSI is disabled). This bit is read/write.	
		0	The function is prohibited from using MSI to request service
		1	The function can use MSI to request service
15:8 (R/W)	OFFSET	Next Offset.	
7:0 (R/NW)	ID	MSI Capability ID. The value of 0x5 in the `PCIE_MSI_CAPB_NPTR_[n].ID` bit field identifies the function as message signaled interrupt capable. This field is read only.

15:0 (R/NW)	VALUE	MSI Offset. For a description of this standard PCIe register field, see the PCI Express Base Specification 3.0

MSI Controller Lower Address Register

The `PCIE_MSI_CTL_LADDR_[n]` register contains the system specified lower address for MSI memory write transaction termination. Within the SCB bridge, every received memory write request is examined to see if it targets the MSI address that has been specified in the MSI Controller Address Register and also to see if it satisfies the definition of an MSI interrupt request. When these conditions are satisfied the memory write request is marked as an MSI request.

31:0 (R/W)	VALUE	MSI Interrupt 2 Mask. The `PCIE_MSI_IMSK2_[n].VALUE` bit field masks enabled interrupts.

MSI Controller Interrupt 3 Mask Register

The `PCIE_MSI_IMSK3_[n]` register allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set high. Each bit corresponds to a single MSI interrupt vector.

MSI Controller Interrupt 0 Status Register

When an MSI is detected for End Point 0, one bit in the `PCIE_MSI_ISTAT0_[n]` register is set. The decoding of the data payload of the MSI memory write request determines which bit is set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI interrupt vector.

GEN2_6[5:4] (R/W)
Tx De-emphasis at 6 dB

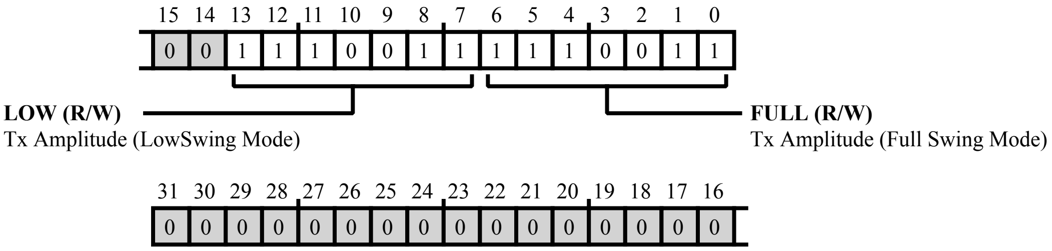
Figure 29-170: PCIE_PHY_TXDEEMPH Register Diagram

Table 29-179: PCIE_PHY_TXDEEMPH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:12 (R/W)	GEN2_6	Tx De-emphasis at 6 dB. The `PCIE_PHY_TXDEEMPH.GEN2_6` bit field is a static value that sets the Tx driver de-emphasis value in the case where pipeP_tx_deemph is set to 1'b0 and the PHY is running at the Gen2 rate. This bus is provided for completeness and as a second potential launch amplitude.
11:6 (R/W)	GEN2_35	Tx De-emphasis at 3.5 dB. The `PCIE_PHY_TXDEEMPH.GEN2_35` bit field is a static value that sets the Tx driver de-emphasis value in the case where pipeP_tx_deemph is set to 1'b1 (default setting) and the PHY is running at the Gen2 rate. To enable tuning at the board level for Rx eye compliance, connect this signal to a register.
5:0 (R/W)	GEN1	Tx De-emphasis at 3.5 dB. The `PCIE_PHY_TXDEEMPH.GEN1` bit field is a static value that sets the Tx driver de-emphasis value in the case where pipeP_tx_deemph is set to 1'b1 (default setting) and the PHY is running at the Gen1 rate. To enable tuning at the board level for Rx eye compliance, connect this signal to a register.

TX Launch Amplitude Register

The `PCIE_PHY_TXSWING` register is used to modify the voltage swing level of the transmitter.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 1 1 1 0 0 1 1 1 1 1 0 0 1 1

Figure 29-171: PCIE_PHY_TXSWING Register Diagram

Table 29-180: PCIE_PHY_TXSWING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:7 (R/W)	LOW	Tx Amplitude (LowSwing Mode). The `PCIE_PHY_TXSWING.LOW` bit field is a static value that sets the launch amplitude of the transmitter when pipeP_tx_swing is set to 1'b0 (default state). To enable tuning at the board level for Rx eye compliance, connect this signal to a register.
6:0 (R/W)	FULL	Tx Amplitude (Full Swing Mode). The `PCIE_PHY_TXSWING.FULL` bit field is a static value that sets the launch amplitude of the transmitter when pipeP_tx_swing is set to 1'b0 (default state). To enable tuning at the board level for Rx eye compliance, connect this signal to a register.

Port Logic Link Control Register

The `PCIE_PLCTL_[n]` register controls various functions of the port logic including DLL use, loopback control, and reset recovery.

Figure 29-172: PCIE_PLCTL_[n] Register Diagram

Table 29-181: PCIE_PLCTL_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21:16 (R/W)	LCAPB	Link Mode Enable. The `PCIE_PLCTL_[n].LCAPB` bit field sets the number of lanes in the link that are needed to connect to the link partner. When there are unused lanes in a system, then the value in this bit field must change to reflect the number of lanes. The value in the "Predetermined Number of Lanes" field of the "Link Width and Speed Change Control Register" also must change. For more information, see "How to Tie Off Unused Lanes". For information on upsizing and downsizing the link width, see "Link Establishment". This register field is sticky.	
		0	x1
		1	x2
		2	x4
		3	x8
		4	x16
		5	x32 (not supported)

Table 29-181: PCIE_PLCTL_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W)	FLM	Fast Link Mode. The `PCIE_PLCTL_[n].FLM` bit enables Fast Link mode. All internal timers are set to Fast Mode to speed up simulation. This mode forces the LTSSM training (link initialization) to use shorter time-outs and to link up faster. The scaling factor is 1024 for all internal timers. Fast Link Mode can also be activated by setting the diag_ctrl_bus[2] pin to 1. This register field is sticky.
5 (R/W)	DLEN	DLL Link Enable. The `PCIE_PLCTL_[n].DLEN` bit enables link initialization. When DLL Link Enable =0, the core does not transmit InitFC DLLPs and does not establish a link. This register field is sticky.
3 (R/W)	RSTA	Reset Assert. The `PCIE_PLCTL_[n].RSTA` bit triggers a recovery and forces the LTSSM to the hot reset state for a downstream port only. This bit is sticky.
2 (R/W)	LPBKEN	Loopback Enable. The `PCIE_PLCTL_[n].LPBKEN` bit turns on loopback. This register field is sticky.
1 (R/W)	SDIS	Scramble Disable. The `PCIE_PLCTL_[n].SDIS` bit turns off data scrambling. This register field is sticky.
0 (R/W)	VDLLP	Vendor Specific DLLP Request. When the `PCIE_PLCTL_[n].VDLLP` bit is set (=1), the core transmits the DLLP contained in the "Vendor Specific DLLP Register". Reading from this self-clearing register field always returns 0.

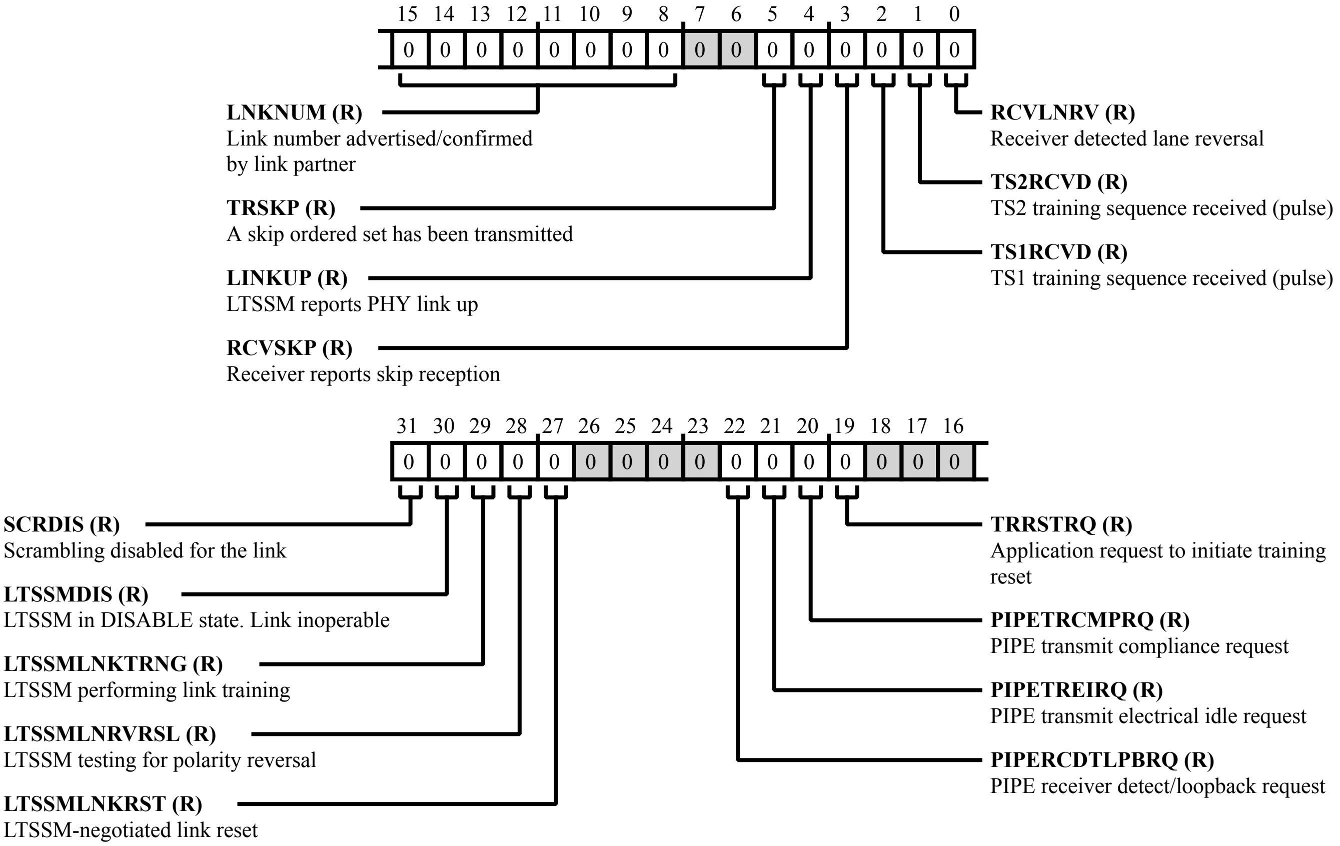
Port Logic Debug1 Register

The `PCIE_PLDBG1_[n]` register provides information regarding the state of the PCIe link.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LNKNUM (R)
Link number advertised/confirmed by link partner
TRSKP (R)
A skip ordered set has been transmitted
LINKUP (R)
LTSSM reports PHY link up
RCVSKP (R)
Receiver reports skip reception
RCVLNRV (R)
Receiver detected lane reversal
TS2RCVD (R)
TS2 training sequence received (pulse)
TS1RCVD (R)
TS1 training sequence received (pulse)
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SCRDIS (R)
Scrambling disabled for the link
LTSSMDIS (R)
LTSSM in DISABLE state. Link inoperable
LTSSMLNKTRNG (R)
LTSSM performing link training
LTSSMLNRVRSL (R)
LTSSM testing for polarity reversal
LTSSMLNKRST (R)
LTSSM-negotiated link reset
TRRSTRQ (R)
Application request to initiate training reset
PIPETRCMPRQ (R)
PIPE transmit compliance request
PIPETREIRQ (R)
PIPE transmit electrical idle request
PIPERCDTLPBRQ (R)
PIPE receiver detect/loopback request

Table 29-183: PCIE_PLDBG1_[n] Register Fields

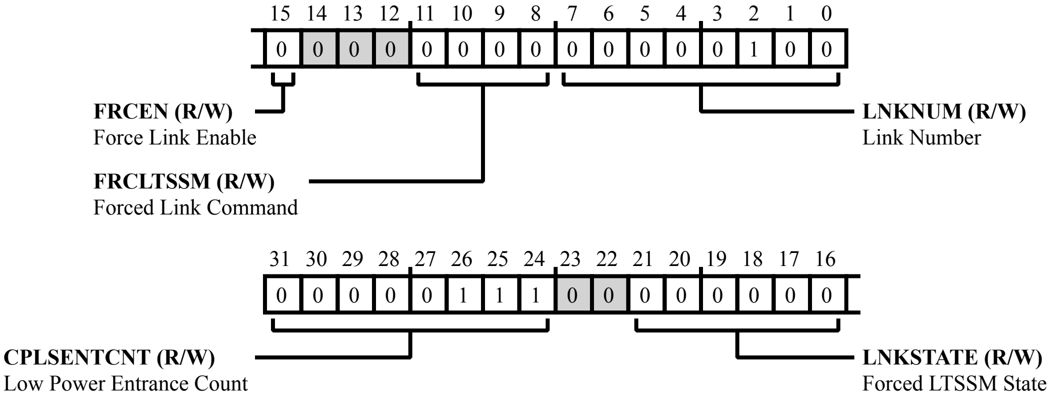
Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	SCRDIS	Scrambling disabled for the link.
30 (R/NW)	LTSSMDIS	LTSSM in DISABLE state. Link inoperable.
29 (R/NW)	LTSSMLNKTRNG	LTSSM performing link training.
28 (R/NW)	LTSSMLNRVRSL	LTSSM testing for polarity reversal.

Table 29-183: PCIE_PLDBG1_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/NW)	LTSSMLNKRST	LTSSM-negotiated link reset.
22 (R/NW)	PIPERCDTLPBRQ	PIPE receiver detect/loopback request.
21 (R/NW)	PIPETREIRQ	PIPE transmit electrical idle request.
20 (R/NW)	PIPETRCMPRQ	PIPE transmit compliance request.
19 (R/NW)	TRRSTRQ	Application request to initiate training reset.
15:8 (R/NW)	LNKNUM	Link number advertised/confirmed by link partner.
5 (R/NW)	TRSKP	A skip ordered set has been transmitted.
4 (R/NW)	LINKUP	LTSSM reports PHY link up.
3 (R/NW)	RCVSKP	Receiver reports skip reception.
2 (R/NW)	TS1RCVD	TS1 training sequence received (pulse).
1 (R/NW)	TS2RCVD	TS2 training sequence received (pulse).
0 (R/NW)	RCVLNRV	Receiver detected lane reversal.

Port Force Link Register

The `PCIE_PL_FRC_[n]` register implements core support for testing and debug that allows software to force the LTSSM state machine into a specific state, and to force the core to transmit a specific Link Command.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0
FRCEN (R/W)
Force Link Enable
FRCLTSSM (R/W)
Forced Link Command
LNKNUM (R/W)
Link Number
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 1 1 1 0 0 0 0 0 0 0 0
CPLSENTCNT (R/W)
Low Power Entrance Count
LNKSTATE (R/W)
Forced LTSSM State

Figure 29-175: PCIE_PL_FRC_[n] Register Diagram

Table 29-184: PCIE_PL_FRC_[n] Register Fields

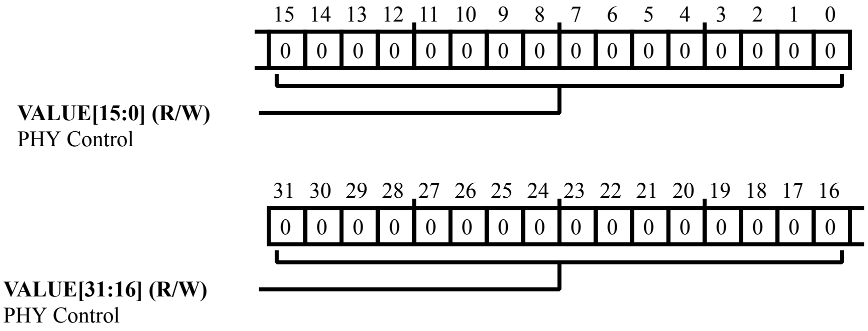
Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	CPLSENTCNT	Low Power Entrance Count. The `PCIE_PL_FRC_[n].CPLSENTCNT` bit field reports the number of clock cycles for the associated completion of a CfgWr to D-state register to go low-power. This bit field is intended for applications that do not let the core handle a completion for configuration request to the PMCSCR register. Not used in downstream ports. <br><i>Note</i>: This register field is sticky.
21:16 (R/W)	LNKSTATE	Forced LTSSM State. The `PCIE_PL_FRC_[n].LNKSTATE` bit field reports the LTSSM state that the core is forced to when the `PCIE_PL_FRC_[n].FRCEN` bit is set. LTSSM state encoding is defined by the lts_state variable in workspace/src/Layer1/xmlh_ltssm.v. This register field is sticky.
15 (R/W)	FRCEN	Force Link Enable. The `PCIE_PL_FRC_[n].FRCEN` bit enables the force link functionality where the LTSSM is in the state specified by the `PCIE_PL_FRC_[n].LNKSTATE` bit field. Also the core is forced to transmit the command specified by the Forced Link Command field. This is a self-clearing bit. Reading from this bit always returns 0.
11:8 (R/W)	FRCLTSSM	Forced Link Command. The `PCIE_PL_FRC_[n].FRCLTSSM` bit field reports the link command that the core is forced to transmit when the `PCIE_PL_FRC_[n].FRCEN` bit is set. Link command encoding is defined by the ltssm_cmd variable in workspace/src/Layer1/xmlh_ltssm.v. This register field is sticky.

Table 29-184: PCIE_PL_FRC_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	LNKNUM	Link Number. The `PCIE_PL_FRC_[n].LNKNUM` bit field reports the link number. This bit field is not used for endpoint.

Port Control PHY Control Register

The `PCIE_PL_PHYCTL_[n]` register is a memory-mapped register that reflects the values on the the static phy_cfg_control output signals. Using this register does not in any way influence core function. The `PCIE_PL_PHYCTL_[n]` register can be used for any static sideband status signaling requirements for the PHY.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[15:0] (R/W)
PHY Control
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
PHY Control

Figure 29-176: PCIE_PL_PHYCTL_[n] Register Diagram

Table 29-185: PCIE_PL_PHYCTL_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	PHY Control. The `PCIE_PL_PHYCTL_[n].VALUE` bit field holds the data sent directly from the phy_cfg_control bus.

Port Control PHY Status Register

The `PCIE_PL_PHYSTAT_[n]` register is a memory-mapped register that reflects the values on the the static phy_cfg_status input signals. Using this register does not in any way influence core functionality. The `PCIE_PL_PHYSTAT_[n]` register can be used for any static sideband status signaling requirements for the PHY.

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R)
PHY Status Value

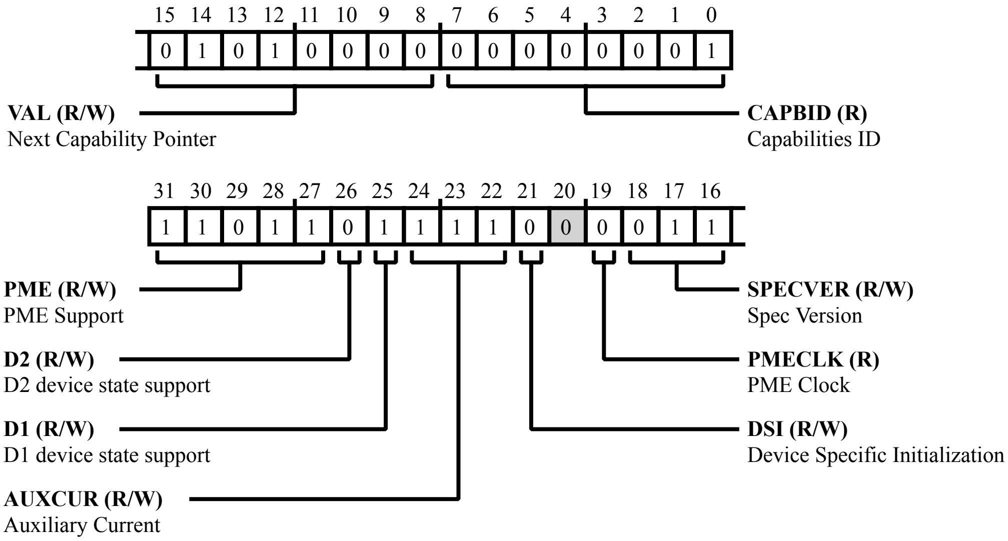
Figure 29-177: PCIE_PL_PHYSTAT_[n] Register Diagram

Table 29-186: PCIE_PL_PHYSTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	PHY Status Value. The `PCIE_PL_PHYSTAT_[n].VALUE` bit field holds the data received directly from the phy_cfg_status bus.

Power Management Capabilities Register

The `PCIE_PMT_CAPB_[n]` register indicates various settings for the power management module.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 0 1 0 0 0 0 0 0 0 0 0 0 0 1
VAL (R/W)
Next Capability Pointer
CAPBID (R)
Capabilities ID
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
1 1 0 1 1 0 1 1 1 1 0 0 0 0 1 1
PME (R/W)
PME Support
D2 (R/W)
D2 device state support
D1 (R/W)
D1 device state support
AUXCUR (R/W)
Auxiliary Current
SPECVER (R/W)
Spec Version
PMECLK (R)
PME Clock
DSI (R/W)
Device Specific Initialization

Figure 29-178: PCIE_PMT_CAPB_[n] Register Diagram

Table 29-187: PCIE_PMT_CAPB_[n] Register Fields

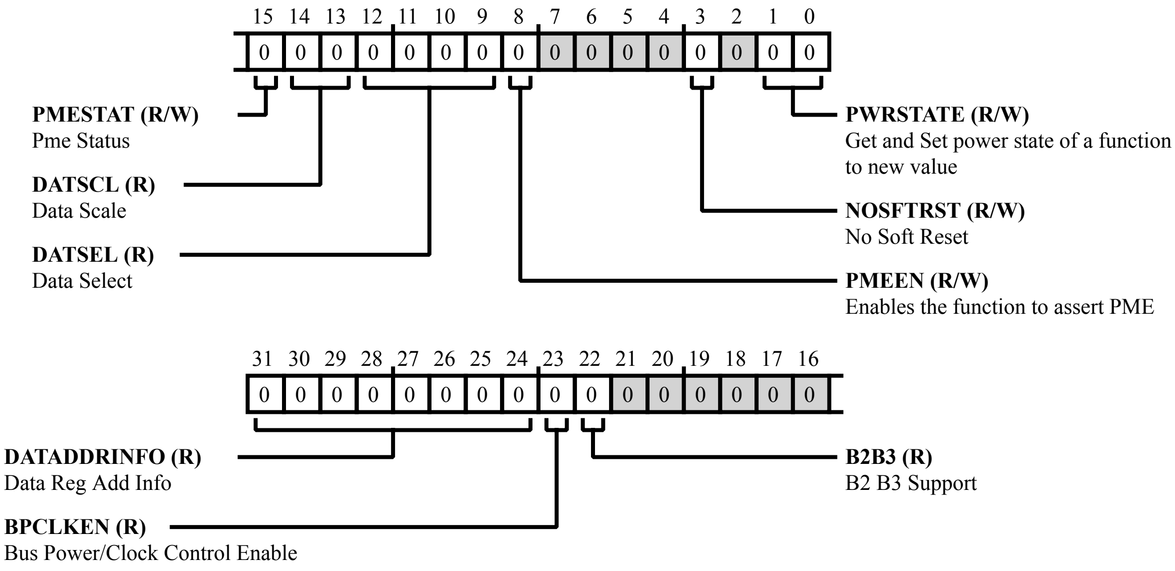
Bit No. (Access)	Bit Name	Description/Enumeration
31:27 (R/W)	PME	PME Support. For a device Function, the `PCIE_PMT_CAPB_[n].PME` bit field indicates the power states in which the Function may generate a PME. Bits 31, 30, and 27 must be set for PCI-PCI Bridge structures representing ports on Root Complexes/Switches to indicate that the Bridge will forward PME Messages.
26 (R/W)	D2	D2 device state support. If the `PCIE_PMT_CAPB_[n].D2` bit =1, this function supports the D2 Power Management State. Functions that do not support D2 must always return a value of 0.
25 (R/W)	D1	D1 device state support. If the `PCIE_PMT_CAPB_[n].D1` bit =1, this function supports the D1 Power Management State. Functions that do not support D1 must always return a value of 0.
24:22 (R/W)	AUXCUR	Auxiliary Current. The `PCIE_PMT_CAPB_[n].AUXCUR` bit field reports the 3.3V auxiliary current requirements for the PCI function.
21 (R/W)	DSI	Device Specific Initialization. The `PCIE_PMT_CAPB_[n].DSI` bit indicates whether special initialization of this function is required (beyond the standard PCI configuration header) before the generic class device driver is able to use it

Table 29-187: PCIE_PMT_CAPB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/NW)	PMECLK	PME Clock. Does not apply to PCI Express. Must be set to 0
18:16 (R/W)	SPECVER	Spec Version. When the `PCIE_PMT_CAPB_[n].SPECVER` bit field = 011 it indicates that this function complies with revision 1.2 of the PCI Power Management Interface Specification.
15:8 (R/W)	VAL	Next Capability Pointer. The `PCIE_PMT_CAPB_[n].VAL` bit field provides an offset into the functions PCI Configuration Space pointing to the location of next item in the functions capability list. If there are no additional items in the Capabilities List, this bit field is set to 0.
7:0 (R/NW)	CAPBID	Capabilities ID. When the `PCIE_PMT_CAPB_[n].CAPBID` bit field = 0x1, it identifies the linked list item as being the PCI Power Management registers.

Power Management Control and Status Register

The `PCIE_PMT_CTLSTAT_[n]` register controls/indicates various settings for the power management module.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PMESTAT (R/W)
Pme Status
DATSCL (R)
Data Scale
DATSEL (R)
Data Select
PWRSTATE (R/W)
Get and Set power state of a function to new value
NOSFTRST (R/W)
No Soft Reset
PMEEN (R/W)
Enables the function to assert PME
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
DATADDRINFO (R)
Data Reg Add Info
BPCLKEN (R)
Bus Power/Clock Control Enable
B2B3 (R)
B2 B3 Support

Figure 29-179: PCIE_PMT_CTLSTAT_[n] Register Diagram

Table 29-188: PCIE_PMT_CTLSTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/NW)	DATADDRINFO	Data Reg Add Info. The `PCIE_PMT_CTLSTAT_[n].DATADDRINFO` bit field provides a mechanism for a function to report state dependent operating data such as power consumed or heat dissipation (read-only).	
23 (R/NW)	BPCLKEN	Bus Power/Clock Control Enable. The `PCIE_PMT_CTLSTAT_[n].BPCLKEN` bit determines whether the bridges PMCSR PowerState field can be used by system software to control the power or clock of the bridges secondary bus.	
		0	Indicates that the bus power/clock control policies have been disabled
		1	Indicates that the bus power/clock control mechanism is enabled

Table 29-188: PCIE_PMT_CTLSTAT_[n] Register Fields (Continued)

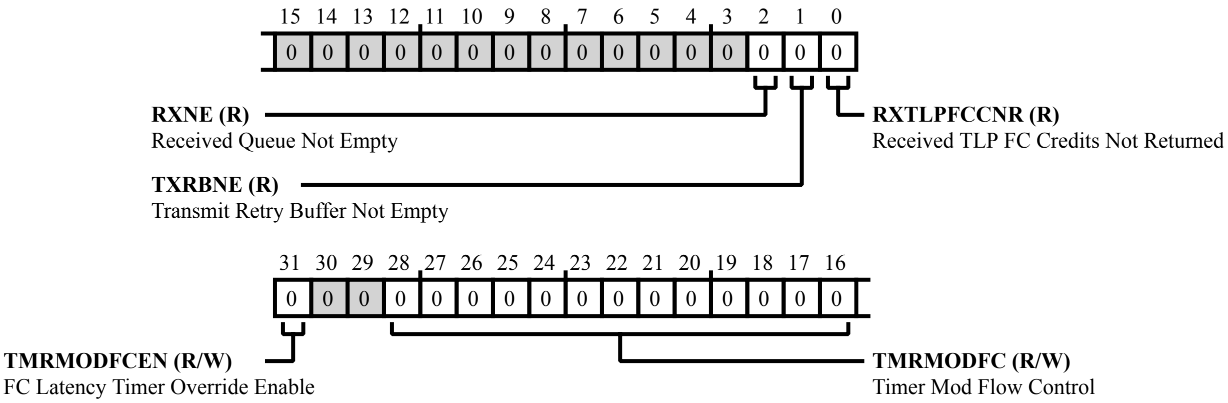
Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/NW)	B2B3	B2 B3 Support. The state of the `PCIE_PMT_CTLSTAT_[n].B2B3` bit determines the action that is to occur as a direct result of programming the function to D3hot. This bit is only meaningful if the `PCIE_PMT_CTLSTAT_[n].BPCLKEN` bit is enabled.	
		0	Indicates that when the bridge function is programmed to D3hot, its secondary bus will have its power removed (B3)
		1	Indicates that when the bridge function is programmed to D3hot, its secondary buss PCI clock will be stopped (B2)
15 (R/W)	PMESTAT	Pme Status. The `PCIE_PMT_CTLSTAT_[n].PMESTAT` bit is set when the function would normally assert the PME# signal independent of the state of the PME_En bit. Writing a 1 to this bit clears it and causes the function to stop asserting a PME# (if enabled). Writing a 0 has no effect. This bit defaults to 0 if the function does not support PME# generation from D3cold. If the function supports PME# from D3cold, then this bit is sticky and must be explicitly cleared by the operating system each time the operating system is initially loaded.	
14:13 (R/NW)	DATSCL	Data Scale. The `PCIE_PMT_CTLSTAT_[n].DATSCL` bit field indicates the scaling factor to be used when interpreting the value of the Data register. The value and meaning of this field varies depending on which data value has been selected by the Data_Select field.	
12:9 (R/NW)	DATSEL	Data Select. The `PCIE_PMT_CTLSTAT_[n].DATSEL` bit field is used to select which data is to be reported through the Data register and Data_Scale field.	
8 (R/W)	PMEEN	Enables the function to assert PME. The `PCIE_PMT_CTLSTAT_[n].PMEEN` bit enables the function to assert PME.	
3 (R/W)	NOSFTRST	No Soft Reset. The `PCIE_PMT_CTLSTAT_[n].NOSFTRST` bit enables or disables No_soft_Reset.	
		0	Functional context is not required to be maintained by the Function in the D3hot state
		1	Functional context should be maintained by the Function in the D3hot state

Table 29-188: PCIE_PMT_CTLSTAT_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	PWRSTATE	Get and Set power state of a function to new value. The `PCIE_PMT_CTLSTAT_[n].PWRSTATE` bit field is used both to determine the current power state of a function and to set the function into a new power state. If software attempts to write an unsupported, optional state to this field, the write operation must complete normally on the bus. However, the data is discarded and no state change occurs.	
		0	D0
		1	D1
		2	D2
		3	D3 hot

Queue Status Register

The `PCIE_QSTAT_[n]` register reports the status of data transfers and the FC Latency Timer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RXNE (R)
Received Queue Not Empty
TXRBNE (R)
Transmit Retry Buffer Not Empty
RXTLPFCCNR (R)
Received TLP FC Credits Not Returned
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TMRMODFCEN (R/W)
FC Latency Timer Override Enable
TMRMODFC (R/W)
Timer Mod Flow Control

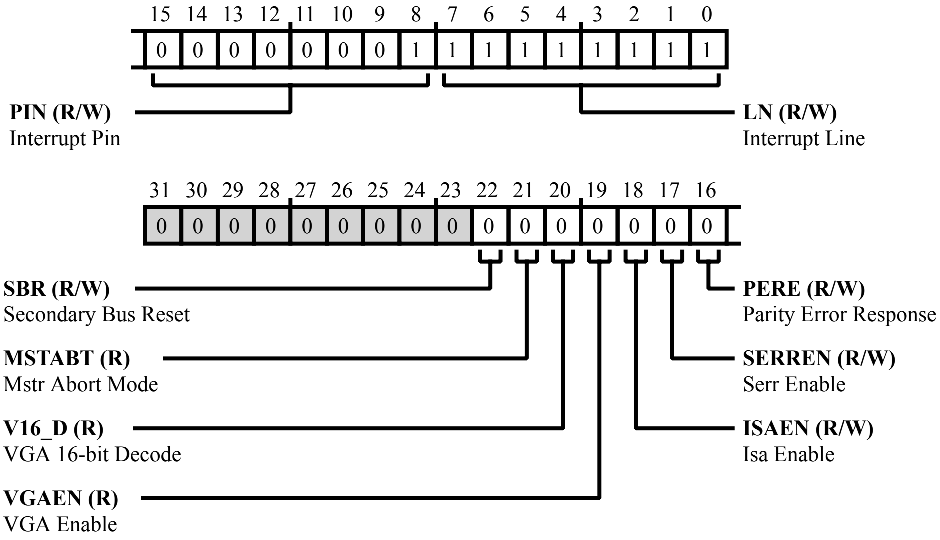
Figure 29-180: PCIE_QSTAT_[n] Register Diagram

Table 29-189: PCIE_QSTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	TMRMODFCEN	FC Latency Timer Override Enable. The `PCIE_QSTAT_[n].TMRMODFCEN` bit indicates the FC Latency Timer Override Enable. When this bit is set, the value from the `PCIE_QSTAT_[n].TMRMODFC` bit field overrides the FC latency timer value that the core calculates according to the PCIe specification.
28:16 (R/W)	TMRMODFC	Timer Mod Flow Control. The `PCIE_QSTAT_[n].TMRMODFC` bit field indicates the FC Latency Timer Override value. When the `PCIE_QSTAT_[n].TMRMODFCEN` bit is set, the value in this field overrides the FC latency timer value that the core calculates according to the PCIe specification.
2 (R/NW)	RXNE	Received Queue Not Empty. The `PCIE_QSTAT_[n].RXNE` bit indicates there is data in one or more of the receive buffers.
1 (R/NW)	TXRBNE	Transmit Retry Buffer Not Empty. The `PCIE_QSTAT_[n].TXRBNE` bit indicates that there is data in the transmit retry buffer.
0 (R/NW)	RXTLPFCCNR	Received TLP FC Credits Not Returned. The `PCIE_QSTAT_[n].RXTLPFCCNR` bit indicates that the core has sent a TLP but has not yet received an UpdateFC DLLP indicating that the credits for that TLP have been restored by the receiver at the other end of the link.

Interrupt Bridge Line and Pin Control Register

Interrupt Bridge, Line and Pin Control Register



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 1 1 1 1 1 1 1 1 1
PIN (R/W)
Interrupt Pin
LN (R/W)
Interrupt Line

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SBR (R/W)
Secondary Bus Reset
MSTABT (R)
Mstr Abort Mode
V16_D (R)
VGA 16-bit Decode
VGAEN (R)
VGA Enable
PERE (R/W)
Parity Error Response
SERREN (R/W)
Serr Enable
ISAEN (R/W)
Isa Enable

Figure 29-181: PCIE_RC_BRDG_ILPCTL_[n] Register Diagram

Table 29-190: PCIE_RC_BRDG_ILPCTL_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22 (R/W)	SBR	Secondary Bus Reset. Setting the `PCIE_RC_BRDG_ILPCTL_[n].SBR` bit triggers a hot reset on the corresponding PCIe port.
21 (R/NW)	MSTABT	Mstr Abort Mode. The `PCIE_RC_BRDG_ILPCTL_[n].MSTABT` bit controls the behavior of a bridge when a Master-Abort termination occurs on either interface while the bridge is the master of the transaction. Does not apply to PCIe and must be set to 0.
20 (R/NW)	V16_D	VGA 16-bit Decode. The `PCIE_RC_BRDG_ILPCTL_[n].V16_D` bit only has meaning if either bit 3 (VGA Enable) of this register or bit 5 (VGA Palette Snoop Enable) of the Command Register, is also set to 1, enabling VGA I/O decoding and forwarding by the bridge. This read/write bit enables system configuration software to select between 10-bit (=0) and 16-bit (=1) I/O address decoding for all VGA I/O register accesses that are forwarded from primary to secondary.

Table 29-190: PCIE_RC_BRDG_ILPCTL_[n] Register Fields (Continued)

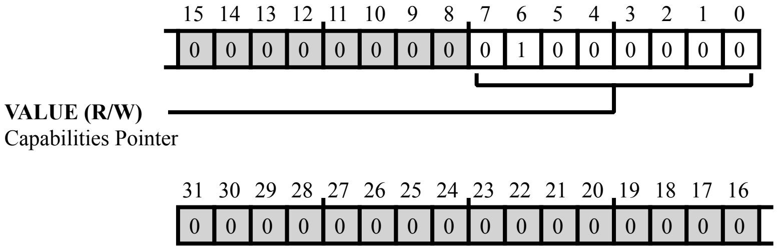
Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	VGAEN	VGA Enable. The `PCIE_RC_BRDG_ILPCTL_[n].VGAEN` bit modifies the response by the bridge to VGA compatible addresses.	
		0	Do not forward VGA compatible memory and I/O addresses from the primary to the secondary interface (addresses defined above) unless they are enabled for forwarding by the defined I/O and memory address ranges
		1	Forward VGA compatible memory and I/O addresses (addresses defined above) from the primary interface to the secondary interface (if the I/O Enable and Memory Enable bits are set) independent of the I/O and memory address ranges and independent of the ISA Enable bit
18 (R/W)	ISAEN	Isa Enable. The `PCIE_RC_BRDG_ILPCTL_[n].ISAEN` bit modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64 KB of PCI I/O address space (0000 0000h to 0000 FFFFh). The default state of this bit after reset must be 0.	
		0	Forward downstream all I/O addresses in the address range defined by the I/O Base and I/O Limit registers
		1	Forward upstream ISA I/O addresses in the address range defined by the I/O Base and I/O Limit registers that are in the first 64 KB of PCI I/O address space (top 768 bytes of each 1-KB block)
17 (R/W)	SERREN	Serr Enable. The `PCIE_RC_BRDG_ILPCTL_[n].SERREN` bit controls forwarding of correctable, nonfatal and fatal error from secondary to primary.	
16 (R/W)	PERE	Parity Error Response. The `PCIE_RC_BRDG_ILPCTL_[n].PERE` bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Secondary Status register.	
15:8 (R/W)	PIN	Interrupt Pin. The `PCIE_RC_BRDG_ILPCTL_[n].PIN` bit field identifies the legacy interrupt Message(s) the Function uses. Valid values are 0x1, 0x2, 0x3, and 0x4 that map to legacy interrupt Messages for INTA, INTB, INTC, and INTD respectively. A value of 0x0 indicates that the Function uses no legacy interrupt Message(s).	

Table 29-190: PCIE_RC_BRDG_ILPCTL_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	LN	Interrupt Line. The `PCIE_RC_BRDG_ILPCTL_[n].LN` bit field communicates interrupt line routing information. This bit field is read/write and must be implemented by any Function that uses an interrupt pin. Values in this register are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this register is used by device drivers and operating systems

Capability Pointer Register.

The PCIE_RC_CAPBPTR_[n] register points to the first item in the list of capabilities.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 1 0 0 0 0 0 0
VALUE (R/W)
Capabilities Pointer
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

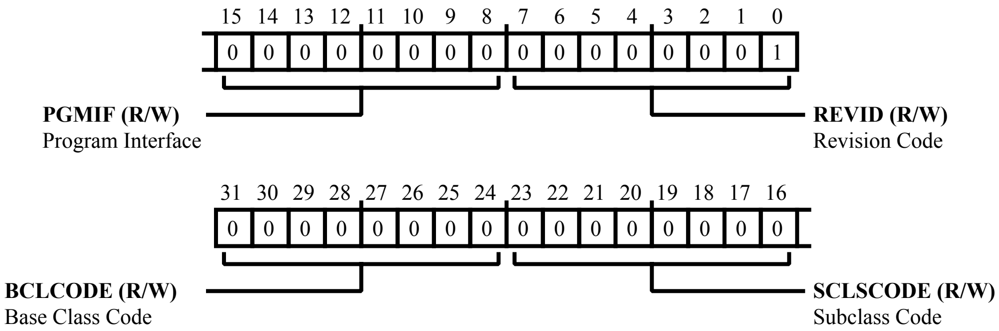
Figure 29-182: PCIE_RC_CAPBPTR_[n] Register Diagram

Table 29-191: PCIE_RC_CAPBPTR_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Capabilities Pointer. The `PCIE_RC_CAPBPTR_[n].VALUE` bit field points to the first item in the list of capabilities. Each capability in the list consists of an 8-bit ID field assigned by the PCI SIG, an 8 bit pointer in configuration space to the next capability, and some number of additional registers immediately following the pointer to implement that capability. Each capability must be DWORD aligned. The bottom two bits of all pointers (including the initial pointer at 0x34) are reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits. A pointer value of 0x00 is used to indicate the last capability in the list

Class Code and Revision ID Register

The `PCIE_RC_CCRID_[n]` register provides the Class Code and Revision ID.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1
PGMIF (R/W)
Program Interface
REVID (R/W)
Revision Code
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BCLCODE (R/W)
Base Class Code
SCLSCODE (R/W)
Subclass Code

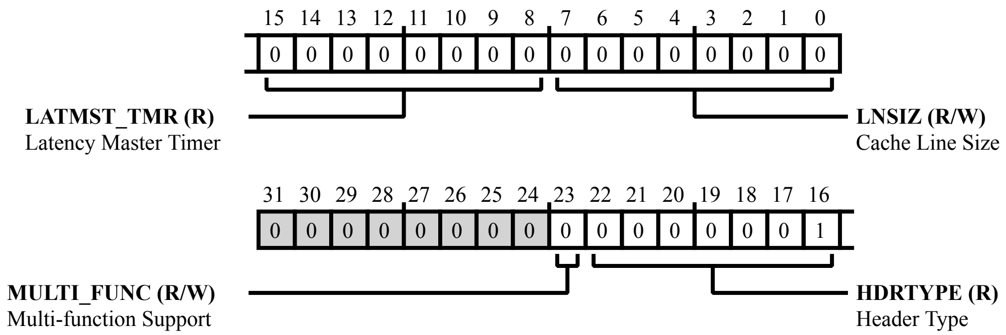
Figure 29-183: PCIE_RC_CCRID_[n] Register Diagram

Table 29-192: PCIE_RC_CCRID_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BCLCODE	Base Class Code. The `PCIE_RC_CCRID_[n].BCLCODE` bit field broadly classifies the type of function the device performs.
23:16 (R/W)	SCLSCODE	Subclass Code. The `PCIE_RC_CCRID_[n].SCLSCODE` bit field identifies more specifically the function of the device.
15:8 (R/W)	PGMIF	Program Interface. The `PCIE_RC_CCRID_[n].PGMIF` bit field identifies a specific register-level programming interface (if any) so that device independent software can interact with the device.
7:0 (R/W)	REVID	Revision Code. The `PCIE_RC_CCRID_[n].REVID` bit field is the device-specific revision identifier.

Root Complex Configuration Register

The `PCIE_RC_CFG_[n]` register provides bits to configure the header type, cache line size, and master latency timer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LATMST_TMR (R)
Latency Master Timer
LNSIZ (R/W)
Cache Line Size

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1
MULTI_FUNC (R/W)
Multi-function Support
HDRTYPE (R)
Header Type

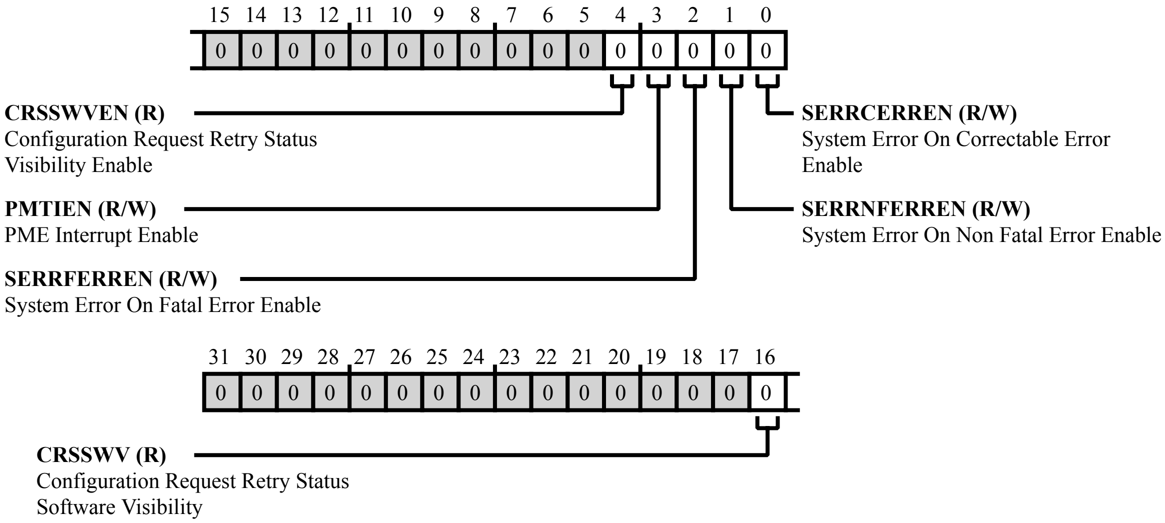
Figure 29-184: PCIE_RC_CFG_[n] Register Diagram

Table 29-193: PCIE_RC_CFG_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/W)	MULTI_FUNC	Multi-function Support. This bit must be set to 0.
22:16 (R/NW)	HDRTYPE	Header Type. The `PCIE_RC_CFG_[n].HDRTYPE` bit field identifies the layout of the second part of the predefined header and also whether or not the device contains multiple functions. Bit 7 in this register is used to identify a multifunction device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. Bits 6 through 0 identify the layout of the second part of the predefined header.
15:8 (R/NW)	LATMST_TMR	Latency Master Timer. The `PCIE_RC_CFG_[n].LATMST_TMR` bit field specifies the value of the latency timer in units of PCI bus clocks.
7:0 (R/W)	LNSIZ	Cache Line Size. The `PCIE_RC_CFG_[n].LNSIZ` bit field specifies the system cache line size in units of DWORDS.

Root Control and Capabilities Register

The `PCIE_RC_CTLCAPB_[n]` register identifies PCI Express Root Port specific control and capabilities.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CRSSWVEN (R)
Configuration Request Retry Status Visibility Enable
PMTIEN (R/W)
PME Interrupt Enable
SERRFERREN (R/W)
System Error On Fatal Error Enable
SERRCERREN (R/W)
System Error On Correctable Error Enable
SERRNFERREN (R/W)
System Error On Non Fatal Error Enable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CRSSWV (R)
Configuration Request Retry Status Software Visibility

Figure 29-185: PCIE_RC_CTLCAPB_[n] Register Diagram

Table 29-194: PCIE_RC_CTLCAPB_[n] Register Fields

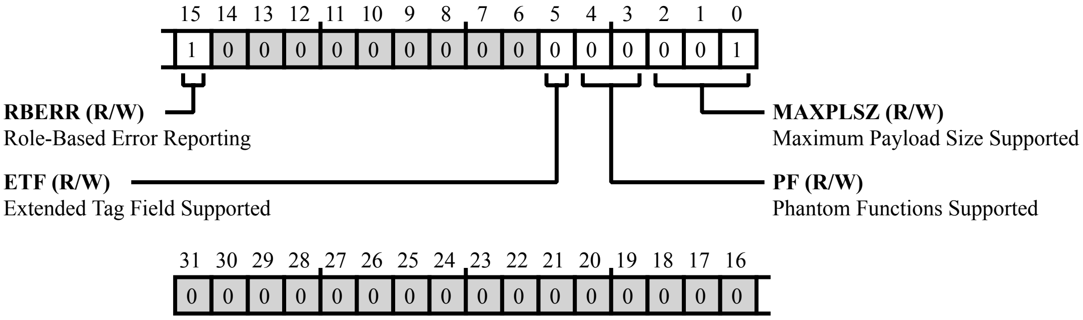
Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/NW)	CRSSWV	Configuration Request Retry Status Software Visibility. When Set, this bit indicates that the Root Port is capable of returning Configuration Request Retry Status (CRS) Completion Status to software.
4 (R/NW)	CRSSWVEN	Configuration Request Retry Status Visibility Enable. The `PCIE_RC_CTLCAPB_[n].CRSSWVEN` bit enables the Root Port to return Configuration Request Retry Status (CRS) Completion Status to software. Root Ports that do not implement this capability must set this bit to 0. Default value of this bit is 0.
3 (R/W)	PMTIEN	PME Interrupt Enable. The `PCIE_RC_CTLCAPB_[n].PMTIEN` bit enables PME interrupt generation upon receipt of a PME Message as reflected in the PME Status bit. A PME interrupt is also generated if the PME Status bit is set when this bit is changed from clear to set. Default value of this bit is 0.

Table 29-194: PCIE_RC_CTLCAPB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	SERRFERREN	System Error On Fatal Error Enable. The `PCIE_RC_CTLCAPB_[n].SERRFERREN` bit indicates that a System Error should be generated if a Fatal error is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific. Root Complex Event Collectors provide support for the above described functionality for Root Complex Integrated Endpoints. Default value of this bit is 0.
1 (R/W)	SERRNFERREN	System Error On Non Fatal Error Enable. The `PCIE_RC_CTLCAPB_[n].SERRNFERREN` bit indicates that a System Error should be generated if a Non-fatal error is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific. Root Complex Event Collectors provide support for the above described functionality for Root Complex Integrated Endpoints. Default value of this bit is 0.
0 (R/W)	SERRCERREN	System Error On Correctable Error Enable. The `PCIE_RC_CTLCAPB_[n].SERRCERREN` bit indicates that a System Error should be generated if a correctable error is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific. Root Complex Event Collectors provide support for the above described functionality for Root Complex Integrated Endpoints. Default value of this bit is 0.

Device Capabilities Register

The `PCIE_RC_DEVCAPB_[n]` register identifies PCI Express device Function specific capabilities.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1
RBERR (R/W)
Role-Based Error Reporting
ETF (R/W)
Extended Tag Field Supported
MAXPLSZ (R/W)
Maximum Payload Size Supported
PF (R/W)
Phantom Functions Supported
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 29-186: PCIE_RC_DEVCAPB_[n] Register Diagram

Table 29-195: PCIE_RC_DEVCAPB_[n] Register Fields

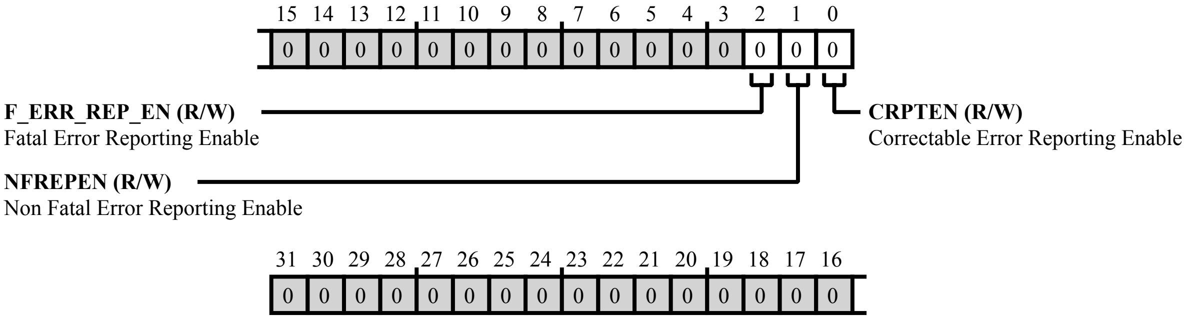
Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	RBERR	Role-Based Error Reporting. When the `PCIE_RC_DEVCAPB_[n].RBERR` bit is set, (=1) it indicates that the Function implements the functionality originally defined in the PCI Express Base Specification. This bit is read-only and always set to 1.	
5 (R/W)	ETF	Extended Tag Field Supported. The `PCIE_RC_DEVCAPB_[n].ETF` bit indicates the maximum supported size of the Tag field as a Requester. Note that 8-bit Tag field generation must be enabled by the Extended Tag Field Enable bit in the Device Control register of the Requester Function before 8-bit Tags can be generated by the Requester.	
		0	5-bit Tag field supported
		1	8-bit Tag field supported
4:3 (R/W)	PF	Phantom Functions Supported. The `PCIE_RC_DEVCAPB_[n].PF` bit field indicates the support for use of unclaimed Function Numbers to extend the number of outstanding transactions allowed by logically combining unclaimed Function Numbers (called Phantom Functions) with the Tag identifier.	
2:0 (R/W)	MAXPLSZ	Maximum Payload Size Supported. The `PCIE_RC_DEVCAPB_[n].MAXPLSZ` bit field indicates the maximum payload size that the Function can support for TLPs. The Functions of a multi-Function device are permitted to report different values for this field.	
		0	128 bytes max payload size
		1	256 bytes max payload size
		2	512 bytes max payload size

Table 29-195: PCIE_RC_DEVCAPB_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	1024 bytes max payload size
		4	2048 bytes max payload size
		5	4096 bytes max payload size
		6	Reserved
		7	Reserved

Root Complex Error Command Register

The PCIE_RC_ERRCMD_[n] register allows further control of Root Complex response to Correctable, Non-Fatal, and Fatal error Messages than the basic Root Complex capability to generate system errors in response to error Messages (either received or internally generated). Bit fields enable or disable generation of interrupts (claimed by the Root Port or Root Complex Event Collector) in addition to system error Messages.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
F_ERR_REP_EN (R/W)
Fatal Error Reporting Enable
NFREPEN (R/W)
Non Fatal Error Reporting Enable
CRPTEN (R/W)
Correctable Error Reporting Enable
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

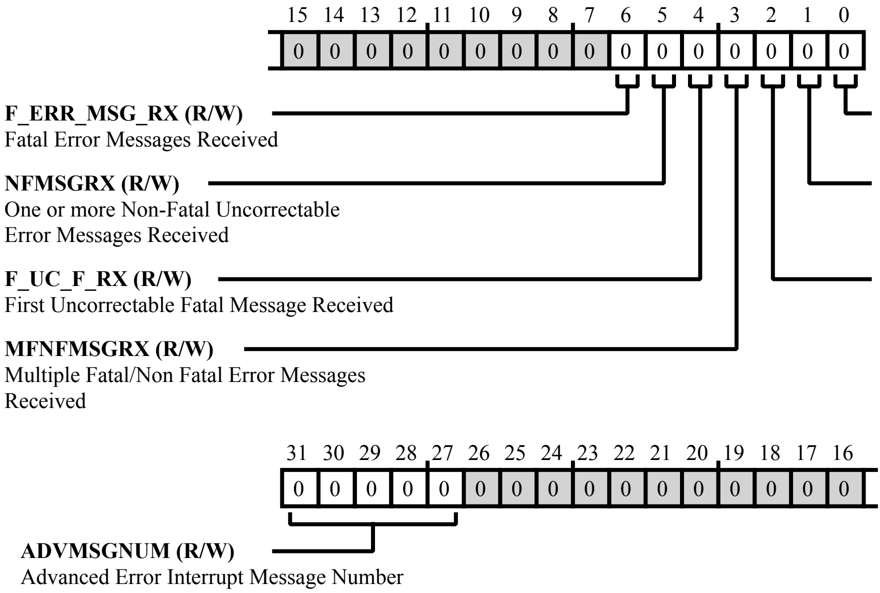
Figure 29-187: PCIE_RC_ERRCMD_[n] Register Diagram

Table 29-196: PCIE_RC_ERRCMD_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	F_ERR_REP_EN	Fatal Error Reporting Enable. The PCIE_RC_ERRCMD_[n].F_ERR_REP_EN bit enables the generation of an interrupt when a Fatal error is reported by any of the Functions in the hierarchy associated with this Root Complex Port. Root Complex Event Collectors provide support for the above described functionality for Root Complex Integrated Endpoints.
1 (R/W)	NFREPEN	Non Fatal Error Reporting Enable. The PCIE_RC_ERRCMD_[n].NFREPEN bit enables the generation of an interrupt when a Non-fatal error is reported by any of the Functions in the hierarchy associated with this Root Complex Port. Root Complex Event Collectors provide support for the above described functionality for Root Complex Integrated Endpoints.
0 (R/W)	CRPTEN	Correctable Error Reporting Enable. When Set, this bit enables the generation of an interrupt when a correctable error is reported by any of the Functions in the hierarchy associated with this Root Complex Port. Root Complex Event Collectors provide support for the above described functionality for Root Complex Integrated Endpoints.

Root Error Status Register

The `PCIE_RC_ERRSTAT_[n]` register reports status of error Messages (ERR_COR, ERR_NONFATAL, and ERR_FATAL) received by the Root Port, and of errors detected by the Root Port itself (which are treated conceptually as if the Root Port had sent an error Message to itself).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

One or more Non-Fatal Uncorrectable Error Messages Received
F_UC_F_RX (R/W)
First Uncorrectable Fatal Message Received
MFNFMSGRX (R/W)
Multiple Fatal/Non Fatal Error Messages Received
CORMSGRX (R/W)
Correctable Error Message Received
MCORMSGRX (R/W)
Multiple Correctable Error Messages Received
FNFMSGRX (R/W)
Fatal/Non Fatal Error Received
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADVMSGNUM (R/W)
Advanced Error Interrupt Message Number

Figure 29-188: PCIE_RC_ERRSTAT_[n] Register Diagram

Table 29-197: PCIE_RC_ERRSTAT_[n] Register Fields

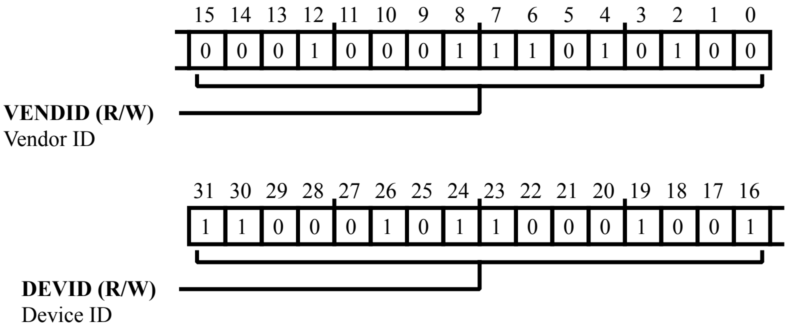
Bit No. (Access)	Bit Name	Description/Enumeration
31:27 (R/W)	ADVMSGNUM	Advanced Error Interrupt Message Number. The `PCIE_RC_ERRSTAT_[n].ADVMSGNUM` bit field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this Capability. For MSI, the value in this register indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the MSI Message Control register. For MSI-X, the value in this register indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this register must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this register must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this register is undefined.
6 (R/W)	F_ERR_MSG_RX	Fatal Error Messages Received. The `PCIE_RC_ERRSTAT_[n].F_ERR_MSG_RX` bit is set when one or more Fatal Uncorrectable error Messages have been received. Default value of this bit is 0.
5 (R/W)	NFMSGRX	One or more Non-Fatal Uncorrectable Error Messages Received. The `PCIE_RC_ERRSTAT_[n].NFMSGRX` bit is set when one or more Non-Fatal Uncorrectable error Messages have been received. Default value of this bit is 0.
4 (R/W)	F_UC_F_RX	First Uncorrectable Fatal Message Received. The `PCIE_RC_ERRSTAT_[n].F_UC_F_RX` bit is set when the first Uncorrectable error Message received is for a Fatal error. Default value of this field is 0.
3 (R/W)	MFNFMSGRX	Multiple Fatal/Non Fatal Error Messages Received. The `PCIE_RC_ERRSTAT_[n].MFNFMSGRX` bit is set when either a Fatal or a Non-fatal error is received and ERR_FATAL/NONFATAL Received is already Set. Default value of this bit is 0.
2 (R/W)	FNFMSGRX	Fatal/Non Fatal Error Received. The `PCIE_RC_ERRSTAT_[n].FNFMSGRX` bit is set when either a Fatal or a Non-fatal error Message is received and this bit is not already Set. Default value of this bit is 0.

Table 29-197: PCIE_RC_ERRSTAT_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	MCORMSGRX	Multiple Correctable Error Messages Received. The `PCIE_RC_ERRSTAT_[n].MCORMSGRX` bit is set when a Correctable error Message is received and ERR_COR Received is already Set. Default value of this bit is 0.
0 (R/W)	CORMSGRX	Correctable Error Message Received. The `PCIE_RC_ERRSTAT_[n].CORMSGRX` bit is set when a Correctable error Message is received and this bit is not already set. Default value of this bit is 0.

Device ID and Vendor ID Register

The `PCIE_RC_ID_[n]` register provides the Device ID and Vendor ID.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 1 0 0 0 1 1 1 0 1 0 1 0 0
VENDID (R/W)
Vendor ID

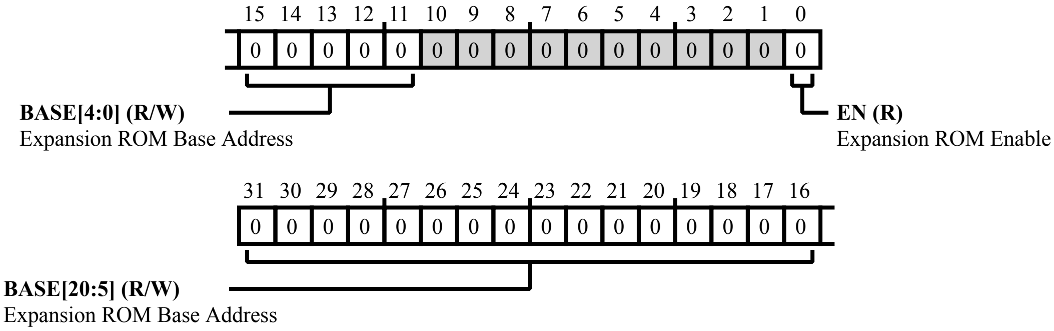
31:0 (R/NW)	VALUE	Prefetchable Limit Upper 32 bit Address. The `PCIE_RC_PREF_LMT_UP_[n].VALUE` bit field contains the prefetchable limit upper 32 bit address.

Root Complex Expansion ROM Base Address Register

The `PCIE_RC_ROMCFG_[n]` register controls whether or not the device accepts accesses to its expansion ROM and indicates the upper 21 bits of the Expansion ROM base address.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Expansion ROM Base Address

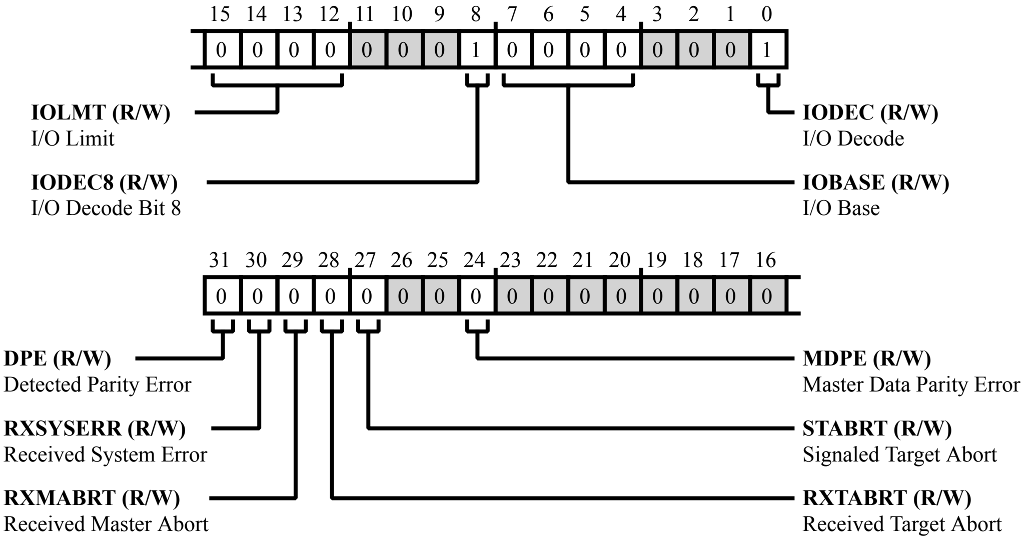
Figure 29-195: PCIE_RC_ROMCFG_[n] Register Diagram

Table 29-204: PCIE_RC_ROMCFG_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:11 (R/W)	BASE	Expansion ROM Base Address. The `PCIE_RC_ROMCFG_[n].BASE` bit field corresponds to the upper 21 bits of the Expansion ROM base address. The number of bits (out of these 21) that a device actually implements depends on how much address space the device requires. For instance, a device that requires a 64 KB area to map its expansion ROM would implement the top 16 bits in the register, leaving the bottom 5 (out of these 21) hardwired to 0. Devices that support an expansion ROM must implement this register
0 (R/NW)	EN	Expansion ROM Enable. The `PCIE_RC_ROMCFG_[n].EN` bit controls whether or not the device accepts accesses to its expansion ROM. When this bit is 0, the devices expansion ROM address space is disabled. When the bit is 1, address decoding is enabled using the parameters in the other part of the base register. This allows a device to be used with or without an expansion ROM depending on system configuration.

Secondary Status and I/O Base and Limit Register

The `PCIE_RC_SECSTAT_[n]` register provides error and status information for the secondary status and I/O base and limit. This register also provides the upper 4 bits of the 16-bit limit address (bits 15:12) and the upper 4 bits of the 16- bit base address (bits 15:12).



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Detected Parity Error
RXSYSERR (R/W)
Received System Error
RXMABRT (R/W)
Received Master Abort
MDPE (R/W)
Master Data Parity Error
STABRT (R/W)
Signaled Target Abort
RXTABRT (R/W)
Received Target Abort

Figure 29-196: PCIE_RC_SECSTAT_[n] Register Diagram

Table 29-205: PCIE_RC_SECSTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	DPE	Detected Parity Error. The `PCIE_RC_SECSTAT_[n].DPE` bit reports the detection of an address or data parity error by the bridge on its secondary interface. This bit must be set when any of the following conditions is true: • Detects an address parity error as a potential target • Detects a data parity error when the target of a write transaction • Detects a data parity error when the master of a read transaction The bit is set regardless of the state of the PERREN bit (bit 0) in the Bridge Control register. Once set, this bit remains set until it is reset by writing a 1 to this bit location. A bridge must implement this bit, and the default state must be 0 after reset.	
		0	Address or data parity error not detected by the bridge on its secondary interface
		1	Address or data parity error detected by the bridge on its secondary interface

Table 29-205: PCIE_RC_SECSTAT_[n] Register Fields (Continued)

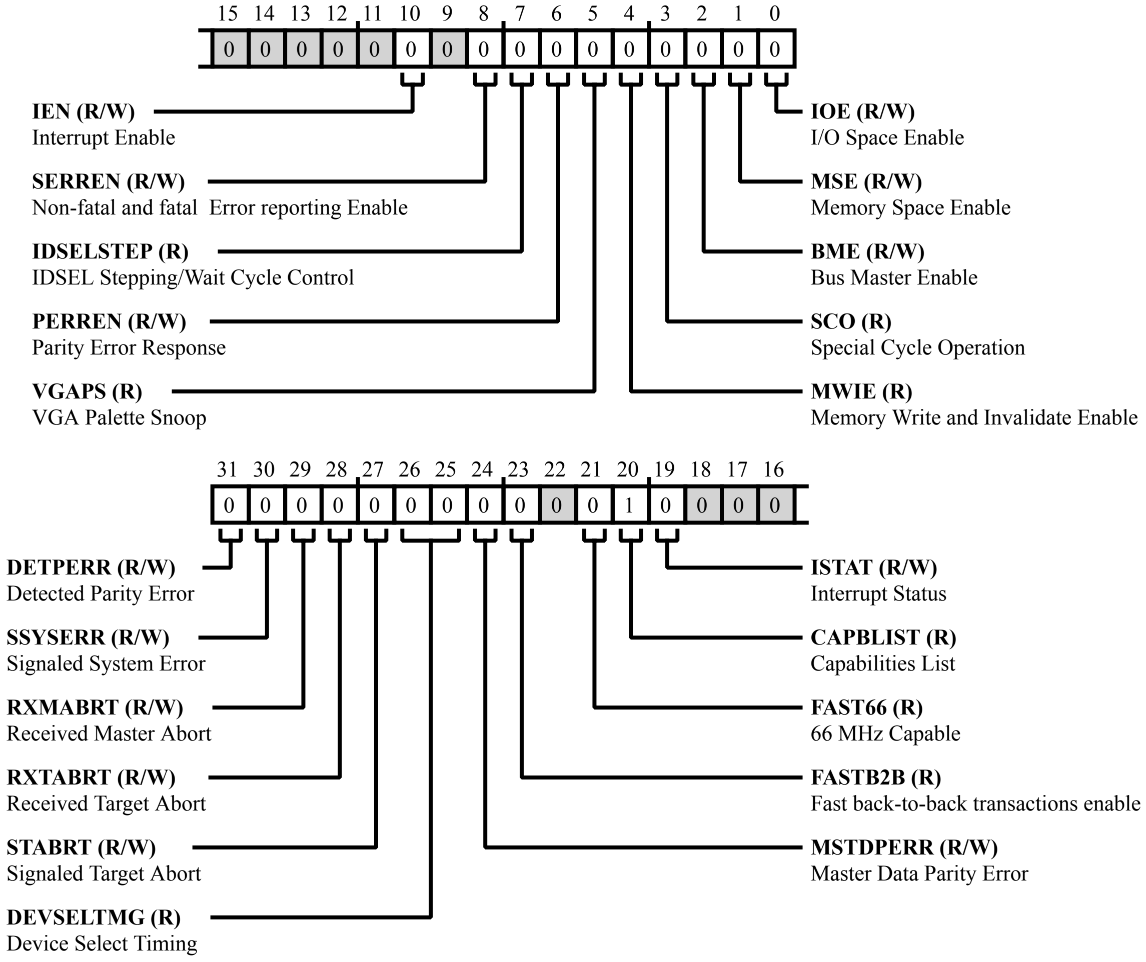
Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	RXSYSERR	Received System Error. The `PCIE_RC_SECSTAT_[n].RXSYSERR` bit reports the detection of an SERR# assertion on the secondary interface of the bridge. Once set, this bit remains set until it is reset by writing a 1 to this bit location. The default state must be 0 after reset.	
		0	SERR# assertion on the secondary interface has not been detected
		1	SERR# assertion on the secondary interface has been detected
29 (R/W)	RXMABRT	Received Master Abort. The `PCIE_RC_SECSTAT_[n].RXMABRT` bit reports the detection of a Master-Abort termination by the bridge when it is the master of a transaction on its secondary interface. Once set, this bit remains set until it is reset by writing a 1 to this bit location. A bridge must implement this bit and the default state must be 0 after reset.	
		0	Master-Abort not detected by the bridge on its secondary interface
		1	Master-Abort detected by the bridge on its secondary interface
28 (R/W)	RXTABRT	Received Target Abort. The `PCIE_RC_SECSTAT_[n].RXTABRT` bit reports the detection of a Target-Abort termination by the bridge when it is the master of a transaction on its secondary interface. Once set, this bit remains set until it is reset by writing a 1 to this bit location. A bridge must implement this bit. The default state of this bit must be 0 after reset.	
		0	Target-Abort not detected by the bridge on its secondary interface
		1	Target-Abort detected by the bridge on its secondary interface
27 (R/W)	STABRT	Signaled Target Abort. The `PCIE_RC_SECSTAT_[n].STABRT` bit reports the signaling of a Target-Abort termination by the bridge when it responds as the target of a transaction on its secondary interface. Once set, this bit remains set until it is reset by writing a 1 to this bit location. A bridge must implement this bit and the default state must be 0 after reset.	
		0	Target-Abort not signaled by the bridge on its secondary interface
		1	Target-Abort signaled by the bridge on its secondary interface

Table 29-205: PCIE_RC_SECSTAT_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	MDPE	Master Data Parity Error. The `PCIE_RC_SECSTAT_[n].MDPE` bit is used to report the detection of a parity error by the bridge when it is the master of a transaction. This bit is set if all the following conditions are true: • The bridge is the bus master of the transaction on the secondary interface. • The bridge asserted PERR# (read transaction) or detected PERR# asserted (write transaction). • The Parity Error Response bit in the Bridge Control register is set. Once set, this bit remains set until it is reset by writing a 1 to this bit location. A bridge must implement this bit and the default state must be 0 after reset.	
		0	No parity error detected on the secondary interface
		1	Parity error detected on the secondary interface
15:12 (R/W)	IOLMT	I/O Limit. The `PCIE_RC_SECSTAT_[n].IOLMT` bit field contains the upper 4 bits of the 16-bit Limit address (bits 15:12). The lower 12 bits of the limit address are implied to be all F's.	
8 (R/W)	IODEC8	I/O Decode Bit 8.	
7:4 (R/W)	IOBASE	I/O Base. The `PCIE_RC_SECSTAT_[n].IOBASE` bit field contains the upper 4 bits of the 16-bit Base address (bits 15:12). The lower 12 bits of the base address are implied to be all 0's, meaning that the base address is always aligned on a 4KB boundary.	
0 (R/W)	IODEC	I/O Decode.	

Command and Status Register

The `PCIE_RC_STATCMD_[n]` register contains bits that enable various memory spaces. The register also reports several errors.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
IEN (R/W)
Interrupt Enable
SERREN (R/W)
Non-fatal and fatal Error reporting Enable
IDSELSTEP (R)
IDSEL Stepping/Wait Cycle Control
PERREN (R/W)
Parity Error Response
VGAPS (R)
VGA Palette Snoop
IOE (R/W)
I/O Space Enable
MSE (R/W)
Memory Space Enable
BME (R/W)
Bus Master Enable
SCO (R)
Special Cycle Operation
MWIE (R)
Memory Write and Invalidate Enable

0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0
DETPERR (R/W)
Detected Parity Error
SSYSERR (R/W)
Signaled System Error
RXMABRT (R/W)
Received Master Abort
RXTABRT (R/W)
Received Target Abort
STABRT (R/W)
Signaled Target Abort
DEVSELTMG (R)
Device Select Timing
ISTAT (R/W)
Interrupt Status
CAPBLIST (R)
Capabilities List
FAST66 (R)
66 MHz Capable
FASTB2B (R)
Fast back-to-back transactions enable
MSTDPERR (R/W)
Master Data Parity Error

Figure 29-197: PCIE_RC_STATCMD_[n] Register Diagram

Table 29-206: PCIE_RC_STATCMD_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	DETPERR	Detected Parity Error. The `PCIE_RC_STATCMD_[n].DETPERR` bit is set by a Function whenever it receives a Poisoned TLP, regardless of the state of the `PCIE_RC_STATCMD_[n].PERREN` bit. On a Function with a Type 1 Configuration header, the bit is Set when the Poisoned TLP is received by its Primary Side. Default value of this bit is 0.

Table 29-206: PCIE_RC_STATCMD_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	SSYSERR	Signaled System Error. The `PCIE_RC_STATCMD_[n].SSYSERR` bit is Set when a Function sends an ERR_FATAL or ERR_NONFATAL Message, and the `PCIE_RC_STATCMD_[n].SERREN` bit is set to 1. Default value of this bit is 0.
29 (R/W)	RXMABRT	Received Master Abort. The `PCIE_RC_STATCMD_[n].RXMABRT` bit is set when a Requester receives a Completion with Unsupported Request Completion Status. On a Function with a Type 1 Configuration header, the bit is Set when the Unsupported Request is received by its Primary Side. Default value of this bit is 0.
28 (R/W)	RXTABRT	Received Target Abort. The `PCIE_RC_STATCMD_[n].RXTABRT` bit is Set when a Requester receives a Completion with Completer Abort Completion Status. On a Function with a Type 1 Configuration header, the bit is Set when the Completer Abort is received by its Primary Side. Default value of this bit is 0.
27 (R/W)	STABRT	Signaled Target Abort. The `PCIE_RC_STATCMD_[n].STABRT` bit is set when a Function completes a Posted or Non-Posted Request as a Completer Abort error. This applies to a Function with a Type 1 Configuration header when the Completer Abort was generated by its Primary Side. Default value of this bit is 0.
26:25 (R/NW)	DEVSELTMG	Device Select Timing. Does not apply to PCI express and must be set to 0.
24 (R/W)	MSTDPERR	Master Data Parity Error. The `PCIE_RC_STATCMD_[n].MSTDPERR` bit is set by a Root Port, Switch Upstream Port, or Switch Downstream Port if the `PCIE_RC_STATCMD_[n].PERREN` bit is set to 1 and either of the following two conditions occurs: • Port receives a Poisoned Completion going Downstream • Port transmits a Poisoned Request Upstream If the `PCIE_RC_STATCMD_[n].PERREN` bit is set to 0, this bit is never set. Default value of this bit is 0.
23 (R/NW)	FASTB2B	Fast back-to-back transactions enable. Does not apply to PCI express and must be set to 0.
21 (R/NW)	FAST66	66 MHz Capable. Does not apply to PCI express and must be set to 0.

Table 29-206: PCIE_RC_STATCMD_[n] Register Fields (Continued)

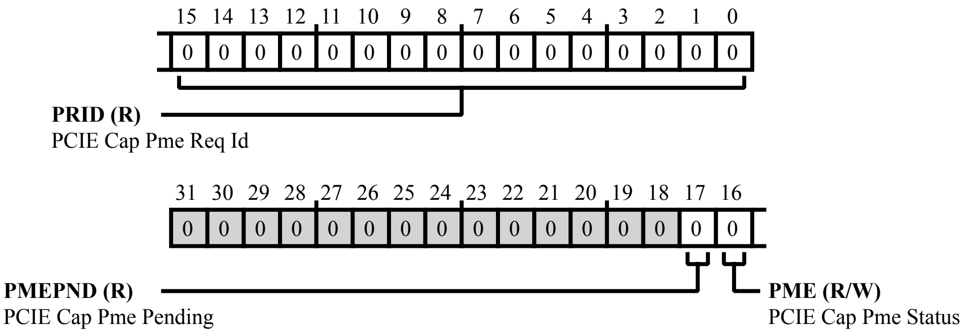
Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/NW)	CAPBLIST	Capabilities List. The `PCIE_RC_STATCMD_[n].CAPBLIST` bit indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, this bit is always set to 1.
19 (R/W)	ISTAT	Interrupt Status. The `PCIE_RC_STATCMD_[n].ISTAT` bit indicates that an INTx emulation interrupt is pending internally in the function. Note that INTx emulation interrupts forwarded by Root and Switch Ports from devices Downstream of the Root or Switch Port are not reflected in this bit. Default value of this bit is 0.
10 (R/W)	IEN	Interrupt Enable. The `PCIE_RC_STATCMD_[n].IEN` bit controls the ability of a PCI Express Function to generate INTx interrupts. When set, functions are prevented from asserting INTx interrupts. Any INTx emulation interrupts already asserted by the function must be de-asserted when this bit is set. Note that INTx interrupts use virtual wires that must, if asserted, be de-asserted using the appropriate Deassert_INTx message(s) when this bit is Set. Only the INTx virtual wire interrupt(s) associated with the function(s) for which this bit is Set are affected. For Endpoints that generate INTx interrupts, this bit is required. The `PCIE_RC_STATCMD_[n].IEN` bit has no effect on interrupts that pass through the port from the secondary side. For root ports, switch ports, and bridges that do not generate INTx interrupts on their own behalf this bit is optional. If not implemented, this bit must be hardwired to 0. Default value of this bit is 0.
8 (R/W)	SERREN	Non-fatal and fatal Error reporting Enable. When the `PCIE_RC_STATCMD_[n].SERREN` bit is set, the PCIE reports non-fatal and fatal errors detected by the function to the root complex. Note that errors are reported if enabled either through this bit or through the PCI Express specific bits in the Device Control register. In addition, for functions with Type 1 configuration space headers, this bit controls transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error Messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages. A root complex integrated endpoint that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0. The default value of this bit is 0.
7 (R/NW)	IDSELSTEP	IDSEL Stepping/Wait Cycle Control. Does not apply to PCI Express and must be set to 0.

Table 29-206: PCIE_RC_STATCMD_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	PERREN	Parity Error Response. The `PCIE_RC_STATCMD_[n].PERREN` bit controls the logging of poisoned TLPs in the `PCIE_EP_STATCMD_[n].MSTDPERR` bit. A Root Complex Integrated Endpoint that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0. Default value of this bit is 0.
5 (R/NW)	VGAPS	VGA Palette Snoop. Does not apply to PCI Express and must be set to 0.
4 (R/NW)	MWIE	Memory Write and Invalidate Enable. Does not apply to PCI Express and must be set to 0.
3 (R/NW)	SCO	Special Cycle Operation. Does not apply to PCI Express and must be set to 0.
2 (R/W)	BME	Bus Master Enable. The `PCIE_RC_STATCMD_[n].BME` bit controls the ability of a PCI Express Endpoint to issue Memory and I/O Read/Write Requests, and the ability of a Root or Switch Port to forward Memory and I/O Read/Write Requests in the Upstream direction. For root complex, the `PCIE_RC_STATCMD_[n].BME` bit controls forwarding of memory or I/O requests by a switch or root port in the upstream direction. When this bit is 0, memory and I/O requests received at a root port or the downstream side of a switch port must be handled as unsupported requests (UR), and for non-posted requests a completion with UR completion status must be returned. This bit does not affect forwarding of completions in either the upstream or downstream direction. The forwarding of requests other than memory or I/O requests is not controlled by this bit. The default value of this bit is 0.
1 (R/W)	MSE	Memory Space Enable. The `PCIE_RC_STATCMD_[n].MSE` bit enables memory space.
0 (R/W)	IOE	I/O Space Enable. The `PCIE_RC_STATCMD_[n].IOE` bit enables I/O space.

Root Status Register

The `PCIE_RC_STAT_[n]` register provides information about PCI Express device specific parameters.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PRID (R)
PCIE Cap Pme Req Id

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PMEPND (R)
PCIE Cap Pme Pending
PME (R/W)
PCIE Cap Pme Status

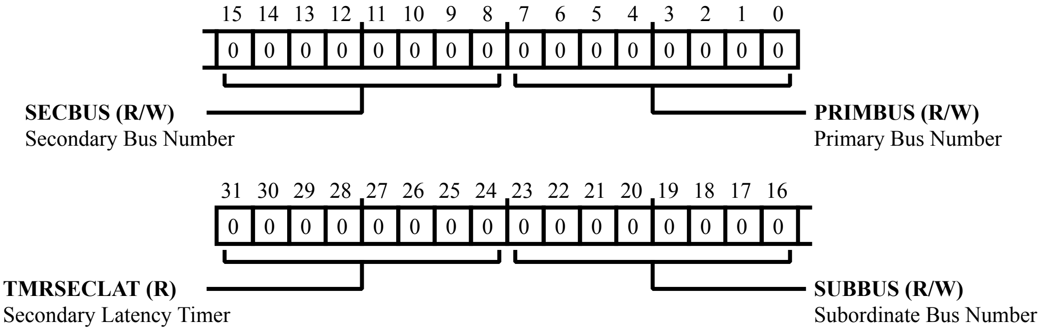
Figure 29-198: PCIE_RC_STAT_[n] Register Diagram

Table 29-207: PCIE_RC_STAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/NW)	PMEPND	PCIE Cap Pme Pending. The `PCIE_RC_STAT_[n].PMEPND` bit indicates that another PME is pending when the PME Status bit is Set. When the PME Status bit is cleared by software; the PME is delivered by hardware by setting the PME Status bit again and updating the PME Requester ID field appropriately. The PME Pending bit is cleared by hardware if no more PMEs are pending.
16 (R/W)	PME	PCIE Cap Pme Status. The `PCIE_RC_STAT_[n].PME` bit indicates that PME was asserted by the PME Requester indicated in the PME Requester ID field. Subsequent PMEs are kept pending until the status register is cleared by software by writing a 1. Default value of this bit is 0.
15:0 (R/NW)	PRID	PCIE Cap Pme Req Id. The `PCIE_RC_STAT_[n].PRID` bit field indicates the PCI Requester ID of the last PME Requester. This field is only valid when the PME Status bit is Set.

Latency Timer Register

The `PCIE_RC_TMRLAT_[n]` register provides the primary, secondary and subordinate bus numbers and the latency timer value.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

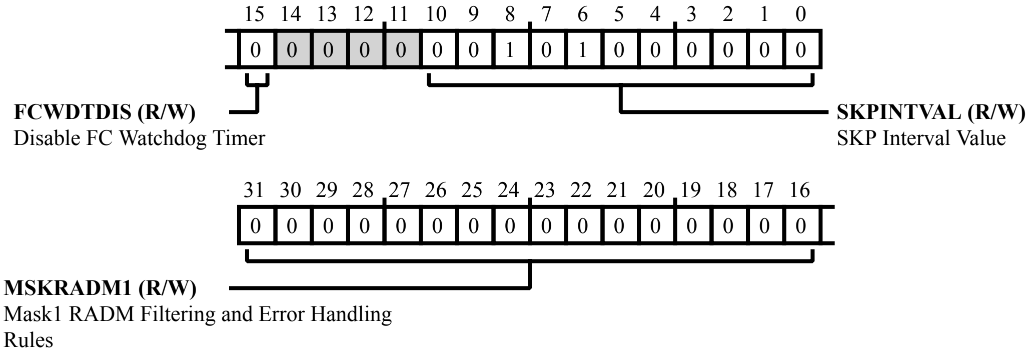
		0	The PCIe Core is out of reset
		1	The PCIe Core is Reset

Symbol Timer Filter 1 Off

Bits [31:16] of the `PCIE_SYM_TMRFILT1_[n]` register are the Mask RADM Filtering and Error Handling Rules for Mask 1. There are several mask bits to turn off the filtering and error handling rules (For more details, see "Receive Filtering". In each case, 0 applies the associated filtering rule and 1 masks the associated filtering rule. Default is DEFAULT_FILTER_MSK_1.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 1 0 1 0 0 0 0 0 0
FCWDTDIS (R/W)
Disable FC Watchdog Timer
SKPINTVAL (R/W)
SKP Interval Value
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
MSKRADM1 (R/W)
Mask1 RADM Filtering and Error Handling Rules

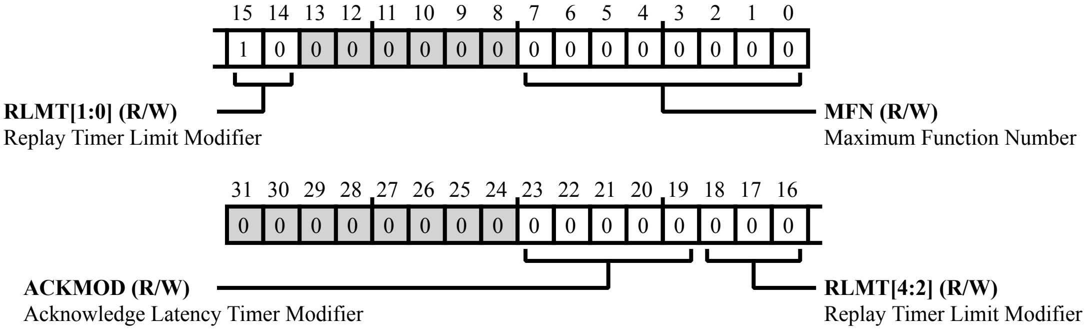
Figure 29-202: PCIE_SYM_TMRFILT1_[n] Register Diagram

Table 29-211: PCIE_SYM_TMRFILT1_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	MSKRADM1	Mask1 RADM Filtering and Error Handling Rules. The `PCIE_SYM_TMRFILT1_[n].MSKRADM1` bit field mask bits turn off the filtering and error handling rules. In each case, 0 applies the associated filtering rule and 1 masks the associated filtering rule.
15 (R/W)	FCWDTDIS	Disable FC Watchdog Timer. The `PCIE_SYM_TMRFILT1_[n].FCWDTDIS` bit disables the FC Watchdog Timer. This register field is sticky.
10:0 (R/W)	SKPINTVAL	SKP Interval Value. The `PCIE_SYM_TMRFILT1_[n].SKPINTVAL` bit field sets the number of symbol times to wait between transmitting SKP ordered sets. Note that the core actually waits the number of symbol times in this register plus 1 between transmitting SKP ordered sets. The application must program this register accordingly. For example, if 1536 is programmed into this bit field (in a 250 MHz core), then the core actually transmits SKP ordered sets once every 1537 symbol times. The value programmed to this register is actually clock ticks and not symbol times. In a 125 MHz core, programming the value programmed to this register should be scaled down by a factor of 2 (because 1 clock tick = 2 symbol times in this case). This bit field is sticky.

Timer Control and Max Function Number Register

The `PCIE_TMRCTL_MFN_[n]` register provides bits that configure and control the timer and requests targeted at function numbers.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RLMT[1:0] (R/W)
Replay Timer Limit Modifier
MFN (R/W)
Maximum Function Number
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ACKMOD (R/W)
Acknowledge Latency Timer Modifier
RLMT[4:2] (R/W)
Replay Timer Limit Modifier

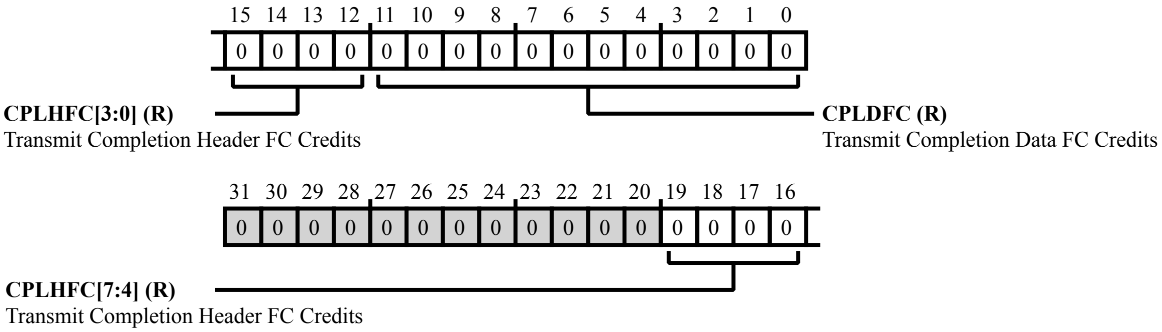
Figure 29-203: PCIE_TMRCTL_MFN_[n] Register Diagram

Table 29-212: PCIE_TMRCTL_MFN_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:19 (R/W)	ACKMOD	Acknowledge Latency Timer Modifier. The `PCIE_TMRCTL_MFN_[n].ACKMOD` bit field increases the timer value for the Ack latency timer in increments of 64 clock cycles. A value of 0 represents no modification to the timer value. <br><i>Note</i>: This register field is sticky.
18:14 (R/W)	RLMT	Replay Timer Limit Modifier. The `PCIE_TMRCTL_MFN_[n].RLMT` bit field increases the time-out value for the replay timer in increments of 64 clock cycles at Gen1 or Gen2 speed, and in increments of 256 clock cycles at Gen3 speed. A value of 0 represents no modification to the timer limit. At Gen3 speed, the core automatically changes the value of this field to DEFAULT_GEN3_REPLAY_ADJ. <br><i>Note</i>: This register field is sticky.
7:0 (R/W)	MFN	Maximum Function Number. The `PCIE_TMRCTL_MFN_[n].MFN` bit field configures requests targeted at function numbers. Value higher than this are returned with UR (unsupported request). This register field is sticky.

Transmit Completion FC Credit Status Register

The `PCIE_TXCOMP_FCCSTAT_[n]` register reports the completion data credits and the completion header credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CPLHFC[3:0] (R)
Transmit Completion Header FC Credits
CPLDFC (R)

Transmit Completion Header FC Credits

Figure 29-204: PCIE_TXCOMP_FCCSTAT_[n] Register Diagram

Table 29-213: PCIE_TXCOMP_FCCSTAT_[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:12 (R/NW)	CPLHFC	Transmit Completion Header FC Credits. The `PCIE_TXCOMP_FCCSTAT_[n].CPLHFC` bit field reports the Completion Header credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP. Default value depends on the number of advertised credits for header and data [12'b0, xtlh_xadm_cplh_cdts, xtlh_xadm_cpld_cdts]; When the number of advertised completion credits (both header and data) are infinite, then the default is [12'b0, 8'hFF, 12'hFFF].
11:0 (R/NW)	CPLDFC	Transmit Completion Data FC Credits. The `PCIE_TXCOMP_FCCSTAT_[n].CPLDFC` bit field reports the completion data credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP. Default value depends on the number of advertised credits for header and data [12'b0, xtlh_xadm_cplh_cdts, xtlh_xadm_cpld_cdts]; When the number of advertised completion credits (both header and data) are infinite, then the default is [12'b0, 8'hFF, 12'hFFF].

Transmit Non-Posted FC Credit Status Register

The `PCIE_TX_NPST_FCCSTAT_[n]` register reports the non-posted data credits and the non-posted header credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP.

Bit No. (Access)	Bit Name	Description/Enumeration
19:12 (R/NW)	PHFC	Transmit Posted Header FC Credits. The `PCIE_TX_PST_FCCSTAT_[n].PHFC` bit field reports the posted header credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP. The default value depends on the number of advertised credits for header and data [12'b0, xtlh_xadm_ph_cdts, xtlh_xadm_pd_cdts]; When the number of advertised completion credits (both header and data) are infinite, then the default is [12'b0, 8'hFF, 12'hFFF].
11:0 (R/NW)	PDFC	Transmit Posted Data FC Credits. The `PCIE_TX_PST_FCCSTAT_[n].PDFC` bit field reports the posted data credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP. The default value depends on the number of advertised credits for header and data [12'b0, xtlh_xadm_ph_cdts, xtlh_xadm_pd_cdts]. When the number of advertised completion credits (both header and data) are infinite, then the default is [12'b0, 8'hFF, 12'hFFF].

Uncorrectable Error Mask Register

The `PCIE_UNCOR_ERRMSK_[n]` register controls reporting of individual errors by the device Function to the PCI Express Root Complex via a PCI Express error message. A masked error (indicated by a set bit) is not recorded or reported in the Header Log register. Also the First Error Pointer is not updated or reported to the PCI Express Root Complex by this function. There is a mask bit per error bit of the Uncorrectable Error Status register (`PCIE_UNCOR_ERRSTAT_[n]`). Register fields for bits not implemented by the Function are set to 0.

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/NW)	TLPPRFXBLK	TLP Prefix Blocked Error Mask. The `PCIE_UNCOR_ERRMSK_[n].TLPPRFXBLK` bit indicates whether the LP Prefix Blocked Error Severity error is masked (=1) or unmasked (=0).
24 (R/NW)	ATOMEGBLK	Atomic Operation Egress Blocked Mask. The `PCIE_UNCOR_ERRMSK_[n].ATOMEGBLK` bit indicates whether the AtomicOp Egress Blocked Severity error is masked (=1) or unmasked (=0).
22 (R/W)	UIER	Uncorrectable Internal Error Mask. The `PCIE_UNCOR_ERRMSK_[n].UIER` bit indicates whether the Uncorrectable Internal Error Severity error is masked (=1) or unmasked (=0).

Table 29-216: PCIE_UNCOR_ERRMSK_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	UNSUPREQ	Unsupported Request Error Mask. The `PCIE_UNCOR_ERRMSK_[n].UNSUPREQ` bit indicates whether the Unsupported Request Error Severity error is masked (=1) or unmasked (=0).
19 (R/W)	ECRC	ECRC Error Mask. The `PCIE_UNCOR_ERRMSK_[n].ECRC` bit indicates whether the ECRC Error Severity error is masked (=1) or unmasked (=0).
18 (R/W)	MALFTLP	Malformed TLP Mask. The `PCIE_UNCOR_ERRMSK_[n].MALFTLP` bit indicates whether the Malformed TLP Severity error is masked (=1) or unmasked (=0).
17 (R/W)	RXOVR	Receiver Overflow Mask. The `PCIE_UNCOR_ERRMSK_[n].RXOVR` bit indicates whether the Receiver Overflow Error Severity error is masked (=1) or unmasked (=0).
16 (R/W)	UNXPCMPL	Unexpected Completion Mask. The `PCIE_UNCOR_ERRMSK_[n].UNXPCMPL` bit indicates whether the Unexpected Completion Error Severity error is masked (=1) or unmasked (=0).
15 (R/W)	CMPLABRT	Completer Abort Mask. The `PCIE_UNCOR_ERRMSK_[n].CMPLABRT` bit indicates whether the Completer Abort Error Severity error is masked (=1) or unmasked (=0).
14 (R/W)	CMPLTMO	Completion Timeout Mask. The `PCIE_UNCOR_ERRMSK_[n].CMPLTMO` bit indicates whether the Completion Timeout Error Severity error is masked (=1) or unmasked (=0).
13 (R/W)	FCPROTO	Flow Control Protocol Error Mask. The `PCIE_UNCOR_ERRMSK_[n].FCPROTO` bit indicates whether the Flow Control Protocol Error Severity error is masked (=1) or unmasked (=0).
12 (R/W)	TLPPOIS	Poisoned TLP Mask. The `PCIE_UNCOR_ERRMSK_[n].TLPPOIS` bit indicates whether the Poisoned TLP Severity error is masked (=1) or unmasked (=0).
5 (R/NW)	SURPDN	Surprise Down Error Mask. The `PCIE_UNCOR_ERRMSK_[n].SURPDN` bit indicates whether the Surprise Down Error Severity error is masked (=1) or unmasked (=0).
4 (R/W)	DLPROTO	Data Link Protocol Error Mask. The `PCIE_UNCOR_ERRMSK_[n].DLPROTO` bit indicates whether the Data Link Protocol Error Severity error is masked (=1) or unmasked (=0).

Uncorrectable Error Severity Register

The `PCIE_UNCOR_ERRSEV_[n]` register controls whether an individual error is reported as a Nonfatal or Fatal error. An error is reported as fatal when the corresponding error bit in the severity register is set (=1). If the bit is clear (=0), the corresponding error is considered non-fatal. Register fields for bits not implemented by the Function are hardwired to an implementation specific value.

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/NW)	TLPPRFXBLK	TLP Prefix Blocked Error Severity. The `PCIE_UNCOR_ERRSEV_[n].TLPPRFXBLK` bit indicates that the TLP Prefix Blocked Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
24 (R/NW)	ATOMEGBLK	Atomic Operation Egress Blocked Severity. The `PCIE_UNCOR_ERRSEV_[n].ATOMEGBLK` bit indicates that the AtomicOp Egress Blocked Severity error is fatal (=1) or non-fatal (=0) non-fatal.
22 (R/W)	UIER	Uncorrectable Internal Error Severity. The `PCIE_UNCOR_ERRSEV_[n].UIER` bit indicates that the Uncorrectable Internal Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.

Table 29-217: PCIE_UNCOR_ERRSEV_[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	UNSUPREQ	Unsupported Request Error Severity. The `PCIE_UNCOR_ERRSEV_[n].UNSUPREQ` bit indicates that the Unsupported Request Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
19 (R/W)	ECRC	ECRC Error Severity. The `PCIE_UNCOR_ERRSEV_[n].ECRC` bit indicates that the ECRC Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
18 (R/W)	MALFTLP	Malformed TLP Severity. The `PCIE_UNCOR_ERRSEV_[n].MALFTLP` bit indicates that the Malformed TLP Severity error is fatal (=1) or non-fatal (=0) non-fatal.
17 (R/W)	RXOVR	Receiver Overflow Error Severity. The `PCIE_UNCOR_ERRSEV_[n].RXOVR` bit indicates that the Receiver Overflow Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
16 (R/W)	UNXPCMPL	Unexpected Completion Error Severity. The `PCIE_UNCOR_ERRSEV_[n].UNXPCMPL` bit indicates that the Unexpected Completion Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
15 (R/W)	CMPLABRT	Completer Abort Error Severity. The `PCIE_UNCOR_ERRSEV_[n].CMPLABRT` bit indicates that the Completer Abort Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
14 (R/W)	CMPLTMO	Completion Timeout Error Severity. The `PCIE_UNCOR_ERRSEV_[n].CMPLTMO` bit indicates that the Completion Timeout Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
13 (R/W)	FCPROTO	Flow Control Protocol Error Severity. The `PCIE_UNCOR_ERRSEV_[n].FCPROTO` bit indicates that the Flow Control Protocol Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
12 (R/W)	TLPPOIS	Poisoned TLP Severity. The `PCIE_UNCOR_ERRSEV_[n].TLPPOIS` bit indicates that the Poisoned TLP Severity error is fatal (=1) or non-fatal (=0) non-fatal.
5 (R/NW)	SURPDN	Surprise Down Error Severity. The `PCIE_UNCOR_ERRSEV_[n].SURPDN` bit indicates that the Surprise Down Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.
4 (R/W)	DLPROTO	Data Link Protocol Error Severity. The `PCIE_UNCOR_ERRSEV_[n].DLPROTO` bit indicates that the Data Link Protocol Error Severity error is fatal (=1) or non-fatal (=0) non-fatal.

Uncorrectable Error Status Register

The `PCIE_UNCOR_ERRSTAT_[n]` register indicates error detection status of individual errors on a PCI Express device Function. An individual error status bit that is set (=1) indicates that a particular error was detected. Software may clear an error status by writing a 1 to the respective bit. Register bits not implemented by the Function are set to 0.

An application writes the 8-bit DLLP type and 24-bits of payload data into this bit field, then sets bit 0 of the Port Link Control Register (PCIE_PLCTL_[n]) to send the DLLP.

30 Two-Wire Interface (TWI)

The processor has a two-wire interface (TWI), that provides a simple exchange method of control data between multiple devices. The TWI module is compatible with the widely used I^2C bus standard. Additionally, the TWI module is fully compatible with serial camera control bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

The TWI module offers the capabilities of simultaneous master and slave operation and support for both 7-bit addressing and multimedia data arbitration. The TWI interface uses two pins for transferring clock (`TWI_SCL`) and data (`TWI_SDA`) and supports the protocol at speeds up to 400K bits/sec. The TWI interface pins are compatible with 5-V logic levels.

To preserve processor bandwidth, the TWI module can be set up with transfer-initiated interrupts to only service FIFO buffer data reads and writes. Protocol-related interrupts are optional. The TWI externally moves 8-bit data while maintaining compliance with the I^2C bus protocol.

TWI Features

The TWI is fully compatible with the widely used I^2C bus standard.

The TWI controller includes the following features.

- Simultaneous master and slave operation on multiple device systems
- Support for multi-master bus arbitration
- 7-bit addressing
- 100K bits/second and 400K bits/second data rates
- General call address support
- Master clock synchronization and support for clock low extension
- Separate multiple-byte receive and transmit FIFOs
- Low interrupt rate
- Individual override control of data and clock lines in the event of bus lock-up
- Input filter for spike suppression

- Serial camera control bus support as specified in the *OmniVision Serial Camera Control Bus (SCCB) Functional Specification*

TWI Functional Description

The TWI interface is a shift register that serially transmits and receives data bits. It moves data 1 bit at a time at the SCL rate, to and from other TWI devices. The SCL signal synchronizes the shifting and sampling of the data on the serial data pin.

ADSP-SC58x TWI Register List

The Two-Wire Interface controller TWI allows a device to interface to an inter-IC bus as specified by the Philips I^2C Bus Specification version 2.1, dated January 2000. A set of registers governs TWI operations. For more information on TWI functionality, see the TWI register descriptions.

Table 30-1: ADSP-SC58x TWI Register List

Name	Description
`TWI_CLKDIV`	SCL Clock Divider Register
`TWI_CTL`	Control Register
`TWI_FIFOCTL`	FIFO Control Register
`TWI_FIFOSTAT`	FIFO Status Register
`TWI_IMSK`	Interrupt Mask Register
`TWI_ISTAT`	Interrupt Status Register
`TWI_MSTRADDR`	Master Mode Address Register
`TWI_MSTRCTL`	Master Mode Control Registers
`TWI_MSTRSTAT`	Master Mode Status Register
`TWI_RXDATA16`	Rx Data Double-Byte Register
`TWI_RXDATA8`	Rx Data Single-Byte Register
`TWI_SLVADDR`	Slave Mode Address Register
`TWI_SLVCTL`	Slave Mode Control Register
`TWI_SLVSTAT`	Slave Mode Status Register

External Interface

The `TWI_SDA` (serial data) and `TWI_SCL` (serial clock) signals are open drain and require pull-up resistors. These bidirectional signals externally interface the TWI controller to the I^2C bus and no other external connections or logic are necessary.

Serial Clock Signal (SCL)

The serial clock signal (`TWI_SCL`) is an input in slave mode. In master mode, the TWI controller must set this signal to the desired frequency.

The TWI controller supports the standard mode of operation (up to 100 kHz) or fast mode (up to 400 kHz). The TWI control register (`TWI_CTL`) sets the `TWI_CTL.PRESCALE` value which sets the relationship between the system clock (SCLK0_0) and the internally timed events of the TWI controller. The internal time reference is derived from SCLK0_0 using a prescaled value. The prescale value is the number of SCLK0_0 periods used in the generation of one internal time reference. Set the value of prescale to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value as follows.

$\text{PRESCALE} = f_{\text{SCLK0\_0}}/10\text{MHz}$

NOTE: It is not always possible to achieve 10-MHz accuracy. In such cases, it is safe to round up the PRESCALE value to the next highest integer. For example, if SCLK0_0 is 100 MHz, the PRESCALE value is calculated as 100 MHz/10 MHz = 10. A prescale value of 14 in this case ensures that all timing requirements are met.

During master mode operation, the TWI module uses the `TWI_CLKDIV` register values to create the minimum `TWI_CLKDIV.CLKHI` and `TWI_CLKDIV.CLKLO` durations of the `TWI_SCL` signal. The `TWI_CLKDIV.CLKHI` field specifies the minimum number of 10-MHz time reference periods the `TWI_SCL` waits before a new clock low period begins, assuming a single master. (The 10-MHz time reference periods are represented as an 8-bit binary value). The TWI uses the `TWI_CLKDIV.CLKLO` field to specify the minimum number of internal time reference periods (represented as an 8-bit binary value). The `TWI_SCL` signal is held low.

Serial clock frequencies can vary from 400 kHz to less than 20 kHz. The resolution of the clock generated is 1/10 MHz or 100 ns. The following equation describes the frequency.

`TWI_CLKDIV` = `TWI_SCL` period/10 MHz time reference.

For example, for an `TWI_SCL` of 400 kHz (period = 1/400 kHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns), the following equation applies:

`TWI_CLKDIV` = 2500 ns/100 ns = 25

Therefore, a `TWI_SCL` signal with a 30% duty cycle has `TWI_CLKDIV.CLKLO`=17 and `TWI_CLKDIV.CLKHI`=8. Adding `TWI_CLKDIV.CLKLO` and `TWI_CLKDIV.CLKHI` equals `TWI_CLKDIV`.

NOTE: The `TWI_CLKDIV.CLKHI` and `TWI_CLKDIV.CLKLO` fields are not intended to guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for the `TWI_SCL` signal. Slew rate controls falling edges. The *RC* time constant governs the rising edges. The pull-up resistor and the `TWI_SCL` capacitance form the time constant. See the “Register Descriptions” section for more details.

Serial Data Signal (SDA)

The TWI transmits and receives serial data, depending on the direction of the transfer, on the bidirectional serial data signal (SDA).

Internal Interface

The peripheral bus interface supports the transfer of 16-bit wide data. The processor uses the interface in the support of register and FIFO buffer reads and writes. The TWI internal interface is comprised of the blocks described as follows.

Register block. Contains all control and status bits and reflects what can be written or read as outlined by the programming model. Each function block updates their corresponding status bits.

FIFO buffer. Configured as a 1-byte-wide, 2-deep transmit FIFO buffer and a 1-byte-wide, 2-deep receive FIFO buffer.

Transmit shift register. Serially shifts its data out externally off chip. The output can be controlled for generation of acknowledgments or it can be manually overwritten.

Receive shift register. Receives its data serially from off chip. The receive shift register is 1 byte wide and data received can either be transferred to the FIFO buffer or used in an address comparison.

Address compare block. Supports address comparison in the event the TWI controller module is accessed as a slave.

Prescaler block. Must be programmed to generate a 10-MHz time reference relative to the system clock. The block uses this time base for filtering of data and timing events specified by the electrical data sheet (See the Philips specification). The block uses the time base to generate the `TWI_SCL` clock as well.

Clock generation module. Generates an external `TWI_SCL` clock when in master mode. It includes the logic necessary for synchronization in a multi-master clock configuration and clock stretching when configured in slave mode.

NOTE: The TWI does not support DMA based operation.

TWI Architectural Concepts

The TWI controller follows the transfer protocol of the Philips I^{2}C Bus specification version 2.1 dated January 2000.

NOTE: The TWI unit does not support DMA-based operation.

TWI Protocol

The ***Data Transfer*** figure shows a simple complete transfer.

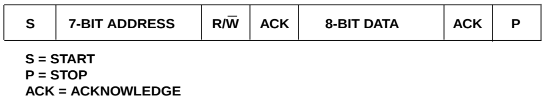

Figure 30-2: Data Transfer

The TWI controller register contents maps to a basic transfer. The ***Data Transfer with Bit Illustration*** figure details the same transfer from the ***Data Transfer*** figure noting the corresponding TWI controller bit names. In this illustration, the TWI controller successfully transmits 1 byte of data. The slave has acknowledged both address and data.

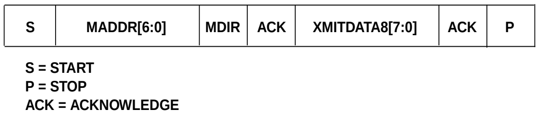

Figure 30-3: Data Transfer with Bit Illustration

Clock Generation and Synchronization

The TWI controller implementation only issues a clock during master mode operation and only at the time a transfer initiates. If arbitration for the bus is lost, the serial clock output immediately three-states. If multiple clocks attempt to drive the serial clock line, the TWI controller synchronizes its clock with the other remaining clocks. The *Clock Synchronization* figure shows this functionality.

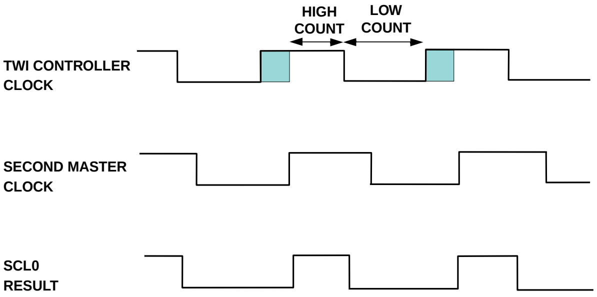

Figure 30-4: Clock Synchronization

The TWI controller serial clock (`TWI_SCL`) output follows these rules:

- Once the clock high (`TWI_CLKDIV.CLKHI`) count is complete, the serial clock output is driven low and the clock low (`TWI_CLKDIV.CLKLO`) count begins.
- Once the clock low count is complete, the serial clock line is three-stated. This state allows the external pull-up resistor to pull the `TWI_SCL` signal high. The clock synchronization logic enters into a delay mode (shaded area) until the `TWI_SCL` signal is detected at logic 1 level. Now, the clock high count begins.

Bus Arbitration

The TWI controller initiates a master mode transmission only when the bus is idle. If the bus is idle and two masters initiate a transfer, arbitration for the bus begins. The ***Bus Arbitration*** figure shows the arbitration.

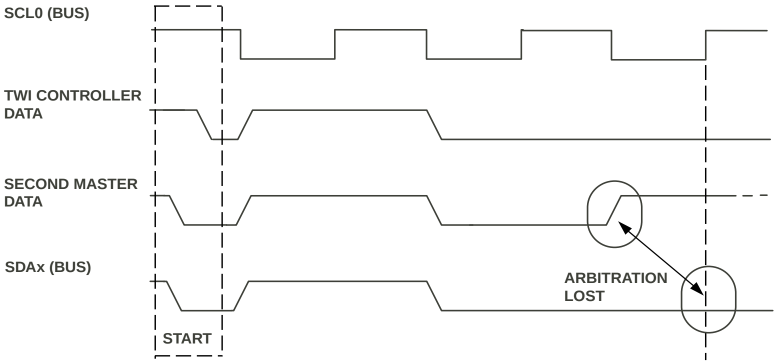

Figure 30-5: Bus Arbitration

The TWI controller monitors the serial data bus (SDA) while the `TWI_SCL` signal is high. If the `TWI_SDA` signal is determined to be an active logic 0 level while the data of the TWI controller is a logic 1 level, the TWI controller has lost arbitration. It stops generating the clock and data signals. Arbitration is not only performed at the serial clock edges, but also during the entire time the `TWI_SCL` signal is high.

Start and Stop Conditions

Start and stop conditions involve serial data transitions while the serial clock is a logic 1 level. The TWI controller generates and recognizes these transitions. Typically, start and stop conditions occur at the beginning and at the conclusion of a transmission, except repeated start combined transfers. The ***Start and Stop Conditions*** figure shows the transitions.

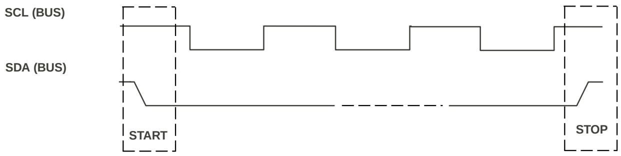

Figure 30-6: Start and Stop Conditions

The TWI special case start and stop conditions of the TWI controller include the following.

- Controller addressed as a slave-receiver. If the master asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (`TWI_ISTAT.SCOMP`).
- Controller addressed as a slave-transmitter. If the master asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (`TWI_ISTAT.SCOMP`) and indicates a slave transfer error (`TWI_ISTAT.SERR`).
- Controller as a master-transmitter or master-receiver. If the stop bit (`TWI_MSTRCTL.STOP`) is set during an active master transfer, the TWI controller issues a stop condition as soon as possible avoiding any error conditions. The TWI controller operates as if data transfer count had been reached.

General Call Support

The TWI controller always decodes and acknowledges a general call address if:

- The TWI controller is enabled as a slave
- General call is enabled

The `TWI_SLVCTL.GEN` bit configures general call addressing (0x00) only when the TWI controller is a slave-receiver.

If the data associated with the transfer is (NAK) not acknowledged, the `TWI_SLVCTL.NAK` bit can be set. If the TWI controller issues a general call as a master-transmitter, set the appropriate address (`TWI_MSTRADDR` register) and transfer direction (`TWI_MSTRCTL.DIR` bit) and load the transmit FIFO data.

NOTE: The byte following the general call address usually defines the slaves response to the call. The interpretation of the command in the second byte is based on the value of its LSB. For a TWI slave device, the bytes received after the general call address are considered data.

Fast Mode

Fast mode essentially uses the same mechanics as the standard mode of operation. Fast mode affects electrical specifications and timing. When fast mode is enabled, (FAST) timing is modified to meet the following electrical requirements.

- Serial data rise times before arbitration evaluation (t_r)
- Stop condition set-up time from serial clock to serial data (t_{SUSTO})
- Bus free time between a stop and start condition (t_{BUF})

TWI Operating Modes

The TWI has two modes of operation: repeated start and clock stretching. The following sections describe the operating modes.

Repeated Start

A repeated start condition is the absence of a stop condition between two transfers. The two transfers can be of any direction type. Examples include a transmit followed by a receive, or a receive followed by a transmit. The following sections guide the programmer in developing a service routine.

Transmit Receive Repeated Start

The *Repeated Start Followed by Data Receive* figure shows a repeated start followed by a data receive sequence. The shading in the figure indicates that the slave has control of the bus.

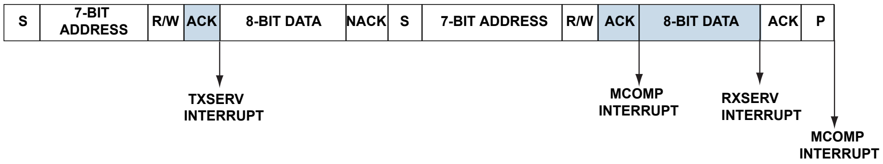

Figure 30-7: Repeated Start Followed by Data Receive

The tasks performed at each interrupt are:

- Transmit FIFO service (`TWI_ISTAT.TXSERV`) interrupt request. This interrupt is generated due to a FIFO access. Since this byte is the last of this transfer, the TWI uses the `TWI_FIFOSTAT` register to indicate that the transmit FIFO is empty. When read, `TWI_MSTRCTL.DCNT` bit field=0. Set the `TWI_MSTRCTL.RSTART` bit to indicate a repeated start and set the `TWI_MSTRCTL.DIR` bit if the following transfer is a data receive.
- Master transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request is generated when all data transfers (`TWI_MSTRCTL.DCNT` bit field=0). If no errors occur, a start condition initiates. Clear the `TWI_MSTRCTL.RSTART` bit and program the `TWI_MSTRCTL.DCNT` bits with the desired number of bytes to receive.

- Receive FIFO service (`TWI_ISTAT.RXSERV`) interrupt. This interrupt request is generated due to the arrival of a byte in the receive FIFO. Simple data handling is the only requirement.
- Master transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request is generated when the transfer completes.

Receive Transmit Repeated Start

The ***Repeated Start Data Receive Followed by Data Transmit*** figure illustrates a repeated start data receive followed by a data transmit sequence. The shading in the figure indicates that the slave has control of the bus.

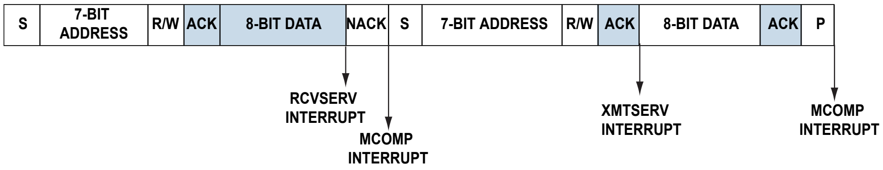

Figure 30-8: Repeated Start Data Receive Followed by Data Transmit

The tasks performed at each interrupt are:

- Receive FIFO service (`TWI_ISTAT.RXSERV`) interrupt. This interrupt request is generated due to the arrival of a data byte in the receive FIFO. Set the `TWI_MSTRCTL.RSTART` bit to indicate a repeated start and clear the `TWI_MSTRCTL.DIR` bit if the following transfer is a data transmit.
- Master transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request has occurred due to the completion of the data receive transfer. If no errors occur, a start condition initiates. Clear the `TWI_MSTRCTL.RSTART` bit and program the `TWI_MSTRCTL.DCNT` bits with the desired number of bytes to transmit.
- Transmit FIFO service (`TWI_ISTAT.TXSERV`) interrupt. This interrupt request is generated due to a FIFO access. Simple data handling is the only requirement.
- Master transfer complete (`TWI_ISTAT.MCOMP`) interrupt. This interrupt request is generated when the transfer completes.

NOTE: There is no timing constraint to meet the conditions—program the bits as required. Refer to Clock Stretching During Repeated Start section for more on how the controller stretches the clock during repeated start transfers.

Clock Stretching

Clock stretching is an added function of the TWI controller in master mode operation. This behavior uses self-induced stretching of the I^2C clock while waiting to service interrupts. Hardware initiates stretching automatically. No programming is necessary. The TWI controller as a master supports three modes of clock stretching:

- Clock Stretching During FIFO Underflow
- Clock Stretching During FIFO Overflow

- Clock Stretching During Repeated Start

Clock Stretching During FIFO Underflow

During a master mode transmit, an interrupt request occurs the instant the transmit FIFO becomes empty. The most recent byte begins transmission. If the `TWI_ISTAT.TXSERV` interrupt request is not serviced, the concluding acknowledge phase of the transfer stretches.

Stretching of the clock continues until new data bytes are written to the transmit FIFO (`TWI_TXDATA8` or `TWI_TXDATA16` registers). No other action is required to release the clock and continue the transmission. This behavior continues until the transmission completes (`TWI_MSTRCTL.DCNT`=0). The transmission concludes (`TWI_ISTAT.MCOMP`). The ***Clock Stretching during FIFO Underflow*** figure and table show the stretching.

...	...
Interrupt: MCOMP – Master transmit complete (DCNT= 0x00).	Acknowledge: Clear the interrupt request source bits.

Clock Stretching During FIFO Overflow

During a master mode receive operation, an interrupt occurs at the instant the receive FIFO becomes full. It is during the acknowledge phase of this received byte that clock stretching begins. The TWI module makes no attempt to initiate the reception of another byte. Stretching of the clock continues until the data bytes previously received are read from the receive FIFO buffer (`TWI_RXDATA8` or `TWI_RXDATA16` registers). No other action is required to release the clock and continue the reception of data. This behavior continues until the reception is complete (`TWI_MSTRCTL.DCNT`=0). Reception concludes (`TWI_ISTAT.MCOMP`). The ***Clock Stretching During FIFO Overflow*** figure and table show the clock stretching.

Clock Stretching During Repeated Start

The repeated start feature in I^2C protocol requires a transition between two subsequent transfers. With the use of clock stretching, the task of managing transitions becomes simpler and common to all transfer types.

Once an initial TWI master transfer completes (transmit or receive), the clock initiates a stretch during the repeated start phase between transfers. Concurrent with this event, the initial transfer generates a `TWI_ISTAT.MCOMP` interrupt to signify the initial transfer has completed (`TWI_MSTRCTL.DCNT`=0). This initial transfer is handled without any special bit setting sequences or timing.

The clock stretching logic described applies here. With no system-related timing constraints, the subsequent transfer (receive or transmit) is set up and activated. This sequence can repeat as many times as required to string a series of repeated start transfers together. The ***Clock Stretching during Repeated Start Condition*** figure and table show the clock stretching.

TWI Programming Model

The topics in this section provide information on the basic programming steps required to set up and run the two wire interface.

General Setup

General setup refers to register writes that are required for both slave mode and master mode operations.

Perform general setup before setting either the master or slave enable bits.

1. Program the `TWI_CTL.EN` bit to enable the TWI controller and set the prescale value (`TWI_CTL.PRESCALE` bit).
2. Program the prescale value to the binary representation of f_{SCLK0}/10 MHz. Round up all values to the next whole number.
3. Set the `TWI_CTL.EN` bit to enable the controller.

Once the TWI controller is enabled, a bus busy condition can be detected. This condition clears after t_{BUF} has expired, assuming no additional bus activity has been detected.

Slave Mode

When enabled, slave mode operation supports both receive and transmit data transfers.

It is not possible to enable only one data transfer direction and not acknowledge (NAK) the other. The following setup reflects this functionality.

1. Program the `TWI_SLVADDR` register. The TWI uses the appropriate 7 bits in determining a match during the address phase of the transfer.
2. Program the `TWI_TXDATA8.VALUE` or `TWI_TXDATA16` registers. These values are the initial data values for transmission when the slave is addressed and transmission is needed. This step is optional. If no data is written when the slave is addressed and transmission is needed, the serial clock (`TWI_SCL`) stretches. An interrupt is generated until data is written to the transmit FIFO.
3. Program the `TWI_IMSK` register. There are enable-bits associated with the desired interrupt sources. For example, programming the value 0x000F results in an interrupt request output to the processor, when the TWI module detects a valid address match. An interrupt request also occurs when a valid slave transfer completes or has an error, or a subsequent transfer has begun and the previous transfer has not been serviced.
4. Program the `TWI_SLVCTL` register. This step prepares and enables slave mode operation. For example, programming the value 0x0005 enables slave mode operation and requires 7-bit addressing. It indicates that data in the transmit FIFO buffer is for slave mode transmission.

The ***Slave Mode Interaction*** table and ***TWI Slave Mode Program Flow*** diagram represent the interaction between the TWI controller and the processor using this example.

Figure 30-13: Master Mode Program Flow

Master Mode Clock Setup

Master mode operation is set up and executed on a per-transfer basis.

An example of programming steps for a receive and for a transmit is given separately in following sections. The programming step for clock setup listed here is common to both transfer types.

1. Program the `TWI_CLKDIV` register to define the minimum high and minimum low duration for the clock.

The `TWI_CLKDIV.CLKHI` and `TWI_CLKDIV.CLKLO` fields do not guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for `TWI_SCL`. The slew rate controls falling edges. The RC time constant formed by the pull-up resistor and the SCL capacitance govern rising edges. See the “Register Descriptions” section for more details.

Master Mode Transmit

Follow these programming steps for a single master mode transmission:

1. Program the `TWI_MSTRADDR` register. This step defines the address transmitted during the address phase of the transfer.

2. Program the `TWI_TXDATA8` or `TWI_TXDATA16` register. This step configures the initial data transmitted. It is an error to complete the address phase of the transfer and not have data available in the transmit FIFO buffer.
3. Program the `TWI_FIFOCTL` register. The programming indicates if the transmit FIFO buffer interrupt requests occur with each byte transmitted (8-bits) or with every 2 bytes transmitted (16-bits).
4. Program the `TWI_IMSK` register. This step enables the bits associated with the desired interrupt request sources. For example, programming the value 0x0030 results in an interrupt output to the processor when the master transfer completes, and the master transfer has an error.
5. Program the `TWI_MSTRCTL` register. This step prepares and enables master mode operation. For example, programming the value 0x0201: enables master mode operation, generates a 7-bit address, sets the direction to master-transmit, uses standard mode timing, and transmits 8 data bytes before generating a stop condition.

The ***Master Mode Transmit Setup Interaction*** table represents the interaction between the TWI controller and the processor using this example.

Table 30-4: Master Mode Transmit Setup Interaction

TWI Controller	Processor
Interrupt: XMTSERV – Transmit buffer is empty.	Acknowledge: Clear the interrupt request source bits. Write to the transmit FIFO buffer.
...	...
Interrupt: MCOMP – Master transfer complete.	Acknowledge: Clear the interrupt request source bits.

Master Mode Receive

Follow these programming steps for a single master mode receive.

1. Program the `TWI_MSTRADDR` register. This step defines the address transmitted during the address phase of the transfer.
2. Program the `TWI_FIFOCTL` register. This step indicates if the receive FIFO buffer interrupt requests occur with each byte received (8-bits) or with every 2 bytes received (16-bits).
3. Program the `TWI_IMSK` register. This step configures the enable bits associated with the desired interrupt sources. For example, programming the value 0x0030 results in an interrupt request output to the processor when the master transfer completes, and the master transfer has an error.
4. Program the `TWI_MSTRCTL` register. This step prepares and enables master mode operation. For example, programming the value 0x0205: enables master mode operation, generates a 7-bit address, sets the direction to master-receive, uses standard mode timing, and receives 8 data bytes before generating a stop condition.

The ***Master Mode Receive Setup Interaction*** table shows the interaction between the TWI controller and the processor using this example.

Table 30-5: Master Mode Receive Setup Interaction

TWI Controller	Processor
Interrupt: RCVSERV – Receive buffer is full.	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer.
...	...
Interrupt: MCOMP – Master transfer complete.	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer.

NOTE: After the `TWI_MSTRCTL.DCNT` bit decrements to zero, the TWI master device sends a NAK to indicate to the slave transmitter to release the bus. This operation allows the master to send the stop signal to terminate the transfer.

ADSP-SC58x TWI Register Descriptions

Two-Wire Interface (TWI) contains the following registers.

Table 30-6: ADSP-SC58x TWI Register List

Name	Description
`TWI_CLKDIV`	SCL Clock Divider Register
`TWI_CTL`	Control Register
`TWI_FIFOCTL`	FIFO Control Register
`TWI_FIFOSTAT`	FIFO Status Register
`TWI_IMSK`	Interrupt Mask Register
`TWI_ISTAT`	Interrupt Status Register
`TWI_MSTRADDR`	Master Mode Address Register
`TWI_MSTRCTL`	Master Mode Control Registers
`TWI_MSTRSTAT`	Master Mode Status Register
`TWI_RXDATA16`	Rx Data Double-Byte Register
`TWI_RXDATA8`	Rx Data Single-Byte Register
`TWI_SLVADDR`	Slave Mode Address Register
`TWI_SLVCTL`	Slave Mode Control Register
`TWI_SLVSTAT`	Slave Mode Status Register
`TWI_TXDATA16`	Tx Data Double-Byte Register
`TWI_TXDATA8`	Tx Data Single-Byte Register

SCL Clock Divider Register

During master mode operation, the `TWI_CLKDIV` holds values, which the TWI uses to create the high and low durations of the serial clock (SCL). The clock signal SCL is an output in master mode and an input in slave mode. The values in the `TWI_CLKDIV.CLKLO` and `TWI_CLKDIV.CLKHI` fields add up to the CLKDIV value the following equation.

CLKDIV = TWI SCL period / 10 MHz time reference

Serial clock frequencies can vary from 400 KHz to less than 20 KHz. The resolution of the clock generated is 1/10 MHz or 100 ns. For example, for an SCL of 400 KHz (period = 1/400 KHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns):

CLKDIV = 2500 ns / 100 ns = 25

For an SCL with a 30% duty cycle, use `TWI_CLKDIV.CLKLO` = 17 and `TWI_CLKDIV.CLKHI` = 8.

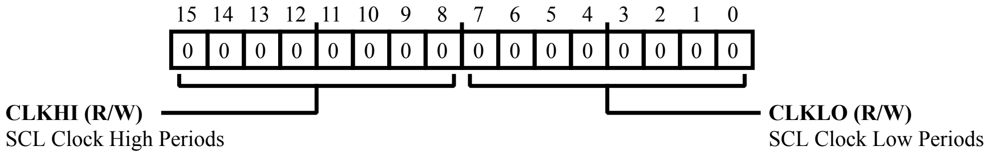

Figure 30-14: TWI_CLKDIV Register Diagram

Table 30-7: TWI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	CLKHI	SCL Clock High Periods. The `TWI_CLKDIV.CLKHI` specifies the number of 10 MHz time reference periods the serial clock (SCL) waits before a new clock low period begins, assuming a single master.
7:0 (R/W)	CLKLO	SCL Clock Low Periods. The `TWI_CLKDIV.CLKLO` specifies the number of internal time reference periods the serial clock (SCL) is held low.

Control Register

The `TWI_CTL` enables the TWI, establishes a relationship between the system clock (SCLK0_0) and the TWI controller's internally timed events, and enables SCCB compatibility.

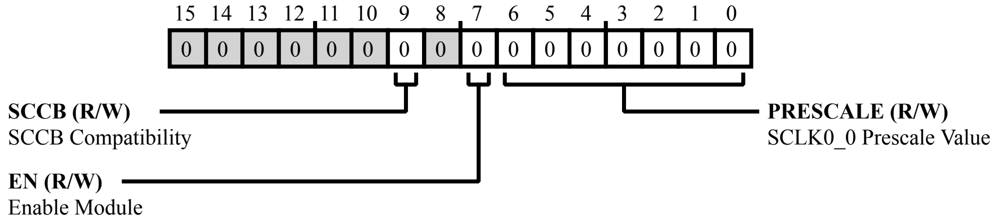

Figure 30-15: TWI_CTL Register Diagram

Table 30-8: TWI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	SCCB	SCCB Compatibility. The `TWI_CTL.SCCB` enables SCCB compatible operation for the TWI. SCCB compatibility is an optional feature and should not be used in an I^{2}C bus system. When this feature is enabled, all slave asserted acknowledgement bits are ignored by this master. This feature is valid only during transfers where the TWI is mastering an SCCB bus. Slave mode transfers should be avoided when this feature is enabled because the TWI controller always generates an acknowledge in slave mode.	
		0	Disable SCCB compatibility. When disabled, master transfers are not SCCB compatible.
		1	Enable SCCB compatibility. When enabled, master transfers are SCCB compatible. All slave-asserted acknowledgment bits are ignored by this master.
7 (R/W)	EN	Enable Module. The `TWI_CTL.EN` enables TWI controller operation for either master and/or slave mode of operation. It is recommended that this bit be set at the time `TWI_CTL.PRESCALE` is initialized and remain set. This method guarantees accurate operation of bus busy detection logic.	
		0	Disable
		1	Enable

Table 30-8: TWI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	PRESCALE	SCLK0_0 Prescale Value. The `TWI_CTL.PRESCALE` holds the pre-scaled value for the TWI internal time reference. This reference is derived from SCLK0_0 according to the formula: `TWI_CTL.PRESCALE` = f_{SCLK0_0}/10MHz The `TWI_CTL.PRESCALE` specifies the number of system clock (SCLK0_0) periods used in the generation of one internal time reference. The value of `TWI_CTL.PRESCALE` must be set to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value.

FIFO Control Register

The `TWI_FIFOCTL` control bits affect only the FIFO and are not tied in any way with master or slave mode operation.

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RXILEN	Rx Buffer Interrupt Length. The `TWI_FIFOCTL.RXILEN` determines the rate at which receive buffer interrupts are to be generated. Interrupts may be generated with each byte received or after two bytes are received. Interrupt status is available in `TWI_FIFOSTAT.RXSTAT`.	
		0	RXSERVI on 1 or 2 Bytes in FIFO
		1	RXSERVI on 2 Bytes in FIFO
2 (R/W)	TXILEN	Tx Buffer Interrupt Length. The `TWI_FIFOCTL.TXILEN` determines the rate at which transmit buffer interrupts are to be generated. Interrupts may be generated with each byte transmitted or after two bytes are transmitted. Interrupt status is available in `TWI_FIFOSTAT.TXSTAT`.	
		0	TXSERVI on 1 Byte of FIFO Empty
		1	TXSERVI on 2 Bytes of FIFO Empty
1 (R/W)	RXFLUSH	Rx Buffer Flush. The `TWI_FIFOCTL.RXFLUSH` directs the TWI to flush the contents of the receive buffer and update `TWI_FIFOSTAT.RXSTAT` to indicate the buffer is empty. This state is held until this bit is cleared. During an active receive, the receive buffer in this state responds to the receive logic as if it is full.	
		0	Normal Operation of Rx Buffer

FIFO Status Register

The `TWI_FIFOSTAT` fields indicate the state of the FIFO buffers' receive and transmit contents. The FIFO buffers do not discriminate between master data and slave data. By using the status and control bits provided, the FIFO can be managed to allow simultaneous master and slave operation.

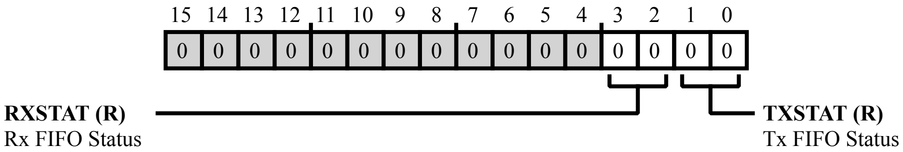

Figure 30-17: TWI_FIFOSTAT Register Diagram

Table 30-10: TWI_FIFOSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/NW)	RXSTAT	Rx FIFO Status. The read-only `TWI_FIFOSTAT.RXSTAT` indicates the number of valid data bytes in the receive FIFO buffer. The status is updated with each FIFO buffer read using the peripheral data bus or write access by the receive shift register. Simultaneous accesses are allowed.	
		0	Empty. The FIFO is empty.
		1	Contains 1 Byte. The FIFO contains one byte of data. A single byte peripheral read of the FIFO is allowed.
		2	Reserved
		3	Full. The FIFO is full and contains two bytes of data. Either a single or double byte peripheral read of the FIFO is allowed.
1:0 (R/NW)	TXSTAT	Tx FIFO Status. The read-only `TWI_FIFOSTAT.TXSTAT` field indicates the number of valid data bytes in the FIFO buffer. The status is updated with each FIFO buffer write using the peripheral data bus or read access by the transmit shift register. Simultaneous accesses are allowed.	
		0	Empty. The FIFO is empty. Either a single or double byte peripheral write of the FIFO is allowed.
		1	Contains 1 Byte. The FIFO contains one byte of data. A single byte peripheral write of the FIFO is allowed.
		2	Reserved
		3	Full. The FIFO is full and contains two bytes of data.

Interrupt Mask Register

The TWI_IMSK enables interrupt sources to assert the interrupt output. Each mask bit corresponds with one interrupt request source bit in TWI_ISTAT. Reading and writing TWI_IMSK does not affect the contents of the TWI_ISTAT.

Interrupt Status Register

The `TWI_ISTAT` contains information about functional areas requiring servicing. Many of the bits serve as an indicator to further read and service various status registers. After servicing the interrupt source associated with a bit, the user must clear that interrupt source bit by writing a 1 to it.

Figure 30-19: TWI_ISTAT Register Diagram

Table 30-12: TWI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	SCLI	Serial Clock Interrupt. If the TWI is enabled (`TWI_CTL.EN`), SCLI is set on a high-to-low transition of the serial clock pin (SCLx). Normally, this bit is not required for I^2C bus transfers. It will be initially set on an I^2C transfer and does not require clearing.	
		0	No Interrupt. No transition was detected on the SCLx pin.
		1	Interrupt Detected. A high-to-low transition was detected on the SCLx pin. This bit is W1C.
14 (R/W1C)	SDAI	Serial Data Interrupt. If the TWI is enabled (`TWI_CTL.EN`), SDAI is set on a high-to-low transition of the serial data pin (SDAx). Normally, this bit is not required for I^2C bus transfers. It will be initially set on an I^2C transfer and does not require clearing.	
		0	No Interrupt. No transition was detected on the SDAx pin.
		1	Interrupt Detected. A high-to-low transition was detected on the SDAx pin. This bit is W1C.

Table 30-12: TWI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	RXSERV	Rx FIFO Service. If `TWI_FIFOCTL.RXILEN` =0, the `TWI_ISTAT.RXSERV` is set each time the `TWI_FIFOSTAT.RXSTAT` field is updated to either 01 or 11. If `TWI_FIFOCTL.RXILEN` =1, the `TWI_ISTAT.RXSERV` is set each time `TWI_FIFOSTAT.RXSTAT` is updated to 11.	
		0	No Interrupt. The FIFO does not require servicing, or the `TWI_FIFOSTAT.RXSTAT` field has not changed since this bit was last cleared.
		1	Interrupt Detected. The receive FIFO buffer has one or two 8-bit words of data available to be read.
6 (R/W1C)	TXSERV	Tx FIFO Service. If `TWI_FIFOCTL.TXILEN` =0, the `TWI_ISTAT.TXSERV` is set each time the `TWI_FIFOSTAT.TXSTAT` field is updated to either 01 or 00. If `TWI_FIFOCTL.TXILEN` =1, the `TWI_ISTAT.TXSERV` is set each time `TWI_FIFOSTAT.TXSTAT` is updated to 00.	
		0	No Interrupt. FIFO does not require servicing, or the `TWI_FIFOSTAT.TXSTAT` field has not changed since this bit was last cleared.
		1	Interrupt Detected. The transmit FIFO buffer has one or two 8-bit locations available to be written.
5 (R/W1C)	MERR	Master Transfer Error. The `TWI_ISTAT.MERR` indicates that a master error has occurred. The conditions surrounding the error are indicated by the master status register (`TWI_MSTRSTAT`).	
		0	No Interrupt
		1	Interrupt Detected
4 (R/W1C)	MCOMP	Master Transfer Complete. The `TWI_ISTAT.MCOMP` indicates that the initiated master transfer has completed. In the absence of a repeat start, the bus has been released.	
		0	No Interrupt
		1	Interrupt Detected
3 (R/W1C)	SOVF	Slave Overflow. The `TWI_ISTAT.SOVF` indicates that the `TWI_ISTAT.SCOMP` bit was set at the time a subsequent transfer has acknowledged an address phase. The transfer continues, however, it may be difficult to delineate data of one transfer from another.	
		0	No Interrupt
		1	Interrupt Detected

Table 30-12: TWI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	SERR	Slave Transfer Error. The `TWI_ISTAT.SERR` indicates that a slave error has occurred. A restart or stop condition has occurred during the data receive phase of a transfer.	
		0	No Interrupt
		1	Interrupt Detected
1 (R/W1C)	SCOMP	Slave Transfer Complete. The `TWI_ISTAT.SCOMP` indicates that the transfer is complete and either a stop, or a restart was detected.	
		0	No Interrupt
		1	Interrupt Detected
0 (R/W1C)	SINIT	Slave Transfer Initiated. The `TWI_ISTAT.SINIT` indicates whether or not a slave transfer is in progress.	
		0	No Interrupt. A transfer is not in progress, or an address match has not occurred since the last time this bit was cleared.
		1	Interrupt Detected. The slave has detected an address match, and a transfer has been initiated.

Master Mode Address Register

During the addressing phase of a transfer, the TWI controller, with its master enabled, transmits the contents of `TWI_MSTRADDR`. When programming this register, omit the read/write bit. That is, only the upper 7 bits that make up the slave address should be written to this register. For example, if the slave address is b#1010000X, where X is the read/write bit, the `TWI_MSTRADDR` is programmed with b#1010000, which corresponds to 0x50. When sending out the address on the bus, the TWI controller appends the read/write bit as appropriate based on the state of the `TWI_MSTRCTL.DIR` bit.

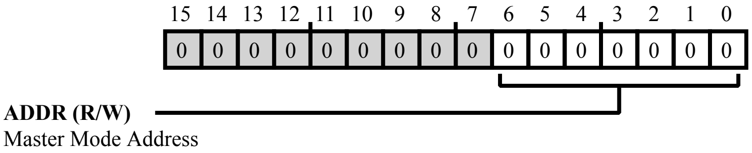

Figure 30-20: TWI_MSTRADDR Register Diagram

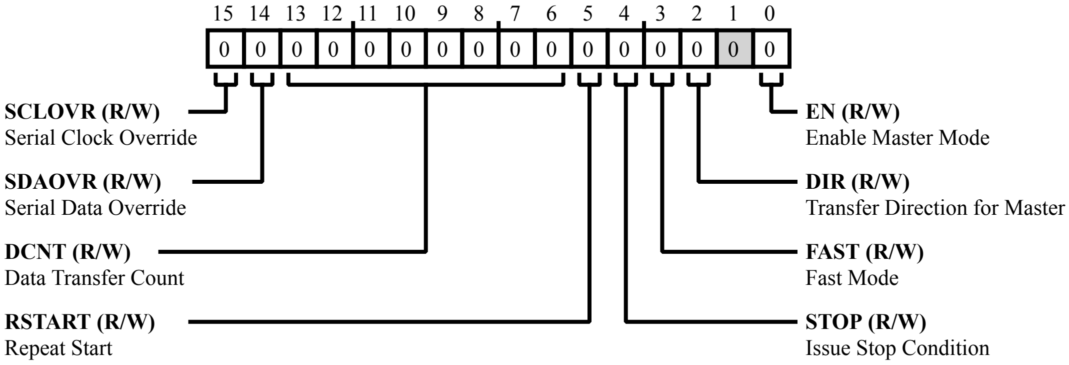
Table 30-13: TWI_MSTRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	ADDR	Master Mode Address.

Master Mode Control Registers

The TWI_MSTRCTL controls the logic associated with master mode operation. Bits in this register do not affect slave mode operation and should not be modified to control slave mode functionality.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 30-21: TWI_MSTRCTL Register Diagram

Table 30-14: TWI_MSTRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SCLOVR	Serial Clock Override. The TWI_MSTRCTL.SCLOVR provides direct control of the serial clock line when required. Normal master and slave mode operation should not require override operation. When TWI_MSTRCTL.SCLOVR is set, the TWI overrides normal serial clock output, driving it to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SCLOVR is cleared, the TWI permits normal serial clock operation under the control of master mode clock generation and slave mode clock stretching logic.	
		0	Permit Normal SCL Operation
		1	Override Normal SCL Operation
14 (R/W)	SDAOVR	Serial Data Override. The TWI_MSTRCTL.SDAOVR provides direct control of the serial data line when required. Normal master and slave mode operation should not require override operation. When TWI_MSTRCTL.SDAOVR is set, the TWI overrides normal serial data operation under the control of the transmit shift register and acknowledge logic, driving serial data output to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SDAOVR is cleared, the TWI permits normal serial data operation.	
		0	Permit Normal SDA Operation
		1	Override Normal SDA Operation

Table 30-14: TWI_MSTRCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13:6 (R/W)	DCNT	Data Transfer Count. The `TWI_MSTRCTL.DCNT` indicates the number of data bytes to transfer. As each data word is transferred, the TWI decrements this counter. When `TWI_MSTRCTL.DCNT` decrements to 0, a stop condition is generated. Setting `TWI_MSTRCTL.DCNT` to 0xFF disables the counter. In this transfer mode, data continues to be transferred until it is concluded by setting the `TWI_MSTRCTL.STOP` bit. In the event a master transmit is aborted due to a slave data NAK, the value of `TWI_MSTRCTL.DCNT` equals the number of bytes not sent. The byte which was NAK'ed by the slave is counted as a sent byte.
5 (R/W)	RSTART	Repeat Start. The `TWI_MSTRCTL.RSTART` enables the TWI to issue a repeat start condition at the conclusion of the current transfer (`TWI_MSTRCTL.DCNT` =0) and begin the next transfer. The current transfer concludes with updates to the appropriate status and interrupt bits. If errors occurred during the previous transfer, a repeat start does not occur. In the absence of any errors, master enable (`TWI_MSTRCTL.EN`) does not self clear on a repeat start. 0 Disable Repeat Start 1 Enable Repeat Start
4 (R/W)	STOP	Issue Stop Condition. The `TWI_MSTRCTL.STOP` directs the TWI to issue a stop condition. The transfer concludes as soon as possible avoiding any error conditions (as if data transfer count had been reached). At that time, the `TWI_IMSK` is updated along with any associated status bits. 0 Permit Normal Operation 1 Issue Stop
3 (R/W)	FAST	Fast Mode. The `TWI_MSTRCTL.FAST` selects whether the TWI operates in fast mode or standard mode. In fast mode, the TWI uses timing specifications for transfers at up to 400K bits/s. In standard mode, the TWI uses timing specifications for transfers at up to 100K bits/s. 0 Select Standard Mode 1 Select Fast Mode
2 (R/W)	DIR	Transfer Direction for Master. The `TWI_MSTRCTL.DIR` selects the transfer direction for the TWI as master initiated receive or transmit. 0 Master Transmit 1 Master Receive

Table 30-14: TWI_MSTRCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable Master Mode. The `TWI_MSTRCTL.EN` enables master mode functionality. A start condition is generated if the bus is idle. This bit self clears at the completion of a transfer (after `TWI_MSTRCTL.DCNT` decrements to zero), including transfers terminated due to errors. If disabled (=0) during operation, the transfer is aborted, and all logic associated with master mode transfers are reset. Serial data and serial clock (SDA, SCL) are no longer driven. Write-1-to-clear status bits are not affected.	
		0	Disable
		1	Enable

Master Mode Status Register

The `TWI_MSTRSTAT` holds information during master mode transfers and at their conclusion. Generally, master mode status bits are not directly associated with the generation of interrupt requests, but these bits offer information on the current transfer. Slave mode operation does not affect master mode status bits.

Note that while `TWI_MSTRSTAT.SCLSEN` is set (this condition could be due to having no pull-up resistor on `TWI_SCL` or another agent is driving `TWI_SCL` low), the acknowledge bits (`TWI_MSTRSTAT.ANAK` and `TWI_MSTRSTAT.DNAK`) do not update. This result occurs because the acknowledge conditions are sampled during the high phase of `TWI_SCL`.

Figure 30-22: TWI_MSTRSTAT Register Diagram

Table 30-15: TWI_MSTRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	BUSBUSY	Bus Busy. The `TWI_MSTRSTAT.BUSBUSY` indicates whether the bus is currently busy or free. This indication is not limited to only this device but is for all devices. On a start condition, the setting of the register value is delayed due to the input filtering. On a stop condition the clearing of the register value occurs after t_{BUF}.	
		0	Bus Free. The bus is free. The clock and data bus signals have been inactive for the appropriate bus free time.
		1	Bus Busy. The bus is busy. Clock or data activity has been detected.

Table 30-15: TWI_MSTRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	SCLSEN	Serial Clock Sense. The `TWI_MSTRSTAT.SCLSEN` indicates the active or inactive state of the serial clock. Use this status bit when direct sensing of the serial clock line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal master and slave mode operation should not require this feature.	
		0	SCL Inactive "One". An inactive "one" is being sensed on the serial clock.
		1	SCL Active "Zero". An active "zero" is being sensed on the serial clock. The source of the active driver is not known and can be internal or external.
6 (R/NW)	SDASEN	Serial Data Sense. The `TWI_MSTRSTAT.SDASEN` indicates the active or inactive status of the serial data. Use this status bit when direct sensing of the serial data line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal master and slave mode operation should not require this feature.	
		0	SDA Inactive "One". An inactive "one" is currently being sensed on the serial data line.
		1	SDA Active "Zero". An active "zero" is currently being sensed on the serial data line. The source of the active driver is not known and can be internal or external.
5 (R/W1C)	BUFWRERR	Buffer Write Error. The `TWI_MSTRSTAT.BUFWRERR` indicates whether the current master transfer was aborted due to a receive buffer write error. The receive buffer and receive shift register were both full at the same time. This bit is W1C.	
		0	No Status
		1	Buffer Write Error
4 (R/W1C)	BUFRDERR	Buffer Read Error. The `TWI_MSTRSTAT.BUFRDERR` indicates whether the current master transfer was aborted due to the detection of a NAK during data transmission. This bit is W1C.	
		0	No Status
		1	Buffer Read Error
3 (R/W1C)	DNAK	Data Not Acknowledged. The `TWI_MSTRSTAT.DNAK` indicates whether the current master transfer was aborted due to the detection of a NAK during data transmission. This bit is W1C.	
		0	No Status
		1	Data NAK

Table 30-15: TWI_MSTRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	ANAK	Address Not Acknowledged. The `TWI_MSTRSTAT.ANAK` indicates whether the current master transfer was aborted due to the detection of a NAK during the address phase of the transfer. This bit is W1C.	
		0	No Status
		1	Address NAK
1 (R/W1C)	LOSTARB	Lost Arbitration. The `TWI_MSTRSTAT.LOSTARB` indicates whether the current transfer was aborted due to the loss of arbitration with another master. This bit is W1C.	
		0	No Status
		1	Lost Arbitration
0 (R/NW)	MPROG	Master Transfer in Progress. The `TWI_MSTRSTAT.MPROG` indicates whether or not a master transfer is in progress. If clear (`TWI_MSTRSTAT.MPROG` =0), currently no transfer is taking place. This can occur after a transfer is complete or while an enabled master is waiting for an idle bus.	
		0	No Status
		1	Master Transfer in Progress

Rx Data Double-Byte Register

The `TWI_RXDATA16` holds a 16-bit data value read from the FIFO buffer. To reduce interrupt output rates and peripheral bus access times, a double byte receive data access can be performed. Two data bytes can be read, effectively emptying the receive FIFO buffer with a single access.

The data is read in little endian byte order, where byte 0 is the first byte received and byte 1 is the second byte received. With each access, the receive status (`TWI_FIFOSTAT.RXSTAT`) field is updated to indicate it is empty. If an access is performed while the FIFO buffer is not full, the read data is unknown and the existing FIFO buffer data and its status remains unchanged.

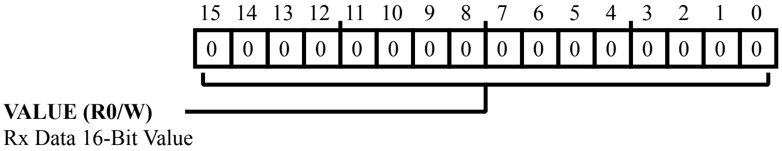

Figure 30-23: TWI_RXDATA16 Register Diagram

Table 30-16: TWI_RXDATA16 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W)	VALUE	Rx Data 16-Bit Value.

Rx Data Single-Byte Register

The `TWI_RXDATA8` holds an 8-bit data value read from the FIFO buffer. Receive data is read from the corresponding receive buffer in a first-in first-out order. Although peripheral bus reads are 16 bits, a read access to `TWI_RXDATA8` accesses only one transmit data byte from the FIFO buffer. With each access, the receive status (`TWI_FIFOSTAT.RXSTAT`) field is updated. If an access is performed while the FIFO buffer is empty, the data is unknown and the FIFO buffer status remains indicating it is empty.

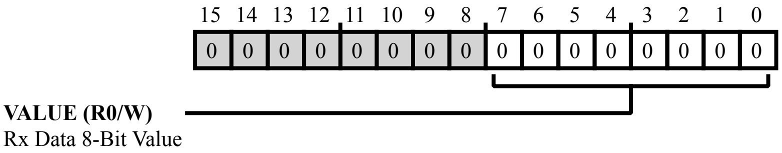

Figure 30-24: TWI_RXDATA8 Register Diagram

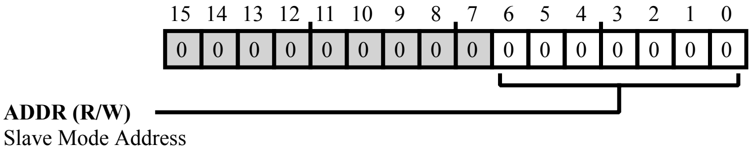
Table 30-17: TWI_RXDATA8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	VALUE	Rx Data 8-Bit Value.

Slave Mode Address Register

The `TWI_SLVADDR` holds the slave mode address, which is the valid address to which the slave-enabled TWI controller responds. The TWI controller compares this value with the received address during the addressing phase of a transfer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDR (R/W)
Slave Mode Address

Figure 30-25: TWI_SLVADDR Register Diagram

Table 30-18: TWI_SLVADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	ADDR	Slave Mode Address.

Slave Mode Control Register

The TWI_SLVCTL controls the logic associated with slave mode operation. Settings in this register do not affect master mode operation and should not be modified to control master mode functionality.

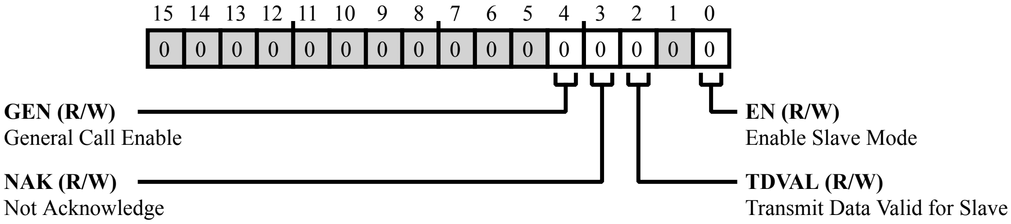


Figure 30-26: TWI_SLVCTL Register Diagram

Table 30-19: TWI_SLVCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	GEN	General Call Enable. The TWI_SLVCTL.GEN enables general call address matching. When enabled, a general call slave receive transfer is accepted. All status and interrupt source bits associated with transfers are updated. Note that general call address detection is available only when slave mode is enabled.	
		0	Disable General Call Matching
		1	Enable General Call Matching
3 (R/W)	NAK	Not Acknowledge. The TWI_SLVCTL.NAK directs the TWI to generate a NAK (if set) or an ACK (if cleared) at the conclusion of data transfer for slave receive. For NAK, the slave is still considered to be addressed at the conclusion of transfer.	
		0	Generate ACK
		1	Generate NAK
2 (R/W)	TDVAL	Transmit Data Valid for Slave. The TWI_SLVCTL.TDVAL selects whether the data in the transmit FIFO is available (valid) for slave transmission (TWI_SLVCTL.TDVAL set). If the FIFO data is not available (invalid) for slave transmission (TWI_SLVCTL.TDVAL cleared), the data in the transmit FIFO is for master mode transmits, and the data is not allowed to be used during a slave transmit; the transmit FIFO is treated as if it is empty.	
		0	Data Invalid for Slave Tx
		1	Data Valid for Slave Tx

Table 30-19: TWI_SLVCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable Slave Mode. The `TWI_SLVCTL.EN` enables slave operation. Enabling slave and master modes of operation concurrently is allowed. If disabled, no attempt is made to identify a valid address. If `TWI_SLVCTL.EN` is cleared during a valid transfer, clock stretching ceases, the serial data line is released, and the current byte is not acknowledged.	
		0	Disable
		1	Enable

Slave Mode Status Register

During and at the conclusion of register slave mode transfers, the `TWI_SLVSTAT` holds information on the current transfer. Generally slave mode status bits are not associated with the generation of interrupt requests. Master mode operation does not affect slave mode status bits.

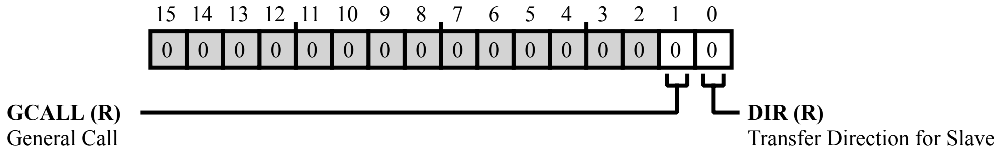

Figure 30-27: TWI_SLVSTAT Register Diagram

Table 30-20: TWI_SLVSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	GCALL	General Call. The `TWI_SLVSTAT.GCALL` indicates whether or not--at the time of addressing--the address was determined to be a general call. This bit self clears if slave mode is disabled (`TWI_SLVCTL.EN` =0).	
		0	Not a General Call Address
		1	General Call Address
0 (R/NW)	DIR	Transfer Direction for Slave. The `TWI_SLVSTAT.DIR` indicates whether--at the time of addressing--the transfer direction was determined to be slave transmit or receive. This bit self clears if slave mode is disabled (`TWI_SLVCTL.EN` =0).	
		0	Slave Receive
		1	Slave Transmit

Tx Data Double-Byte Register

The `TWI_TXDATA16` register holds a 16-bit data value written into the FIFO buffer. To reduce interrupt latency output rates and peripheral bus access times, a double byte transfer data access can be done. Two data bytes can be written, effectively filling the transmit FIFO buffer with a single access.

The data is written in little endian byte order, where byte 0 is the first byte to be transferred and byte 1 is the second byte to be transferred. With each access, the transmit status (`TWI_FIFOSTAT.TXSTAT`) field is updated. If an access is performed while the FIFO buffer is not empty, the write is ignored and the existing FIFO buffer data and its status remains unchanged. This register when read back returns zero.

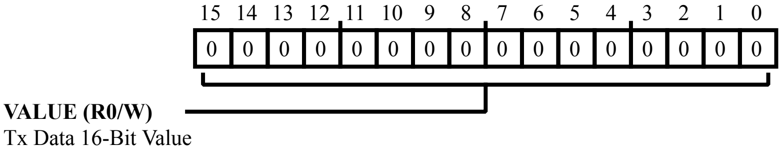

Figure 30-28: TWI_TXDATA16 Register Diagram

Table 30-21: TWI_TXDATA16 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W)	VALUE	Tx Data 16-Bit Value.

Tx Data Single-Byte Register

The `TWI_TXDATA8` register holds an 8-bit data value written into the FIFO buffer. Transmit data is entered into the corresponding transmit buffer in a first-in first-out order. For 16-bit peripheral bus writes, a write access to this register adds only one transmit data byte to the FIFO buffer. With each access, the transmit status (`TWI_FIFOSTAT.TXSTAT`) field is updated. If an access is performed while the FIFO buffer is full, the write is ignored and the existing FIFO buffer data and its status remains unchanged. This register returns zero when read back.

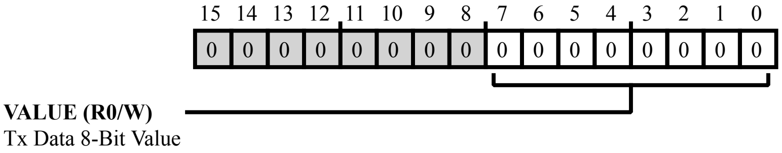

Figure 30-29: TWI_TXDATA8 Register Diagram

Table 30-22: TWI_TXDATA8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	VALUE	Tx Data 8-Bit Value.

31 Ethernet Media Access Controller (EMAC)

The EMAC peripheral in the processor enables network connectivity to applications through an Ethernet interface. The module is fully compliant to the following standards:

NOTE: On the processor, EMAC0 is 10/100/1000 BaseT-compliant and supports AVB (Audio Video Bridging) standards.

- Carrier Sense Multiple Access With Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications, Standard 802.3-2005, Institute of Electrical and Electronics Engineers (IEEE).
- Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, Standard 1588–2008, Institute of Electrical and Electronics Engineers (IEEE).
- Reduced Media Independent Interface Specification, Revision 1.2, RMII Consortium.
- Reduced Gigabit Media Independent Interface (RGMII), Revision 2.6, HP/Marvell.
- Timing and Synchronization for Time-Sensitive Applications in Bridged LANs, Standard 802.1AS-2011, Institute of Electrical and Electronics Engineers (IEEE).
- Forwarding and Queuing Enhancements for Time-Sensitive Streams, Standard 802.1Qav-2009, Institute of Electrical and Electronics Engineers (IEEE).
- The EMAC supports IEEE 803.3az-2010 standard for Energy Efficient Ethernet. This feature enables the Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode.

NOTE: Copyright © 2010 Synopsys, Inc.; portions of this chapter are included with permission from Synopsys, Inc.

EMAC Features

The Ethernet features include the following:

- Supports 10/100 Mbps data transfer rates with external PHY interfaced through RMII
- Full-duplex and half-duplex support for Ethernet
- Dedicated DMA controller with independent read write channels

- Supports dual-buffer (ring) or linked-list (chained) descriptor chaining
- Direct interface with the system crossbar bus
- Provides support for CSMA/CD protocol for half-duplex operation
- IEEE 802.3x flow control for full-duplex and half-duplex
- Automatic network monitoring statistics with management counters
- Flexible address filtering options for uni-cast, multi-cast, and broadcast addresses
- Support for promiscuous mode in reception
- Supports IEEE 802.1Q VLAN tag detection
- VLAN tag-based frame filtering - Perfect match and hash-based filtering
- Supports programmable Inter-frame Gap (IFG)
- Checksum offload engine for checking IPv4 header checksum and TCP/UDP/ICMP checksum encapsulated in IPv4 or IPv6 datagrams
- Station management interface for PHY device configuration and management
- Includes FIFOs for buffering: 1024 bytes for transmit FIFO and 512 bytes for receive FIFO
- Automatic CRC and pad generation controllable on a per-frame basis
- CRC replacement, source address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted frames with per-frame control
- Layer 3 and layer 4-based frame filtering - TCP or UDP over IPv4 or IPv6

The Ethernet MAC EMAC0 supports the following extra features

- Supports Gigabit data transfer rates with external PHY interfaced through RGMII
- Ethernet frame timestamping as described in IEEE 1588–2002 and IEEE 1588–2008. The transmit or receive status of each frame include 64-bit timestamps
- Hardware assisted time stamping capable of up to 8-ns resolution
- Automatic detection of PTP messages through Ethernet, IPv4, and IPv6 packets
- Four programmable PPS outputs that physically represent PTP system time
- Auxiliary snapshot to timestamp external events
- Four auxiliary input pins available
- Two separate channels (channel 1 and channel 2) or queues for transmission and reception of time-sensitive traffic. Channel 0 is available by default and carries the legacy best-effort Ethernet traffic on the transmit side.
- IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm for channel 1 and channel 2

- Slot number function to schedule the data fetching by DMA from the system memory for channel 1 and channel 2
- Separate DMA, Tx FIFO, and Rx FIFO (MTL) for each additional channel
- Programmable control to route received VLAN tagged non-AV packets to channels or queues
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet
- EMAC0 supports the following FIFO sizes: 2048 bytes for transmit FIFO and also for receive FIFO
-

EMAC Functional Description

This section provides information on the function of Ethernet MAC peripheral.

Hardware for the Media Access Control protocol

This function allows applications to support TCP/IP based network communication. At the system end, the module supports direct connection with the system crossbar bus for memory or MMR transactions. It supports RMII (Reduced Media Independent Interface), RGMII (Reduced Gigabit Media Independent Interface), and SMI (Station Management Interface) for interfacing with the external PHY chip.

Dedicated DMA Controller with independent read/write channels

Performs both data and status transfers between the application and the media independent interfaces. Internal transmit and receive FIFOs are used to buffer and regulate the frames. A dedicated interrupt line connects the EMAC interrupt sources to the System Event Controller (SEC).

MAC Management Counters (MMC) block

An extended set of registers that collect various statistics compliant with IEEE 802.3 definitions regarding the operation of the interface. The registers are updated for each new transmitted or received frame when the condition to update the counter is met. The EMAC provides a set of such counters, along with extended usage control.

PTP (Precision Time Protocol) engine

Provides hardware assistance for the implementation of the IEEE 1588 version 1 and version 2 standards, which allows time synchronization between systems.

Audio Video (AV) functionality

Enables transmission of time-sensitive traffic over bridged local area networks (LANs). The EMAC provides hardware support for IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm. In addition, slot number function allows scheduling of fetching of data by DMA from system memory.

ADSP-SC58x EMAC Register List

The Ethernet MAC (EMAC) module provides an Ethernet interface to the processor. The interface is compliant to IEEE Standard 802.3-2005. A set of registers govern EMAC operations. For more information on EMAC functionality, see the EMAC register descriptions.

Table 31-1: ADSP-SC58x EMAC Register List

Name	Description

EMAC Definitions

The following definitions are helpful for using the EMAC.

EMAC SCB

System Crossbar Interface of EMAC

AVB

Audio Video Bridging

EEE

Energy Efficient Ethernet

EMAC DMA

DMA Controller of EMAC

EMAC MFL

MAC FIFO Layer inside EMAC

EMAC CORE

CORE layer inside EMAC which performs the actual Ethernet operations, including interface with PHY through the reduced media interface(s).

MMC

MAC Management Counter

SMI

Station Management Interface that controls PHY through MDIO and MDC signals.

RMII

Reduced Media Independent Interface

MAC

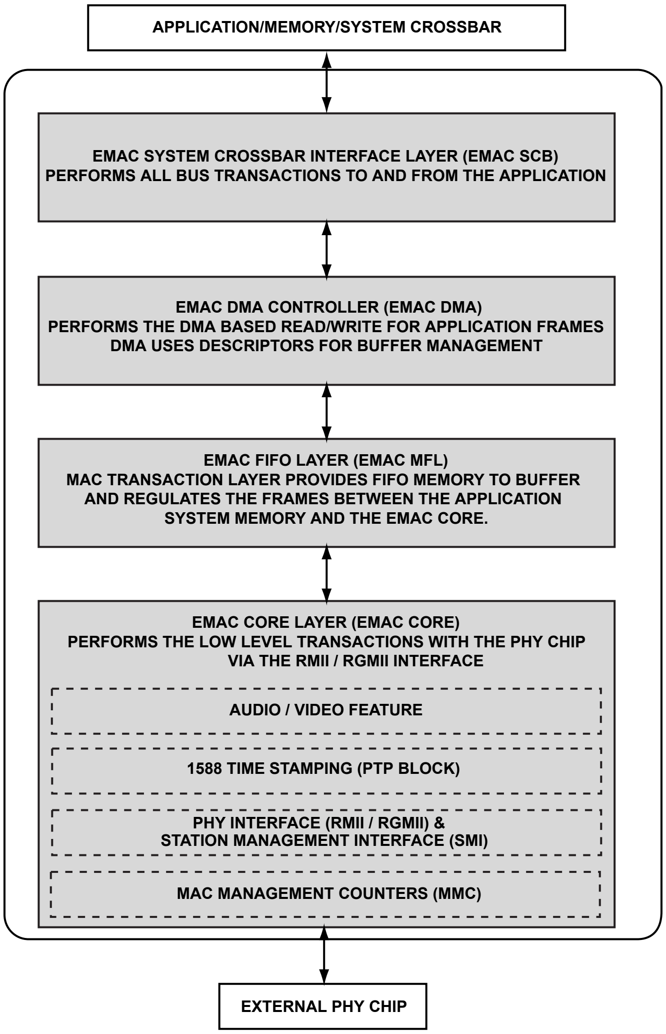
Media Access Control

PTP

Precision Time Protocol

EMAC Block Diagram and Interfaces

The ***EMAC Simplified Block Diagram*** illustrates the overall functional architecture of the Ethernet MAC peripheral. The EMAC module is comprised of four major layers: EMAC SCB, EMAC DMA, EMAC MFL, and EMAC CORE. Each of these layers (subblocks) is explained in depth in their respective sections in this chapter.



APPLICATION/MEMORY/SYSTEM CROSSBAR
EMAC SYSTEM CROSSBAR INTERFACE LAYER (EMAC SCB)
PERFORMS ALL BUS TRANSACTIONS TO AND FROM THE APPLICATION
EMAC DMA CONTROLLER (EMAC DMA)
PERFORMS THE DMA BASED READ/WRITE FOR APPLICATION FRAMES
DMA USES DESCRIPTORS FOR BUFFER MANAGEMENT
EMAC FIFO LAYER (EMAC MFL)
MAC TRANSACTION LAYER PROVIDES FIFO MEMORY TO BUFFER
AND REGULATES THE FRAMES BETWEEN THE APPLICATION
SYSTEM MEMORY AND THE EMAC CORE.
EMAC CORE LAYER (EMAC CORE)
PERFORMS THE LOW LEVEL TRANSACTIONS WITH THE PHY CHIP
VIA THE RMII / RGMII INTERFACE
AUDIO / VIDEO FEATURE
1588 TIME STAMPING (PTP BLOCK)
PHY INTERFACE (RMII / RGMII) &
STATION MANAGEMENT INTERFACE (SMI)
MAC MANAGEMENT COUNTERS (MMC)
EXTERNAL PHY CHIP

Figure 31-1: EMAC Simplified Block Diagram (RGMII, AV Features, and PTP are only available on EMAC0)

A more comprehensive block diagram is shown in the ***EMAC Complete Block Diagram***. It includes most of the important blocks inside the EMAC. The EMAC is connected to processor memory and the system crossbar through the System Crossbar Bus Interface (SCB) and System Peripheral Bus Interface (SPB). These connections are which are part of the SCB layer. The SPB interface is connected to all modules that require MMR programming.

The DMA controller performs application data transfer frame by frame, through well-defined descriptor structures. A FIFO layer acts as a buffer between the DMA controller and EMAC CORE.

The EMAC CORE is the most important block because it contains subblocks to support IEEE802.3 based communication with external network interfaces of 10/100/1000 Mbps speeds. It includes the PTP subblock, which assists applications requiring time synchronization; the AV Feature subblock, which enables transmission of time-sensitive traffic over bridged LANs; and a MMC subblock, which generates packet transfer statistics.

EMAC CORE Subblocks

The *Core Transmit Engine Subblocks* table summarizes the core transmit engine subblocks and their functions. Refer to the EMAC CORE section for further explanation of each of these subblocks.

Table 31-5: CORE Transmit Engine Subblocks

CORE Transmit Engine Sub Block	Function
Transmit Bus Interface	Interface to the FIFO.
Transmit Frame Controller	Appends Zero-PAD data, if required, for short frames. Appends CRC for frame checksum from the CRC generator.
Transmit Protocol Engine	Generates preamble and SFD, as per 802.3 protocol. Generates jam pattern in half-duplex mode, for collisions. Jabber timeout, for excessively large frames. Flow control for half-duplex mode (back pressure). Generates transmit frame status.
Transmit Scheduler	Maintains the inter-frame gap between two transmitted frames. Follows the truncated binary exponential back-off algorithm for half-duplex mode.

Table 31-5: CORE Transmit Engine Subblocks (Continued)

CORE Transmit Engine Sub Block	Function
Transmit CRC Generator	Generate CRC for the frame checksum field of the Ethernet frame.
Transmit Flow Control	Receives the pause frame, appends the calculated CRC, and sends the frame to the protocol engine module.
Transmit Checksum Offload Engine	Supports checksum calculation and insertion in the transmit path, for IPV4/TCP/UDP/ICMP packets.

The ***Core Receive Engine Subblocks*** table summarizes the core receive engine subblocks and their function. Refer to the EMAC CORE section for more information on each of these subblocks.

Table 31-6: Core Receive Engine Subblocks

CORE Receive Engine Subblock	Functionality Overview
Receive Protocol Engine	Strips the incoming preamble and SFD. Checks for correct length or type field. Performs internal loopback, if necessary. Generates receive status. Supports watchdog of received frames. Supports jumbo frames.
Receive CRC Module	Checks for CRC error, by comparing with FCS.
Receive Frame Controller Module	Packs incoming 8-bit input stream to 32-bit data internally. Performs frame filtering, for uni-cast, multi-cast, and broadcast frames. Attaches the calculated IP checksum input from checksum offload engine. Updates the receive status to bus interface.
Receive Flow Control Module	Detects the receiving pause frame and pauses the frame transmission for the delay specified within the received pause frame. Works in full duplex mode.
Receive IP Checksum Offload Engine	Calculates IPv4 header checksums and verify against the received IPv4 header checksums. Identifies a TCP, UDP, or ICMP payload in the received IP datagrams.
Receive Bus Interface Unit Module	Interface to the FIFO.
Address Filtering Module	Filters destination and source address based on uni-cast, multi-cast, and broadcast frames. Provides CRC hash filtering.

EMAC PHY Interface

The EMAC can interface to the PHY through the RMII interface standard. The ***RMII Pins*** table shows the RMII pins available in the EMAC, in terms of their generic names. Refer to the data sheet for exact pin names.

Table 31-7: RMII Pins

Sl. No.	Generic Signal Name (IEEE Standards)	RMII Pin Functionality
1.	TXD0	RMII transmit data pin D0 (di-bit lower)
2.	TXD1	RMII transmit data pin D1 (di-bit higher)
3.	RXD0	RMII receive data pin D0 (di-bit lower)
4.	RXD1	RMII receive data pin D1 (di-bit higher)
5.	RMII CLK	RMII common clock (for TX and RX), also called reference clock
6.	TXEN	RMII transmit enable pin (TX valid)
7.	CRS	RMII carrier sense / receive data valid
8.	MDC	Serial management clock driven by EMAC
9.	MDIO	Serial management bidirectional data

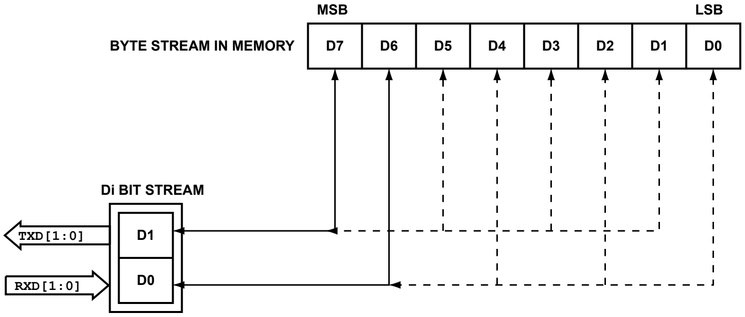

Figure 31-3: RMII Di-bit Data Transfer

Extended EMAC PHY Interface

The EMAC can interface to the PHY through the RGMII interface standard. The ***RGMII Pins*** table shows the RGMII pins available in the EMAC, in terms of their generic names. Refer to the data sheet for exact pin names.

Table 31-8: RGMII Pins

Sl. No.	Generic Signal Name (IEEE Standards)	RGMII Pin Functionality
1.	TXD3-0	RGMII transmit data pins D3-0
2.	RXD3-0	RGMII receive data pins D3-0
3.	TXCLK	RGMII transmit reference clock driven by EMAC
4.	RXCLK	RGMII receive reference clock driven by PHY
5.	TXCTL	RGMII transmit enable pin (TX valid)
6.	RXCTL	RGMII receive data valid

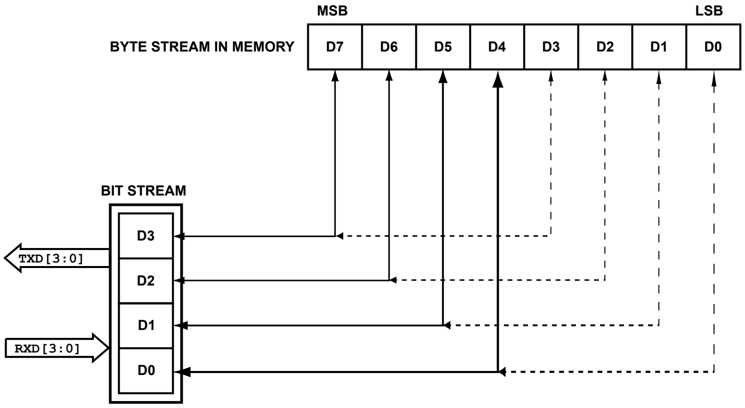

Figure 31-4: RGMII Data Bit Transfer

PHY Interface Selection

The EMAC1 supports only 10/100 Mbps data-transfer rates with external PHY interfaced through RMII. The EMAC0 supports both 10/100 Mbps data-transfer rates with external PHY interfaced through RMII and 10/100/1000 Mbps data-transfer rates with external PHY interfaced through RGMII.

Select the external PHY interface for EMAC0 using the `PADS_PCFG0` register, as shown in the following table.

`PADS_PCFG0.EMACPHYISEL`	0 = RMII Interface 1 = RGMII Interface
`PADS_PCFG0.EMACRESET`	0 = reset is asserted 1 = reset is deasserted To select PHY interface, set `PADS_PCFG0.EMACPHYISEL` bit as required and then set `PADS_PCFG0.EMACRESET`.

RGMII Board Design Recommendations

Use the following guidelines during when performing board design when using the RGMII interface.

MAC to PHY (Transmit)

The Ethernet MAC transmits data to the Ethernet PHY. The Ethernet MAC sends data with tskewT (the timing of TXC at the MAC) that meets the RGMII specification (tskewT = –500 ps to +500 ps skew window for transmitter to drive data). The RGMII specification requires that at the PHY end, tskewR is sampled at 1.0 to 2.6 ns. According to the RGMII standard, clocks must be routed such that an additional trace delay of greater than 1.5 ns and less than 2 ns is added to the associated clock signal.

To meet this standard without adding trace delays, most of the PHYs in the industry already include delay logic that can compensate for this on-board delay. These PHY types can manage a tskewR of ±500 ps (the skew for TXC data sampling seen inside the PHY).

The PHY or the on-board delay must delay the clock signal by 1.5 to 2.0 ns so that tskewR is sampled at 1.0 to 2.6 ns. The ***MAC to PHY Delay Diagram (Transmitting Data)*** figure shows where the delays must occur.

RXC

Figure 31-5: MAC to PHY Delay Diagram (Transmitting Data)

PHY to MAC (Receive)

The Ethernet MAC receives data from the Ethernet PHY. Just as in the transmit case, a trace delay of greater than 1.5 ns and less than 2 ns must be added to the associated clock signal, as required by the RGMII specification. Also similar to the transmit case, most of the PHYs in the industry already include delay logic that can compensate for the RXC clock as well.

As shown in the ***MAC to PHY Delay Diagram (Receiving Data)*** figure, a board trace or the PHY can be used to generate the required 1.5–2.0 ns delay to RXC and the 1.0–2.6 ns tskewR.

1.5 ns to 2.0 ns Delay
(3 options)
0 ns Delay
0.5 ns to 0.5 ns
tskewT

Figure 31-6: MAC to PHY Delay Diagram (Receiving Data)

There following are two options for board design.

- The on-board delay must delay the clock signal by 1.5 to 2.0 ns. In this case, no additional delay must be introduced by the PHY.
- Most of the PHYs in the industry already include a mode that can introduce a delay logic. If this mode of the PHY is used then the trace lengths on the board need to be matched exactly.

The second option is recommended since it is easier to implement the delay by using the mode in the PHY rather than during the board design. This is the approach followed in the ADI EZ-Kits.

NOTE: Refer to the product specific datasheet for exact processor timing.

For the trace length recommendations for the EMAC signals, please refer to the [SYNOPSIS?] datasheet.

For the exact requirements as recommended by the RGMII protocol, please refer to the RGMII specification.

Clock Sources

The Ethernet MAC is clocked internally from SCLK0_0. Check the processor data sheet for the valid frequency range of the appropriate SCLK0_0 signal for Ethernet operation.

Source a 50-MHz clock externally to operate the EMAC in RMII mode. This clock is the same for both transmit and receive. The MDC station management clock is derived from the SCLK0_0 and driven from the MAC to the PHY, when accessing any PHY registers. EMAC1 only supports the RMII interface.

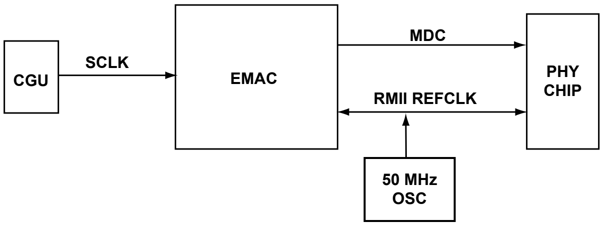

Figure 31-7: EMAC Clock Sources for RMII PHY interface

EMAC0 Clock Sources

EMAC0 supports RGMII and RMII interfaces. The external PHY sources a 2.5 MHz or 25 MHz clock (for 10/100 or gigabit Ethernet respectively) to operate the EMAC RXCLK in RGMII mode. The RGMII TXCLK is driven from CLK07 of the CDU (Clock Distribution Unit) and needs to be configured to 125 MHz regardless of the EMAC0 speeds (10/100/1000 Mbit/s). The `EMAC_MACCFG.PS` and `EMAC_MACCFG.FES` bits are used to divide the clocks down.

For EMAC0 to operate in RMII mode, configuration similar to the one shown in the ***EMAC Clock Sources for RGMII PHY Interface*** is required.

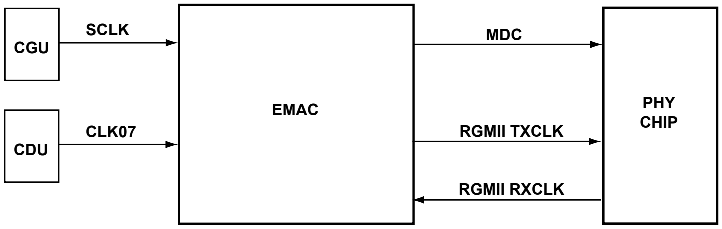

Figure 31-8: EMAC Clock Sources - RGMII PHY Interface

EMAC Architectural Concepts

This section explains different architectural concepts relevant to EMAC peripheral, such as EMAC SCB, EMAC DMA, EMAC MFL, EMAC CORE, and others.

EMAC Feature Summary

The ***EMAC Feature Summary*** table provides a summary of the features that are available on EMAC0 and EMAC1.

Table 31-9: EMAC Feature Summary

Feature	Value (EMAC0)	Value (EMAC1)
Speed of Operation	10/100/1000 Mbps	10/100 Mbps
EMAC_VER.UVER hardcoded value	0x10	0x11
PHY Interface	RGMII or RMII	RMII
Receive FIFO Size (in Bytes)	2048	512
Transmit FIFO Size (in Bytes)	2048	1024
Energy Efficient Ethernet (EEE)	Yes	No
PTP (IEEE 1588)	Yes	No
AV Feature	Yes	No
No of TX Channels	3	1
No of RX Channels	3	1

EMAC System Crossbar Interface (EMAC SCB)

The EMAC SCB bus interface provides the bus connectivity to support highly effective throughput of data traffic. System bus use is maximized by allowing simultaneous read and write transfers initiated from different DMA channels. The EMAC controller connects directly to the SCB0 crossbar. The following interfaces are available with the design.

- A 32-bit SCB master interface for reading and writing to and from the application memory.
- A 32-bit SPB slave interface for register programming.

Refer to the “System Crossbars (SCB)” chapter for more information on how the crossbar operates. This chapter details only the EMAC-specific information.

Table 31-10: EMAC-SCB Interface Data Transfer Specifications with Crossbar

Specification Term	Comments
1 beat in SCB	SINGLE burst
BLEN4 bursts	4 beats in SCB
BLEN8 bursts	8 beats in SCB
BLEN16 bursts	16 beats in SCB

Table 31-10: EMAC-SCB Interface Data Transfer Specifications with Crossbar (Continued)

Specification Term	Comments
Bus size	32-bit fixed bus size; equals 1 beat
INCR bursts	Incrementing Bursts
INCR ALIGNED bursts	Incrementing aligned bursts
UNDEF bursts	Undefined burst length
PBL	Programmable Burst Length for DMA

The ***EMAC DMA Read/Write channels with System Crossbar*** figure shows DMA write channel and read channel datapaths and their connection to the system crossbar.

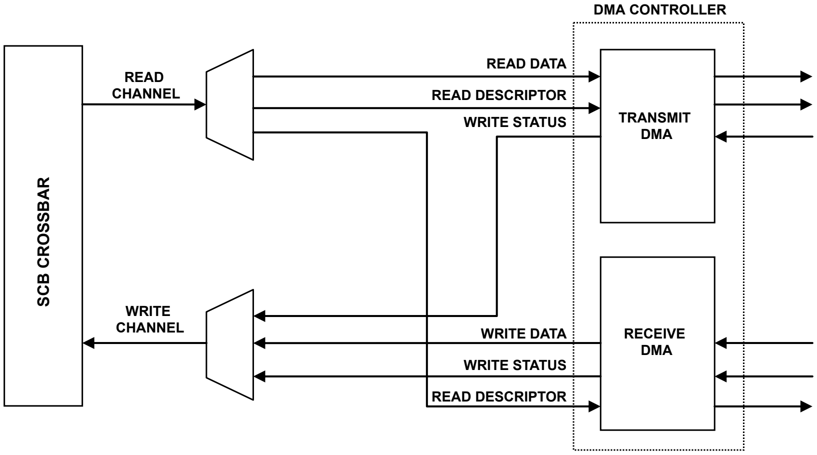

Figure 31-9: EMAC DMA Read/Write channels with System Crossbar

NOTE: Transmit descriptor read and receive descriptor write-back (status update) operations can occur simultaneously. However, transmit descriptor read and write-back operations cannot occur simultaneously. Transmit DMA (or receive DMA) does not initiate the next transfer unless the previous one is complete.

Priority of SCB Requests

The descriptor transfers have higher priority than the data transfers. For example, if there are two bus requests, such as a receive descriptor read and a transmit data read, the receive descriptor read has a higher priority. The next receive data write (subsequent to the receive descriptor read) does not depend on the completion of the transmit data-read transfer.

If there are requests for descriptor reads from both DMA channels, they are serviced based on a first-come first-serve. Receive DMA has higher priority if the descriptor-read requests are generated from both the DMA channels in the same clock cycle. Similarly, in the write channel, descriptor writes from DMA have higher priority than the data-write transfers for the receive DMA.

SCB Interface Programming Options

The SCB bus interface supports the following programmable options for the EMAC module. These options are available using the `EMAC_DMA0_BMMODE` register with the `EMAC_DMA0_BUSMODE` register. These programming options apply to DMA1 and DMA2 as well.

- *Outstanding transactions.* The EMAC-SCB supports up to four outstanding read/write requests on the SCB bus. Software can control these requests by programming the `EMAC_DMA0_BMMODE.WROSRLMT` and `EMAC_DMA0_BMMODE.RDOSRLMT` bits. Maximum outstanding requests = `EMAC_DMA0_BMMODE.WROSRLMT` + 1 (or) `EMAC_DMA0_BMMODE.RDOSRLMT` + 1.
- *Allowed burst sizes.* The allowed burst sizes are 4 (`EMAC_DMA0_BMMODE.BLEN4`), 8 (`EMAC_DMA0_BMMODE.BLEN8`), 16 (`EMAC_DMA0_BMMODE.BLEN16`) and the SINGLE burst. The EMAC-SCB uses only those burst sizes configured by the program (through the `EMAC_DMA0_BMMODE` register) for data transfer through the SCB bus. However, SINGLE burst is available by default, when the `EMAC_DMA0_BMMODE.UNDEF` bit is cleared. Data transfers are restricted to the maximum burst size from this list of programmed burst sizes.
- *Burst splitting and burst selection.* The EMAC-SCB splits the DMA requests into multiple bursts on the SCB system bus. Splitting is based on DMA count and software controllable burst enable bits (shown in the allowed burst sizes) as well as burst types (INCR and INCR_ALIGNED). Burst types are also controllable through the software. SINGLE burst is enabled when the `EMAC_DMA0_BMMODE.UNDEF` bit is not set. Burst length select priority is in the sequence: UNDEF, 16, 8, and 4.
- *INCR burst type*
  - If the `EMAC_DMA0_BMMODE.UNDEF` bit is set, the EMAC-SCB always chooses the maximum allowed burst length based on the `EMAC_DMA0_BMMODE.BLEN16`, `EMAC_DMA0_BMMODE.BLEN8`, `EMAC_DMA0_BMMODE.BLEN4` bits. When the DMA requests are not multiples of the maximum allowed burst length, the SCB can choose a burst-length of any value less than the maximum enabled. (All lesser burst-length enables are redundant). For example, when length bits are enabled and the DMA requests a burst of 42 beats, the SCB splits it into three bursts of 16, 16 and 10 beats respectively.
  - If `EMAC_DMA0_BMMODE.UNDEF` is not enabled, then the burst length is based on the priority of the enabled bits in the following order `EMAC_DMA0_BMMODE.BLEN16`, `EMAC_DMA0_BMMODE.BLEN8`, `EMAC_DMA0_BMMODE.BLEN4`. When the DMA requests a burst transfer, the SCB interface splits the requested bursts into multiple transfers using only the enabled burst lengths. This splitting can occur when the requested burst is not a multiple of the maximum enabled burst. If it cannot choose any of the enabled burst lengths, then it selects the burst length as 1.

  For example, the DMA requests a burst transfer of 42 beats, the SCB interface splits it into multiple bursts of size 16, 16, 8, 1 and 1 beats respectively. (In this case, the allowed burst sizes are enabled and the sequence is in decreasing burst sizes).
- *INCR_ALIGNED burst type.* When the address-aligned burst-type is enabled (`EMAC_DMA0_BMMODE.AAL`), the SCB interface splits the DMA requested bursts. The "INCR Burst Type" section explains burst splitting conditions further. Each burst-size aligns to the least significant bits of the start

address. The SCB interface initially generates smaller bursts so that the remaining transfers move with the maximum (enabled) fixed burst lengths.

For example, in the same setting as explained earlier for `EMAC_DMA0_BMMODE.UNDEF` set, the DMA requests a burst size of 42 beats at the start address of 0x000003A4.(`EMAC_DMA0_BMMODE.BLEN16`, `EMAC_DMA0_BMMODE.BLEN8`, and `EMAC_DMA0_BMMODE.BLEN4` are enabled). The SCB starts the first transfer with size 3 such that the address of the next burst is aligned (0x000003B0) for a burst of 16. Therefore, the sequence of bursts is 3, 16, 16, and 7, respectively.

When `EMAC_DMA0_BMMODE.UNDEF` is not set, then (having a start address of 0x000003A4 with 42 beats), the sequence of burst transfers is 1, 1, 1, 16, 16, 4, and 3 respectively. The sequence of smaller bursts at the beginning is used to align the address to the next higher enabled burst-lengths programmed in the register.

- ***Burst operations for DMA transactions.*** The `EMAC_DMA0_BUSMODE.PBL` (programmable burst length) field indicates the maximum number of beats to transfer in one DMA transaction. This value is also the maximum used in a single block read/write. It is shown in the following table.
  - For example, if `EMAC_DMA0_BUSMODE.PBL`=32 and if `EMAC_DMA0_BMMODE.BLEN16` is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If `EMAC_DMA0_BUSMODE.PBL`=8, and if `EMAC_DMA0_BMMODE.BLEN16` and `EMAC_DMA0_BMMODE.BLEN8` are enabled, the maximum burst is limited to `EMAC_DMA0_BMMODE.BLEN8`. If the `EMAC_DMA0_BUSMODE.PBL8` bit is set, the programmed `EMAC_DMA0_BUSMODE.PBL` value is multiplied by 8 times internally. However, the result cannot be more than the maximum limits specified.
  - Set the `EMAC_DMA0_BUSMODE.USP` bit to make the receive DMA burst length configuration independent of the transmit DMA configuration. When this bit is set, the EMAC uses the `EMAC_DMA0_BUSMODE.RPBL` bits to define the burst length of receive DMA. If the `EMAC_DMA0_BUSMODE.USP` bit is not set, the `EMAC_DMA0_BUSMODE.RPBL` bits are used for both transmit and receive. Programs must ensure that the PBL maximum limit is not violated.
  - The receive and transmit descriptors are always accessed in the maximum burst-size for the 16-bytes to be read (PBL-max limit is (TX or RX FIFO size/2)/4 words. (PBL maximum for transmit and receive limits burst-size).

Table 31-11: DMA PBL Max Limits

Burst Limit Max Term	Definition
PBL-maximum limit	(FIFO size/2)/4 words
PBL-maximum limit (transmit)	2048 bytes/2 /4 = 256 words
PBL-maximum limit (receive)	2048 bytes/2 /4 = 256 words

DMA Bursts Using the SCB Interface

The transmit DMA initiates a data transfer when sufficient space to accommodate the configured burst is available in the transmit FIFO. Or, the transmit DMA initiates a data transfer when the number of bytes until the end of frame is less than the configured burst-length. The DMA indicates the start address and the number of transfers required to the SCB master interface. When the SCB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4/8/16 and 1 beat transaction.

The receive DMA initiates a data transfer when sufficient data to accommodate the configured burst is available in the MTL receive FIFO. Or, the receive DMA initiates a data transfer when the end of frame is detected in the receive FIFO. For example, when the amount is less than the configured burst-length. The DMA indicates the start address and the number of transfers required to the SCB master interface. When the SCB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR 4, 8, 16 or 1 beat transaction. If the end-of frame is reached before the fixed-burst ends on the SCB interface, then dummy transfers are performed to complete the fixed-burst. Otherwise (if `EMAC_DMA0_BUSMODE.FB` is reset), it transfers data using INCR (undefined length) transactions.

When the SCB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer is less than or equal to the configured PBL size. (The address-aligned beats configuration uses the `EMAC_DMA0_BUSMODE.AAL` bit). Therefore, all subsequent beats start at an address that is aligned to the configured PBL.

SCB Bus Transaction Status

The SCB uses the `EMAC_DMA0_BMSTAT.BUSRD` and `EMAC_DMA0_BMSTAT.BUSWR` bits to indicate whether the channel is active or not.

Fatal Bus Error

The EMAC SCB asserts the error interrupt (`EMAC_DMA0_STAT.FBI`) when the corresponding fatal bus error interrupt is enabled in the DMA interrupt enable register. The application must reset the core to restart the DMA.

DMA Controller (EMAC DMA)

The EMAC has a built-in DMA controller that performs reads and writes of application data and descriptors through the SCB master interface.

The DMA controller has independent transmit and receive engines, and a CSR (control and status register) space. The transmit engine transfers data from system memory to a FIFO, while the receive engine transfers data from the FIFO to the system memory. The controller uses a descriptor chain-based transfer mechanism to move data efficiently from source to destination with minimal processor core intervention. The DMA is specially designed for packet-oriented data transfers such as Ethernet frames. The controller can be programmed to interrupt the application for situations such as frame transmit and receive transfer completion, and other normal or abnormal conditions.

The DMA and the application device driver communicate through two internal data structures:

1. DMA control and status registers (CSR).
2. Data buffers and descriptor lists. Descriptor lists operate in ring mode and chain mode, as shown in the ***EMAC DMA Descriptor Models*** figure.

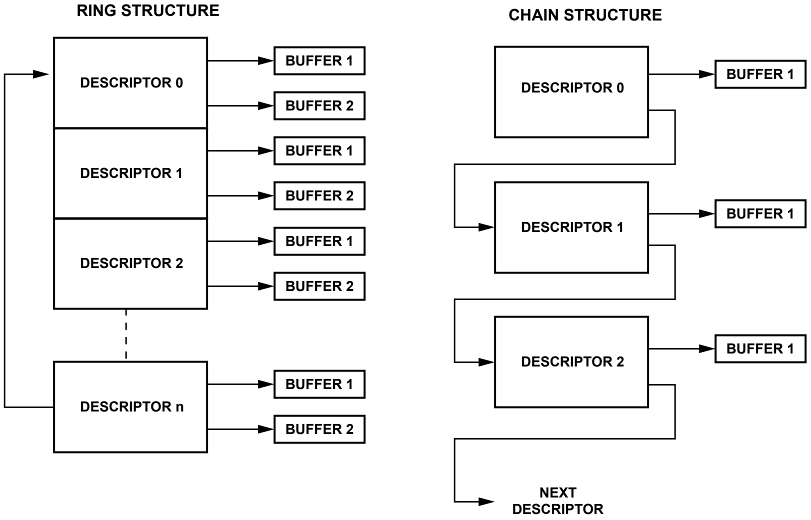

Figure 31-10: EMAC DMA Descriptor Models

Descriptors that reside in the application memory act as pointers to receive and transmit buffers. Descriptors have the following extra attributes.

- There are two descriptor lists, one for receive, and one for transmit. The base address of each list is written into the address registers of the receive and transmit descriptor lists respectively.
- A descriptor list is forward linked (either implicitly or explicitly). The last descriptor can point back to the first entry to create a ring structure.
- Explicit chaining of descriptors is accomplished by setting the second address chained in both receive and transmit descriptors.
- The descriptor lists reside in the address space of the application memory.
- Each descriptor can point to a maximum of two buffers. This attribute enables two buffers, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the physical memory space of the application. It consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers can contain only data. The descriptor maintains buffer status. *Data chaining* refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when the end-of-frame is detected. Data chaining is enabled or disabled.

NOTE: It is possible to define a skip length (in terms of N × 32-bit words) between two subsequent descriptors, when using ring mode. Program the `EMAC_DMA0_BUSMODE.DSL`/`EMAC_DMA1_BUSMODE.DSL`/`EMAC_DMA2_BUSMODE.DSL` field to enable this attribute. With this option available, programs are not always restricted to a contiguous memory location in ring mode.

DMA Related Registers

The *Summary of DMA Related Registers* table provides a summary of DMA registers relative to their function. Refer to the “Register Descriptions” sections for complete bit descriptions of each of these registers.

Table 31-12: Summary of DMA Related Registers

Register Name	Description
Bus Mode[*1]	Establishes the bus operating modes for the DMA based on the SCB master interface.
Transmit Poll Demand	Enables the transmit DMA to check whether the DMA owns the current descriptor. The transmit poll demand command wakes up the TxDMA when it is in suspend mode. The TxDMA can go into suspend mode because of an underflow error in a transmitted frame or because of the unavailability of descriptors owned by transmit DMA. Issue this command anytime and the TxDMA resets this command once it starts refetching the current descriptor from host memory.
Receive Poll Demand	Enables the receive DMA to check for new descriptors. This command wakes up the RxDMA from the SUSPEND state. The RxDMA can go into SUSPEND state only because of the unavailability of descriptors owned by it.
Receive Descriptor List Address	Points to the start of the receive descriptor list. The descriptor lists reside in the application memory space and must be word-aligned (32- bit data bus). The DMA internally converts the descriptor list to a bus width aligned address by making the corresponding LSBs low.
Transmit Descriptor List Address	Points to the start of the transmit descriptor list. The descriptor lists reside in the application memory space and must be word-aligned (for 32-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.
DMA Status	Contains all the status bits that the DMA reports to the application. The software driver reads this register during an interrupt service routine or during polling. Most of the fields in this register interrupt the host.
Operation Mode	Establishes the transmit and receive operating modes and commands. The operation mode register is the last control register written as part of DMA initialization.
Interrupt Enable	Enables the interrupts reported by DMA status register. After a hardware or software reset, all interrupts are disabled.
Missed Frame and Buffer Overflow Counter	The DMA maintains two counters to track the number of missed frames during reception. This register reports the current value of the counter, which is used for diagnostic purposes.
Receive Interrupt Watchdog Timer	When written with non-zero value, enables the watchdog timer for receive interrupt (RI) in the DMA status register.
SCB Bus Mode	Controls the SCB interface master behavior. It controls the burst splitting and the number of outstanding requests.
SCB Status	Provides the active status of the SCB interface read and write channels.
Current Host Transmit Descriptor	Points to the start address of the current transmit descriptor read by the DMA.
Current Host Receive Descriptor	Points to the start address of the current receive descriptor read by the DMA.
Current Host Transmit Buffer Address	Points to the current transmit buffer address the DMA is reading.
Current Host Receive Buffer Address	Points to the current receive buffer address the DMA is reading.

[*1] Do not write to the `EMAC_DMA0_BUSMODE.DSL`/`EMAC_DMA1_BUSMODE.DSL`/`EMAC_DMA2_BUSMODE.DSL` registers until the first write updates. Otherwise, the second write operation does not update properly. For correct operation, the delay between two writes to the same register location must be at least 8 cycles of 50 MHz RMII REFCLK.

Table 31-13: DMA Registers with Consecutive Writes

Registers with Implications for Consecutive Writes
DMA Bus Mode

DMA Descriptors

The DMA module in the Ethernet subsystem transfers data based on a linked list of descriptors. The descriptor addresses must be aligned to the 32-bit bus width. The descriptors can be either 4 x 32-bit words (16 bytes) or 8 x 32-bit words (32 bytes). Configure the controller for the appropriate word length using the DMA bus mode register. The descriptor words are numbered from 0 to 7 for both the transmit and receive engine.

Typical factors for deciding the descriptor word size are as follows:

- When the time stamping or receive checksum engines are not enabled, the extended descriptors are not required. The software can use descriptors with the default size of 16 bytes (4 words).
- When the time stamping feature is enabled, the software must allocate 32 bytes (8 words) of memory for every descriptor. (The time stamping feature is used with the IEEE 1588 PTP engine).
- When only the receive checksum offload is enabled (time stamping disabled), software must allocate 32 bytes (8 words) of memory for every descriptor. However, only word 4 of the extended words (descriptors 4–7) contains the required status information. Treat the rest of the extended words as reserved or dummy.

Transmit Descriptor

The *Transmit Descriptor Words* figure shows the transmit descriptor structure in memory. The application software must program the TDES0 control bits during descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits except the OWN bit (which it clears) and updates the status bits. The following tables give the contents of the transmitter descriptor word 0 (TDES0) through word 7 (TDES7).

Figure 31-11: Transmit Descriptor Words

Table 31-14: Transmit Descriptor Fields (TDES0)

Bit	Name	Description
31	OWN	Ownership. When set, this bit indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the first descriptor of the frame must be set after all subsequent descriptors belonging to the same frame have been set. This configuration avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.
30	IC	Interrupt on Completion. When set, this bit sets the transmit interrupt (DMA status register [0]) after the present frame is transmitted.
29	LS	Last Segment. When set, this bit indicates that the buffer contains the last segment of the frame.
28	FS	First Segment. When set, this bit indicates that the buffer contains the first segment of a frame.
27	DC	Disable CRC. When this bit is set, the EMAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This functionality is valid only when the first segment (TDES0[28]) is set.
26	DP	Disable Pad. When set, the EMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes. The CRC field is added despite the state of the DC (TDES0[27]) bit. This functionality is valid only when the first segment (TDES0[28]) is set.
25	TTSE	Transmit Time Stamp Enable. When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the first segment control bit (TDES0[28]) is set.
24	CRCR	CRC Replacement Control. When set, the EMAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The host should ensure that the CRC bytes are present in the frame being transferred from the transmit buffer. This bit is valid when the first segment bit (TDES0[28]) and the disable CRC bit (TDES0[27]) are set.
24	Reserved	
23:22	CIC	Checksum Insertion Control. These bits control the checksum calculation and insertion. Bit encodings are as follows: 00 = Checksum Insertion disabled. 01 = Only IP header checksum calculation and insertion are enabled. 10 = IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. 11 = IP header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.
21	TER	Transmit End of Ring. When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.

Table 31-14: Transmit Descriptor Fields (TDES0) (Continued)

Bit	Name	Description
20	TCH	Second Address Chained. When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When TDES0[20] bit is set, TBS2 (TDES1[28:16]) is a ***do-not-care*** value. TDES0[21] takes precedence over TDES0[20].
19:18	Reserved	
19:18	VLIC	VLAN Insertion Control. When set, these bits request the MAC to perform VLAN tagging or untagging before transmitting the frames. If the frame is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. Bit encodings are as follows. 00 = Do not add a VLAN tag. 01 = Remove the VLAN tag from the frames before transmission. This option should be used only with the VLAN frames. 10 = Insert a VLAN tag with the tag value programmed in the VLAN tag inclusion or replacement `EMAC_VLAN_INCL` register. 11 = Replace the VLAN tag in frames with the tag value programmed in the VLAN tag inclusion or replacement `EMAC_VLAN_INCL` register. This option should be used only with the VLAN frames. These bits are valid when the first segment bit (TDES0[28]) is set.
17	TTSS	Transmit Time Stamp Status. This bit is a status bit to indicate that a time stamp is captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the last segment control bit of the descriptor (TDES0[29]) is set.
16	IHE	IP Header Error. When set, this bit indicates that the EMAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application. It indicates an error status when there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet length or type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the header length field has a value less than 0x5.
15	ES	Error Summary. Indicates the logical OR of the following bits: TDES0[14] = Jabber Timeout TDES0[13] = Frame Flush TDES0[11] = Loss of Carrier TDES0[10] = No Carrier TDES0[9] = Late Collision TDES0[8] = Excessive Collision TDES0[2] = Excessive Deferral TDES0[1] = Underflow Error TDES0[16] = IP Header Error TDES0[12] = IP Payload Error

Table 31-14: Transmit Descriptor Fields (TDES0) (Continued)

Bit	Name	Description
14	JT	Jabber Timeout. When set, this bit indicates that the EMAC transmitter has experienced a jabber timeout. This bit is only set when the `EMAC_MACCFG.JB` bit is not set.
13	FF	Frame Flushed. When set, this bit indicates that the DMA or MFL flushed the frame due to a software flush command given by the CPU.
12	IPE	IP Payload Error. When set, this bit indicates that EMAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application. It issues an error status when there is a mismatch.
11	LC	Loss of Carrier. When set, this bit indicates a loss of carrier occurred during frame transmission. This functionality is valid only for the frames transmitted without collision when the EMAC operates in half-duplex mode. Loss of Carrier. When set, this bit indicates that the EMAC aborted the frame transmission because of a collision occurring after the collision window (64 byte-times, including preamble, in RMII mode; 512 byte-times, including preamble and carrier extension, in RGMII mode). This bit is not valid if the underflow error bit is set.
10	NC	No Carrier. When set, this bit indicates that the carrier sense signal from the PHY did not assert during transmission.
9	LC	Late Collision. When set, this bit indicates that the EMAC aborted the frame transmission because of a collision occurring after the collision window (64 byte-times, including preamble). This bit is not valid if the underflow error bit is set. Late Collision. When set, this bit indicates that the EMAC aborted the frame transmission because of a collision occurring after the collision window (64 byte-times, including preamble, in RMII mode; 512 byte-times, including preamble and carrier extension, in RGMII mode). This bit is not valid if the underflow error bit is set.
8	EC	Excessive Collision. When set, this bit indicates that the EMAC aborted the transmission after 16 successive collisions, while attempting to transmit the current frame. If the `EMAC_MACCFG.DR` disable retry bit is set, this bit is set after the first collision, and the transmission of the frame aborts.
7	VF	VLAN Frame. When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	CC	Collision Count. When set, these bit indicate that the EMAC aborted the frame transmission due to a collision occurring after the collision window (64 byte-times, including preamble). This bit is not valid if the Underflow Error bit is set. This field is updated only in half-duplex mode.
6:3	SLOTNUM	Slot Number Control Bits. In AV mode, these bits indicate the slot interval in which the data should be fetched from the corresponding buffers, addressed by TDES2 or TDES3. When the transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot function control and status register (RSN). It fetches the data from the buffers only if there is a match in values. These bits are valid only for AV channels (not channel 0).
2	ED	Excessive Deferral. When set, this bit indicates that the transmission has ended because of excessive deferral when the `EMAC_MACCFG.DC` deferral check bit is set high. Excessive deferral is

Table 31-14: Transmit Descriptor Fields (TDES0) (Continued)

Bit	Name	Description
		over 24,288-bit times. (155,680-bits times in 1,000-Mbps mode or when jumbo frame is enabled).
1	UF	Underflow Error. When set, this bit indicates that the EMAC aborted the frame because data arrived late from the application memory. Underflow error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the suspended state and sets both transmit underflow (`EMAC_DMA0_STAT.UNF`) and transmit interrupt (`EMAC_DMA0_STAT.TI`) bits.
0	DB	Deferred Bit. When set, this bit indicates that the EMAC defers before transmission because of the presence of carrier. This bit is valid only in half-duplex mode.

Table 31-15: Transmit Descriptor Word 1 (TDES1)

Bit	Name	Description
31-29	Reserved	
31–29	SAIC	Source Address Insertion Control. Request the MAC to add or replace the source address field in the Ethernet frame with the value given in the MAC address register 0 or MAC address register 1. If the source address field is modified in a frame, the MAC automatically recalculates and replaces the CRC bytes. SAIC[2] chooses between MAC address register 0 and MAC address register 1 for source address insertion or replacement. The following list describes SAIC[1:0]. 00 = Do not include the source address. 01 = Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. 10 = Replace the source address. For reliable transmission, the application must provide frames with source addresses. 11 = Reserved. This field is valid only when the first segment bit (TDES0[28]) is set.
28–16	TBS2	Transmit Buffer 2 Size. These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set.
15–13	Reserved	
12–0	TBS1	Transmit Buffer 1 Size. These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).

Table 31-16: Transmit Descriptor 2 (TDES2)

Bit	Name	Description
31–0	Buffer 1 Address Pointer	These bits indicate the physical address of buffer 1. There is no limitation on the buffer address alignment

Table 31-17: Transmit Descriptor 3 (TDES3)

Bit	Name	Description
31–0	Buffer 2 Address Pointer (Next Descriptor Address)	Indicates the physical address of buffer 2 when DMA uses a descriptor ring structure. If the second address chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. The buffer address pointer must align to the bus width only when TDES1[24] is set. LSBs are ignored internally.

Table 31-18: Transmit Descriptor 6 (TDES6)

Bit	Name	Description
31–0	TTSL	Transmit Frame Time Stamp Low. The DMA updates this field with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the last segment bit (LS) in the descriptor is set and time stamp status (TTSS) bit is set.

Table 31-19: Transmit Descriptor 7 (TDES7)

Bit	Name	Description
31–0	TTSH	Transmit Frame Time Stamp High. The DMA updates this field with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field has the time stamp only if the last segment bit (LS) in the descriptor is set and time stamp status (TTSS) bit is set.

DMA Transmit Process

The following sections describe how the transmission process works for direct memory access on the EMAC controller.

- Default (Non-OSF) Mode
- OSF Mode Enabled
- Transmit Frame Processing
- Transmit Polling Suspended

Default (Non-OSF) Mode

The following sequence decribes the default process for DMA transmit works. The sequence applies DMA1 and DMA2 as well.

1. The application sets up the transmit descriptor (using TDES0- TDES3) and sets the OWN bit (TDES0) after setting up the corresponding data buffers with Ethernet frame data.
2. Once the `EMAC_DMA0_OPMODE.ST` bit is set, the DMA enters the run state.
3. While in the run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the application, or if an error condition occurs, transmission suspends. Both the transmit buffer unavailable (`EMAC_DMA0_STAT.TU`) and normal interrupt summary (`EMAC_DMA0_STAT.NIS`) bits are set. The transmit engine proceeds to Step 9.

4. If the acquired descriptor is flagged as owned by DMA (TDES0 [31] = 1#b1), the DMA decodes the transmit data buffer address from the acquired descriptor.
5. The DMA fetches the transmit data from the application memory and transfers the data to the MFL for transmission.
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 repeat until the end-of-Ethernet-frame data transfers to the MFL.
7. Frame transmission completes. If IEEE 1588 time stamping was enabled for the frame, the time stamp value obtained from MFL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. (The transmit status indicates if IEEE 1588 time stamping enables). The status information is then written to this transmit descriptor (TDES0). Because the OWN bit is cleared during this step, the application now owns this descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3.
8. Transmit interrupt (`EMAC_DMA0_STAT.TI`) is set after completing transmission of a frame. The frame has interrupt on completion (TDES1 [31]) set in its last descriptor. The DMA engine then returns to Step 3.
9. In the suspend state, the DMA tries to reacquire the descriptor (and returns to Step 3) when it receives a transmit poll demand and the `EMAC_DMA0_STAT.UNF` bit is cleared.

NOTE: If the `EMAC_DMA0_OPMODE.OSF` bit is not set, the actual inter frame gap (IFG) is more than the value programmed in the `EMAC_MACCFG` register.

OSF Mode Enabled

While in the run state, the transmit process can simultaneously acquire two frames without closing the status descriptor of the first (if the `EMAC_DMA0_OPMODE.OSF` bit is set). As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the status information of the first frame.

In OSF mode, the run state transmit DMA operates in the following sequence.

1. The DMA operates as described in steps 1–6 of Default (Non-OSF) Mode.
2. Without closing the previous last descriptor of the frame, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into suspend mode and skips to Step 7.
4. The DMA fetches the transmit frame from the application memory and transfers the frame to the MFL until the end-of-frame data is transferred. It closes the intermediate descriptors when this frame splits across multiple descriptors.
5. The DMA waits for the frame transmission status and time stamp of the previous frame. Once the status is available, the DMA writes the time stamp to TDES2 and TDES3, if the time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES0, thus

closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.

6. If enabled, the transmit interrupt is set; the DMA fetches the next descriptor, and then proceeds to Step 3 (when status is normal). If the previous transmission status shows an underflow error, the DMA goes into suspend mode (Step 7).
7. In suspend mode, if a pending status and time stamp are received from the MFL, the DMA writes the time stamp (if enabled for the current frame) to TDES2 and TDES3. The DMA then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to suspend mode.
8. After receiving a transmit poll demand (`EMAC_DMA0_TXPOLL`), the DMA can exit suspend mode and enter the run state. (Go to Step 1 or Step 2 depending on pending status)

NOTE: If the `EMAC_DMA0_OPMODE.OSF` bit is set, the DMA fetches the next descriptor in advance of closing the current descriptor. Therefore, the descriptor chain must have more than two different descriptors for proper operation.

NOTE: If the `EMAC_DMA0_OPMODE.OSF` bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to update. In the meantime, the MFL receives the second frame into the FIFO while transmitting the first frame. The difference in cycles is not seen for the first descriptor, because the time taken for the complete descriptor processing remains the same whether `EMAC_DMA0_OPMODE.OSF` is set or not. The difference appears only for the following descriptor because its processing began earlier.

Transmit Frame Processing

The transmit DMA engine expects that the data buffers contain complete Ethernet frames, excluding: preamble, pad bytes, and FCS fields. The destination address, source address, and type or length fields contain valid data. If the transmit descriptor indicates that the EMAC CORE must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes.

Frames can be data-chained and can span several buffers. Frames must be delimited by the first descriptor (TDES0[28]) and the last descriptor (TDES0[29]), respectively.

As transmission starts, the first descriptor must have (TDES0[28]) set. Frame data transfers from the application buffer to the transmit FIFO. Concurrently, if last descriptor (TDES0[29]) of the current frame clears, the transmit process attempts to acquire the next descriptor. The transmit process expects this descriptor to have TDES0[28] clear. If TDES1[29] is clear, it indicates an intermediary buffer. If TDES0[29] is set, it indicates the last buffer of the frame.

After the last buffer of the frame has been transmitted, the DMA writes back the final status information. The DMA writes to the transmit descriptor 0 (TDES0) word of the descriptor that has the last segment set in transmit descriptor 0 (TDES0[29]). Now, if interrupt-on-completion (TDES0[30]) is set, the transmit interrupt (DMA_STAT [0]) is set, the next descriptor is fetched, and the process repeats.

Actual frame transmission begins after the MFL transmit FIFO has reached either a programmable transmit threshold (`EMAC_DMA0_OPMODE.TTC`), or a full frame is contained in the FIFO. There is also an option for store-and-forward mode (`EMAC_DMA0_OPMODE.TSF`). Descriptors are released (`OWN` bit TDES0 [31] clears) when the DMA finishes transferring the frame.

Transmit Polling Suspended

Either of the following conditions suspends transmit polling:

1. The DMA detects a descriptor owned by the application (TDES0 [31] = 0).
2. A frame transmission aborts when a transmit error due to underflow is detected. The appropriate transmit descriptor 0 (TDES0) bit is set.

If the second condition occurs, both of the abnormal interrupt summary ([15]) and transmit underflow bits ([5]) are set. The information is written to transmit descriptor 0, causing the suspension. If the DMA goes into a SUSPEND state due to the first condition, then both `EMAC_DMA0_STAT.NIS` and `EMAC_DMA0_STAT.TU` are set.

In both cases, the position in the transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA.

The driver must explicitly issue a transmit poll demand command after rectifying the suspension cause. If the first condition occurs, the driver must give descriptor ownership to the DMA and then issue a poll demand command to resume the transfer.

Receive Descriptor

The ***Receive Descriptor Words*** figure shows the structure of the receive descriptor. It can have 32 bytes of descriptor data (8 DWORDs) when advanced time stamping or checksum is enabled.

Figure 31-12: Receive Descriptor Words

Table 31-20: Receive Descriptor Fields (RDES0)

Bit	Name	Description
31	OWN	Ownership. When set, this bit indicates that the DMA of the EMAC subsystem owns the descriptor. When this bit is reset, this bit indicates that the application owns the descriptor. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	AFM	Destination Address Filter Fail. When set, this bit indicates a frame that failed in the DA filter in the EMAC CORE.
29–16	FL	Frame Length. These bits indicate the byte length of the received frame that transferred to application memory (including CRC). This field is valid when last descriptor (RDES0[8]) is set and either the descriptor error (RDES0[14]) or overflow error bits are reset. This field is valid when last descriptor (RDES0[8]) is set. When the last descriptor and error summary bits are not set, this field indicates the accumulated number of bytes that transferred for the current frame.
15	ES	Error Summary. Indicates the logical OR of the following bits. RDES0[1] = CRC Error RDES0[3] = RGMII Receive Error RDES0[4] = Watchdog Timeout RDES0[6] = Late Collision RDES0[7] = Time Stamp Available RDES4[4:3] = IP Header/Payload Error RDES0[11] = Overflow Error RDES0[14] = Descriptor Error. This field is valid only when the last descriptor (RDES0[8]) is set.
14	DE	Descriptor Error. When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers. The DMA does not own the next descriptor. The frame is truncated. This field is valid only when the last descriptor (RDES0[8]) is set.
13	Reserved	
13	SAF	Source Address Filter Fail. When set, this bit indicates that the SA field of frame failed the SA filter in the EMAC Core.
12	LE	Length Error. When set, this bit indicates that the actual length of the frame received and that the length or type field does not match. This bit is valid only when the frame type (RDES0[5]) bit is reset.
11	OE	Overflow Error. When set, this bit indicates that the received frame is damaged due to buffer overflow in MFL.
10	VLAN	VLAN Tag. When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the EMAC CORE.
9	FS	First Descriptor. When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next descriptor contains the beginning of the frame.
8	LS	Last Descriptor. When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame

Table 31-20: Receive Descriptor Fields (RDES0) (Continued)

Bit	Name	Description
7	Time Stamp Available	When set, this bit indicates that a snapshot of the time stamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This functionality is valid only when the last descriptor bit (RDES0[8]) is set
6	LC	Late Collision. When set, this bit indicates that a late collision has occurred while receiving the frame in half-duplex mode.
5	FT	Frame Type. When set, this bit indicates that the receive frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for runt frames less than 14 bytes.
4	RWT	Receive Watchdog Timeout. When set, this bit indicates that the receive watchdog timer has expired while receiving the current frame. The current frame is truncated after the watchdog timeout.
3	Reserved	
3	RE	Receive Error. When set, this bit indicates that the RGMII PHY sent RGMII RXERR on RXCTL pin during frame reception. This error also includes the carrier extension error in RGMII and half-duplex mode.
2	DE	Dribble Bit Error. When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles).
1	CE	CRC Error. When set, this bit indicates that a Cyclic Redundancy Check (CRC) error occurred on the received frame. This field is valid only when the last descriptor (RDES0[8]) is set.
0	Extended Status Available	When set, this bit indicates that the extended status is available in descriptor word 4 (RDES4). This functionality is valid only when the last descriptor bit (RDES0[8]) is set.

Table 31-21: Receive Descriptor Fields 1 (RDES1)

Bit	Name	Description
31	DIC	Disable Interrupt on Completion. When set, this bit prevents setting the `EMAC_DMA0_STAT.RI` bit of the status register for the received frame ending in the buffer indicated by this descriptor. This activity, in turn, disables the assertion of the interrupt to the application due to RI for that frame.
30–29	Reserved	
28–16	RBS2	Receive Buffer 2 Size. These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4 (32-bit bus), even if the value of RDES3 (buffer2 address pointer) does not align to bus width. If the buffer size is not an appropriate multiple of 4, 8, or 16, the resulting behavior is undefined. This field is not valid if RDES1[14] is set.
15	RER	Receive End of Ring. When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
14	RCH	Second Address Chained. When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a *do-not-care* value. RDES1[15] takes precedence over RDES1[14].
13	Reserved	

Table 31-21: Receive Descriptor Fields 1 (RDES1) (Continued)

Bit	Name	Description
12–0	RBS1	Receive Buffer 1 Size. Indicates the size of the first data buffer in bytes. The buffer size must be a multiple of 4 (32-bit bus), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses buffer 2 or next descriptor depending on the value of RCH (Bit 14).

Table 31-22: Receive Descriptor Fields 2 (RDES2)

Bit	Name	Description
31–0	Buffer 1 Address Pointer	These bits indicate the physical address of buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value stores the start of frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of frame. However, the frame data shifts per the address pointer of the actual buffer. The DMA ignores RDES2[1:0] when the address pointer is to a buffer where the middle or last part of the frame is stored. (RDES2[1:0] corresponds to a bus width of 32).

Table 31-23: Receive Descriptor Fields 3 (RDES3)

Bit	Name	Description
31–0	Buffer 2 Address Pointer (Next Descriptor Address)	These bits indicate the physical address of buffer 2 when DMA uses a descriptor ring structure. If the second address chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. If RDES1[24] is set, the buffer (next descriptor) address pointer must be bus width-aligned (RDES3[1:0] = 0, corresponding to a bus width of 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value stores the start of frame. The DMA ignores RDES3[1:0] when the address pointer is to a buffer where the middle or last part of the frame is stored. (RDES3[1:0] corresponds to a bus width of 32.)

Table 31-24: Receive Descriptor Fields 4 (RDES4)

Bit	Name	Description
31-26	Reserved	
25	Layer 4 Filter Match	When set, this bit indicates that the received frame matches layer 4 filter fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match. • All enabled layer 3 and layer 4 filter fields match.
24	Layer 3 Filter Match	When set, this bit indicates that the received frame matches layer 3 IP address fields. This status is given only when one of the following conditions is true: • All enabled layer 3 fields match and all enabled layer 4 fields are bypassed. • All enabled filter fields match.

Table 31-24: Receive Descriptor Fields 4 (RDES4) (Continued)

Bit	Name	Description
23-21	Reserved	
20-18	VLAN Tag Priority	These bits give the VLAN tag's user value in the received packet. These bits are valid only when the RDES4[16] and RDES4[17] are set.
17	AV Tagged Packet Received	When set, this bit indicates that an AV tagged packet is received. Otherwise, this bit indicates that an untagged AV packet is received. This bit is valid when RDES4[16] is set.
16	AV Packet Received	When set, this bit indicates that an AV packet is received.
15	Reserved	
14	Timestamp Dropped	When set, this bit indicates that the time stamp is captured for this frame but dropped in the MFL RxFIFO because of overflow.
13	PTP Version	When set, this bit indicates that the received PTP message has the IEEE 1588 version 2 format. When reset, it has the version 1 format. This description is valid only if the message type (RDES4[11:8]) is non-zero.
12	PTP Frame Type	When set, this bit indicates that the PTP message transfers directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message transfers over UDP-IPv4 or UDP-IPv6. Bits 6 and 7 have the information on IPv4 or IPv6.
11–8	Message Type	These bits are encoded to give the type of the message received. 0000 = No PTP message received 0001 = SYNC (all clock types) 0010 = Follow_Up (all clock types) 0011 = Delay_Req (all clock types) 0100 = Delay_Resp (all clock types) 0101 = Pdelay_Req (in peer-to-peer transparent clock) or Announce (in ordinary or boundary clock) 0110 = Pdelay_Resp (in peer-to-peer transparent clock) or Management (in ordinary or boundary clock) 0111 = Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) or Signaling (for ordinary or boundary clock) 1xxx - Reserved
7	IPv6 Packet Received	When set, this bit indicates that the received packet is an IPv6 packet.
6	IPv4 Packet Received	When set, this bit indicates that the received packet is an IPv4 packet.
5	IP Checksum Bypassed	When set, this bit indicates that the checksum offload engine is bypassed.
4	IP Payload Error	When set, this bit indicates that the 16-bit IP payload checksum that the core calculated does not match the corresponding checksum field in the received segment. (For example: the TCP, UDP, or ICMP checksum). The bit is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP header field.

Table 31-24: Receive Descriptor Fields 4 (RDES4) (Continued)

Bit	Name	Description
3	IP Header Error	When set, this bit indicates that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes. Or, it indicates that the IP datagram version is not consistent with the Ethernet type value.
2–0	IP Payload Type	These bits indicate the type of payload encapsulated in the IP datagram processed by the receive checksum offload engine (COE). The COE also sets these bits to 2'b00 when it does not process the payload of the IP datagram. It does not process the payload because of an IP header error or fragmented IP. 000 = Unknown or did not process IP payload 001 = UDP 010 = TCP 011 = ICMP 1xx = Reserved

Table 31-25: Extended Receive Descriptor Fields 4 (RDES4)

Bit	Name	Description
31-26	Reserved	
25	Layer 4 Filter Match	When set, this bit indicates that the received frame matches layer 4 filter fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match. • All enabled layer 3 and layer 4 filter fields match.
24	Layer 3 Filter Match	When set, this bit indicates that the received frame matches layer 3 IP address fields. This status is given only when one of the following conditions is true: • All enabled layer 3 fields match and all enabled layer 4 fields are bypassed. • All enabled filter fields match.
23-21	Reserved	
20-18	VLAN Tag Priority	These bits give the VLAN tag’s user value in the received packet. These bits are valid only when the RDES4[16] and RDES4[17] are set.
17	AV Tagged Packet Received	When set, this bit indicates that an AV tagged packet is received. Otherwise, this bit indicates that an untagged AV packet is received. This bit is valid when RDES4[16] is set.
16	AV Packet Received	When set, this bit indicates that an AV packet is received.
15	Reserved	
14	Timestamp Dropped	When set, this bit indicates that the timestamp was captured for this frame but got dropped in the MFL RxFIFO because of overflow.

Table 31-26: Receive Descriptor Fields 6 (RDES6)

Bit	Name	Description
31–0	RTSL	Receive Frame Time Stamp Low. The DMA updates this field with the least significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame. The status bit (RDES0[8]) indicates the last descriptor.

Table 31-27: Receive Descriptor Fields 7 (RDES7)

Bit	Name	Description
31–0	RTSH	Receive Frame Time Stamp High. The DMA updates this field with the most significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame. The status bit (RDES0[8]) indicates the last descriptor.

EMAC DMA Receive Process

The following sections describe how the receive process for direct memory access works on the EMAC controller.

- Receive Frame Processing
- Receive Descriptor Acquisition
- Receive Process Suspended

The reception process for DMA works as follows:

1. The application sets up receive descriptors (RDES0–RDES3) and sets the OWN bit (RDES0 [31]).
2. Once the `EMAC_DMA0_OPMODE.SR` bit is set, the DMA enters the run state. While in the run state, the DMA attempts to acquire free descriptors by polling the receive descriptor list. If the fetched descriptor is not free (the application owns the descriptor), the DMA enters the suspend state and jumps to Step 9.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the data buffers of the acquired descriptor.
5. When the buffer is full or the frame transfer is complete, the receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor. If the DMA does not own the next fetched descriptor and the frame transfer is not complete, the DMA sets the descriptor error bit in the RDES0. (The bit is set unless flushing is disabled.) The DMA closes the current descriptor (clears the OWN bit). The DMA marks it as intermediate by clearing the last segment (LS) bit in the RDES0 value (marks it as last descriptor if flushing is not disabled). The DMA then proceeds to Step 8. If the DMA owns the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 4.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to RDES2 and RDES3 of the current descriptor. The DMA then takes the status of the receive frame from the MFL and writes the status word to RDES0 of the current descriptor. The OWN bit is cleared and the last segment bit is set.

8. The receive engine checks the OWN bit of the latest descriptor. If the host owns the descriptor (OWN bit is 0), the `EMAC_DMA0_STAT.RU` bit is set. The DMA receive engine enters the suspended state (Step 9). If the DMA owns the descriptor, the engine returns to Step 4 and awaits the next frame.
9. Before the receive engine enters the suspend state, partial frames are flushed from the receive FIFO (programs control flushing using the `EMAC_DMA0_OPMODE.DFF` bit).
10. The receive DMA exits the suspend state when a receive poll demand is given or the start of next frame is available from the receive FIFO of the MFL. The engine proceeds to Step 2 and refetches the next descriptor.

Receive Frame Processing

The EMAC transfers the received frames to the application memory only when:

- the frame passes the address filter subblock, and
- the frame size is greater than or equal to configurable threshold bytes set for the receive FIFO of MFL, or
- the complete frame is written to the FIFO in store-and-forward mode.

If the frame fails the address filtering, the EMAC block drops the frame (unless the `EMAC_MACFRMFILT.RA` bit is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the receive FIFO.

After receiving 64 bytes (configurable threshold), the MFL block requests that the DMA block begin transferring the frame data to the receive buffer pointed to by the current descriptor. The DMA sets first descriptor (RDES0 [9]) after the SCB becomes ready to receive the data (if DMA is not fetching transmit data from the application). The descriptors release when the `OWN` (RDES [31]) bit is reset to 0. The bit is reset either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both the last descriptor (RDES [8]) and the first descriptor (RDES [9]) are set.

The DMA fetches the next descriptor, sets the last descriptor (RDES [8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then, the DMA sets the `EMAC_DMA0_STAT.RI` bit. The same process repeats unless the DMA encounters a descriptor the application owns. If this encounter occurs, the receive process sets the `EMAC_DMA0_STAT.RU` bit and then enters the suspend state. The position in the receive list is retained.

Receive Descriptor Acquisition

The receive engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted when any of the following conditions is satisfied:

- The `EMAC_DMA0_OPMODE.SR` bit is set immediately after being placed in the run state.
- The data buffer of current descriptor is full before the frame ends for the current transfer.
- The controller completes frame reception, but the current receive descriptor is not yet closed.
- The receive process suspends because of an application-owned buffer (RDES0 [31] = 0) and a new frame is received.
- A receive poll demand issues.

Receive Process Suspended

If a new receive frame arrives while the receive process is in the suspend state, the DMA refetches the current descriptor in the application memory. If the DMA now owns the descriptor, the receive process reenters the run state and starts frame reception. If the application still owns the descriptor, by default, the DMA discards the current frame at the top of the receive FIFO and increments the missed frame counter. If more than one frame is stored in the receive FIFO, the process repeats.

Avoid the discarding or flushing of the frame at the top of the receive FIFO by setting the `EMAC_DMA0_OPMODE.DFF` bit. In such conditions, the receive process sets the receive buffer unavailable status and returns to the suspend state.

OWN Bit (Ownership) Semaphore

Usage or ownership of the transmit or receive descriptor between the application and EMAC is mutually exclusive. While the EMAC accesses the descriptor, the application cannot modify it. Conversely, while the host updates the descriptor, the EMAC cannot use the content of the descriptor. This functionality is implemented through the OWN bit in the transmit or receive descriptor, acting as a semaphore to prevent multiple, simultaneous access to the descriptors.

The following example is based on a usage case of 4 WORDs enabled for descriptors. A chain structure configuration is assumed. (The `EMAC_DMA0_BUSMODE.ATDS` bit is not set). However, the explanation of the `OWN` bit semaphore remains consistent irrespective of any particular mode of operation.

1. Transmit OWN Bit:
    - TDES0 – TDES3 words implement the transmit descriptors. TDES0 [31] is defined as the OWN bit. When TDES0 [31] is set to 0, this bit indicates that the descriptor is available for the application to update. The application sets up the descriptors, including the buffer addresses, by updating TDES0 through TDES3.
    - To release ownership of the descriptor to the EMAC, the application sets the transmit `OWN` bit, TDES0 [31], to 1. TDES0 [31] = 1 indicates that the descriptor is ready for the EMAC to use. DMA reads the descriptors, then fetches the data for transmission from the buffer locations pointed to by the transmit descriptors (TDES2 and TDES3). When either the last data buffer is empty or the end-of-frame is reached, DMA clears the TDES0 [31] bit to 0. Now, the transmit descriptor releases to the application for updates.
2. Receive `OWN` Bit:
    - RDES0 – RDES3 words implement the receive descriptors. RDES0 [31] is defined as the `OWN` bit. When RDES0 [31] is set to 0, this bit indicates that the descriptor is available for the application to update. The application sets up the descriptors, including the buffer locations for writing the received data, by updating RDES0 through RDES3. To give ownership of the descriptor to the EMAC, the host sets the receive `OWN` bit, RDES0 [31], to 1.
    - RDES0 [31] = 1 indicates that the descriptor is ready for use by the EMAC. DMA reads the descriptors, then writes the received data to the buffers with locations pointed to by the receive descriptors (RDES2

and RDES3). When either the last data buffer is full or the end-of-frame is reached, DMA clears the RDES0 [31] bit to 0. Now, the receive descriptor releases to the application for updates

Application Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on the start address alignment. The start address for the buffers aligns to any of the 4 bytes. However, the DMA always initiates transfers with the address aligned to the bus width with dummy data for the byte lanes not required. This alignment typically happens during the transfer of the beginning or end of an Ethernet frame.

Example for Buffer Read

If the transmit buffer address is 0x0002 and 15 bytes must transfer, the DMA reads 5 full words (5 x 32-bit data) from address 0x0000. However, when transferring data to the EMAC transmit FIFO, the extra bytes (the first 2 bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always transfers a full 32-bit data to the transmit FIFO, unless it is the end-of-frame.

Example for Buffer Write

If the receive buffer address is 0x0002 and 15 bytes of a received frame must transfer, the DMA writes 5 full words (5 x 32-bit data) to address 0x0000. However, the first 2 bytes of first transfer and the last 3 bytes of the third transfer have dummy data.

Buffer Size Calculations

The DMA engines do not update the size fields in the transmit and receive descriptors alone. The DMA updates only the status fields (RDES0 and TDES0) of the descriptors. The driver must perform the size calculations. The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) towards the EMAC CORE. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as last (LS bit of TDES1), the DMA marks the last transfer from that data buffer as the end-of frame to the EMAC.

The receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MFL. If a descriptor is not marked as last (LS bit of RDES0), then the buffers of the descriptor are full. The amount of valid data in a buffer is its buffer size field minus the data buffer pointer offset, when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer aligns to the data bus width. If a descriptor is marked as last, then the buffer cannot be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must:

- Read the frame length (FL bits of RDES0 [29:16]), and
- Subtract the sum of the buffer sizes of the preceding buffers in the frame

The receive DMA always transfers the start of next frame with a new descriptor.

EMAC FIFO Layer (EMAC MFL)

The MAC FIFO layer provides FIFO memory to buffer and regulates the frames between the application system memory and the EMAC CORE. It also allows the transfer of data between the application clock domain and the

EMAC clock domains. The MFL layer has transfer controllers for each direction, called the transmit controller (TxFIFO) and the receive controller (RxFIFO). The datapath for both directions is 32-bit wide and each controller has a dedicated FIFO.

The EMAC0 transmit FIFO size is fixed to 2048 bytes. The EMAC0 receive FIFO size is fixed to 2048 bytes.

The EMAC1 transmit FIFO size is fixed to 1024 bytes. The EMAC1 receive FIFO size is fixed to 512 bytes.

FIFO Layer Transmit Path

The DMA engine controls all transactions for the transmit path with the application. Ethernet frames read from the system memory are pushed into the FIFO by the DMA. The frame is then popped out and transferred to the EMAC CORE when triggered. When the end-of-frame transfers, the status of the transmission is taken from the EMAC CORE and transferred back to the DMA. The FIFO fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory through the SCB interface.

When the DMA enables the `EMAC_DMA0_OPMODE.OSF` bit, the MFL receives the second frame into the FIFO while transmitting the first frame. When the first frame has transferred, the status is sent to DMA. If the DMA has already completed sending the second packet to the MFL, it waits for the status of the first packet before proceeding to the next frame.

The following are the modes of operation for FIFO transactions.

1. Threshold mode. When the number of bytes in the FIFO crosses the configured threshold level, the data is ready to be popped out and forwarded to the EMAC CORE. The data is also ready when the end-of-frame is written before the threshold is crossed. The DMA uses the `TTC` bits of the DMA bus mode register to configure the threshold level.
2. Store-and-Forward mode. In this mode, the MFL pops the frame towards the EMAC CORE after a complete frame is stored in the FIFO. If the TX FIFO size is smaller than the Ethernet frame for transmission (such as a jumbo frame), then the frame forwards in two cases. The TX FIFO is almost full or the requested FIFO does not have space to accommodate the requested burst-length. Therefore, the FIFO read controller never stalls in store-and-forward mode even if the Ethernet frame length is bigger than the TX FIFO depth.

   The FIFO threshold in the store-and-forward mode is given by the following formula.

   FIFO threshold = FIFO_SIZE [(PBL + 3) (DataWidth/8)) where

   DataWidth = 32 bits and PBL = Burst Length programmed through the DMA_BUSMODE register.

   NOTE: To avoid occurrences of a TX underflow event when using the store-and-forward mode, or in other words, to ensure that the entire frame is stored in the FIFO before the MFL pops the frame towards the EMAC CORE for transmission, ensure that the FIFO threshold (calculated with the above formula) is greater than the packet size. The PBL needs to be programmed accordingly.

Transmit FIFO and Half-Duplex Retransmissions

While a frame transfers from the FIFO, a collision event can occur on the EMAC line interface in half-duplex mode. The EMAC then indicates a retry attempt to the MFL. The EMAC gives the status before the end-of-frame transfers from MFL. Then, the MFL enables the retransmission by popping out the frame again from the FIFO.

After more than 96 bytes pop out of FIFO, the FIFO controller frees up that space. The controller makes it available to the DMA to push in more data. Retransmission is not possible after this threshold is crossed or when the EMAC CORE indicates a late-collision event.

Transmit FIFO Flush Operation

The EMAC provides control to the software to flush the transmit FIFO in the MFL layer using the `EMAC_DMA0_OPMODE.FTF` bit. The flush operation is immediate. The MFL clears the transmit FIFO and the corresponding pointers to the initial state. It clears the FIFO and pointers even if it is in the middle of transferring a frame to the EMAC CORE. The data that the MAC transmitter has already accepted is not flushed. The data is scheduled for transmission and results in underflow. The transmit FIFO does not complete the transfer of the rest of the frame. As in all underflow conditions, a runt frame is transmitted and observed on the line. The status of the frame is marked with both underflow and frame flush events (TDES0 bits 13 and 1).

The MFL also stops accepting any data from the application (DMA) during the flush operation. The MFL generates and transfers transmit status words to the application for the number of frames flushed inside the MFL (including partial frames). Frames that completely flush in the MFL have the status bit for frame flush (TDES0 bit 13) set. The MFL completes the flush operation when the application (DMA) accepts all of the status words for the frames that flushed. The MFL then clears the transmit FIFO flush control register bit. The MFL starts accepting new frames from the application (DMA).

FIFO Layer Receive Path

The receive controller operates in the following sequence:

1. When the EMAC CORE receives a frame, it pushes in data with the frame start and end indicators. The MFL accepts the data and pushes it into the FIFO.
2. The receive controller takes the data out of the FIFO and sends it to the DMA.
    - Threshold mode (default). This mode is configured using `EMAC_DMA0_OPMODE.RTC`. When the FIFO receives 64 bytes or a full packet of data, the receive controller pops out the data and indicates its availability to the DMA. Some error frames cannot be dropped, because the error status is received at the end-of-frame. By this time, the start of that frame has already been read out of the FIFO.
    - Rx FIFO Store-and-Forward mode. This mode is configured using `EMAC_DMA0_OPMODE.RSF`. A frame is read out only after being written completely into the receive FIFO. In this mode, all error frames are dropped such that only valid frames are read out and forwarded to the application. Error frames are dropped when the EMAC CORE is configured for this feature.
3. After the end-of-frame transfers, the status word from the EMAC CORE is also the pushed FIFO. When the status of a partial frame due to overflow is given out, the frame length field in the status word is not valid.

Receive FIFO Multi-Frame Handling

Since the status is available immediately following the data, the MFL stores any number of frames into the FIFO, as long as it is not full.

Receive FIFO Error Handling

If the MFL Rx FIFO is full before it receives the end of frame data from the EMAC, the DMA declares an overflow condition. The whole frame (including the status word) drops. The overflow counter in the DMA (overflow counter-register) increments. This activity occurs even if the `EMAC_DMA0_OPMODE.FEF` bit is set. If the start address of such a frame has already transferred, the rest of the frame drops. A dummy end of frame is written to the FIFO along with the status word. The status indicates a partial frame due to overflow. In such frames, the frame length field is invalid.

The MFL receive control logic can filter error and undersized frames using the `EMAC_DMA0_OPMODE.FEF` and `EMAC_DMA0_OPMODE.FUF` bits. If the start address of the frame has already transferred to the Rx FIFO read controller, that frame is not filtered. The start address of the frame transfers to the read controller after the frame crosses the receive threshold (set by the `EMAC_DMA0_OPMODE.RTC` bits).

If the MFL receive FIFO is configured for store-and-forward mode, it can filter and drop all error frames.

EMAC CORE

The EMAC CORE is the lowest block in the EMAC peripheral and it performs all operations with the external world (PHY chip). It has independent transmit and receive modules. The modules interact with the EMAC FIFO layer at one end and interacts with the PHY chip through the RMII interface at the other end. Both modules have several subblocks which are discussed in subsequent sections.

Transmission is initiated when the MFL (FIFO layer) pushes in data with the start of frame. The CORE then transmits to the reduced media-independent interface. After the end of frame transfers out, the CORE gives the status of the transmission back to the MFL. The MFL forwards the transmission to the application through DMA.

A receive operation initiates when the EMAC detects an SFD on the RMII/RGMII. The CORE strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The frame drops in the core when it fails the address filter.

NOTE: The term *CORE* (written in capitals) refers to the internal block of Ethernet peripheral. Do not confuse the term with the *processor core*.

Table 31-28: EMAC CORE Related Registers

Register Name	Description
MAC Configuration*1	Establishes receive and transmit operating modes including: • Watchdog, Jabber, and Jumbo frame sizes • Inter Frame Gap • Speed Control – 10/100/1000 Mbps • Full or Half Duplex • Loopback Mode • Checksum Offload • Enabling Tx or Rx Engines

Table 31-28: EMAC CORE Related Registers (Continued)

Register Name	Description
MAC Frame Filter	Contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as pass bad frames and pass control frames.
Hash Table High/Low[1]	A 64-bit hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame passes through the CRC logic. The upper 6 bits of the CRC register index the contents of the hash table.
SMI Address[1]	Controls the management cycles to the external PHY through the Station Management interface. The register also includes a field to program the frequency of MDC.
SMI Data[1]	Stores write data for the PHY register at the address specified in SMI Address register. This register also stores read data from the PHY register at the address specified by SMI address register.
Flow Control[1]	Controls the generation and reception of the control (pause command) frames by the flow control module of the EMAC. The fields of the control frame are selected as specified in the 802.3x specification. The EMAC uses the pause time value from this register in the pause time field of the control frame. The host must make sure that the activate bit is cleared before writing to the register.
VLAN Tag[1]	Contains the IEEE 802.1Q VLAN tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (length or type) with 16.h8100. The following 2 bytes are compared with the VLAN tag. If a match occurs, it sets the received VLAN bit in the receive frame status. The legal length of the frame increases from 1518 bytes to 1522 bytes.
Debug	Provides the status of all main modules of the transmit and receive datapaths and the FIFOs. An all-zero status indicates that the MAC core is in idle state (and FIFOs are empty) and no activity exists in the datapaths.
Interrupt Status	The contents of this register identify the events in the EMAC-CORE that can generate MMC and PTP-related interrupts.
Interrupt Mask	Enables the program to mask the interrupt signal because of the corresponding PTP event in the interrupt status register.
MAC Address0 High/Low[1]	Holds the upper or lower 16 bits of the MAC address of the station. The first DA byte that is received on the RMII interface corresponds to the LS byte (bits [7:0]) of the MAC address low register. For example, if 0x112233445566 is received (0x11 is the first byte) on the RMII as the destination address, then the macaddress0 register [47:0] is compared with 0x665544332211.
Operation Mode[1]	

*1 There must not be any further writes to these registers until the first write updates. Otherwise, the second write operation is not updated properly. For correct operation, the delay between two writes to the same register location must be at least 8 cycles of 50MHz RMII REFCLK.

NOTE: Refer to the “Register Description” section for the detailed bit-level explanation of the registers.

EMAC CORE Transmission Engine

The following modules constitute the transmission function (transmission engine components) of the EMAC:

- Transmit Bus Interface Module (TBU)
- Transmit Frame Controller Module (TFC)
- Transmit Checksum Offload Engine (TCOE)
- Transmit Protocol Engine Module (TPE)
- Transmit Scheduler Module (STX)
- Transmit CRC Generator Module (CTX)
- Transmit Flow Control Module (FTX)

Transmit Bus Interface Module (TBU)

This module interfaces the transmit path of the EMAC CORE with the MAC Layer FIFO interface. This module outputs the transmit status to the application at the end of normal transmission or collision.

Transmit Frame Controller Module (TFC)

The transmit frame controller regulates frames as well as converts the 32-bit input data into an 8-bit stream.

When the number of bytes received from the application falls below 60 (DA+SA+LT+DATA), the state machine automatically appends zeros to the transmitting frame. The state machine makes the data length exactly 46 bytes to meet the requirement for minimum data field of IEEE 802.3. The EMAC module can also be programmed to not append any padding.

The frame controller receives the computed CRC and appends it as the FCS field to the data transmitting out. When the EMAC is programmed to not append the CRC value to the end of Ethernet frames, the TFC module ignores the computed CRC. However, when the EMAC is programmed to append pads for frames (DA+SA+LT +DATA) less than 60 bytes, then the CRC is always appended at the end of padded frame.

Transmit Checksum Offload Engine (TCOE)

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the EMAC has a checksum offload engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path.

NOTE: The checksum for TCP, UDP, or ICMP is calculated over a complete frame, and then inserted into its corresponding header field. Because of this requirement, this function is enabled only when the transmit FIFO configuration is for store-and-forward mode. (The `EMAC_DMA0_OPMODE.TSF` bit is set.) If the MAC configuration is for threshold (cut-through) mode, the transmit COE is bypassed.

NOTE: Programs must make sure that the transmit FIFO is deep enough to store a complete frame before that frame transfers to the EMAC CORE transmitter. The program must enable the checksum insertion only in the frames that are less than the following number of bytes in size (even in the store-and-forward mode):

FIFO depth – PBL – 3 FIFO locations, where PBL is the programmed burst-length in the DMA bus mode register.

IP Header Checksum

In IPv4 datagrams, the 16-bit header checksum field indicates the integrity of the header fields (bytes 11 and 12 of the IPv4 datagram). The COE detects an IPv4 datagram when the Ethernet type field of the frame has the value 0x0800 and the version field of the IP datagram has the value 0x4. The checksum field of the input frame is ignored during calculation and replaced with the calculated value.

The IP header error status bit in transmit descriptor word TDES0 indicates the result of this IP header checksum calculation. The status bit is set whenever the values of the Ethernet type field and the IP header version field are not consistent. Or, the status bit is set when the Ethernet frame does not have enough data, as indicated by the IP header length field. In other words, this bit is set when an IP header error is asserted under the following circumstances.

For IPv4 datagrams:

- The received Ethernet type is 0x0800, but the version field of the IP header is not equal to 0x4.
- The IPv4 header length field indicates a value less than 0x5 (20 bytes).
- The total frame length is less than the value given in the IPv4 header length field.

For IPv6 datagrams:

- The Ethernet type is 0x86dd but the IP header version field is not equal to 0x6.
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding header length field in an extension header) is received.

If the COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload.

NOTE: IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

TCP/UDP/ICMP Checksum

The TCP/UDP/ICMP checksum engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP.

NOTE: See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

NOTE: For non-TCP/UDP/ICMP/ICMPv6 payloads, this checksum engine is bypassed and nothing further is modified in the frame.

NOTE: For ICMP-over-IPv4 packets, the checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum can be inserted into the packet.

NOTE: This engine does not process fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an encapsulated security payload), and IPv6 frames with routing headers. The checksum engine bypasses the checksum insertion for such frames even if the checksum insertion is enabled.

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. This engine can work in the following two ways.

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the checksum field of the input frame. This engine includes the checksum field in the checksum calculation, and then replaces the checksum field with the final calculated checksum.
- The engine ignores the checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

The status bit for the payload checksum error in the transmit descriptor word TDES0 indicates the result of this operation. The checksum engine sets the status bit for the payload checksum error when:

- The checksum engine detects that the frame has been forwarded to the MAC transmitter engine in the store-and-forward mode, *and*
- The end of frame (EOF) has not been written to the FIFO, *or*
- The packet ends before the number of bytes indicated by the payload length field in the IP header is received.

When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When the engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Transmit checksum offloading is enabled by setting the CIC bits [23:22] of TDES0 word in the transmit descriptor.

Transmit Protocol Engine Module (TPE)

The transmit protocol engine consists of a state-machine that controls the protocol-level operation of Ethernet frame transmission. The module performs the following functions to meet the IEEE 802.3 specifications.

- Generates preamble and SFD
- Generates carrier extension in half-duplex mode (only in RGMII mode)
- Supports frame bursting in half-duplex mode (only in RGMII mode)
- Generates jam pattern in half-duplex mode
- Contains time stamp snapshot logic for IEEE 1588 support
- Jabber timeout
- Flow control for half-duplex mode (back pressure)
- Generates transmit frame status

When a new frame transmission is requested, the protocol engine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 10101010 pattern. The SFD is defined as 1 byte of 10101011 pattern.

The collision window is defined as 1 slot time (512-bit times for 10/100 Mbps and 4096 bit times for 1000 Mbps). The jam pattern generation is applicable only to half-duplex mode, not to full-duplex mode. A collision can occur any time from the beginning of the frame to the end of the CRC field. When a collision happens, the state machine sends a 32-bit jam pattern of 0x55555555 on the RMII/RGMII. The pattern informs all other stations that a collision has occurred. If the collision happens during the preamble transmission phase, it completes the transmission of preamble and SFD and then sends the jam pattern. If the collision occurs after the collision window and before the end of the FCS field, it sends a 32-bit jam pattern. It also sets the late collision bit in the transmit frame status.

In RGMII half-duplex mode (1,000 Mbps), the transmit state machine ensures that all valid carrier events exceed a slot time of 4,096 bit times. To accomplish this, any transmit frame shorter than 512 bytes from the TFC module is extended using a carrier extension. This is signaled to the PHY using RGMII_TXCTL pin and sending 0x00 through RGMII_TXD.

The module maintains a jabber timer to cut off the transmission of Ethernet frames when the TFC module transfers more than 2,048 (default) bytes. The timeout changes to 10,240 bytes when the jumbo frame is enabled.

The transmit state machine uses the deferral mechanism for the flow control (back pressure) in half-duplex mode. When the application asks to stop receiving frames, the module sends a jam pattern of 32 bytes. It sends the pattern whenever it senses a reception of a frame. Transmit flow control must be enabled. This activity results in a collision and the remote station backs off.

The application can request a flow control signal by setting the `EMAC_FLOWCTL.FCBBPA` bit. If the application requests a frame transmission, then it is scheduled and transmitted even when the back pressure is activated. If the back pressure is activated for a long time, then the remote stations abort their transmissions due to excessive collisions. (For example, a long time is when more than 16 consecutive collision events occur.)

If PTP time stamping is enabled for the transmit frame, this block takes a snapshot of the PTP system time when the SFD is put onto the transmit bus.

Transmit Scheduler Module (STX)

The transmit scheduler is responsible for scheduling the frame transmission on the RMII/RGMII . The two major functions of this module are:

- Maintain the inter-frame gap between two transmitted frames.
- Follow the truncated binary exponential back-off algorithm for half-duplex mode.

The scheduler maintains an idle period of the configured inter-frame gap (`EMAC_MACCFG.IFG` bits) between any two transmitted frames. The scheduler starts its IFG counter when the carrier signal of the reduced media-independent interface goes inactive. In half-duplex mode and when IFG is configured for 96-bit times, the scheduler follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3 specification. The module resets its IFG counter when a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the carrier is detected during the final one third of the IFG interval, the scheduler continues the IFG count and enables the transmitter after the IFG interval.

Transmit CRC Generator Module (CTX)

The transmit CRC generator module generates the CRC for the FCS field of the Ethernet frame (DA + SA + LT + DATA + PAD).

This module calculates the 32-bit CRC for the FCS field of the Ethernet frame. The following polynomial defines the encoding:

$G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1.$

Transmit Flow Control Module (FTX)

The transmit flow control module generates pause frames and transmits them to the frame controller as necessary, in full-duplex mode. The application can request the flow control module to send a pause frame by setting the `EMAC_FLOWCTL.FCBBPA` bit.

If the application has requested flow control, the flow control module generates and transmits a single pause frame. The value of the pause time in the generated frame contains the programmed pause time value configured using the `EMAC_FLOWCTL.PT` bit. The module can extend the pause or end the pause prior to the time specified in the previously transmitted pause frame. To change the pause, the application must request another pause frame transmission after programming the `EMAC_FLOWCTL.PT` bit with an appropriate value.

If the flow control signal goes inactive prior to the sampling time, the flow control module transmits a pause frame with zero pause time. This event indicates to the remote end that the receive buffer is ready to receive new data frames.

Source Address, VLAN, and CRC Insertion, Replacement, or Deletion

The MAC supports the following functions for transmit frames:

- Source address insertion or replacement
- VLAN insertion, replacement, or deletion
- CRC replacement

Source Address Insertion or Replacement

The software can use the SA insertion or replacement feature to instruct the MAC to do the following for transmit frames:

- Insert the content of the MAC address registers in the SA field.
- Replace the content of the SA field with the content of the MAC address registers.

The software can enable the SA insertion or replacement feature for all transmit frames or selective frames.

- To enable SA insertion or replacement feature for all frames, program bits[30:28] of the MAC Configuration register.

- To enable the SA insertion or replacement feature for selective frames, program the SA insertion control field (TDES1 Bits [31:29]) in the first transmit descriptor of the frame. When bit 31 of TDES1 is set, the SA insertion control field indicates insertion or replacement by MAC address1 registers. When bit 31 of TDES1 is reset, it indicates insertion or replacement by MAC address 0 registers. If MAC address1 registers are not enabled, then EMAC uses MAC address0 registers for insertion or replacement. The choice is not based on the value of the most significant bit of the SA insertion control field.

When SA insertion is enabled, the application ensures that the frames sent to the MAC do not have the SA field. This functionality is because the MAC does not check the presence of SA field in the transmit frame. MAC inserts the content of the MAC address registers in the SA field. Similarly, when SA replacement is enabled, the application ensures that frames sent to the MAC have the SA field. The MAC replaces the 6 bytes, following the destination address field in the transmit frame, with the content of the MAC address registers.

VLAN Insertion, Replacement, or Deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for transmit frames:

- Insert or replace the VLAN type field (C-VLAN or S-VLAN indicated by bit 19 (CSVL) of VLAN tag inclusion or replacement register and VLAN tag field in the transmit frame with bit [15:0], VLT, of VLAN tag inclusion or replacement register.
- Delete the VLAN type and VLAN tag fields in transmit frame.

The software can enable the VLAN insertion, replacement, or deletion feature for all transmit frames or selective frames. To enable this function for all transmit frames, program Bits[17:16] of the VLAN Tag Inclusion or Replacement register. To enable this function for selective, program the VLAN insertion control field (TDES0 Bits [19:18]) in the first transmit descriptor of the frame. When VLAN replacement or deletion is enabled, the MAC checks the presence of the VLAN type field (0x8100 or 0x88a8), after the Destination Address (DA) and SA fields, in the transmit frame. The replace or delete operation does not occur when the VLAN type field is not detected in the 2 bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN type field in the transmit frame. MAC inserts the VLAN type and VLAN tag fields.

CRC Replacement

The software can use the CRC replacement feature to instruct the MAC to replace the FCS field in the transmit frame with the CRC computed by the MAC. This feature works on per-frame basis. To enable the CRC replacement feature, program the CRC replacement control field (bit 24 of transmit descriptor word 0 (TDES0)) in the first transmit descriptor of the frame.

NOTE: This feature is valid only when disable CRC control (bit 27 in TDES0) is enabled. The software provides the FCS field in the transmit frame. If SA or VLAN insertion control is enabled, the MAC appends or replaces the FCS field with the computed CRC when Disable CRC Control is enabled or disabled, respectively.

The ***CRC Replacement*** table shows how CRC replacement is performed based on the values of bit 27 (DC) and bit 24 (CRCR) of transmit descriptor word 0 (TDES0).

Table 31-29: CRC Replacement

DC	CRCR	Description
0	x	Append CRC. When DC = 0, the MAC appends the computed CRC irrespective of the CRCR setting.
1		Replace CRC
1	0	No operation (User has appended the CRC)

Source Address Filtering

The ***Source Address Filtering*** table provides filtering possibilities for the source address using the EMAC AFM module. The MAC receive frame filter register (`EMAC_MACFRMFILT`) contains these bits.

Table 31-30: Source Address Filtering

	SA Filter Operation			
Frame Type	PR	SAIF	SAF	Result
Unicast	1	X	X	Pass all frames
	0	0	0	Pass on perfect or group filter match but do not drop failing frames
	0	1	0	Fail on perfect or group filter match but do not drop frame
	0	0	1	Pass on perfect or group filter match and drop failing frames
	0	1	1	Fail on perfect or group filter match and drop failing frames

EMAC CORE Reception Engine

The following are the functional blocks (reception engine components) in the receive path of the EMAC core.

- Receive Protocol Engine Module (RPE)
- Receive CRC Module (CRX)
- Receive Frame Controller Module (RFC)
- Receive Flow Control Module (FRX)
- Receive Checksum Offload Engine (RCOE)
- Receive Bus Interface Unit Module (RBU)
- Address Filtering Module (AFM)

Receive Protocol Engine Module (RPE)

The receive protocol engine is a state-machine that strips the preamble, SFD, and carrier extension (in 1000 Mbps half-duplex mode) of received frame. Once the receive data valid signal (`ETH0_CRS/ETH1_CRS` signal of RMII or

RXCTL signal of RGMII) becomes active, the protocol engine begins hunting for the SFD field from the receive modifier logic. Until then, the state machine drops the receiving preambles. Once the SFD is detected, it begins sending the data of the Ethernet frame to the frame controller, beginning with the first byte following the SFD (destination address).

NOTE: According to the IEEE 802.3 Ethernet specifications, the EMAC receiver does not need to look or check for the preamble pattern. It has to wait only for the SFD pattern to identify the start of a frame. Then the EMAC receiver accepts a frame even when no preamble is received before the SFD pattern.

If PTP time stamping is enabled, the RPE takes a snapshot of the PTP system time when detecting any SFD of the frame on the reduced media-independent interface. Unless the MAC filters out and drops the frame, this time stamp passes on to the application

The protocol engine also decodes the length or type field of the receiving Ethernet frame. The state machine sends the data of the frame up to the count specified in the length or type field if these conditions are met:

- The length or type field is less than 0x600
- The MAC is programmed for the auto CRC or PAD stripping option

It then starts dropping bytes (including the FCS field).

If the length or type field is greater than or equal to 0x600, the protocol engine sends all received Ethernet frame data to the frame controller. The transfer does not depend on the value of the programmed auto-CRC strip option.

The EMAC is programmed with the watchdog timer enabled (default setting). In this configuration, frames above 2,048 (10,240 if jumbo frame is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the protocol engine. Set the `EMAC_MACCFG.WD` bit to disable this feature. However, even when the watchdog timer is disabled, frames greater than 16 KB are cut off and a watchdog timeout status is issued.

The EMAC supports loopback of transmitted frames onto its receiver. By default, the EMAC loopback function is disabled. Set the `EMAC_MACCFG.LM` bit to enable the function.

At the end of every received frame, the protocol engine generates received frame status and sends it to the frame controller. Control, missed frame, and filter fail status are added to the receive status in the frame controller.

Receive CRC Module (CRX)

The receive CRC module checks for any CRC errors in the receiving frame.

This module calculates the 32-bit CRC for the received frame that includes the destination address field through the FCS field (DA+SA+LT+DATA+PAD+FCS). The following generating polynomial defines the encoding.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

Irrespective of the auto pad or CRC strip, the CRC module receives the entire frame to compute the CRC check for received frame.

Receive Frame Controller Module (RFC)

The main functions of the frame controller are:

- Converting the 8-bit stream data to 32-bit data
- Frame filtering
- Attaching the calculated IP checksum
- Updating the receive status

If the `EMAC_MACFRMFILT.RA` bit is set, the RFC module initiates the data transfer as soon as possible. At the end of the data transfer, the frame controller sends out the received frame status that includes the address filtering pass or fail status.

If the `EMAC_MACFRMFILT.RA` bit is reset, the frame controller performs frame filtering based on the destination or source address. (The application still must perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, for example.) After receiving the destination or source address bytes, the frame controller checks the filter-fail signal from the AFM module for an address match. On detecting a filter-fail from AFM, the frame is dropped and not transferred to the application.

Receive Flow Control Module (FRX)

The receive flow controller detects the receiving pause frame and pauses the frame transmission for the delay specified within the received pause frame. The flow controller is enabled only in full-duplex mode. The EMAC uses the `EMAC_FLOWCTL.RFE` bit to enable or disable the function for pause frame detection.

Once the receive flow control is enabled, the flow controller begins monitoring the received frame destination address for any match with the multicast address of the control frame (0x0180C2000001). If a match is detected, it indicates to the frame controller, that the destination address of the received frame matches the reserved control frame destination address. The RFC module then decides whether to transfer the received control frame to the application, based on the `EMAC_MACFRMFILT.PCF` bit setting.

The receive flow controller also decodes the type, opcode, and pause timer field of the receiving control frame. The flow controller requests the MAC transmitter pause the transmission of any data frame.

- If the byte count of the frame status indicates 64 bytes, ***and***
- If there is no CRC error

The transmission is paused for the decoded pause time value, multiplied by the slot time (64-byte times). Meanwhile, if another pause frame is detected with a zero pause time value, the module resets the pause time and gives another pause request to the transmitter. The module does not generate a pause request to the transmitter:

- If the received control frame does not match the type field (0x8808), opcode (0x00001), or byte length (64 bytes), ***or***
- If there is a CRC error

For a pause frame with a multicast destination address, the frame controller filters the frame based on the address match from the flow controller. For a pause frame with a unicast destination address, the filtering in the FRX module depends on:

- If the destination address matched the contents of the MAC address register 0 (`EMAC_ADDR0_HI` or `EMAC_ADDR0_LO`), ***and***
- If the `EMAC_FLOWCTL.UP` bit is set

The module detects a pause frame even with a unicast destination address. The EMAC uses the `EMAC_MACFRMFILT.PCF` bits to control the filtering for control frames in addition to the address filter module.

Receive Checksum Offload Engine (RCOE)

When checksum offloading is enabled, both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. Programs can enable this module by setting the `EMAC_MACCFG.IPC` bit. The EMAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet type field of frames. This identification applies to VLAN-tagged frames as well. *Extended descriptor mode (8 x32-bit words) must be enabled to get the IPC checksum engine status in RDES4.* To check status, poll bit 0 of RDES0 word of receive descriptor. Then, if this bit is set, parse bits [7:0] of RDES4 word.

The receive checksum offload engine calculates IPv4 header checksums and checks if they match the received IPv4 header checksums. The IP header error bit is set for any mismatch between the indicated payload type (Ethernet type field) and the IP header version. The IP header error bit is also set when the received frame does not have enough bytes, as indicated by the length field of the IPv4 header. (The bit is set when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6). The engine calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation appears as a payload checksum error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not tally to the expected payload length given in the IP header.

NOTE: The COE engine bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP, or ICMP. This information is given in the receive status(whether the checksum engine is bypassed or not).

The ***Checksum Error Status*** table shows bit combination in receive descriptors (frame status with full checksum offload engine enabled and advanced timestamps not enabled).

Table 31-31: Checksum Error Status

IEEE802.3 Frame: bit 5 of RDES0	Header Checksum Error (HCE): bit 3 of RDES4	Payload Checksum Error (PCE): bit 4 of RDES4	Frame Status
0	0	0	The frame is an IEEE 802.3 frame (length field value is less than 0x0600).
1	0	0	IPv4/IPv6 type frame in which no checksum error is detected.

Table 31-31: Checksum Error Status (Continued)

IEEE802.3 Frame: bit 5 of RDES0	Header Checksum Error (HCE): bit 3 of RDES4	Payload Checksum Error (PCE): bit 4 of RDES4	Frame Status
1	0	1	IPv4/IPv6 type frame in which a payload checksum error (as described for PCE) is detected
1	1	0	IPv4/IPv6 type frame in which IP header checksum error (as described for IPC HCE) is detected.
1	1	1	IPv4/IPv6 type frame in which both PCE and IPC HCE is detected.
0	0	1	IPv4/IPv6 type frame in which there is no IP HCE and the payload check is bypassed due to unsupported payload.
0	1	1	Type frame which is neither IPv4 or IPv6 (COE bypasses the checksum check completely)
0	1	0	Reserved

Receive Bus Interface Unit Module (RBU)

The receive bus interface unit (RBU) constructs the 32-bit data received from the frame controller into a 32-bit FIFO-based protocol.

Address Filtering Module (AFM)

The address filtering (AFM) module performs the destination checking function on all received frames and reports the address filtering status to the frame controller. The address checking is based on different parameters (frame filter register, `EMAC_MACFRMFILT`) chosen by the application. These parameters are inputs to the AFM module as control signals. The AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module also reports whether the receiving frame is a multicast frame or a broadcast frame, as well as the address filter status. The AFM module uses the physical (MAC) address of the station and the multicast hash table for address checking.

- *Hash or Perfect Address Filter.* The destination address filter can be configured to pass a frame when its destination address matches either the hash filter or the perfect filter. Set the `EMAC_MACFRMFILT.HPF` bit, the corresponding `EMAC_MACFRMFILT.HUC`, or `EMAC_MACFRMFILT.HMC` bits. This configuration applies to both unicast and multicast frames. If the `EMAC_MACFRMFILT.HPF` bit is reset, only one of the filters (hash or perfect) is applied to the received frame.

  NOTE: Hash filtering is not perfect filtering because a 48-bit MAC address is reduced to a 6-bit hash value. So, there can be instances where more than one address has the same hash value.

- *Unicast Destination Address Filter.*
  - The AFM supports one MAC address two MAC addresses for unicast perfect filtering. If perfect filtering is selected, the AFM compares all 48 bits of the received unicast address with the programmed MAC address for any match. (The `EMAC_MACFRMFILT.HUC` bit is reset for perfect filtering).

  - In hash filtering mode, the AFM performs imperfect filtering for unicast addresses using a 64-bit hash table. (The `EMAC_MACFRMFILT.HUC` bit is set in hash filtering mode.) For hash filtering, the AFM uses the upper 6-bit CRC of the received destination address to index the content of the hash table. A value of 000000 selects bit 0 of the selected register, and a value of 111111 selects bit 63 of the hash table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast frame has passed the hash filter. Otherwise, the frame has failed the hash filter.
- *Multicast Destination Address Filter.*
  - Program the EMAC to pass all multicast frames by setting the `EMAC_MACFRMFILT.PM` bit. If the `EMAC_MACFRMFILT.PM` bit is reset, the AFM filters multicast addresses based on the `EMAC_MACFRMFILT.HMC` bit. In perfect filtering mode, the multicast address is compared with the programmed MAC destination address register. The EMAC also supports group address filtering.
  - In hash filtering mode, the AFM performs imperfect filtering using a 64-bit hash table. For hash filtering, the AFM uses the upper 6-bit CRC of the received multicast address to index the content of the hash table. A value of 000000 selects bit 0 of the selected register and a value of 111111 selects bit 63 of the hash table register. If the corresponding bit is set to 1, then the multicast frame has passed the hash filter. Otherwise, the frame has failed the hash filter.
- *Broadcast Address Filter.* The AFM does not filter any broadcast frames in the default mode. However, if the EMAC is programmed to reject all broadcast frames by setting the `EMAC_MACFRMFILT.DBF` bit, the AFM asserts the filter fail signal, whenever a broadcast frame is received.
- *Unicast Source Addrress Filter.* EMAC can also perform a perfect filtering, based on the source address field of the received frames. By default, the AFM compares the SA field with the values programmed in the SA registers. The MAC address register 1 can be configured to contain SA instead of DA for comparison, by setting bit 30 of the corresponding register. Group filtering with SA is also supported. User can filter a group of addresses by masking one or more bytes of the address. The frames that fail the SA filter are dropped by the MAC if the `EMAC_MACFRMFILT.SAF` bit is set. When the bit is set, the result of SA filter and DA filter is AND'ed to decide whether the frame needs to be forwarded. This means that either of the filter fail result drops the frame and both filters have to pass in order to forward the frame to the application.
- *Inverse Filtering Operation.* There is an option to invert the filter-match result at the final output. The EMAC uses the `EMAC_MACFRMFILT.DAIF` bit to control this operation. The function of this bit applies to both unicast and multicast DA frames. The result of the unicast or multicast destination address filter is inverted in this mode.
- *Inverse Filtering Operation.* For both destination and source address filtering, there is an option to invert the filter-match result at the final output. This is controlled by the `EMAC_MACFRMFILT.DAIF` or `EMAC_MACFRMFILT.SAIF` bits. The `EMAC_MACFRMFILT.DAIF` bit is applicable for both unicast and multicast DA frames. The result of the unicast /multicast destination address filter is inverted in this mode. Similarly, when the `EMAC_MACFRMFILT.SAIF` bit is set, the result of unicast source address filter is reversed.

- ***Inverse Filtering Operation.*** There is an option to invert the filter-match result at the final output. The EMAC uses the `EMAC_MACFRMFILT.DAIF` bit to control this operation. The function of this bit applies to both unicast and multicast DA frames. The result of the unicast or multicast destination address filter is inverted in this mode.

Destination Address Filtering

The ***Destination Address Filtering*** table provides filtering possibilities for the destination address using the EMAC AFM module. The MAC receive frame filter register (`EMAC_MACFRMFILT`) contains these bits.

Table 31-32: Destination Address Filtering

Frame Type	Bit Setting (0 = Cleared, 1 = Set, X = Do-not-care)							DA Filter Operation
	PR	HPF	HUC	HMC	DAIF	PM	DBF	
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames
	0	X	0	X	0	X	X	Pass on perfect or group filter match
	0	X	0	X	1	X	X	Fail on perfect or group filter match
	0	0	1	X	0	X	X	Pass on hash filter match
	0	0	1	X	1	X	X	Fail on hash filter match
	0	1	1	X	0	X	X	Pass on hash or perfect or group filter match
	0	1	1	X	1	X	X	Fail on hash or perfect or group filter match
Multicast	1	X	X	X	X	X	X	Pass all frames
	X	X	X	X	X	1	X	Pass all frames
	0	X	X	0	0	0	X	Pass on perfect or group filter match and drop PAUSE control frames if PCF = 0x
	0	0	X	1	0	0	X	Pass on hash filter match and drop PAUSE control frames if PCF = 0x
	0	1	X	1	0	0	X	Pass on hash or perfect or group filter match and drop PAUSE control frames if PCF = 0x

Table 31-32: Destination Address Filtering (Continued)

Frame Type	Bit Setting (0 = Cleared, 1 = Set, X = Do-not-care)							DA Filter Operation
	PR	HPF	HUC	HMC	DAIF	PM	DBF	
	0	X	X	0	1	0	X	Fail on perfect or group filter match and drop PAUSE control frames if PCF = 0x
	0	0	X	1	1	0	X	Fail on hash filter match and drop PAUSE control frames if PCF = 0x
	0	1	X	1	1	0	X	Fail on hash or perfect or group filter match and drop PAUSE control frames if PCF = 0x

Source Address Filtering

The *Source Address Filtering* table provides filtering possibilities for the source address using the EMAC AFM module. The MAC receive frame filter register (`EMAC_MACFRMFILT`) contains these bits.

Table 31-33: Source Address Filtering

Frame Type	SA Filter Operation			Result
	PR	SAIF	SAF	
Unicast	1	X	X	Pass all frames
	0	0	0	Pass on perfect or group filter match but do not drop failing frames
	0	1	0	Fail on perfect or group filter match but do not drop frame
	0	0	1	Pass on perfect or group filter match and drop failing frames
	0	1	1	Fail on perfect or group filter match and drop failing frames

VLAN Tag Based Filtering

EMAC0 supports VLAN tag perfect filtering and VLAN tag hash filtering.

VLAN Tag Perfect Filtering

In VLAN tag perfect filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status. It drops the VLAN frames that do not match. Inverse matching for VLAN frames can be enabled using the `EMAC_VLANTAG.VTIM` bit. In addition, matching of S-VLAN tagged frames along with the default C-VLAN tagged frames can be enabled using `EMAC_VLANTAG.ESVL` bit. The VLAN frame status bit (Bit 10 of RDES0) indicates the VLAN tag match status for the matched frames.

NOTE: The source or destination address (if enabled) has precedence over the VLAN tag filters. A frame which fails the source or destination address filter is dropped irrespective of the VLAN tag filter results. By default, the VLAN tag-based perfect filter is available in all configurations.

VLAN Tag Hash Filtering

The MAC provides VLAN tag hash filtering with a 16-bit hash table. The MAC performs the VLAN hash matching based on the `EMAC_VLANTAG.VTHM` bit setting. If the `EMAC_VLANTAG.VTHM` bit is set, the most significant 4 bits of VLAN tag's CRC-32 are used to index the content of the VLAN hash table register (`EMAC_VLAN_HSHTBL`). A value of 1 in the `EMAC_VLAN_HSHTBL` register, corresponding to the index, indicates that the VLAN tag of the frame matched and the packet is forwarded. A value of 0 indicates that VLAN-tagged frame is dropped.

The MAC also supports the inverse matching of the VLAN frames. In the inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet is dropped. If the VLAN perfect and VLAN hash match are enabled, a frame matches if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch. The ***VLAN Matching and Final VLAN Match Status*** table shows the possibilities for VLAN matching and the final VLAN match status. When the `EMAC_MACFRMFILT.RA` bit is set, all frames are received and the VLAN match status is indicated in bit 10 of receive descriptor word 0 (RDES0). When the `EMAC_MACFRMFILT.RA` bit is not set and the `EMAC_MACFRMFILT.VTFE` bit register is set, the frame is dropped when the final VLAN match status is fail.

When VLAN VID is programmed to 0 in the `EMAC_VLANTAG.VL` bit field, all VLAN-tagged frames are perfect matches. But the status of the VLAN hash match depends on the VLAN hash enable bit and VLAN inverse filter bit. The ***VLAN Matching and Final VLAN Match Status*** table shows the possibilities for VLAN matching and the final VLAN match status.

Table 31-34: VLAN Matching and Final VLAN Match Status

VID	VLAN Perfect Filter Match Status (VPF)	VLAN Hash Enable Bit	VLAN Hash filter Match Status (VTHMS)	VLAN Inverse Filter Bit (VTIM)	Final VLAN Match Status
VID=0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!=0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail

Table 31-34: VLAN Matching and Final VLAN Match Status (Continued)

VID	VLAN Perfect Filter Match Status (VPF)	VLAN Hash Enable Bit	VLAN Hash filter Match Status (VTHMS)	VLAN Inverse Filter Bit (VTIM)	Final VLAN Match Status
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

Layer 3 and Layer 4 Frame Filtering

The MAC supports Layer 3 and Layer 4 based frame filtering. The Layer 3 filtering refers to the IP source or destination address filtering in the IPv4 or IPv6 frames whereas Layer 4 filtering refers to the source or destination port number filtering in TCP or UDP. The Layer 3 and Layer 4 frame filtering feature automatically enables the IPC full checksum offload engine on the receive side.

When Layer 3 and Layer 4 filtering is enabled, the frames are filtered in the following way:

Matched Frames. The MAC forwards the frames, which match all enabled fields, to the application along with the status. The MAC gives the matched field status only if the `EMAC_MACCFG.IPC` bit is set. The MAC forwards the frames, which match all enabled fields, to the application along with the status.

> **NOTE:** The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filtering. This means that a frame which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

Unmatched Frames. The MAC drops the frames that do not match any of the enabled fields. You can use the inverse match feature to block or drop a frame with specific TCP or UDP over IP fields and forward all other frames. If the Rx FIFO operates in the threshold mode and threshold is programmed to a small value, such that frame transfer to application starts before the failed Layer 3 and Layer 4 filter results are available, a partial frame with appropriate abort status may be received by the application.

Non-TCP or UDP IP Frames. By default, all non-TCP or UDP IP frames are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP frames.

Layer 3 and Layer 4 Filters Register Set

The MAC implements a set of registers for Layer 3 and Layer 4 based frame filtering. In a register set, there is a control register, such as the `EMAC_L3L4_CTL` register (Layer 3 and Layer 4 control register), to control the frame filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, which are:

- `EMAC_L4_ADDR` (Layer 4 Address Register)
- `EMAC_L3_ADDR0` (Layer 3 Address 0 Register)
- `EMAC_L3_ADDR1` (Layer 3 Address 1 Register)
- `EMAC_L3_ADDR2` (Layer 3 Address 2 Register)

- `EMAC_L3_ADDR3` (Layer 3 Address 3 Register)

Layer 3 Filtering

The MAC supports perfect matching or inverse matching for IP source and destination address. In addition, a program can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 frames filtering, programs can enable the last four data registers of a register set to contain the 128-bit IP source or IP destination address. Program the IP source or destination address in the order defined in the IPv6 specification, that is, the first byte of the IP source or destination address in the received frame is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 frames filtering, a program can enable the second and third data registers of a register set to contain the 32-bit IP source address and IP destination address. The remaining two data registers are reserved. Program the IP source and destination address in the order defined in the IPv4 specification, that is, the first byte of IP source and destination address in the received frame in the higher byte of the respective register.

Layer 4 Filtering

The MAC supports perfect matching or inverse matching for TCP or UDP source and destination port numbers. Only one type (TCP or UDP) is programmable at a time. The first data register contains the 16-bit source and destination port numbers of TCP or UDP, that is, the lower 16 bits for source port number and higher 16 bits for destination port number. Program the TCP or UDP source and destination port numbers in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP source and destination port number in the received frame is in the higher byte of the register.

EMAC Station Management Interface (SMI)

The IEEE 802.3 MII station management interface, also known as the MDIO management interface, allows the processor to monitor and control one or more external Ethernet physical-layer transceivers. (Physical-layer transceivers are commonly called PHYs). The management interface physically consists of a 2-wire serial connection composed of the MDC (management data clock) output signal and the MDIO (management data input/output) bidirectional data signal. The IEEE 802.3 MII station management interface also applies to RMII and RGMII.

The application can address only one register in the PHY in any given time and send control data or receive status information. All the transfers are initiated by the EMAC CORE, and the PHY chip only acts as a slave device.

Standard PHY control and status registers typically provide

- Device capability status bits (for example: auto-negotiation, duplex modes, 10/100 speeds, and protocols)
- Device status bits (for example: auto-negotiation complete, link status, remote fault)
- Device control bits (for example: reset, speed selection, loopback, and auto-negotiation start)

Upon power-up, an MDIO read access (at default rates) of device capabilities in PHY status registers can determine the supported PHY features.

The MII management logical interface specifies:

- A set of 16-bit device control or status registers within the PHYs, including both required registers with standardized bit definitions as well as optional vendor-specified registers.
- A 5-bit device addressing scheme which allows the MAC to select one of up to 32 externally connected PHY devices.
- A 5-bit register addressing scheme for selecting the target register within the addressed device.
- A transfer frame protocol for 16-bit read and write accesses to PHY registers through the MDC and MDIO signals under control of the MAC.

Table 31-35: Station Management Interface pins

Station Management Interface Pins	Pin Description
MDIO – Management Data I/O	A periodic clock that runs at a maximum period of 400 ns. Always driven by the EMAC to PHY.
MDC – Management Data Clock	Data signal driven by EMAC or PHY, depending on write or read access based on EMAC; synchronous to MDC.

MDC Clock Frequency

The EMAC uses the `EMAC_SMI_ADDR.CR` bit field to determine the frequency of MDC as shown in the ***MDC Clock Frequency Selection*** table. The clock range selection determines the frequency of the clock relative to the SCLK0_0 frequency. The table shows the suggested range of SCLK0_0 frequency applicable for each value of the `EMAC_SMI_ADDR.CR` field. The programmability based on SCLK0_0 frequency range ensures that the MDC clock frequency range is within the IEEE specifications of 1.0 MHz to 2.4 MHz. However, the EMAC MDC can also support higher frequencies for PHY devices that support the frequencies.

Table 31-36: MDC Clock Frequency Selection

`EMAC_SMI_ADDR.CR` Selection	Programmed SCLK0_0 Frequency Range	Frequency of MDC	Min and Max MDC Freq (Per Specifications)
0000	60–100 MHz	SCLK0_0/42	MIN = 1.43 MHz and MAX = 2.39 MHz
0010	20–35 MHz	SCLK0_0/16	MIN = 1.25 MHz and MAX = 2.19 MHz
0011	35–60 MHz	SCLK0_0/26	MIN = 1.35 MHz and MAX = 2.31 MHz

The ***MDIO Frame Parameters*** table provides MDIO data transfer parameters. The write and read sequences provided in the tables, ***MDIO Write Data Sequence*** and ***MDIO Read Data Sequence***, are based on these parameters.

Table 31-37: MDIO Frame Parameters

Parameter	Description
IDLE	The MDIO line is three-state (noted as Z in sequence); there is no clock on MDC.
PREAMBLE	32 continuous bits, each of value 1
START	Start of frame is 01
OPCODE	10 for read and 01 for write
PHY ADDR	5-bit address select for one of 32 PHYs (noted as AAAAA in sequence)
REG ADDR	Register address in the selected PHY (noted as RRRRR in sequence)
TA	Turnaround is Z0 for read and 10 for write (Z = high impedance)
DATA	Any 16-bit value. Driven by MAC or PHY based on direction (noted as DDD...DDD).

Table 31-38: MDIO Write Data Sequence

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	111...111	01	01	AAAAA	RRRRR	10	DDD...DDD	Z

Table 31-39: MDIO Read Data Sequence

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	111...111	01	10	AAAAA	RRRRR	Z0	DDD...DDD	Z

SMI Write Operation

When programs set the `EMAC_SMI_ADDR.SMIW` (write) and `EMAC_SMI_ADDR.SMIB` (busy) bits, the station management interface (SMI) initiates a write operation into the PHY registers. The write operation uses the management frame format (the PHY address, the register address in PHY, and the write data) specified in the IEEE specifications. (Section 22.2.4.5 of IEEE standard). The application must not change the `EMAC_SMI_ADDR` register contents or the `EMAC_SMI_DATA` register while the transaction is ongoing.

Write operations to the `EMAC_SMI_ADDR` register or the `EMAC_SMI_DATA` register during the transfer period are ignored (while the `EMAC_SMI_ADDR.SMIB` bit is high). The transaction completes without error. After the write operation has completed, the SMI indicates the same by resetting the `EMAC_SMI_ADDR.SMIB` bit. The EMAC drives the MDIO line for the complete duration of the frame. The ***SMI Write Operation through MDIO/MDC Pins*** figure shows this operation.

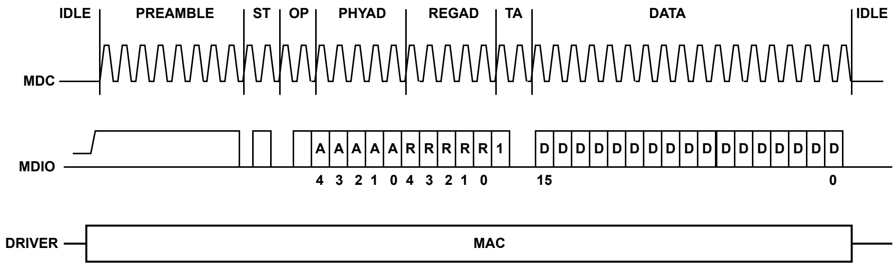

Figure 31-13: SMI Write Operation through MDIO/MDC Pins

SMI Read Operation

When programs set the `EMAC_SMI_ADDR.SMIB` bit with the `EMAC_SMI_ADDR.SMIW` bit cleared (=0), the station management interface (SMI) initiates a read operation in the PHY registers. It transfers the PHY address and the register address in the PHY to the SMI. The application must not change the `EMAC_SMI_ADDR` register contents or the `EMAC_SMI_DATA` register while the transaction is ongoing.

Write operations to the `EMAC_SMI_ADDR` register or the `EMAC_SMI_DATA` register during the transfer period are ignored (while the `EMAC_SMI_ADDR.SMIB` bit is high). The transaction completes without error. After the read operation has completed, the SMI resets the `EMAC_SMI_ADDR.SMIB` bit and updates the `EMAC_SMI_DATA` register with the data read from the PHY. The EMAC drives the MDIO line for the complete duration of the frame except during the data fields when the PHY drives the MDIO line. The ***SMI Read Operation through MDIO/MDC Pins*** figure shows this operation.

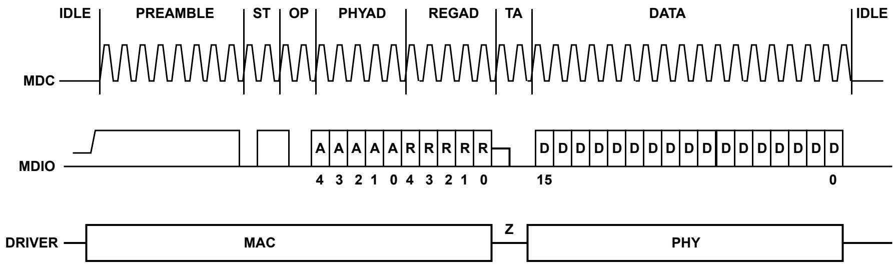

Figure 31-14: SMI Read Operation through MDIO/MDC Pins

EMAC Management Counters (MMC)

The EMAC provides a comprehensive set of 32-bit MAC management counters. It uses these counters for gathering statistics on the received and transmitted frames. The MMC subblock also includes

- A control register (`EMAC_MMC_CTL`) for managing the behavior of the counters
- Two 32-bit registers containing interrupts generated (`EMAC_MMC_RXINT` and `EMAC_MMC_TXINT`)
- Two 32-bit registers containing masks for the interrupt register (`EMAC_MMC_RXIMSK` and `EMAC_MMC_TXIMSK`)

The MMC receive counters are updated for frames passed by the address filtering subblock in the EMAC CORE. Statistics of frames dropped by the AFM module are not updated unless they are runt frames of less than 6 bytes. (Destination address bytes are not received fully.) The module is also capable of gathering statistics on encapsulated IPv4, IPv6, and TCP, UDP, or ICMP payloads in received Ethernet frames.

The MMC register naming conventions are as follows:

- Tx as a prefix or suffix indicates counters associated with transmission.
- Rx as a prefix or suffix indicates counters associated with reception.
- _G as a suffix indicates registers that count good frames only.
- _GB as a suffix indicates registers that count frames regardless of whether they are good or bad.

Transmitted frames are considered *good* when transmitted successfully. In other words, a transmitted frame is good if the frame transmission does not abort due to any of the following errors:

- Jabber timeout
- No carrier or loss of carrier
- Late collision
- Frame underflow
- Excessive deferral
- Excessive collision

Received frames are good when none of the following errors exists:

- CRC error
- Runt frame (shorter than 64 bytes)
- Alignment error
- Length error (non-type frames only)
- Out-of-range (non-type frames only, longer than maximum size)

The maximum frame size depends on the frame type, as follows:

- Untagged frame maxsize = 1518
- VLAN frame maxsize = 1522
- Jumbo frame maxsize = 9018
- Jumbo VLAN frame maxsize = 9022

The `EMAC_MMC_CTL` register also contains bits that control preset, freeze and roll-over of counters. The EMAC uses the `EMAC_MMC_CTL.RDRST` bit to enable an auto-reset feature whenever the counters are read. The EMAC uses the `EMAC_MMC_CTL.RST` bit to reset all the counters.

The MMC can trigger an interrupt when the corresponding bits are enabled in the transmit, receive, and IPC mask registers, and when the particular counter reaches half or full. The status is also updated in the corresponding interrupt register.

MMC Receive Interrupt Register

The `EMAC_MMC_RXINT` register maintains the interrupts that are generated when the receive statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When `EMAC_MMC_CTL.NOROLL` is set, then interrupts are set, but the counter remains at all ones. The `EMAC_MMC_RXINT` register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits 7:0) of the respective counter must be read to clear the interrupt bit.

MMC Transmit Interrupt Register

The `EMAC_MMC_TXINT` register maintains the interrupts generated when the transmit statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When `EMAC_MMC_CTL.NOROLL` is set, then interrupts are set, but the counter remains at all ones. The `EMAC_MMC_TXINT` register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits 7:0) of the respective counter must be read to clear the interrupt bit.

MMC Receive Checksum Offload Interrupt Register

The `EMAC_MMC_RXINT.CRCERR` register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When `EMAC_MMC_CTL.NOROLL` is set, then interrupts are set, but the counter remains at all ones. The `EMAC_MMC_RXINT.CRCERR` register is 32 bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The least-significant byte lane (bits 7:0) of the counter must be read to clear the interrupt bit.

EMAC Precision Time Protocol (PTP) Engine

The following sections describe the precision time protocol (PTP) engine.

IEEE1588 and the PTP Engine

The Ethernet MAC peripheral includes a PTP engine to assist applications requiring time synchronization. The PTP module is tightly integrated with the EMAC CORE to aid hardware time stamping defined in the IEEE1588 2002/2008 standards. Applications can use accurate hardware time stamps through TCP/IP stacks (if using network layer communication) to exchange time information across devices connected over network. Applications can also use accurate hardware timestamps through Ethernet device drivers (if using MAC layer communication) to exchange time information.

PTP Engine

For calculation of drift in time between two Ethernet devices, the device records its system time whenever a timing message is sent or received (IEEE 1588 protocol). Due to the indeterministic delay of a software system for a node, the software is unable to capture an accurate time when the message is sent or received. However, the hardware can monitor the signal on the communication media and get an accurate message of arrival and departure time.

The PTP (precision time protocol) module is closely integrated with the EMAC module. It provides hardware assistance to implement both the IEEE 1588–2002 and IEEE 1588–2008 standards on Ethernet (IEEE 802.3). It takes one input clock signal as its PTP clock and maintains the timing information (called *system time*) at the nanosecond level.

The PTP module includes hardware for clock and system time adjustment. The pulse-per-second (PPS) signals physically represent the system time. PPS can be programmed to a fixed frequency or provide flexibility to the signal in terms of pulse width, interval, start, and stop time of the signals. The PTP module can be programmed to trigger an alarm interrupt when system time reaches specified time.

The PTP module can be programmed to detect different types of received frames, capture the system time, and time stamp those frames with the captured system time. Programs can configure any frame so that the PTP module capture the system time when it is transmitted. The PTP module can also capture the system time when an event is detected on the auxiliary snapshot trigger input pins (`EMAC_PTPAUXIN[n]`).

IEEE1588 Standard

Many systems require two independent devices to operate in a time synchronized fashion. If each system relied solely on its oscillator, differences between the characteristics and operating conditions of each oscillator would limit the ability of the clocks to operate synchronously. To serve applications requiring synchronized clocks, the system uses a periodic correction mechanism.

A simple way to synchronize multiple systems is to choose one system (with the best clock) as a master. The system master broadcasts the clock and timing information to other systems (slaves) and then the slaves adjust their clocks and timing according to that of master. However, this method has limitations. The master cannot broadcast the time at infinitesimal intervals. Path delay (propagation delay) exists between a master and a slave and the delay varies between each slave and master.

IEEE 1588 is also known as precision time protocol or PTP. The standard specifies a protocol used to synchronize the time and clock of multiple devices, dispersed but interconnected by any communication. For example, Ethernet (IEEE 802.3). According to the protocol, timing messages are exchanged between two devices. Then, one of the devices calculates its drift from other device and corrects its system time.(Both devices must have the same representation of their system time). The protocol resolves path delay between devices. It also helps synchronize the clocks of multiple devices and all of the limitations mentioned are resolved.

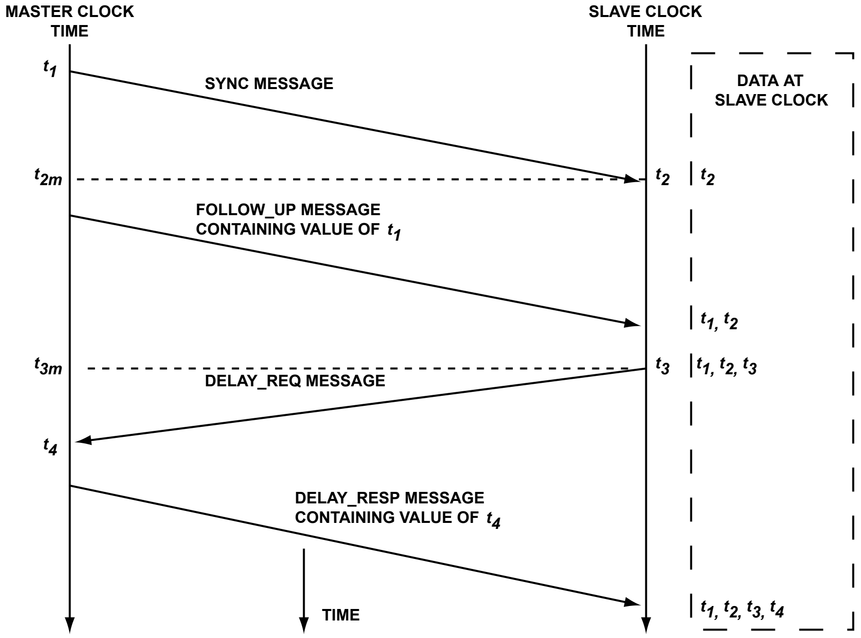
IEEE 1588 was published in 2002 where four types of timing messages were defined: Sync, Follow_Up, Delay_Req, and Delay_Resp. Here the protocol synchronizes two or more devices where one is a master and others are slaves. The master device sends Sync, Follow_Up, and Delay_Resp messages to the slave device in the system. The slave sends the Delay_Req messages to the master device. A following section provides more information on IEEE 1588–2002.

In 2008 a newer version of IEEE 1588 was introduced which provides further mechanisms to measure the peer-to-peer delay. Three more timing messages (PdelayReq, PdelayResp, and PdelayRespFollowup) were added to implement peer-to-peer synchronization. A following section provides more information on IEEE 1588–2008.

IEEE 1588–2002

The IEEE 1588–2002 standard defines the precision time protocol (PTP). The protocol allows precise synchronization of clocks in measurement and control systems that use network communication, local computing, and distributed objects. The protocol applies to systems that communicate by local area networks that support multicast messaging, including (but not limited to) Ethernet. This protocol also allows heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the submicrosecond range with minimal network and local clock computing resources.

The PTP is transported over UDP/IP. The system or network is classified into master and slave nodes for distributing the timing or clock information. The ***IEEE 1588–2002 PTP Process*** figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.



MASTER CLOCK TIME
SLAVE CLOCK TIME

TIME
t1, t2, t3, t4

Figure 31-15: IEEE 1588–2002 PTP Process

As shown in the figure, the PTP uses the following process:

1. The master broadcasts the PTP sync messages to all its nodes. The sync message contains the reference time information of the master. The time at which this message leaves the system of the master is t_1. The master must capture this time for Ethernet ports, at RMII.
2. The slave receives the Sync message and also captures the exact time, t_2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master, noting the exact time, t_3, at which this frame leaves the RMII.
5. The master receives the message, capturing the exact time, t_4, at which it enters its system.
6. The master sends the t_4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t_1, t_2, t_3, and t_4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation happens in the software above the UDP layer. However, the hardware support must capture the exact time when specific PTP packets enter or leave the Ethernet port at the RMII/RGMII. Hardware must capture this timing information and return it to the software for the proper implementation of PTP with high accuracy.

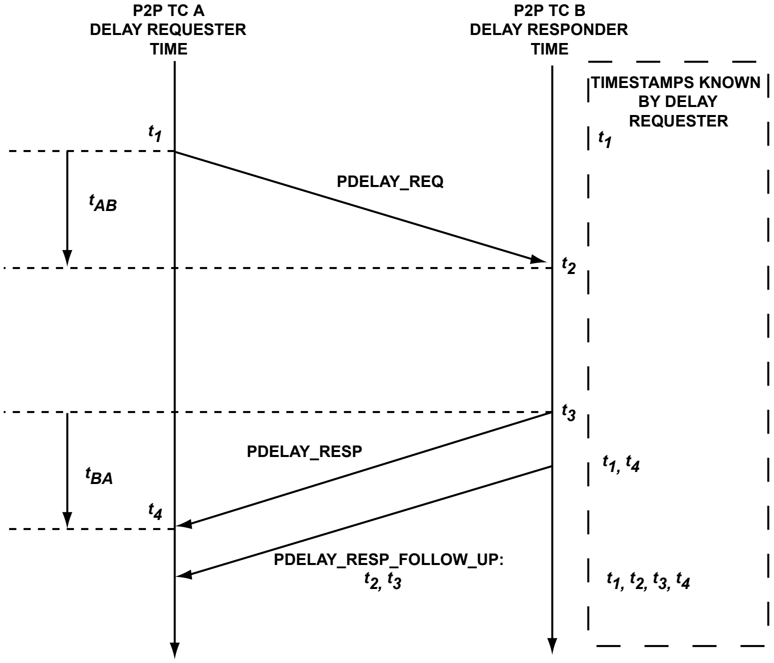
IEEE 1588–2008 Advanced Time Stamps

In addition to the basic time stamp features mentioned in IEEE 1588–2002 time stamps, the EMAC supports the following advanced time stamp features defined in the IEEE 1588–2008 standard.

- Support for the IEEE 1588–2008 (Version 2) time stamp format.
- Provides an option to take snapshot of all frames or only PTP type frames.
- Provides an option to take snapshot of only event messages.
- Provides an option to select the node to be a master or slave.
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.
- Provides an option to run nanoseconds time in digital or binary format.

Peer-to-Peer (P2P) PTP Message Support

The IEEE 1588–2008 version supports Peer-to-Peer PTP (Pdelay) message in addition to SYNC, Delay Request, Follow-up, and Delay Response messages. Refer to the ***Propagation Delay Calculation between Nodes Supporting Peer-to-Peer Path Correction*** figure. The figure shows the method to calculate the propagation delay between nodes supporting peer-to-peer path correction.



P2P TC A DELAY REQUESTER TIME
P2P TC B DELAY RESPONDER TIME
TIMESTAMPS KNOWN BY DELAY REQUESTER
t_1
t_{AB}
PDELAY_REQ
t_2
t_3
PDELAY_RESP
t_{BA}
t_4
t_1, t_4
PDELAY_RESP_FOLLOW_UP: t_2, t_3
t_1, t_2, t_3, t_4

Figure 31-16: Propagation Delay Calculation between Nodes Supporting Peer-to-Peer Path Correction

As shown in the figure, the propagation delay is calculated in the following way:

1. Port-1 issues a Pdelay_Req message and generates a time stamp, t1, for the Pdelay_Req message.
2. Port-2 receives the Pdelay_Req message and generates a time stamp, t2, for this message.
3. Port-2 returns a Pdelay_Resp message and generates a time stamp, t3, for this message. To minimize errors due to frequency offset between the two ports, Port-2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. The Port-2 returns any one of the following:
    - The difference between the time stamps t2 and t3 in the Pdelay_Resp message.
    - The difference between the time stamps t2 and t3 in the Pdelay_Resp_Follow_Up message.
    - The time stamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.
4. Port-1 generates a time stamp, t4, on receiving the Pdelay_Resp message.

Port-1 uses all four time stamps to compute the mean link delay.

Figure 31-17: PTP Block Diagram

A system time module is present which keeps the time of PTP module. It consists of hardware which can be programmed for time initialization, time correction, and clock correction.

The time stamp module captures the time (provided by the system time module) at various conditions. For example, when the EMAC sends or receives a frame or during the rising edge of the auxiliary snapshot trigger (`EMAC_PTPAUXIN[n]`) pins. When system time is captured after detection of a frame, the time stamp module automatically includes the time information in the frame descriptor. Time stamping on the detection of a frame can be programmed on a per frame basis.

The PTP clock drives the PTP module. This clock can be selected from three different clock sources.

The pulse per second (PPS) module generates a pulse or train of pulse on the PPS output pins, (`EMAC_PTPPPS[n]`). It is the physical representation of system time. PPS can be fixed (where only frequency varies) or flexible (where width, interval, start time, and stop time can be programmed).

The target time module acts as an alarm for the PTP module. Whenever system time reaches a value equal to programmed target time, the target time trigger interrupt is generated. By appropriate programming, The target time trigger can also start or stop flexible PPS output at specific time.

PTP Module Clock

The PTP module clock features include Clock Source Selection and Clock Frequency Range.

Clock Source Selection

The PTP module can take one of these clock sources as its input clock — SCLK0_0, RMII reference RGMII Rx clock, or PTP external clock.

As shown in the ***PTP Clock Source Selection*** table, the `PADS_PCFG0` register selects the PTP clock source.

Table 31-40: PTP Clock Source Selection

`PADS_PCFG0`	PTP Clock Source	Clock Description
00	EMAC_RMII	RMII reference clock
00	RGMII_RXCLK	RGMII Rx Clock
10	PTP external clock	Clock available on `EMAC_PTPCLKIN[n]` pin
X1	SCLK0_0	Processor system clock

Clock Frequency Range

The resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance. The timing constraints achievable for logic operating on the selected PTP clock source limit the maximum PTP clock frequency.

The minimum PTP clock frequency depends on the time required between two consecutive frames. The IEEE specification determines the RMII clock frequency. The minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC. See the ***Minimum PTP Clock Frequency*** table.

A minimum delay required between two consecutive time stamp captures is 8 clock cycles of RMII or 4 clock cycles of RGMIIand 3 clock cycles of PTP clocks. If the delay between two time stamp captures is less than this delay, the EMAC does not take a time stamp snapshot for the second frame.

The following table assumes:

- Minimum Ethernet packet size = 64 bytes

- Miminum IFG = 96 bit times = 12 bytes
- Preamble = 8 bytes
- 3 PTP Clock + 4GMII/MII Clock Min gap between two SFDs (start of frame delimiters)
- 3 PTP Clock + 8 RMII Clock Min gap between two SFDs
- 3 PTP Clock + 4 RGMII Clock Min gap between two SFDs

Mode (Full Duplex in all cases)	Minimum Gap between two SFDs	PTP clock	Comments
10 Mbps RMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 8RMII clock cycle 3360 RMII clock cycles	In RMII @ 10 Mbps, 1 byte transmitted in 40 clock cycles
	(2560 + 320 + 480) RMII clock cycles	3 PTP clock cycle 3352 RMII clock cycles	RMII clock = 50 MHz
	3360 RMII clocks	PTP clock cycle 1117.33 20 ns = 22346 ns	1 RMII clock cycle = (1/50 MHz) = 20 ns
		PTP frequency min = 0.045 MHz	
10 Mbps RGMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 4RGMII clock cycle 168 RGMII clock cycles	In RGMII, 1 byte transmitted in 4 clock cycles
	(128 + 16 + 24) MII clock cycles	3 PTP clock cycle<= 164 RGMII clock cycles	RGMII clock at 100 Mbps = 2.5 MHz
	168 MII clock cycles	PTP clock cycle 54.67 400ns = 21860 ns	1 RGMII clock cycle = (1/2.5 MHz) = 400 ns
		PTP frequency min = 0.045 MHz	
100 Mbps RMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 8RMII clock cycle 336 RMII clock cycles	In RMII, 1 byte transmitted in 4 clock cycles
	(256 + 32 + 48) RMII clock cycles	3 PTP clock cycle 328 RMII clock cycles	RMII clock = 50 MHz
	336 RMII clocks	PTP clock cycle 109.33 20 ns = 2186 ns	1 RMII clock cycle = (1/50 MHz) = 20 ns
		PTP frequency min = 0.45 MHz	
100 Mbps RGMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 4RGMII clock cycle 168 RGMII clock cycles	In RGMII, 1 byte transmitted in 4 clock cycles
	(128 + 16 + 24) MII clock cycles	3 PTP clock cycle 164 RGMII clock cycles	RGMII clock at 100 Mbps = 25 MHz
	168 MII clock cycles	PTP clock cycle 54.67 40 ns = 2186 ns	1 RGMII clock cycle = (1/25 MHz) = 40 ns
		PTP frequency min = 0.45 MHz	

Mode (Full Duplex in all cases)	Minimum Gap between two SFDs	PTP clock	Comments
1000 Mbps RGMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 4 RGMII clock cycle 84 RGMII clock cycles	In RGMII @ 1000 Mbps, 1 byte transmitted in 1 clock cycles
	(64 + 8 + 12) RGMII clock cycles	3 PTP clock cycle 80 RGMII clock cycles	RGMII clock at 100 Mbps = 125 MHz
	84 RGMII clocks	PTP clock cycle 26.67 8 ns = 213 ns	1 RGMII clock cycle = (1/125 MHz) = 8 ns
		PTP frequency min = 4.6 MHz	

The minimum PTP clock frequency also depends on the maximum value of the `EMAC_TM_SUBSEC` register, so that even at the highest `EMAC_TM_SUBSEC.SSINC` value, the `EMAC_TM_SEC` register value can be incremented every second. Since the `EMAC_TM_SUBSEC.SSINC` is an 8-bit field, the minimum PTP clock frequency allowed is approximately 4 MHz.

Time Stamp Module

The time stamp module captures time in seconds and nanoseconds maintained as system time. The time stamp module also captures time when specific events occur. Events include detection of a frame transmitted or received over the EMAC and a rising edge on the `EMAC_PTPAUXIN[n]` pins. The time stamp module does not need to time stamp all of the transmitted or received frames over the EMAC. The PTP module can be programmed to detect specific kinds of frames for time stamping.

Frame Detection and Time Stamping

The PTP module automatically monitors all received and transmitted IEEE 1588 event messages on the Ethernet. If the module detects an event message, it takes a snapshot of the system time. The PTP module stores the value to the 64-bit fields in transmit or receive descriptor.

The time stamping occurs at the EMAC RMII/RGMII interface when the module sees the start of frame of an event message packet.

Transmit Path Time Stamping

The EMAC captures a time stamp when a frame transmits on the RMII/RGMII. Time stamp capture is controllable on a per-frame basis. In other words, each transmit frame can be marked to indicate whether a time stamp is captured for that frame or not.

Applications can extend the descriptor word length from 4 words to 8 words by setting the `EMAC_DMA0_BUSMODE.ATDS` bit. To enable the time stamp function, set the TTSE (transmit time stamp enable) bit in transmit descriptor word TDES0. When the PTP module captures a time stamp of a transmitted frame, it notifies the application by setting the TTSS (transmit time stamp status) in TDES0.

The EMAC returns the time stamp to the software inside the corresponding transmit descriptor, automatically connecting the time stamp to the specific frame. The 64-bit time stamp information is written to the TDES6 and TDES7 fields. The TDES6 field holds the 32-bit LSBs of the time stamp (system time nanoseconds), except as described in transmit time stamp field, and the TDES7 field holds the 32-bit MSBs (system time seconds). After the

PTP module time stamps the frame, the application can get the time stamp along with the transmit status from the EMAC.

NOTE: The PTP module time stamps all the transmitting frames having TTSE set in its TDES0. It does not distinguish according to the type of transmitting frame.

Receive Path Time Stamping

The PTP module automatically monitors all received and transmitted IEEE 1588 event messages on the Ethernet. If an event message is detected, the module takes a snapshot of the system time. The module stores its value to the 64-bit fields in transmit or receive descriptor. The time stamping is done at the EMAC RMII/RGMII interface when the module sees the start of frame of an event message packet.

PTP module captures the time stamp of received frames on the RMII/RGMII. Time stamp capture is controllable on a per-frame and per-type basis. In other words, each received frame is time stamped according to the frame type.

Applications can extend the descriptor word length from 4 words to 8 words by setting the `EMAC_DMA0_BUSMODE.ATDS` bit to store time stamp and received message status. The PTP notifies the application of receive time stamp availability when it sets bit 7 (time stamp available) in receive descriptor word RDES0.

When bit 0 (extended status available) is set in RDES0, it indicates that the extended status of the PTP frame is provided in the RDES4 word. Extended status includes PTP version, PTP frame type, and message type. The EMAC returns the time stamp to the software inside the corresponding receive descriptor. The 64-bit time stamp information is written back to the RDES6 and RDES7 fields in memory. The RDES6 holds the 32-bit LSBs of the time stamp (system time nanoseconds), except as mentioned in receive time stamp field, and the RDES7 field holds 32-bit MSBs (system time seconds).

The time stamp is written only to that receive descriptor for which the last descriptor status field has been set to 1. When the time stamp is not available (for example, because of an RxFIFO overflow), an all-ones pattern is written to the descriptors (RDES6 and RDES7). The write operation indicates that the time stamp is not correct. RDES0 [7] indicates whether the time stamp is updated in RDES6/7.

The PTP module processes received frames to identify valid PTP frames. Use the `EMAC_TM_CTL` register to control the snapshot of the time sent to the application.

The PTP module can be programmed to detect all received frames or only some types of PTP frames, according to bit settings in the `EMAC_TM_CTL` register. Refer to the ***PTP Frame Type Selections*** table.

Table 31-41: PTP Frame Type Selections

TSENALL (bit 8)	SNAPTYPSEL (bits [17:16])	TSMSTRENA (bit 15)	TSEVNTENA (bit 14)	Frames

0	00	0	1	Sync
0	00	1	1	Delay_Req

Table 31-41: PTP Frame Type Selections (Continued)

TSENALL (bit 8)	SNAPTYPSEL (bits [17:16])	TSMSTRENA (bit 15)	TSEVNTENA (bit 14)	Frames
0	01	X	0	Sync, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_ Follow_Up
0	01	0	1	Sync, Pdelay_Req, Pdelay_Resp
0	01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
0	10	X	X	Sync, Delay_Req
0	11	X	X	Pdelay_Req, Pdelay_Resp

PTP Processing and Control

When the EMAC receives a frame, frame detection and time stamping are based on some of the PTP fields in the frame. The ***PTP Message Format (IEEE 1588–2008)*** table shows the common message header for the PTP messages. This format is derived from the IEEE standard 1588–2008. When the EMAC sends a PTP frame, the frame follows this format.

When a frame is received, the PTP module compares these fields with standard values and finds out the type of PTP frame and other information. For example, PTP version, IP version, and others. The module then updates the related fields in RDES4. When a frame is transmitted, programs must ensure that all the fields are appropriate. The PTP module on the other end of a communication must correctly detect and decode the frame.

Table 31-42: PTP Message Format (IEEE 1588–2008)

Bits								Octets	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30

Table 31-42: PTP Message Format (IEEE 1588–2008) (Continued)

Bits	Octets	Offset
controlField (used in version 1. For version 2, messageType field is used for detecting different message types.)	1	32
logMessageInterva	1	33

There are some fields in the Ethernet payload that can be used to detect the PTP packet type and control the snapshot taken. These fields are different for the following PTP frames:

- PTP Frames Over IPv4
- PTP Frames Over IPv6
- PTP Frames Over Ethernet

For these PTP frames, EMAC does not consider the PTP version 1 messages as valid when the frame consists of peer delay multicast address as destination address (DA).

PTP Frame Over IPv4

The ***IPv4-UDP PTP Frame Fields Required for Control and Status*** table provides information about the fields that are matched to control snapshot for the PTP packets. The packets are sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. The positions are based on IEEE 1588–2008 standards and the message format. The format is defined in the ***PTP Message Format (IEEE 1588–2008)*** table in the PTP Processing and Control section.

Table 31-43: IPv4-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x0800	IPv4 datagram
IP Version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 Version 1)	30, 31, 32, 33	0xE0,0x00, 0x01,0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed. 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast Address (IEEE 1588 Version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP-Primary multicast address: 224.0.1.129 PTP-Peer delay multicast address: 224.0.0.107

Table 31-43: IPv4-UDP PTP Frame Fields Required for Control and Status (Continued)

Field Matched	Octet Position	Matched Value	Description
UDP Destination Port	36, 37	0x013F 0x0140	0x013F - PTP Event Messages. These are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only). 0x0140 - PTP general messages
PTP Control Field (IEEE version 1)	74	0x00/0x01/0x02/ 0x03/0x04	0x00 - SYNC 0x01 - Delay_Req 0x02 - Follow_Up 0x03 - Delay_Resp 0x04 - Management
PTP Message Type Field (IEEE version 2)	42 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xA/0xB/ 0xC/0xD	0x0 - SYNC 0x1 - Delay_Req 0x2 - Pdelay_Req 0x3 - Pdelay_Resp 0x8 - Follow_Up 0x9 - Delay_Resp 0xA - Pdelay_Resp_Follow_Up 0xB - Announce 0xC - Signaling 0xD - Management
PTP Version	43 (nibble)	0x1 or 0x2	0x1 - Supports PTP version 1 0x2 - Supports PTP version 2

PTP Frame Over IPv6

The ***IPv6-UDP PTP Frame Fields Required for Control And Status*** table provides information about the fields that are matched to control the snapshots for the PTP packets. The packets are sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. The positions are based on IEEE 1588–2008 standards and the message format defined in PTP Message Format (IEEE 1588–2008).

Table 31-44: IPv6-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x86DD	IP datagram
IP Version	14 (bits [7:4])	0x06	IP version is IPv6
Layer 4 Protocol	20 (IPv6 extension header not defined for PTP packets)	0x11	UDP

Table 31-44: IPv6-UDP PTP Frame Fields Required for Control and Status (Continued)

Field Matched	Octet Position	Matched Value	Description
PTP Multicast Address	38–53	FF0x:0:0:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:0:0:6B (Hex)	PTP - primary multicast address: FF0x: 0:0:0:0:0:0:0:0:181 (Hex) PTP - Peer delay multicast address: FF02:0:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57 (IPv6 extension header not defined for PTP packets)	0x013F, 0x0140	0x013F - PTP event messages 0x0140 - PTP general messages

PTP Message Type Field (IEEE version 2)	14 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xA/0xB/ 0xC/0xD	0x0 - SYNC 0x1 - Delay_Req 0x2 - Pdelay_Req 0x3 - Pdelay_Resp 0x8 - Follow_Up 0x9 - Delay_Resp 0xA - Pdelay_Resp_Follow_Up 0xB - Announce 0xC - Signaling 0xD - Management
PTP Version	15(nibble)	0x1 or 0x2	0x1 - Supports PTP version 1 0x2 - Supports PTP version 2

Auxiliary Time Stamp Snapshot

The auxiliary snapshot feature stores snapshots of the system time whenever a rising edge is detected on the EMAC_PTPAUXIN[n] pins.

The PTP stores 64 bits of captured time stamp in a 4-deep FIFO. When a snapshot is stored, the PTP indicates this event to the EMAC with the auxiliary snapshot interrupt. The EMAC_TM_STMPSTAT.ATSTS bit is set. The value of the snapshot is read through the EMAC_TM_AUXSTMP_SEC and EMAC_TM_AUXSTMP_NSEC registers. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then the snapshot trigger-missed status is set in the EMAC_TM_STMPSTAT.ATSSTM bit. The latest snapshot is not written to the FIFO when it is full.

When a host reads the 64-bit time stamp from the FIFO through the EMAC_TM_AUXSTMP_SEC and EMAC_TM_AUXSTMP_NSEC registers, the space becomes available to store the next snapshot.

NOTE: A space in the FIFO is created whenever the `EMAC_TM_AUXSTMP_SEC` register is read. Therefore, read the `EMAC_TM_AUXSTMP_NSEC` register before reading the `EMAC_TM_AUXSTMP_SEC` register.

The program can clear the FIFO by setting the `EMAC_TM_CTL.ATSFC` bit. When multiple snapshots are present in the FIFO, the `EMAC_TM_STMPSTAT.ATSNS` bits indicate the count.

NOTE: The minimum gap between two events on the `EMAC_PTPAUXIN[n]` pin must be 4 cycles of PTP_CLK + 3 cycles of `SCLK0_0`). Otherwise, the logic misses the rising-edge of the trigger.

System Time

To get a snapshot of the time, the EMAC requires a reference time in 64-bit format as defined in the IEEE 1588 specification. The PTP module maintains 80-bit time, known as system time. The PTP clock updates system time.

The 80-bit timing reference is split into the following three registers:

- `EMAC_TM_NSEC` – 32-bit nanoseconds register which provides time in nanoseconds
- `EMAC_TM_SEC` – 32-bit seconds register which provides time in seconds
- `EMAC_TM_HISEC` – 16-bit high seconds register which provides time beyond the seconds register. The IEEE 1588 standard does not include this register. Its use is application-specific.

The 64-bit system time (seconds and nanoseconds) is the source for taking time stamps for Ethernet frames being transmitted or received at the RMII.

Since the PTP clock frequency does not correspond to a 1ns period, the `EMAC_TM_NSEC` register is incremented with a value equal to the PTP clock period for every PTP clock cycle. The function uses the `EMAC_TM_SUBSEC` register. The `EMAC_TM_NSEC` value is incremented with the value programmed in `EMAC_TM_SUBSEC` register every PTP clock cycle.

Whenever the `EMAC_TM_SEC` register overflows from 0xFFFFFFFF to 0x00000000, the seconds overflow interrupt is triggered. The EMAC uses the `EMAC_TM_STMPSTAT.TSSOVF` bit to indicate the event. After a seconds overflow, the `EMAC_TM_HISEC` register increments by one.

The system time module supports the following two types of rollover modes for the `EMAC_TM_NSEC` register.

- Digital rollover mode. The maximum value in the nanoseconds field is 0x3B9AC9FF, that is, 10^9 nanoseconds. After it reaches this value, the `EMAC_TM_SEC` register increments and the `EMAC_TM_NSEC` register restarts counting from zero. Accuracy in digital rollover mode it is 1 ns per bit.
- Binary rollover mode. The nanoseconds field rolls over and increments the seconds field after the value reaches 0x7FFFFFFF. Accuracy in binary rollover mode is ~0.466 ns per bit.

System Time Adjustment

The following sections describe the process for system time adjustment.

System Time Initialization

System time can be initialized with 64-bit time when the PTP module is enabled. The initial value is written to the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT system time update registers. The system time counter is written with the value in the registers when the EMAC_TM_CTL.TSINIT bit is set.

Coarse Correction Method

If slave system time has an offset based on the system time of the master, then the coarse correction method can correct it. The time offset value is written to the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers. The offset value is then added to or subtracted from the system time when the EMAC_TM_CTL.TSUPDT bit is set. Use the EMAC_TM_NSECUPDT.ADDSUB bit to choose addition or subtraction. System time correction occurs in one clock cycle using the coarse correction method.

NOTE: During subtraction, the EMAC_TM_SECUPDT register value must be less than the value of the EMAC_TM_SEC register. Check the value prior to subtracting using coarse correction.

Fine Correction Method

If a slave PTP clock frequency has a drift based on the master PTP clock (as defined in IEEE 1588), it can be corrected using the fine correction method. Using this method, system time is corrected over a period (unlike coarse correction where it happens in one clock cycle). This correction helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals.

Using this method, an accumulator sums the contents of the EMAC_TM_ADDEND register. The ***System Time Update, Fine Correction Method*** figure shows the method. The arithmetic-carry that the accumulator generates acts as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency divider.

Figure 31-18: System Time Update, Fine Correction Method

Calculating Addend Value

This section describes the fine correction process for system time.

In this example, the master clock runs at 50 MHz and the slave clock has drifted to 66 MHz. The goal is to adjust the slave system time to 50 MHz, so that the slave PTP module synchronizes with the master. Using the figure in Fine Correction Method, the nanoseconds increment signal runs at 50 MHz. The nanoseconds increment is the carry from accumulator register. The addend value increments the carry from accumulator at the rate of the slave clock (66 MHz).

The accumulator overflows and generates a carry every N addend value, so $N \times \text{Addend} = 2^{32}$.

The accumulator increments at 66 MHz. This addition brings the carry to 50 MHz $N = 66/50 = 1.32$.

Hence, the addend = $2^{32}/1.32$ = 0xC1F07C1F.

Therefore, if addend is programmed with 0xC1F07C1F, the slave system time runs at 50 MHz which synchronizes with the master.

In the Fine Correction Method figure, the subsecond increment is the value programmed in the `EMAC_TM_SUBSEC` register which increments the `EMAC_TM_NSEC` register according to the frequency of the nanoseconds increment signal.

In the example, the sub second increment is 20 (for digital rollover) or 43 (for binary rollover). This addition increments the `EMAC_TM_NSEC` register by 20 ns (1/50 MHz).

The software must calculate the drift in frequency and update the `EMAC_TM_ADDEND` register accordingly.

NOTE: The PTP reference clock is the clock at which the system time is updated. When the `EMAC_TM_CTL.TSCFUPDT` bit is set to 0, this clock equals the PTP clock. Using fine correction, the PTP reference clock is generated on the nanoseconds increment signal at which the system time updates.

Target Time Trigger (Alarm)

The PTP module provides an alarm function by triggering an alarm at a preset time. It sets the `EMAC_TM_STMPSTAT.TSTARGT0` bit when the system time matches the value of the `EMAC_TM_PPS0TGTM` and `EMAC_TM_PPS0NTGTM` registers. This trigger can generate an interrupt and command the flexible PPS module to start or stop PPS output, depending on value programmed in `EMAC_TM_PPSCTL.TRGTMODSEL0` bits.

The trigger is enabled by setting `EMAC_TM_CTL.TSTRIG` bit. Once an alarm has occurred, if the PTP needs another alarm, the software must:

- Clear the status bit
- Reprogram the `EMAC_TM_PPS0TGTM` and `EMAC_TM_PPS0NTGTM` registers to a future value, and
- Set the `EMAC_TM_CTL.TSTRIG` bit

If the time programmed in the target time registers has elapsed, then a target time programming error is indicated by setting the `EMAC_TM_STMPSTAT.TSTRGTERR0` bit.

The alarm time is represented in absolute units, not relative units. For example, if the software must generate an alarm after 10 seconds, it must read the current system time value. Then, the software must add the number corresponding to 10 seconds, and write the result back to the target time registers.

Pulse-Per-Second (PPS)

Pulse-per-second (PPS) is a physical representation of system time. It consists of a single pulse or train of pulses. The PTP uses PPS for extra synchronization or to monitor the synchronization performance between clocks. With proper configuration, the PTP module can generate PPS signals that are output on the `EMAC_PTPPPS[n]` pins. The PTP supports two kinds of PPS output, fixed and flexible.

Fixed Pulse-Per-Second Output

The EMAC supports fixed pulse-per-second (PPS) output that indicates 1-second intervals (default). Change the frequency of the PPS output by configuring the `EMAC_TM_PPSCTL.PPSCTL0` bits. The default value for these bits is 0000, which configures a 1Hz signal with a pulse width equal to the period of the PTP clock.

The ***PPS Output Frequencies*** table shows various PPS output frequencies.

Table 31-46: PPS Output Frequencies

PPSCTL Bit Setting	Binary Rollover	Digital Rollover
0001	2 Hz	1 Hz

Table 31-46: PPS Output Frequencies (Continued)

PPSCTL Bit Setting	Binary Rollover	Digital Rollover
0010	4 Hz	2 Hz
0011	8 Hz	4 Hz
...	...	...
1111	32.768 kHz	16.384 kHz

In binary rollover mode, the PPS output has a duty cycle of 50% with these frequencies.

In digital rollover mode, the PPS output frequency is an average number. The actual clock is a different frequency that is synchronized every second. PPS output pulses have different periods and duty cycles and this behavior is because of the non-linear toggling of the bits in digital rollover mode. For example:

- When `EMAC_TM_PPSCTL.PPSCTL0` = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.
- When `EMAC_TM_PPSCTL.PPSCTL0` = 0010, the PPS (2 Hz) is a sequence of:
  - One clock of 50-percent duty cycle and 537-ms period
  - Second clock of 463-ms period (268 ms low and 195 ms high)
- When `EMAC_TM_PPSCTL.PPSCTL0` = 0011, the PPS (4 Hz) is a sequence of:
  - Three clocks of 50-percent duty cycle and 268-ms period
  - Fourth clock of 195-ms period (134 ms low and 61 ms high)

Flexible Pulse-Per-Second Output

The EMAC also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the PPS output. Enable this feature, called flexible PPS, by setting the `EMAC_TM_PPSCTL.PPSEN` bit.

The flexible PPS output options are:

- Supports programming the start point of the single pulse and start and stop points of the pulse train in terms of system time. The target time registers program the start and stop time.
- Supports programming the stop time in advance. Programs can configure the stop time before the actual start time has elapsed.
- Supports programming the width, between the rising edge and corresponding falling edge of the PPS signal output, in terms of number of units of subsecond increment. This value is configured in the `EMAC_TM_SUBSEC` register.
- Supports programming the interval, between the rising edges of PPS signal, in terms of number of units of subsecond increment. This value is configured in the `EMAC_TM_SUBSEC` register.
- Provides the option to cancel the programmed PPS start or stop request.

- Indicates error if the start or stop time programmed has already elapsed.

PPS Start or Stop Time

Start time can initially be programmed in the target time registers. If necessary, the start or stop time can be programmed again but only after the earlier programmed value is synchronized to the PTP clock domain. The `EMAC_TM_PPS0NTGTM.TSTRBUSY` bit indicates the status of synchronization. Programs can configure the start or stop time in advance, even before the earlier stop or start time has elapsed.

Program the start or stop time with advanced system time to ensure proper PPS signal output. If the application programs a start or stop time that has already elapsed, then the EMAC sets the `EMAC_TM_STMPSTAT.TSTRGTERR0` bit, indicating the error. If enabled, the EMAC also sets the target time trigger (alarm) interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

PPS Width and Interval

The PPS width and interval are programmed in terms of granularity of system time, that is, the number of the units of subsecond increment value. For example, with the PTP reference clock of 50 MHz, a PPS pulse width of 40 ns, and an interval of 100 ns, program the width and interval to 2 and 5, respectively.

Use a faster PTP reference clock to achieve smaller granularity. Before commanding to trigger a pulse or pulse train on the PPS output, programs must configure or update the interval and width of the PPS signal output.

PPS Command

When the PPS module has a flexible PPS output configuration, the PTP can use the `EMAC_TM_PPSCTL.PPSCTL0` bits to command the PPS module to use any of the flexible PPS features.

Programming these bits with a non-zero value instructs the PPS module to initiate an event. Once the command transfers or synchronizes to the PTP clock domain, these bits clear automatically. Software must ensure that these bits are programmed only when they are all-zero.

The ***Flexible PPS Output Commands*** table explains the different commands and their function.

Table 31-47: Flexible PPS Output Commands

PPSCTL (Bits 3–0)	Command	Description
0000	No Command	
0001	Start Single Pulse	Generates single pulse rising at start point defined in target time registers and of duration defined in `EMAC_TM_PPS0WIDTH` register.
0010	Start Pulse Train	Generates train of pulses rising at the start time configured in the target time registers, of duration configured in the `EMAC_TM_PPS0WIDTH` register. The train of pulses repeats at the interval configured in the `EMAC_TM_PPS0INTVL` register. By default, the PPS pulse train is free-running unless stopped by stop pulse train at time or stop pulse train immediately commands.
0011	Cancel Start	Cancels the start single pulse and start pulse train commands when the system time has not crossed the programmed start time.

Table 31-47: Flexible PPS Output Commands (Continued)

PPSCTL (Bits 3–0)	Command	Description
0100	Stop Pulse Train at Time	Stops the train of pulses initiated by the command for start pulse train after the time programmed in the target time registers elapses.
0101	Stop Pulse Train Immediately	Immediately stops the train of pulses initiated by the command for start pulse train.
0110	Cancel Stop Pulse Train	Cancels the stop pulse train at time command when the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.
0111-1111	Reserved	

PTP Interrupts

Set the `EMAC_IMSK.TS` bit to enable interrupts from the PTP module. The EMAC uses the `EMAC_ISTAT.TS` bit to indicate the status of the interrupt. The PTP supports the following three types of interrupts.

Auxiliary Snapshot Trigger

When an external event occurs on the `EMAC_PTPAUXIN[n]` pins and a time stamp snapshot occurs, an auxiliary snapshot interrupt is triggered. The EMAC uses the `EMAC_TM_STMPSTAT.ATSTS` bit to indicate the interrupt.

Target Time Reached

This interrupt is triggered when the system time becomes equal to the value written in the `EMAC_TM_PPS0NTGTM` and `EMAC_TM_PPS0NTGTM` registers. Enable or disable the interrupt using the `EMAC_TM_CTL.TSTRIG` and `EMAC_TM_PPSCTL.TRGTMODSEL0` bits. This interrupt can be used as an alarm and is indicated on the `EMAC_TM_STMPSTAT.TSTARGT0` bit.

System Time Seconds Register Overflow

This interrupt is triggered when the `EMAC_TM_SEC` register overflows from 0xFFFF FFFF to 0x0000 0000. This interrupt is indicated on the `EMAC_TM_STMPSTAT.TSSOVF` bit. As soon as `EMAC_TM_SEC` register overflows, the `EMAC_TM_HISEC` register increments by one.

Audio Video Data Transmission

The audio video (AV) feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define the various aspects of the AV feature implementation.

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources.
- IEEE 802.1Qat-2009: Allows reservation of the network resources for specific traffic streams traversing a bridged local area network.
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications. For example, audio and video and across bridged and virtual-bridged LANs. Virtual-bridged LANs consist of LAN media where the transmission delays are fixed and

symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration.

As shown in the ***Transmit and Receive Path Block Diagram*** figure, one SCB master interface connects to three DMA channels (channel 0, channel 1, and channel 2). The DMA arbiter helps in arbitration of all the paths (transmit and receive) in channel 0, channel 1 and channel 2. Each channel has a separate control and status register (CSR) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

Figure 31-19: Transmit and Receive Path Block Diagram

Transmit Path Functions

The transmit path of channel 0 supports strict-priority algorithm and is used for best-effort traffic. For a channel, the strict-priority algorithm determines that a frame is available for transmission if the channel contains one or more frames. When the threshold mode for EMAC MFL Tx FIFO is enabled, the strict-priority algorithm determines that a frame is available for transmission. The algorithm determines when the channel contains a partial frame of size equal to the programmed threshold limit.

The transmit paths of channel 1 and channel 2 support traffic management by using the credit-based shaper algorithm. For a channel, the credit-based shaper algorithm determines that a frame is available for transmission if the following conditions are true:

- The channel contains one or more frames.
- The credit for the channel is positive as per the algorithm.

Programs can disable the credit-based shaper algorithm for all channels or for lower-priority channels. The credit-based shaper algorithm can be disabled for channel 1 and channel 2 or for channel 1 only. When the credit-based shaper algorithm for a channel is disabled, the channel uses the default strict-priority algorithm.

Each transmit DMA has a separate descriptor chain for fetching the transmit data. The transmit channel that receives access to the system bus depends on the DMA arbiter. For information about the DMA arbiter, see DMA Arbiter.

The transmit path has separate FIFOs for each channel, as shown in the ***Transmit and Receive Path Block Diagram*** figure. The data fetched by the DMA is placed in the respective FIFO. The traffic management and scheduler unit (TMS) controls which FIFO data the MAC transmits. If the credit-based shaper algorithm is enabled for a channel (1 or 2), then the corresponding channel is selected for transmission when the following conditions are true:

- The frame is available in the channel and has a positive or zero credit.
- The higher priority channel has no frame waiting in the FIFO.

If the credit-based shaper algorithm is disabled for all channels, then the frame awaiting transmission from a channel is selected. The selection is made based on the priority scheme described in the ***Fixed Priority Scheme for DMA Channels*** table.

Receive Path Functions

To differentiate between the AV and non-AV traffic, the MAC provides a status. The status indicates if data is an AV packet and identifies its corresponding VLAN Priority tag value. This status is updated in the extended status field of the receive descriptor as explained in "Receive Descriptor". The `EMAC_MAC_AVCTL.AVT`bit field specifies a value that is compared with the EtherType field of the incoming Ethernet frame to detect an AV packet. The AV packets can be of the following two types:

- ***AV data packets.*** The AV data packets are always tagged. The tagged AV control packets are received based on the programmed priority value. The `EMAC_MAC_AVCTL.AVP` bit field specifies the channel to which an AV packet with a given priority must be sent.
- ***AV control packets.*** The AV control packets are either tagged or untagged. The untagged AV control packets are received on channel 0 by default. To receive these packets on channel 1 or channel 2, program the `EMAC_MAC_AVCTL.AVCH` bit field. Similar to the AV data packets, the tagged AV control packets are received based on the programmed priority value.

The following describes how tagged AV control packets and AV data packets are sent to a channel.

Table 31-48: AV Packets

Receive paths of channel 1 and channel 2 are enabled.	*Channel 2* The following packets, with priority value greater than or equal to the value programmed in `EMAC_MAC_AVCTL.AVP` bit field, are received on channel 2: AV packets Non-AV tagged packets (if `EMAC_MAC_AVCTL.VQE` bit is set)
	Channel 1 The following packets, with priority value less than the value programmed in AV MAC control register, are received on channel 1: AV packets Non-AV tagged packets (if `EMAC_MAC_AVCTL.VQE` bit is set)
	Channel 0 All other packets are received on channel 0.
For example, priority value of 3 is programmed in the `EMAC_MAC_AVCTL.AVP` bit field.	*Channel 2* The following packets with priority value from 3 to 7 are received on channel 2: AV packets Non-AV tagged packets (if the `EMAC_MAC_AVCTL.VQE` bit is set)
	Channel 1 The following packets with priority value 2 are received on channel 1: AV packets Non-AV tagged packets (if the `EMAC_MAC_AVCTL.VQE` bit is set)
	Channel 0 All other packets are received on channel 0.

DMA Arbiter

The DMA arbitrates between the transmit and receive paths of DMA channel 0, channel 1, and channel 2 for accessing descriptors and data buffers.

The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the highest priority channel (channel 2) always wins the arbitration whenever it requests the bus. The ***Fixed Priority Scheme for DMA Channels*** table provides information about the priority levels of the DMA channels.

Table 31-49: Fixed Priority Scheme for DMA Channels

Priority Level	Channel
0 (low)	Channel 0
1	Channel 1
2 (high)	Channel 2

Slot Number Function

The slot number function schedules the data fetching by DMA from the system memory. This feature is useful when the source AV data must transmit at specific intervals. The transmit descriptor word 0 (TDES0) [6:3] bits program the slot number at which the DMA fetches the data from system memory. This 4-bit field allows the host to schedule data up to 16 slots of 125 micro-second each. This field is applicable only for the AV channels (channel 1 and channel 2).

When DMA fetches a transmit descriptor, it compares the slot number of the transmit descriptor with the internally generated reference slot interval. The slot interval is a counter that updates every 125 usec of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the value in the `EMAC_TM_SEC` register increments, that is, `EMAC_TM_NSEC` rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state until there is a match.

Programs can also set the `EMAC_DMA1_CHSFCS.ASC` bit to enable the DMA to fetch the data only if it matches the current slot or the next two slots.

NOTE: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

Programs can enable the check for slot number by setting the `EMAC_DMA1_CHSFCS.ESC` bit. When this check is not enabled, the packets are fetched immediately after the descriptor is read. Programs can read the `EMAC_DMA1_CHSFCS.RSN` bit field to discover the value of the reference slot number in DMA.

Interrupts

The interrupts from different DMA channels are combined. Therefore, the software must read the interrupt status registers of all DMA channels to get the source of an interrupt. The MAC interrupt status (`EMAC_IMSK`) updates only in the interrupt status register of channel 0.

Credit-Based Shaper Algorithm Functions

The Traffic Manager and Scheduler (TMS) block (shown in the ***Transmit and Receive Path Block Diagram*** figure) uses the credit-based shaper algorithm to arbitrate the AV traffic in all channels and the legacy Ethernet traffic in channel 0. Channel 1 and channel 2 can be programmed to use the credit-based shaper algorithm.The following sections provide information about implementing the Credit-Based Shaper Algorithm:

Credit Value

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps or 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional, based on the required idleSlope and sendSlope values as described in the following table.

Table 31-50: idleSlope and sendSlope Values

Mode	Values	Description
100 Mbps	portTransmitRate = 100 Mbps idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) sendSlope = 30 Mbps	Credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when besteffort frame is being transmitted. Credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class frame is being transmitted.

The DMA stores the channel traffic in the respective Tx FIFO based on the slot number in the transmit descriptor (if enabled) or depending on the bandwidth availability on the SCB.

The credit for a channel builds up only when the frame is available but it cannot be transmitted because the MAC is sending a frame from another channel. The EMAC supports another mode in which the credit can build up in advance for a channel in which no frame is available in its FIFO. This enables sending a burst of high priority traffic in a channel as soon as data is available. This can be enabled with the `EMAC_DMA1_CHCBSCTL.CC`/ `EMAC_DMA2_CHCBSCTL.CC` bit of the channel 1 and channel 2 CBS control registers.

When the `EMAC_DMA1_CHCBSCTL.CC`/`EMAC_DMA2_CHCBSCTL.CC` bit is reset, the accumulated credit parameter in the Credit-Based Shaper Algorithm is set to zero if there is positive credit and there is no frame to transmit in a channel. The credit does not accumulate when there is no frame waiting in a channel and other channels are transmitting. When the `EMAC_DMA1_CHCBSCTL.CC`/`EMAC_DMA2_CHCBSCTL.CC` bit is set, the accumulated credit parameter in the Credit-Based Shaper Algorithm is not reset to zero if there is positive credit and no frame to transmit in a channel. The credit accumulates even when there is no frame waiting in a channel and other channels are transmitting.

idleSlopeCredit and sendSlopeCredit Values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8x1024=2867 and 1.2x1024=1229 respectively. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values.

This means that if computed hiCredit and loCredit values are 12000 bits and 3036 bits respectively, then the values to be programmed in the `EMAC_DMA1_CHHIC`/`EMAC_DMA2_CHHIC` and `EMAC_DMA1_CHLOC`/ `EMAC_DMA2_CHLOC` registers are 12000x1024 bits and two's complement of 3036x1024 respectively.

Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority channel (channel 1 and channel 2) in the CBS status registers (`EMAC_DMA1_CHCBSSTAT`/`EMAC_DMA2_CHCBSSTAT`). This allows the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 us) in a channel. The status register is updated even if the Credit-Based Shaper Algorithm is not enabled for a channel. The number of slots over which the average bits transmitted per slot are computed is programmed in the `EMAC_DMA1_CHCBSCTL.SLC`/`EMAC_DMA2_CHCBSCTL.SLC` bits. For example, if these bit fields are programmed for two slots, then the average bits are computed over slot numbers 0-1, 2-3, 4-5, and so on.

The value programmed in the `EMAC_DMA1_CHISC`/`EMAC_DMA2_CHISC` register of a channel is proportional to the bandwidth reserved for the channel. The software can allocate any bandwidth that is not used by the higher priority channel to the reserved bandwidth of the lower priority channel.

A lower priority channel, using the Credit-Based Shaper Algorithm, cannot use the unused reserved bandwidth of any higher priority channel that is using the Credit-Based Shaper Algorithm. However, a lower priority channel that is using the strict-priority algorithm can use the unused reserved bandwidth of any higher priority channel that uses the Credit-Based Shaper Algorithm. For example, channel 1 and channel 2 use the Credit-Based Shaper Algorithm (with reserved bandwidth of 50% and 25% respectively) and channel 0 uses the strict-priority algorithm. If channel 1 uses only 40% of the reserved bandwidth, then the remaining 10% is used by channel 0. The channel 2 cannot exceed the reserved bandwidth of 25%.

Energy-Efficient Ethernet

Energy-Efficient Ethernet (EEE) is an optional operational mode that enables the IEEE 802.3 Media Access Control (MAC) sublayer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps, 1000 Mbps, and 10 Gbps. The MAC supports the IEEE Standard 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off parts of the communication device functionality when there is no data awaiting transmission and receipt. The systems on both sides of the link can disable some functionality and save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported and then select the set of parameters that common to both devices.

NOTE: The EEE feature is not supported when the MAC is configured to use the RMII interface. You should activate the EEE mode only when the MAC is operating with RGMII interface.

NOTE: According to the Energy-Efficient Ethernet standard (IEEE 802.3az-2010), the LPI mode is supported only in the full-duplex mode. Therefore, you should not enable the LPI mode when the MAC Transmitter is configured for the half-duplex mode.

Transmit Path Functions

In the transmit path, the software must set the `EMAC_LPI_CTLSTAT.LPIEN` bit to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and then starts transmitting the LPI pattern instead of the IDLE pattern during Interframe gap (IFG).

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts the `ETH0_TXEN` signal.
2. Asserts the TX_ER signal.
3. Sets `EMAC_TXD[n]`[3:0] to 0x1 (for 100 Mbps) or `EMAC_TXD[n]`[7:0] to 0x01 (for 1000 Mbps).

   NOTE: The MAC maintains the same state of the TX_EN, TX_ER, and `EMAC_TXD[n]` signals for the entire duration during which the PHY remains in the LPI state.

4. Updates the status using the `EMAC_LPI_CTLSTAT.TLPIEN` bit and generates an interrupt.

To bring the PHY out of the LPI state, that is, when the software resets the `EMAC_LPI_CTLSTAT.LPIEN` bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER: The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed using the `EMAC_LPI_TMRSCTL.TWT` bit field.
3. Updates the LPI exit status using the `EMAC_LPI_CTLSTAT.TLPIEX` bit and generates an interrupt.

The ***LPI Transitions (Transmit)*** figure shows the behavior of TX_EN, TX_ER, and `EMAC_TXD[n]` [3:0] signals during the LPI mode transitions.

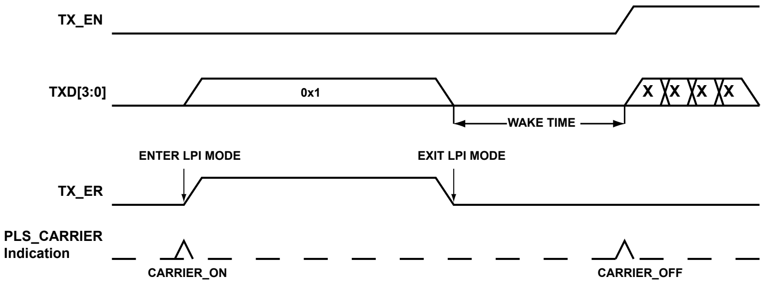

Figure 31-20: LPI Transitions (Transmit)

NOTE: The MAC does not stop the TX_CLK clock.

NOTE: If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.

NOTE: If the MAC is in the LPI mode and the host issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

Receive Path Functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts the `EMAC_RXERR`.
2. The PHY sets `EMAC_RXD[n]`[7:0] to 0x01.
3. The PHY de-asserts RX_DV.

   NOTE: The PHY maintains the same state of the `EMAC_RXERR`, `EMAC_RXD[n]`, and RX_DV signals for the entire duration during which it remains in the LPI state.

4. The MAC updates the `EMAC_LPI_CTLSTAT.RLPIEN` bit and generates an interrupt immediately.

NOTE: If the LPI pattern is detected for a very short duration (that is, less than 2 cycles of Rx clock), the MAC does not enter the Rx LPI mode.

NOTE: If the duration between end of the current Rx LPI pattern and start of the next Rx LPI pattern, is very short (that is, less than 2 cycles of Rx clock), then the MAC exits and again enters the Rx LPI mode. The MAC does not give the Rx LPI Exit and Entry interrupts.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts `EMAC_RXERR` and returns to a normal inter-frame state.
2. The MAC updates the `EMAC_LPI_CTLSTAT.RLPIEX` bit and generates an interrupt immediately.

The ***LPI Transitions (Receive)*** figure shows the behavior of `EMAC_RXERR`, RX_DV, and `EMAC_RXD[n]`[3:0] signals during the LPI mode transitions.

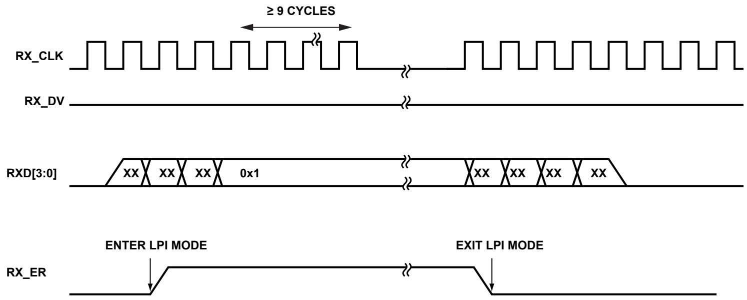

Figure 31-21: LPI Transitions (Receive)

NOTE: If the `RX_CLK_STOPPABLE` bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, then the PHY may halt the RX_CLK at any time more than 9 clock cycles after the start of the LPI state as shown in the ***LPI Transitions (Receive)*** figure.

NOTE: If the MAC is in the LPI mode and the host issues a soft reset or hard reset, the MAC receiver comes out of the LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver again enters the LPI state.

NOTE: If the RX clock is stopped in the RX LPI mode, the host should not write to the CSR registers that are being synchronized to the RX clock domain.

NOTE: When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.

LPI Timers

LPI LS TIMER

The LPI LS timer counts, in milliseconds, the time expired since the link status is up. Programs can enable the monitoring of Bit 3 `EMAC_ISTAT.RGMIIIS` (link status) of Register 54 (SGMII/RGMII/SMII Control and Status Register) by setting the `EMAC_LPI_CTLSTAT.PLSEN` bit.

The link status is indicated to the MAC by Bit 3 (link status) of Register 54 (RGMII Control and Status Register) or the value programmed by the software in the `EMAC_LPI_CTLSTAT.PLS` bit. If the link status is not available in Register 54 (RGMII Control and Status Register), the software should get the PHY link status by reading the PHY register and accordingly update the `EMAC_LPI_CTLSTAT.PLS` bit.

This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. When the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in the `EMAC_LPI_TMRSCTL.LST` bit field. The GMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE standard 802.3-az, version D2.0. The LPI LS timer is 10-bit wide. Therefore, the software can program up to 1023 milliseconds

LPI TW TIMER

The LPI TW timer counts, in microseconds, the time expired since the de-assertion of LPI. The terminal should be programmed using the `EMAC_LPI_TMRSCTL.TWT` bit. The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count.

The MAC supports the LPI TW timer in units of microsecond. The LPI TW timer is 16-bit wide. Therefore, the software can program up to 65535 us.

NOTE: Program the `EMAC_LPI_CTLSTAT.PLS` bit to 1'b0 before switching between the GMII and MII modes. This resets the internal timers. If the mode is changed after the LPI LS timer or LPI TW timer starts, the change in the TX clock frequency can result in incorrect timeout.

LPI Interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the `EMAC_LPI_CTLSTAT` register.

EMAC Event Control

The EMAC has a dedicated interrupt signal registered with the system event controller (SEC) module. Various interrupt sources within the EMAC peripheral are shared through this interrupt line. Refer to the System Event

Controller (SEC) and Generic Interrupt Controller (GIC) chapter for details on how interrupts work in this product and how to configure them.

EMAC Interrupt Signals

Interrupts from the EMAC are triggered from the EMAC DMA layer or the EMAC CORE layer. Interrupts are triggered from EMAC DMA when a particular status bit is set in the `EMAC_DMA0_STAT` register. An interrupt line is asserted only when the corresponding bits are enabled in the DMA interrupt enable register. Similarly, interrupts are triggered from the EMAC CORE when a particular MMC status bit, RGMII Link status bit, or PTP status bit is set in the interrupt status register.

An interrupt line is asserted only when the corresponding bits are enabled in the MMC mask registers for MMC counters or the interrupt mask register for PTP. DMA status register also reflects the MMC interrupt status. The following lists show the two groups of interrupts in the DMA status register.

NIS – Normal Interrupt source summary:

- Transmit Interrupt
- Transmit Buffer Unavailable
- Receive Interrupt
- Early Receive Interrupt

AIS – Abnormal Interrupt source summary:

- Transmit Process Stopped
- Transmit Jabber Timeout
- Receive FIFO Overflow
- Transmit Underflow
- Receive Buffer Unavailable
- Receive Process Stopped
- Receive Watchdog Timeout
- Early Transmit Interrupt
- Fatal Bus Error

The EMAC generates an interrupt only once for simultaneous, multiple events. The driver must read the `EMAC_DMA0_STAT` register for the cause of the interrupt. It can generate a new interrupt once the driver has cleared the appropriate bit in DMA status register.

For example, the controller generates a receive interrupt (`EMAC_DMA0_STAT.RI` bit) and the driver begins reading the `EMAC_DMA0_STAT` register. Next, a receive buffer unavailable interrupt (`EMAC_DMA0_STAT.RU` bit) occurs. The driver clears the `EMAC_DMA0_STAT.RI` bit but the internal interrupt signal is not deasserted, because of the active or pending `EMAC_DMA0_STAT.RU` interrupt. The driver must scan all of the descriptors, from the last recorded position to the first one owned by the DMA, to know which descriptor has asserted the interrupt.

Interrupts are cleared by writing a 1 to the corresponding bit position in the `EMAC_DMA0_STAT` register. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared.

An interrupt delay timer provides (receive interrupt watchdog timer register) flexible control of the receive interrupt.

When the interrupt timer is programmed with a non-zero value, it is activated as soon as the RxDMA transfers a received frame to system memory. The transfer occurs without asserting the receive interrupt. This interrupt is not enabled in the corresponding receive descriptor (`RDES1`[31] in the receive DMA descriptors).

When this timer runs out (per the programmed value), the `EMAC_DMA0_STAT.RI` bit is set. The interrupt is asserted when the corresponding `EMAC_DMA0_STAT.RI` bit is enabled in the interrupt enable register. The timer is disabled before it runs out, when a frame is transferred to memory and when the `EMAC_DMA0_STAT.RI` bit is set because it is enabled for that descriptor.

PHYINT Interrupt Signal

A PHY device can notify the EMAC when it detects changes to the link status, such as auto-negotiation or a duplex-mode change. The external PHY chip typically includes an interrupt generation pin to aid this status change notification to the MAC. This signal is typically called PHYINT. A failing or rising edge on this signal can detect a PHY interrupt at the EMAC.

In the processor, any of the GPIO pins can be a used as a PHYINT signal. Use the following procedure to configure a GPIO as a PHYINT signal.

1. Program the GPIO to detect a falling or rising edge sensitive interrupt.
2. Program the PHY to generate the interrupt on a signal status change.
3. If PHYINT is asserted, read the PHY status register through the station management interface.

NOTE: The PHYINT is not part of EMAC module. However, any GPIO pin can be configured to interrupt the processor when a rising edge generated by PHY is detected.

Refer to the PORT chapter for more info on configuring GPIO pins for input.

EMAC Programming Model

This section provides the programming model of Ethernet MAC peripheral for developers.

EMAC Programming Steps

The following sections provide some general programming information. The steps are written for EMAC DMA0, but apply to DMA1 and DMA2 as well.

DMA Initialization

Use the following procedure to initialize DMA. This procedure applies to all DMA channels.

1. Perform a software reset by setting the `EMAC_DMA0_BUSMODE.SWR` bit. This action resets all of the EMAC internal registers and logic.
2. Wait for the completion of the reset process by polling the `EMAC_DMA0_BUSMODE.SWR` bit which is only cleared (automatically) after the reset operation completes.
3. Poll the `EMAC_DMA0_BMSTAT.BUSRD` and `EMAC_DMA0_BMSTAT.BUSWR` bits to confirm that all previously initiated (before software-reset) or ongoing SCB transactions are complete.
4. Program the required fields in the `EMAC_DMA0_BMMODE` register:
    a. Address aligned bursts
    b. Fixed burst or undefined burst
    c. Burst length values and burst mode values
    d. Descriptor length (only valid when using ring mode)
5. Program the SCB interface options in the `EMAC_DMA0_BMMODE` register. If fixed burst-length is enabled, then select the maximum burst-length possible on the SCB bus (bits `EMAC_DMA0_BMMODE.BLEN4`, `EMAC_DMA0_BMMODE.BLEN8`, `EMAC_DMA0_BMMODE.BLEN16`).

6. Create a proper descriptor chain for transmit and receive. In addition, ensure that the DMA owns the receive descriptors (the `OWN` bit of the descriptor is set). For OSF mode, create at least two descriptors.
7. Ensure that the software creates three or more different transmit or receive descriptors in the chain before reusing any of the descriptors.
8. Initialize the `EMAC_DMA0_RXDSC_CUR` and `EMAC_DMA0_TXDSC_CUR` registers with the base address of the receive and transmit descriptors respectively.
9. Program the required fields in the `EMAC_DMA0_OPMODE` register to initialize the mode of operation as follows:
   a. Receive and transmit store and forward
   b. Receive and transmit threshold control
   c. Error Frame and undersized good frame forwarding enable
   d. OSF mode
10. Clear the interrupt requests by writing to those bits of the `EMAC_DMA0_STAT` register (interrupt bits only) that are set. For example, by writing 1 into bit 16, the normal interrupt summary clears this bit.
11. Enable the interrupts by programming the `EMAC_DMA0_IEN` register.
12. Start the receive and transmit DMA by setting the `EMAC_DMA0_OPMODE.SR` and `EMAC_DMA0_OPMODE.ST` bits.

EMAC CORE Initialization

Use the following procedure to initialize the EMAC CORE.

1. Program the EMAC management address register (`EMAC_SMI_ADDR`) for controlling the management cycles for external PHY. For example, physical layer address (`EMAC_SMI_ADDR.PA`). In addition, set the `EMAC_SMI_ADDR.SMIB` bit for writing into PHY and reading from PHY.
2. Read the 16-bit data of management address register (`EMAC_SMI_DATA`) from the PHY for link up, speed of operation, and mode of operation. Specify the appropriate address value in the `EMAC_SMI_ADDR.PA` bit field.
3. Program the MAC address in the `EMAC_ADDR0_HI` and `EMAC_ADDR0_LO` registers.
4. If using hash filtering, program the hash table high and low registers register (`EMAC_HASHTBL_HI`, `EMAC_HASHTBL_LO`).
5. Program the fields to set the appropriate filters for the incoming frames in the MAC frame filter register (`EMAC_MACFRMFILT`):
   a. Receive all.
   b. Promiscuous mode.

   c. Hash or perfect filter.
   d. Unicast, multicast, broadcast, and control frames filter settings.
6. Program the fields for proper flow control in flow control register (EMAC_FLOWCTL):
   a. Pause time and other pause frame control bits.
   b. Receive and transmit flow control bits.
   c. Flow control busy or backpressure activate.
7. Program the EMAC interrupt mask register bits (EMAC_IMSK), as needed.
8. Program the appropriate fields in MAC configuration register (EMAC_MACCFG). For example, inter-frame gap while transmission and jabber disable. Based on the auto-negotiation desired, set the duplex mode (EMAC_MACCFG.DM bit) or speed select (EMAC_MACCFG.FES bit).
9. Set the transmit enable (EMAC_MACCFG.TE) and receive enable (EMAC_MACCFG.RE) bits.

Performing Normal Transmit and Receive Operations

For normal transmit and receive interrupts, the program must first read the interrupt status.

1. Poll the descriptors, reading the status of the descriptor owned by the application (either transmit or receive).
2. Set the appropriate values for the descriptors, ensuring that transmit and receive descriptors are DMA descriptors to resume the transmission and reception of data.

   ADDITIONAL INFORMATION: If the descriptors are not DMA (or no descriptor is available), the DMA goes into SUSPEND state.
3. Write a 0 into the Tx/Rx poll demand registers (EMAC_DMA0_TXPOLL and EMAC_DMA0_RXPOLL).

   Transmit or receive operations are resumed by freeing the descriptors and issuing a poll demand.
4. Read (for the debug process), the values of the current host transmitter or receiver descriptor address pointer (EMAC_DMA0_TXDSC_CUR, EMAC_DMA0_RXDSC_CUR) registers.
5. Read (for the debug process), the values of the current host transmit buffer address pointer and receive buffer address pointer (EMAC_DMA0_TXBUF_CUR, EMAC_DMA0_TXBUF_CUR) registers.

Stopping and Starting Transfers

Use the following procedure to stop and start EMAC transfers.

1. Disable the transmit DMA (if applicable), by clearing the EMAC_DMA0_OPMODE.ST bit.
2. Wait for any previous frame transmissions to complete. Check for completion by reading the appropriate bits of the debug register (EMAC_DBG).

3. Disable the MAC transmitter and MAC receiver by clearing the `EMAC_MACCFG.TE` and `EMAC_MACCFG.RE` bits.
4. Disable the receive DMA (if applicable), after ensuring that the data in the receive FIFO transfers to the system memory by reading the `EMAC_DBG` register.
5. Make sure that both the transmit and receive FIFOs are empty.
6. To restart the operation, first start the DMA, and then enable the MAC transmitter and receiver.

Interrupts and Interrupt Service Routines

The following procedure describes specific steps for enabling interrupts and using their ISRs.

This procedure is typically performed with EMAC and DMA initialization and operations.

1. Receive interrupts are enabled for descriptors by default. Enable transmit interrupts for individual descriptors by setting the IC bit (bit 30) in the TDES0 word of the transmit descriptor.
2. Enable the required bits in the DMA interrupt enable register (`EMAC_DMA0_IEN.NIE`).

   ADDITIONAL INFORMATION: Setting the `EMAC_DMA0_IEN.NIE` or `EMAC_DMA0_IEN.AIE` bits can turn on the occurrence of all normal or abnormal interrupt conditions. Individual conditions can also be enabled on using individual bits in the `EMAC_DMA0_IEN` register.
3. Enable MMC overflow interrupts by setting appropriate bits in the `EMAC_MMC_RXIMSK` and `EMAC_MMC_TXIMSK` registers.
4. Enable PTP interrupts by setting the `EMAC_IMSK.TS` bit.
5. Once an EMAC interrupt is asserted and the SEC branches execution to the EMAC ISR, perform the following software program sequence.
   a. Read DMA status from the `EMAC_DMA0_STAT` register.
   b. Clear the interrupt source by writing 1 (W1C) to the bits that are set in the `EMAC_DMA0_STAT` register.
   c. Check for normal/abnormal/mmc/ptp interrupts by parsing the status bits read earlier, and call the appropriate service function.

      ADDITIONAL INFORMATION: Normal interrupt assertions include the transmit and receive interrupt. Abnormal interrupt assertions include the receive underflow.
6. The MMC handler functions use the following sequence.
   a. Read the `EMAC_ISTAT` register and parse for the `EMAC_ISTAT.MMCTX` and `EMAC_ISTAT.MMCRX` bits to determine if the interrupt is a transmit counter or receive counter-interrupt.
   b. Read the `EMAC_MMC_RXINT` or `EMAC_MMC_TXINT` registers to determine which of the counters have triggered the interrupt.
   c. Read the respective MMC counter that caused the interrupt to clear it.

7. PTP handler functions use the following sequence:
    a. Read the `EMAC_ISTAT.TS` bit to determine if a PTP interrupt occurred.
    b. Read `EMAC_TM_STMPSTAT` register to determine the interrupt source by parsing the `EMAC_TM_STMPSTAT.ATSTS`, `EMAC_TM_STMPSTAT.TSTARGT0` - `EMAC_TM_STMPSTAT.TSTARGT3`, and `EMAC_TM_STMPSTAT.TSSOVF` bits.
    c. Clear the interrupt source by reading the `EMAC_TM_STMPSTAT` register.

Enabling Checksum for Transmit and Receive

Use the following steps to enable transmit and receive checksums.

Enabling receive and transmit checksums is typically performed with EMAC and DMA initialization and operations. Transmit and receive checksum features are independent of each other.

1. To enable transmit checksum insertion:
    a. Enable store-and-forward mode in the FIFO by setting the `EMAC_DMA0_OPMODE.TSF` bit.
    b. Ensure that the transmit frame can be contained within the 256 byte Tx FIFO conforming to the size rule: FIFO Depth – PBL – 3 FIFO locations, where PBL is burst length.
    c. Program the following necessary parameters for transmit checksum, by programming (CIC) checksum insertion control in TDES0: IP header checksum, IP header checksum and payload checksum, IP header checksum, payload checksum, and pseudo header checksum.

   A higher layer such as the IP stack sends out the packet to the EMAC which inserts the checksum as configured.
2. To enable receive checksum verification:
    a. Enable receive checksum offload engine by setting the `EMAC_MACCFG.IPC` bit.
    b. Enable 8 word descriptor (32 bytes), by setting the `EMAC_DMA0_BUSMODE.ATDS` bit.
    c. Provide a total of 8 x 32-bit word space for the receive descriptor.
    d. Wait for the receive interrupt and check for extended status availability by parsing bit 0 in the RDES0 word.
    e. If extended status available, read RDES4 and pass to a higher layer such as the IP stack.

       The higher software layer can check for IPv4/IPv6/payload type and checksum payload or header errors.

Programming the System Time Module

Use the following procedure to configure the PTP module

1. Enable the PTP module by setting the `EMAC_TM_CTL.TSENA` bit 0.

2. System Time Initialization
    a. The time (seconds and nanoseconds) at which system time is initialized. Write the time into the `EMAC_TM_SECUPDT` and `EMAC_TM_NSECUPDT` registers.
    b. Set `EMAC_TM_CTL.TSINIT` bit. System time is initialized and this bit is cleared automatically.
    c. Configure binary or digital rollover of the `EMAC_TM_NSEC` register using the `EMAC_TM_CTL.TSCTRLSSR` bit.
3. System Time Coarse Correction
    a. Write the offset time (seconds and nanoseconds) to add to or subtract from the system time using the `EMAC_TM_SECUPDT` and `EMAC_TM_NSECUPDT` registers.
    b. Choose between add or subtract offset time using the `EMAC_TM_NSECUPDT.ADDSUB` bit.
    c. Set the `EMAC_TM_CTL.TSUPDT` bit to correct system time with offset time. This bit is cleared automatically.
4. System Time Fine Correction
    a. Calculate the addend value based on the input PTP clock frequency and the frequency requirement. See Fine Correction Method.
    b. Write the calculated addend value in `EMAC_TM_ADDEND` register and set the `EMAC_TM_CTL.TSADDREG` bit to update the addend value. This bit is cleared automatically.
    c. Configure the `EMAC_TM_SUBSEC` register based on new PTP frequency.
5. Target Time Trigger (Alarm)
    a. Set the `EMAC_IMSK.TS` bit to enable PTP interrupts.
    b. Program the `EMAC_TM_PPSCTL.TRGTMODSEL0` bit with 00 or 10 (for PPS start or stop time programming).
    c. Program the time when the interrupt must trigger using the `EMAC_TM_PPS0TGTM` and `EMAC_TM_PPS0NTGTM` registers. The programmed time must be greater than the current system time.

       ADDITIONAL INFORMATION: If the programmed time is not greater than the target time, a programming error occurs. The EMAC uses the `EMAC_TM_STMPSTAT.TSTRGTERR0` bit to indicate the error.
    d. Set the `EMAC_TM_CTL.TSTRIG` bit to enable the target time trigger interrupt.

       After the system time reaches the programmed target time (in step 2), the target time trigger interrupt occurs. The `EMAC_TM_STMPSTAT.TSTRGTERR0` and `EMAC_ISTAT.TS` bits indicate the error. The `EMAC_TM_CTL.TSTRIG` bit is cleared automatically.

Programming the PTP for Frame Detection and Time Stamping

Use the following procedure to configure the PTP module.

1. For time stamping a transmitting frame, set the TTSE bit in the TDES0 register of the corresponding frame.
2. Extend the descriptor word length from 4 words to 8 words by setting the `EMAC_DMA0_BUSMODE.ATDS` bit.
3. Configure bits 18–10 in the `EMAC_TM_CTL` register so that the PTP module detects and time stamps only specific types of received frames. Refer to the `EMAC_TM_CTL` register description for more information.
4. Enable the PTP module by setting the `EMAC_TM_CTL.TSENA` bit.
5. Initialize the system time.
6. Verify the RDES4 register for the status of the received frame and the RDES6 and RDES7 registers for time stamp nanoseconds and seconds value.

Programming for Auxiliary Time Stamps

1. Set the `EMAC_IMSK.TS` bit to enable PTP interrupts.
2. Set the `EMAC_TM_CTL.TSENA` bit to enable the PTP module.
3. Initialize system time.

   ADDITIONAL INFORMATION: Whenever a rising edge on the auxiliary time stamp trigger pin is detected, system time seconds and nanoseconds are captured and stored into 4-deep auxiliary time stamp FIFO. An auxiliary time stamp trigger interrupt occurs. The EMAC uses the `EMAC_TM_STMPSTAT.ATSTS` and the `EMAC_IMSK.TS` bits to indicate the interrupt.
4. Read the contents of the FIFO one-by-one through `EMAC_TM_AUXSTMP_SEC` and `EMAC_TM_AUXSTMP_NSEC` registers. One level of the FIFO is cleared when the `EMAC_TM_AUXSTMP_SEC` register is read. Therefore, read the `EMAC_TM_AUXSTMP_NSEC` register before the `EMAC_TM_AUXSTMP_SEC` register.
5. Set the `EMAC_TM_CTL.ATSFC` bit to clear the FIFO.

Programming Fixed Pulse-Per-Second Output

Use the following procedure to program the fixed PPS output.

1. Enable the PTP module by setting the `EMAC_TM_CTL.TSENA` bit.
2. Output the PPS waveform by configuring the `EMAC_TM_PPSCTL.PPSCTL0` bits and binary or digital rollover using the `EMAC_TM_CTL.TSCTRLSSR` bit. See Fixed Pulse-Per-Second Output.

Programming Flexible Pulse-Per-Second Output

Use the following procedure to program flexible PPS output.

1. Enable the PTP module by setting the `EMAC_TM_CTL.TSENA` bit.
2. Set the `EMAC_TM_PPSCTL.PPSEN` bit to enable flexible PPS output.

3. Program the `EMAC_TM_PPSCTL.TRGTMODSEL0` bits with 11 or 10 (for target time trigger interrupt).
4. Program the start time value when the PPS output starts using the `EMAC_TM_PPS0TGTM` and `EMAC_TM_PPS0NTGTM` registers. Ensure that the `EMAC_TM_PPS0NTGTM.TSTRBUSY` bit is reset before programming the target time registers again.
5. Program the period of the PPS signal output using the `EMAC_TM_PPS0INTVL` register for pulse train output. Program the width of the PPS signal output in the `EMAC_TM_PPS0WIDTH` register for single pulse or pulse train output.
6. Ensure that the `EMAC_TM_PPSCTL.PPSCTL0` bits are cleared. Then, program the bits to 0001 to start single pulse, or to 0010 to start pulse train at programmed start time (Step 4).

   ADDITIONAL INFORMATION: The PPS pulse train is free-running unless stopped by a STOP pulse train at time command (`EMAC_TM_PPSCTL.PPSCTL0` = 0100) or STOP pulse train immediately command `EMAC_TM_PPSCTL.PPSCTL0` = 0101).
7. The start of pulse generation can be canceled by giving the cancel start command (`EMAC_TM_PPSCTL.PPSCTL0` = 0011) before the programmed start time (Step 4) elapses.
8. Program the stop time value when the PPS output must stop using the`EMAC_TM_PPS0TGTM` and `EMAC_TM_PPS0NTGTM` registers. Ensure that the `EMAC_TM_PPS0NTGTM.TSTRBUSY` bit is reset before programming the target time registers again.
9. Ensure that the `EMAC_TM_PPSCTL.PPSCTL0` bits are cleared. Then, program the bits to 0100. This programming stops the train of pulses on PPS signal output after the programmed stop time (Step 8) elapses.

   ADDITIONAL INFORMATION: The pulse train can be stopped immediately by giving the STOP pulse train immediately command (`EMAC_TM_PPSCTL.PPSCTL0` = 0101). Program the `EMAC_TM_PPSCTL.PPSCTL0` bits to 0110 before the programmed stop time (Step 8) elapses to cancel the stop pulse train command (given in Step 9).

EMAC Programming Concepts

The following sections provide basic information and guidelines to help with programming the EMAC module.

IEEE 802.3 Ethernet Packet Structure

The ***IEEE 802.3 Frame Structure*** table provides typical frame format of an Ethernet packet. Refer to the IEEE standards for detailed information on Ethernet packets and their format.

Table 31-51: IEEE 802.3 Frame Structure

Parameter	Description	Position in Ethernet Packet	Total Bytes
PREAMBLE	This parameter is a 56-bit (7-byte) pattern of alternating 1 and 0 bits (#10101010), which allows devices on the network to detect a new incoming frame for synchronization.	1	7
SFD	The SFD (#10101011) is a 1-byte pattern designed to break the preamble pattern, and signal the start of the actual frame.	2	1
DA	48-bit destination address. This parameter can be a unicast, multicast, or broadcast address.	3	6
SA	48-bit long source address, typically a unicast, multicast, or broadcast address.	4	6
LT	Typically this field is the length, in terms of the number of bytes, and can be anywhere between 0–1500. When the value is greater than or equal to 0x0600, this field also indicates the type of special payload carried by the frame. Examples include 0x8808 for flow control and 0x0800 for IPv4.	5	2
DATA	Actual application data payload, usually between 0–1500.	6	0–1500
PAD	This field compensates for data frames that are shorter than 64 bytes long, not including the preamble.	7	0–46
FCS	The frame check sequence is a 32-bit cyclic redundancy check that detects corrupted data within the entire frame. This parameter is generated from a CRC-32 polynomial code (CRC-32-IEEE): G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1.	8	4

Frame Size Statistics for Application Software

Table 31-52: Ethernet Frame Size Statistics

Frame size statistics	VLAN-specific change Comments	
Information bytes/Header	4 byte 802.1Q header inserted after source address and before Type/LAN in 802.3 packets = 22 bytes.	6 x 2 + 2 + 4 = 18 bytes (DA+SA+LT+FCS)
Minimum Frame Size (typical)	If DATA is NULL, 42-byte padding makes 64 bytes (42 +22)	64 bytes. If DATA is NULL, 46-byte padding makes 64 bytes (46 +18)
Maximum Frame Size (typical)	1522 bytes	1518 bytes (1500 bytes DATA and 18-bytes header)
Jumbo Frame Size	9022 bytes	Typical industry standard. Ethernet jumbo frame size treated as 9018 bytes.

Software Visualization of Programmable Packet Size

The *Visualization of Programmable Packet Size* table provides the byte sizes of packets with various configurations.

Table 31-53: Visualization of Programmable Packet Size

Size in Bytes	Comments
16384	Receive watchdog and transmit jabber disabled, jumbo frames enabled.
10240	Receive watchdog and transmit jabber disabled, jumbo frames disabled.
2048	Receive watchdog and transmit jabber enabled.
1518	Typical max size of Ethernet frame. Receive watchdog and transmit jabber enabled.
64	Typical minimum size of Ethernet frame.
< 64	Runt frames requiring Zero-PAD.

Ethernet Packet Structure in C

The following is an example for Ethernet packet structure in the C language.

```
typedef struct ETHER_PACKET
{
    char  dst_addr[6];              //destination address
    char  src_addr[6];              //source address
    char  length[2];                //length of actual data
    char  data[DATA_SIZE];          //application data
    char  fdlimit[DELIMIT_SIZE];    //32-bit delimit (if manual appending)
    char  fcs[4];                   //crc frame checksum, used by RX buffer.
} ETHER_PACKET;
```

DMA Descriptor Implementation in C

The following code is a simple implementation of descriptors in ring and chain model in C language. Typically 4 WORDs (32-bit) are used for descriptors. Using checksum offload or the PTP engine requires 8 WORDs. Only high-level common functions across transmit and receive descriptors are considered here.

```
/* DMA Ring Descriptor */
typedef struct EMAC_DMADESC_RING
{
    unsigned int        Status;     //TDES0 OR RDES0
    unsigned int        ControlDesc;  //TDES1 OR RDES1
    unsigned int        StartAddr1;   //TDES2 OR RDES2
    unsigned int        StartAddr2;   //TDES3 OR RDES3
    #ifdef CHECKSUM_OFFLOAD
    struct EMAC_EXT_STAT      ExtendedStat;
    #endif
} EMAC_DMADESC_RING;
/* DMA Chain Descriptor */
typedef struct EMAC_DMADESC_CHAIN
{
    unsigned int        Status;        //TDES0 OR RDES0
    unsigned int        ControlDesc;      //TDES1 OR RDES1
    unsigned int        StartAddr;     //TDES2 OR RDES2
    struct EMAC_DMADESC_CHAIN     *pNextDesc;  //TDES3 OR RDES3
    #ifdef CHECKSUM_OFFLOAD
    struct EMAC_EXT_STAT     ExtendedStat;
    #endif
} EMAC_DMADESC_CHAIN;
/* Extended Status Descriptor with PTP not enabled*/
typedef struct EMAC_EXT_STAT
{
    #ifdef RX_DESC
    unsigned int        CheckSumStat;    //RDES4
    #ifdef TX_DESC
    unsigned int        Reserved;     //TDES4
    #endif
    unsigned int        Reserved;        //RDES5 OR TDES5
    unsigned int        Reserved;     //RDES6 OR TDES6
    unsigned int        Reserved;     //RDES7 OR TDES7
} EMAC_EXT_STAT;
```

PTP Header Structure in C

The following code is an example of the PTP message format.

```
/* PTP Message Format (Refer to PTP Frame Over IPv4)*/
    typedef struct EMAC_PTP_HEADER
    {
    unsigned char    messageType:4,    //PTP Version 2 message type
    transportSpecific:4;
    unsigned char    versionPTP;       //PTP Version (1 or 2)
    unsigned short    messageLength;
    unsigned char    domainNumber;
    unsigned char    RESERVED1;
    unsigned short    flagField;
    unsigned char    correctionField[8];
    unsigned char    RESERVED2[4];
    unsigned char    sourcePortIdentity[10];
    unsigned short    sequenceid;
    unsigned char    controlField;     //PTP Version 1 message type
    unsigned char    logMessageInterval;
    }EMAC_PTP_HEADER;
```

ADSP-SC58x EMAC Register Descriptions

Ethernet MAC (EMAC) contains the following registers.

Table 31-54: ADSP-SC58x EMAC Register List

Name	Description
`EMAC_ADDR0_HI`	MAC Address 0 High Register

Table 31-54: ADSP-SC58x EMAC Register List (Continued)

Name	Description
EMAC_ADDR0_LO	MAC Address 0 Low Register
EMAC_ADDR1_HI	MAC Address 1 High Register
EMAC_ADDR1_LO	MAC Address 1 Low Register
EMAC_DBG	Debug Register
EMAC_DMA0_BMMODE	DMA SCB Bus Mode Register
EMAC_DMA0_BMSTAT	DMA SCB Status Register
EMAC_DMA0_BUSMODE	DMA Bus Mode Register
EMAC_DMA0_IEN	DMA Interrupt Enable Register
EMAC_DMA0_MISS_FRM	DMA Missed Frame Register
EMAC_DMA0_OPMODE	DMA Operation Mode Register
EMAC_DMA0_RXBUF_CUR	DMA Rx Buffer Current Register
EMAC_DMA0_RXDSC_ADDR	DMA Rx Descriptor List Address Register
EMAC_DMA0_RXDSC_CUR	DMA Rx Descriptor Current Register
EMAC_DMA0_RXIWDOG	DMA Rx Interrupt Watch Dog Register
EMAC_DMA0_RXPOLL	DMA Rx Poll Demand register
EMAC_DMA0_STAT	DMA Status Register
EMAC_DMA0_TXBUF_CUR	DMA Tx Buffer Current Register
EMAC_DMA0_TXDSC_ADDR	DMA Tx Descriptor List Address Register
EMAC_DMA0_TXDSC_CUR	DMA Tx Descriptor Current Register
EMAC_DMA0_TXPOLL	DMA Tx Poll Demand Register
EMAC_DMA1_BUSMODE	DMA Bus Mode Register
EMAC_DMA1_CHCBSCTL	Channel 1 Credit Shaping Control Register
EMAC_DMA1_CHCBSSTAT	Channel 1 Average Traffic Transmitted Register
EMAC_DMA1_CHHIC	Channel 1 High Credit Value Register
EMAC_DMA1_CHISC	Channel 1 Idle Slope Credit Value Register
EMAC_DMA1_CHLOC	Channel 1 Low Credit Value Register
EMAC_DMA1_CHSFCS	Channel 1 Control Bits for Slot Function Register
EMAC_DMA1_CHSSC	Channel 1 Send Slope Credit Value Register
EMAC_DMA1_IEN	DMA Interrupt Enable Register
EMAC_DMA1_MISS_FRM	DMA Missed Frame Register
EMAC_DMA1_OPMODE	DMA Operation Mode Register

Table 31-54: ADSP-SC58x EMAC Register List (Continued)

Name	Description
EMAC_DMA1_RXBUF_CUR	DMA Rx Buffer Current Register
EMAC_DMA1_RXDSC_ADDR	DMA Rx Descriptor List Address Register
EMAC_DMA1_RXDSC_CUR	DMA Rx Descriptor Current Register
EMAC_DMA1_RXIWDOG	DMA Rx Interrupt Watch Dog Register
EMAC_DMA1_RXPOLL	DMA Rx Poll Demand Register
EMAC_DMA1_STAT	DMA Status Register
EMAC_DMA1_TXBUF_CUR	DMA Tx Buffer Current Register
EMAC_DMA1_TXDSC_ADDR	DMA Tx Descriptor List Address Register
EMAC_DMA1_TXDSC_CUR	DMA Tx Descriptor Current Register
EMAC_DMA1_TXPOLL	DMA Tx Poll Demand Register
EMAC_DMA2_BUSMODE	DMA Bus Mode Register
EMAC_DMA2_CHCBSCTL	Channel 2 Credit Shaping Control Register
EMAC_DMA2_CHCBSSTAT	Channel 2 Avg Traffic Transmitted Status Register
EMAC_DMA2_CHHIC	Channel 2 High Credit Value Register
EMAC_DMA2_CHISC	Channel 2 Idle Slope Credit Value Register
EMAC_DMA2_CHLOC	Channel 2 Low Credit Value Register
EMAC_DMA2_CHSFCS	Channel 2 Control Bits for Slot Function Register
EMAC_DMA2_CHSSC	Channel 2 Send Slope Credit Value Register
EMAC_DMA2_IEN	DMA Interrupt Enable Register
EMAC_DMA2_MISS_FRM	DMA Missed Frame Register
EMAC_DMA2_OPMODE	DMA Operation Mode Register
EMAC_DMA2_RXBUF_CUR	DMA Rx Buffer Current Register
EMAC_DMA2_RXDSC_ADDR	DMA Rx Descriptor List Address Register
EMAC_DMA2_RXDSC_CUR	DMA Rx Descriptor Current Register
EMAC_DMA2_RXIWDOG	DMA Rx Interrupt Watch Dog Register
EMAC_DMA2_RXPOLL	DMA Rx Poll Demand register
EMAC_DMA2_STAT	DMA Status Register
EMAC_DMA2_TXBUF_CUR	DMA Tx Buffer Current Register
EMAC_DMA2_TXDSC_ADDR	DMA Tx Descriptor List Address Register
EMAC_DMA2_TXDSC_CUR	DMA Tx Descriptor Current Register
EMAC_DMA2_TXPOLL	DMA Tx Poll Demand Register

Table 31-54: ADSP-SC58x EMAC Register List (Continued)

Name	Description
EMAC_FLOWCTL	FLow Control Register
EMAC_GIGE_CTLSTAT	RGMII Control and Status Register
EMAC_HASHTBL_HI	Hash Table High Register
EMAC_HASHTBL_LO	Hash Table Low Register
EMAC_IMSK	Interrupt Mask Register
EMAC_IPC_RXIMSK	MMC IPC Rx Interrupt Mask Register
EMAC_IPC_RXINT	MMC IPC Rx Interrupt Register
EMAC_ISTAT	Interrupt Status Register
EMAC_L3L4_CTL	Layer3 and Layer4 Control Register
EMAC_L3_ADDR0	Layer 3 Address0 Register
EMAC_L3_ADDR1	Layer 3 Address1 Register
EMAC_L3_ADDR2	Layer 3 Address2 Register
EMAC_L3_ADDR3	Layer 3 Address3 Register
EMAC_L4_ADDR	Layer 4 Address Register
EMAC_LPI_CTLSTAT	Low Power Idle Control and Status Register
EMAC_LPI_TMRSCTL	Low Power Idle Timeout Register
EMAC_MACCFG	MAC Configuration Register
EMAC_MACFRMFILT	MAC Rx Frame Filter Register
EMAC_MAC_AVCTL	AV MAC Control Register
EMAC_MMC_CTL	MMC Control Register
EMAC_MMC_RXIMSK	MMC Rx Interrupt Mask Register
EMAC_MMC_RXINT	MMC Rx Interrupt Register
EMAC_MMC_TXIMSK	MMC TX Interrupt Mask Register
EMAC_MMC_TXINT	MMC Tx Interrupt Register
EMAC_RX1024TOMAX_GB	Rx 1024- to Max-Byte Frames (Good/Bad) Register
EMAC_RX128TO255_GB	Rx 128- to 255-Byte Frames (Good/Bad) Register
EMAC_RX256TO511_GB	Rx 256- to 511-Byte Frames (Good/Bad) Register
EMAC_RX512TO1023_GB	Rx 512- to 1023-Byte Frames (Good/Bad) Register
EMAC_RX64_GB	Rx 64-Byte Frames (Good/Bad) Register
EMAC_RX65TO127_GB	Rx 65- to 127-Byte Frames (Good/Bad) Register
EMAC_RXALIGN_ERR	Rx alignment Error Register

Table 31-54: ADSP-SC58x EMAC Register List (Continued)

Name	Description
EMAC_RXBCASTFRM_G	Rx Broadcast Frames (Good) Register
EMAC_RXCRC_ERR	Rx CRC Error Register
EMAC_RXCTLFRM_G	Rx Good Control Frames Register
EMAC_RXFIFO_OVF	Rx FIFO Overflow Register
EMAC_RXFRMCNT_GB	Rx Frame Count (Good/Bad) Register
EMAC_RXICMP_ERR_FRM	Rx ICMP Error Frames Register
EMAC_RXICMP_ERR_OCT	Rx ICMP Error Octets Register
EMAC_RXICMP_GD_FRM	Rx ICMP Good Frames Register
EMAC_RXICMP_GD_OCT	Rx ICMP Good Octets Register
EMAC_RXIPV4_FRAG_FRM	Rx IPv4 Datagrams Fragmented Frames Register
EMAC_RXIPV4_FRAG_OCT	Rx IPv4 Datagrams Fragmented Octets Register
EMAC_RXIPV4_GD_FRM	Rx IPv4 Datagrams (Good) Register
EMAC_RXIPV4_GD_OCT	Rx IPv4 Datagrams Good Octets Register
EMAC_RXIPV4_HDR_ERR_FRM	Rx IPv4 Datagrams Header Errors Register
EMAC_RXIPV4_HDR_ERR_OCT	Rx IPv4 Datagrams Header Errors Register
EMAC_RXIPV4_NOPAY_FRM	Rx IPv4 Datagrams No Payload Frame Register
EMAC_RXIPV4_NOPAY_OCT	Rx IPv4 Datagrams No Payload Octets Register
EMAC_RXIPV4_UDSBL_FRM	Rx IPv4 UDP Disabled Frames Register
EMAC_RXIPV4_UDSBL_OCT	Rx IPv4 UDP Disabled Octets Register
EMAC_RXIPV6_GD_FRM	Rx IPv6 Datagrams Good Frames Register
EMAC_RXIPV6_GD_OCT	Rx IPv6 Good Octets Register
EMAC_RXIPV6_HDR_ERR_FRM	Rx IPv6 Datagrams Header Error Frames Register
EMAC_RXIPV6_HDR_ERR_OCT	Rx IPv6 Header Errors Register
EMAC_RXIPV6_NOPAY_FRM	Rx IPv6 Datagrams No Payload Frames Register
EMAC_RXIPV6_NOPAY_OCT	Rx IPv6 No Payload Octets Register
EMAC_RXJAB_ERR	Rx Jab Error Register

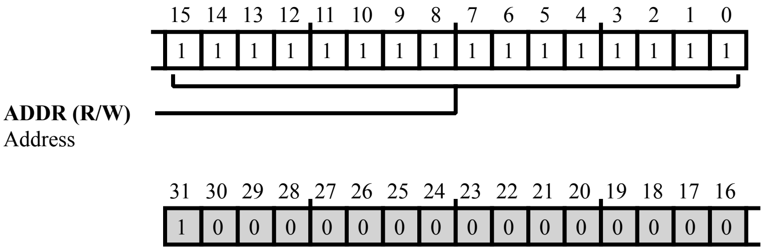
EMAC_TM_SEC	Time Stamp Low Seconds Register
EMAC_TM_SECUPDT	Time Stamp Seconds Update Register
EMAC_TM_STMPSTAT	Time Stamp Status Register
EMAC_TM_SUBSEC	Time Stamp Sub Second Increment Register
EMAC_TX1024TOMAX_GB	Tx 1024- to Max-Byte Frames (Good/Bad) Register
EMAC_TX128TO255_GB	Tx 128- to 255-Byte Frames (Good/Bad) Register
EMAC_TX256TO511_GB	Tx 256- to 511-Byte Frames (Good/Bad) Register
EMAC_TX512TO1023_GB	Tx 512- to 1023-Byte Frames (Good/Bad) Register
EMAC_TX64_GB	Tx 64-Byte Frames (Good/Bad) Register
EMAC_TX65TO127_GB	Tx 65- to 127-Byte Frames (Good/Bad) Register
EMAC_TXBCASTFRM_G	Tx Broadcast Frames (Good) Register
EMAC_TXBCASTFRM_GB	Tx Broadcast Frames (Good/Bad) Register
EMAC_TXCARR_ERR	Tx Carrier Error Register
EMAC_TXDEFERRED	Tx Deferred Register
EMAC_TXEXCESSCOL	Tx Excess Collision Register
EMAC_TXEXCESSDEF	Tx Excess Deferral Register
EMAC_TXFRMCNT_G	Tx Frame Count (Good) Register
EMAC_TXFRMCNT_GB	Tx Frame Count (Good/Bad) Register
EMAC_TXLATECOL	Tx Late Collision Register
EMAC_TXMCASTFRM_G	Tx Multicast Frames (Good) Register

Table 31-54: ADSP-SC58x EMAC Register List (Continued)

Name	Description
`EMAC_TXMCASTFRM_GB`	Tx Multicast Frames (Good/Bad) Register
`EMAC_TXMULTCOL_G`	Tx Multiple Collision (Good) Register
`EMAC_TXOCTCNT_G`	Tx Octet Count (Good) Register
`EMAC_TXOCTCNT_GB`	Tx OCT Count (Good/Bad) Register
`EMAC_TXOVRSIZE_G`	Number of Tx Frames (Good) greater than maxsize
`EMAC_TXPAUSEFRM`	Tx Pause Frame Register
`EMAC_TXSNGCOL_G`	Tx Single Collision (Good) Register
`EMAC_TXUCASTFRM_GB`	Tx Unicast Frames (Good/Bad) Register
`EMAC_TXUNDR_ERR`	Tx Underflow Error Register
`EMAC_TXVLANFRM_G`	Tx VLAN Frames (Good) Register
`EMAC_VLANTAG`	VLAN Tag Register
`EMAC_VLAN_HSHTBL`	VLAN Hash Table Register
`EMAC_VLAN_INCL`	VLAN Tag Inclusion or Replacement Register
`EMAC_WDOG_TIMOUT`	Watchdog Timeout Register

MAC Address 0 High Register

The EMAC_ADDR0_HI register holds the address 0 high bits.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
ADDR (R/W)
Address

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
AE (R/W)
Address Enable
SA (R/W)
Source Address
MBC (R/W)
Mask byte control

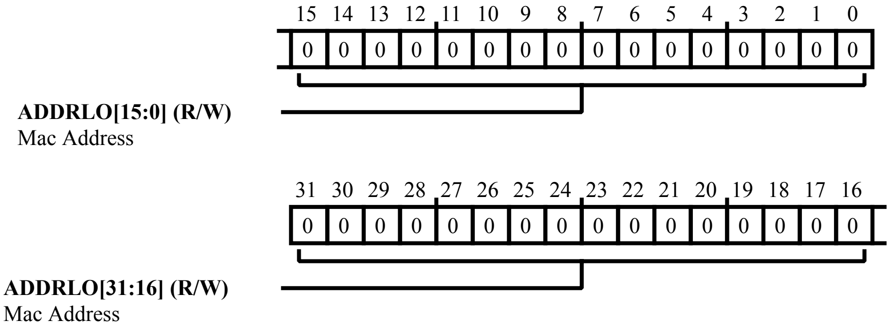
Figure 31-25: EMAC_ADDR1_HI Register Diagram

Table 31-57: EMAC_ADDR1_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	AE	Address Enable. The `EMAC_ADDR1_HI.AE` bit, When this bit is set, the address filter module uses the second MAC address for perfect filtering.
30 (R/W)	SA	Source Address. The `EMAC_ADDR1_HI.SA` bit, When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received frame.
29:24 (R/W)	MBC	Mask byte control. The `EMAC_ADDR1_HI.MBC` bit, are mask control bits for comparison of each of the MAC Address bytes.
15:0 (R/W)	ADDRHI	Mac address. The `EMAC_ADDR1_HI.ADDRHI` bit, contains the upper 16 bits (47:32) of the second 6-byte MAC address.

MAC Address 1 Low Register

The `EMAC_ADDR1_LO` register Contains the lower 32 bits of the second MAC address.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDRLO[15:0] (R/W)
Mac Address

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDRLO[31:16] (R/W)
Mac Address

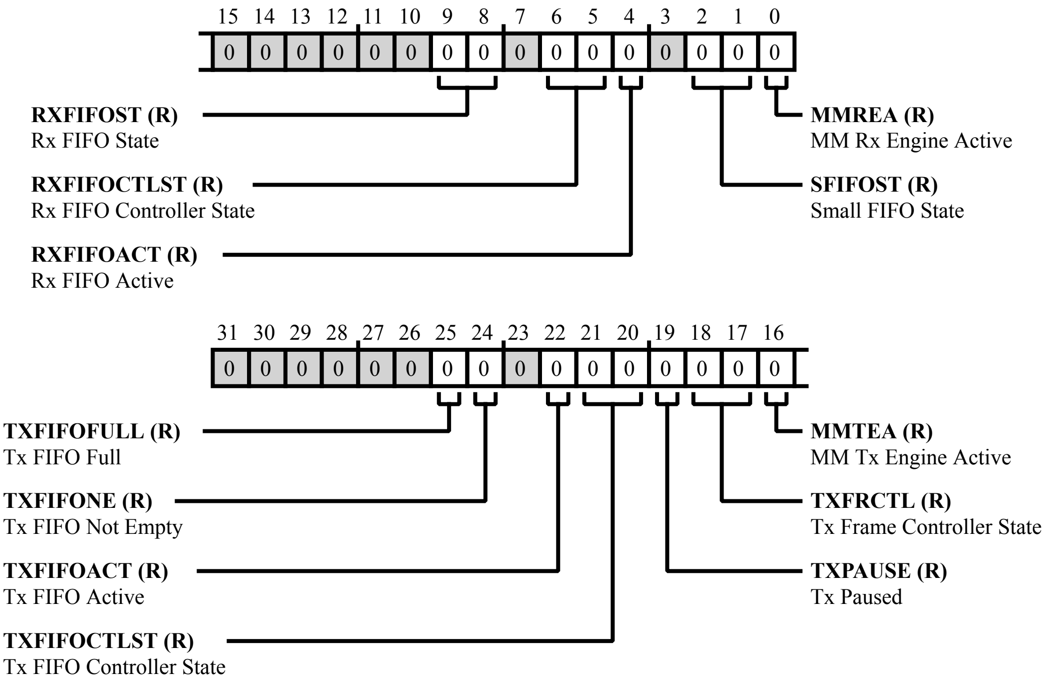
Figure 31-26: EMAC_ADDR1_LO Register Diagram

Table 31-58: EMAC_ADDR1_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDRLO	Mac Address. The `EMAC_ADDR1_LO.ADDRLO` bit, contains the lower 32 bits of the first 6-byte MAC address. This is used by the MAC for filtering the received frames and inserting the MAC address in the Transmit Flow Control (Pause) Frames.

Debug Register

The EMAC_DBG register contains EMAC debug status information.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RXFIFOST (R)
Rx FIFO State
RXFIFOCTLST (R)
Rx FIFO Controller State
RXFIFOACT (R)
Rx FIFO Active
MMREA (R)
MM Rx Engine Active
SFIFOST (R)
Small FIFO State
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TXFIFOFULL (R)
Tx FIFO Full
TXFIFONE (R)
Tx FIFO Not Empty
TXFIFOACT (R)
Tx FIFO Active
TXFIFOCTLST (R)
Tx FIFO Controller State
MMTEA (R)
MM Tx Engine Active
TXFRCTL (R)
Tx Frame Controller State
TXPAUSE (R)
Tx Paused

Figure 31-27: EMAC_DBG Register Diagram

Table 31-59: EMAC_DBG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/NW)	TXFIFOFULL	Tx FIFO Full. The `EMAC_DBG.TXFIFOFULL` bit, when high, indicates that the MFL TxStatus FIFO is full, and the MFL cannot accept any more frames for transmission.
24 (R/NW)	TXFIFONE	Tx FIFO Not Empty. The `EMAC_DBG.TXFIFONE` bit, when high, indicates that the MFL TxFIFO is not empty and has some data left for transmission.
22 (R/NW)	TXFIFOACT	Tx FIFO Active. The `EMAC_DBG.TXFIFOACT` bit, when high, indicates that the MFL TxFIFO write controller is active and transferring data to the TxFIFO.
21:20 (R/NW)	TXFIFOCTLST	Tx FIFO Controller State. The `EMAC_DBG.TXFIFOCTLST` bits indicate the state of the TxFIFO read controller as: 00=IDLE state, 01=READ state (transferring data to MAC transmitter), 10=Waiting for TxStatus from MAC transmitter, and 11=Writing the received TxStatus or flushing the TxFIFO

Table 31-59: EMAC_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	TXPAUSE	Tx Paused. The `EMAC_DBG.TXPAUSE` bit, when high, indicates that the MAC transmitter is in PAUSE condition (in full-duplex only) and does not schedule any frame for transmission.	
18:17 (R/NW)	TXFRCTL	Tx Frame Controller State. The `EMAC_DBG.TXFRCTL` bits indicate the state of the MAC transmit frame controller module.	
		0	Idle Frame controller is in idle state.
		1	Wait Frame controller is waiting for status of previous frame or IFG/backoff period end.
		2	Pause Frame controller is generating and transmitting a PAUSE control frame (in full duplex mode).
		3	Transmit Frame controller is transferring input frame for transmission.
16 (R/NW)	MMTEA	MM Tx Engine Active. The `EMAC_DBG.MMTEA` bit, when high, indicates that the MAC core transmit protocol engine is actively transmitting data and is not in IDLE state.	
9:8 (R/NW)	RXFIFOST	Rx FIFO State. The `EMAC_DBG.RXFIFOST` bits give the status of the RxFIFO fill level and indicate the relationship to the flow-control activation threshold.	
		0	Rx FIFO Empty
		1	Rx FIFO Below De-activate FCT
		2	Rx FIFO Above De-activate FCT
		3	Rx FIFO Full
6:5 (R/NW)	RXFIFOCTLST	Rx FIFO Controller State. The `EMAC_DBG.RXFIFOCTLST` bits give the state of the RxFIFO read controller.	
		0	Idle Read controller is in idle state.
		1	Read Data Read controller is reading frame data.
		2	Read Status Read controller is reading frame status or time-stamp.
		3	Flush Read controller is flushing the frame data and status.
4 (R/NW)	RXFIFOACT	Rx FIFO Active. The `EMAC_DBG.RXFIFOACT` bit, when high, indicates that the MFL RxFIFO write controller is active and is transferring a received frame to the FIFO.	

Table 31-59: EMAC_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:1 (R/NW)	SFIFOST	Small FIFO State. The `EMAC_DBG.SFIFOST` bit, when high, indicates the active state of the small FIFO read and write controllers respectively of the MAC receive frame controller module.
0 (R/NW)	MMREA	MM Rx Engine Active. The `EMAC_DBG.MMREA` bit, when high, indicates that the MAC core receive protocol engine is actively receiving data and is not in IDLE state.

DMA SCB Bus Mode Register

The EMAC_DMA0_BMMODE register selects EMAC DMA system cross bar bus mode features.

ENLPI (R/W)
Enable Low Power Interface
WROSRLMT (R/W)
SCB Maximum Write Outstanding Request
RDOSRLMT (R/W)
SCB Maximum Read Outstanding Request

Figure 31-28: EMAC_DMA0_BMMODE Register Diagram

Table 31-60: EMAC_DMA0_BMMODE Register Fields

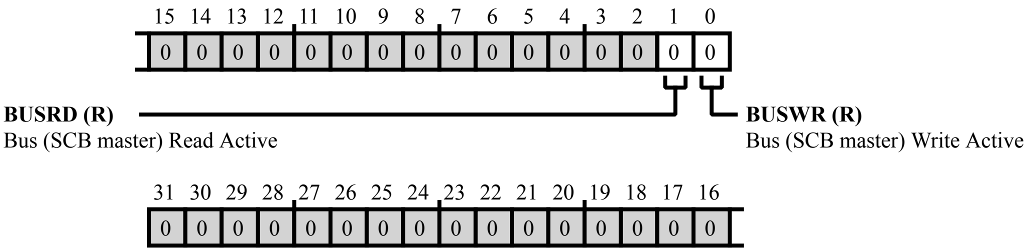
Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ENLPI	Enable Low Power Interface. The EMAC_DMA0_BMMODE.ENLPI bit field's when set to 1, it enable LPI mode supported by the GMAC configuration and accepts the LPI request from the system Clock controller.
22:20 (R/W)	WROSRLMT	SCB Maximum Write Outstanding Request. The EMAC_DMA0_BMMODE.WROSRLMT bit field's value limits the maximum outstanding request on the SCB write interface. Maximum outstanding requests = WR_OSR_LMT+1. EMAC-SCB supports up to 4 outstanding write requests.
18:16 (R/W)	RDOSRLMT	SCB Maximum Read Outstanding Request. The EMAC_DMA0_BMMODE.RDOSRLMT bit field's value limits the maximum outstanding request on the SCB read interface. Maximum outstanding requests = RD_OSR_LMT+1. EMAC-SCB supports up to 4 outstanding read requests.
13 (R/W)	ONEKBBE	1K Boundary Crossing Enable. When the EMAC_DMA0_BMMODE.ONEKBBE bit is set, the GMAC extensible bus master performs burst transfers that do not cross 1 KB boundary. When reset, the GMAC extensible bus master performs burst transfers that do not cross 4 KB boundary.

Table 31-60: EMAC_DMA0_BMMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/NW)	AAL	Address Aligned Beats. The `EMAC_DMA0_BMMODE.AAL` bit (read-only) reflects the state of the `EMAC_DMA0_BUSMODE.AAL` bit. When this bit is set to 1, EMAC-SCB performs address-aligned burst transfers on both read and write channels.
3 (R/W)	BLEN16	SCB Burst Length 16. The `EMAC_DMA0_BMMODE.BLEN16` bit, when set (or when `EMAC_DMA0_BMMODE.UNDEF` is set to 1), directs the EMAC-SCB to select a burst length of 16 on the SCB master interface.
2 (R/W)	BLEN8	SCB Burst Length 8. The `EMAC_DMA0_BMMODE.BLEN8` bit, when set (or when `EMAC_DMA0_BMMODE.UNDEF` is set to 1), directs the EMAC-SCB to select a burst length of 8 on the SCB master interface.
1 (R/W)	BLEN4	SCB Burst Length 4. The `EMAC_DMA0_BMMODE.BLEN4` bit, when set (or when `EMAC_DMA0_BMMODE.UNDEF` is set to 1), directs the EMAC-SCB to select a burst length of 4 on the SCB master interface.
0 (R/NW)	UNDEF	SCB Undefined Burst Length. The `EMAC_DMA0_BMMODE.UNDEF` bit (read-only) indicates the complement (invert) value of `EMAC_DMA0_BUSMODE.FB` bit . When this bit is set to 1, the EMAC-SCB is allowed to perform any burst length equal to or below the maximum allowed burst length as programmed in bits[3:1]. When this bit is set to 0, the EMAC-SCB is allowed to perform only fixed burst lengths as indicated by 16/8/4, or a burst length of 1.

DMA SCB Status Register

The `EMAC_DMA0_BMSTAT` register indicates EMAC DMA system cross bar status.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
BUSRD (R)
Bus (SCB master) Read Active
BUSWR (R)
Bus (SCB master) Write Active
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

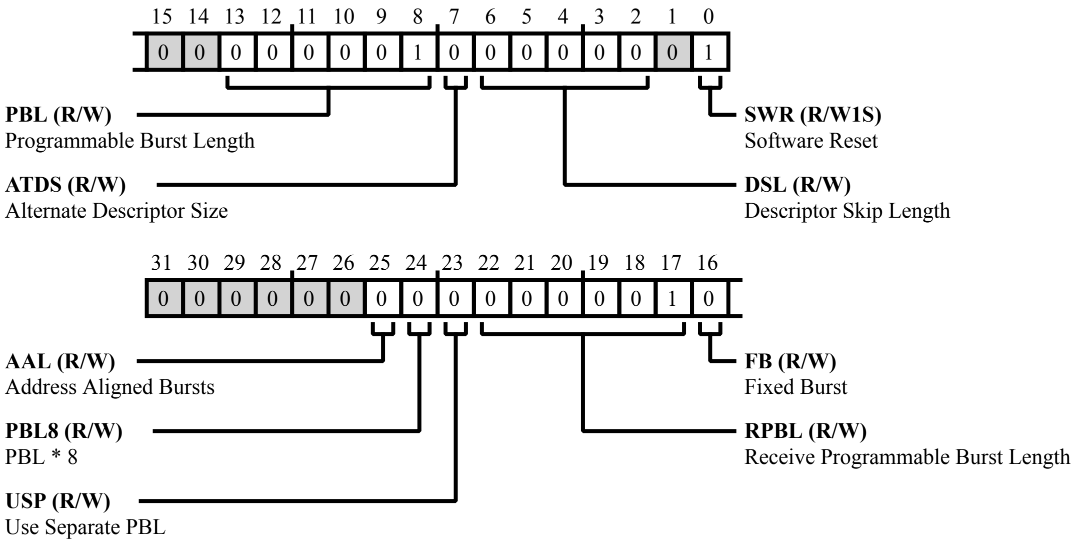
Figure 31-29: EMAC_DMA0_BMSTAT Register Diagram

Table 31-61: EMAC_DMA0_BMSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	BUSRD	Bus (SCB master) Read Active. The `EMAC_DMA0_BMSTAT.BUSRD` bit, when high, indicates that SCB Master's read channel is active and transferring data.
0 (R/NW)	BUSWR	Bus (SCB master) Write Active. The `EMAC_DMA0_BMSTAT.BUSWR` bit, when high, indicates that SCB Master's write channel is active and transferring data.

DMA Bus Mode Register

The `EMAC_DMA0_BUSMODE` register selects the DMA bus operating modes for EMAC DMA.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 1 0 0 0 0 0 0 0 1
PBL (R/W)

PBL * 8
USP (R/W)
Use Separate PBL
FB (R/W)
Fixed Burst
RPBL (R/W)
Receive Programmable Burst Length

Figure 31-30: EMAC_DMA0_BUSMODE Register Diagram

Table 31-62: EMAC_DMA0_BUSMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	AAL	Address Aligned Bursts. The `EMAC_DMA0_BUSMODE.AAL` bit, when set high and the FB bit equals 1, directs the SCB interface to generate all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffers start address) is not aligned, but subsequent bursts are aligned to the address.
24 (R/W)	PBL8	PBL * 8. The `EMAC_DMA0_BUSMODE.PBL8` bit, when set high, multiplies the PBL value programmed (bits [22:17] and bits [13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, and 32 beats depending on the PBL value.
23 (R/W)	USP	Use Separate PBL. The `EMAC_DMA0_BUSMODE.USP` bit, when set high, configures the Rx DMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to Tx DMA operations only.

Table 31-62: EMAC_DMA0_BUSMODE Register Fields (Continued)

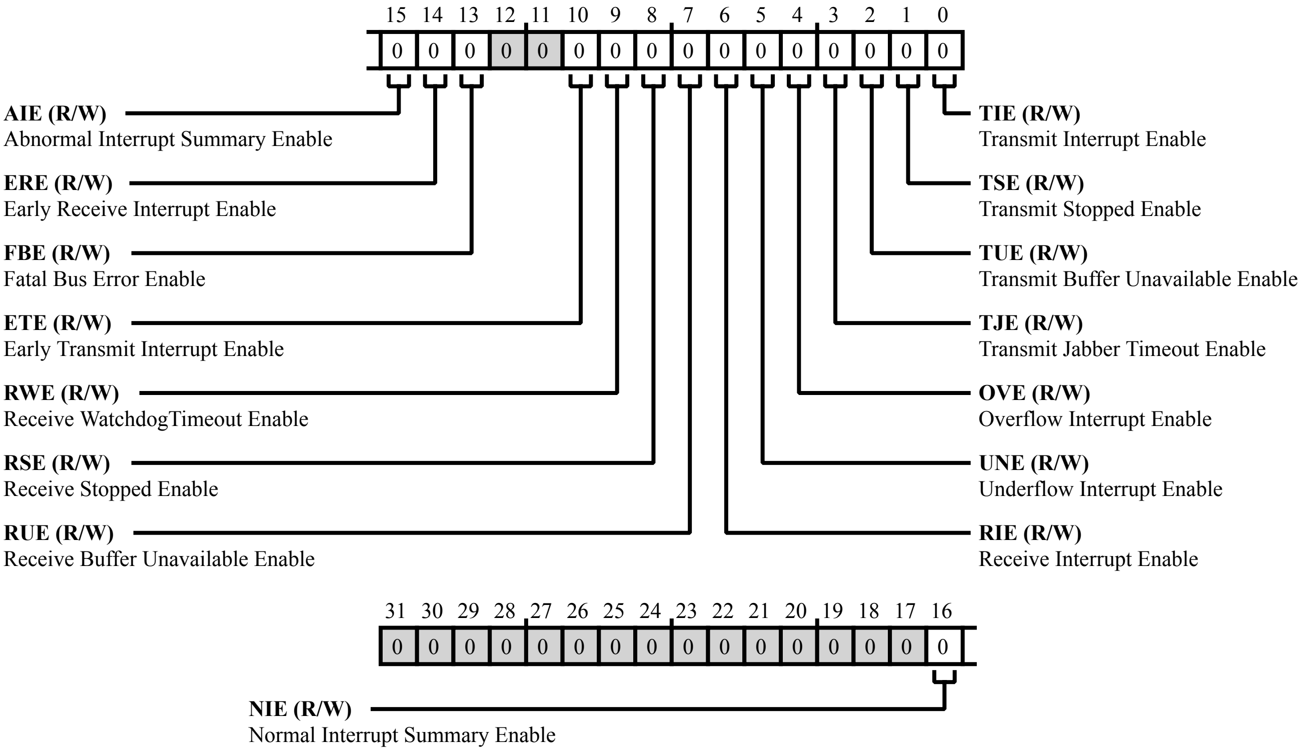
Bit No. (Access)	Bit Name	Description/Enumeration
22:17 (R/W)	RPBL	Receive Programmable Burst Length. The `EMAC_DMA0_BUSMODE.RPBL` bits indicate the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read/Write. The Rx DMA always attempts to burst as specified in RPBL every time it starts a Burst transfer on the host bus. RPBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.
16 (R/W)	FB	Fixed Burst. The `EMAC_DMA0_BUSMODE.FB` bit controls whether the SCB Master interface performs fixed burst transfers or not. See the `EMAC_DMA0_BMMODE.UNDEF` bit description for more information.
13:8 (R/W)	PBL	Programmable Burst Length. The `EMAC_DMA0_BUSMODE.PBL` bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read/Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable for Tx DMA transactions only. PBL-max limit = (FIFO size / 2) / 4. PBL-max limit (transmit) = 256 bytes / 2 /4 = 32. PBL-max limit (receive) = 128 bytes / 2 /4 = 16. Note that this PBL is at the DMA end. If PBL= 32 and if BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If `EMAC_DMA0_BUSMODE.PBL` =8, and if `EMAC_DMA0_BMMODE.BLEN16` is enabled, the max burst is limited to `EMAC_DMA0_BMMODE.BLEN8`. If `EMAC_DMA0_BUSMODE.PBL8` bit is set, the programmed PBL value is multiplied by 8 times internally. However, the result cannot be more than the above maximum limits specified above.
7 (R/W)	ATDS	Alternate Descriptor Size. The `EMAC_DMA0_BUSMODE.ATDS` bit, when set, increases the size of the alternate descriptor to 32 bytes (8 DWORDS). This is required when the Advanced Time Stamp feature or Full IPC Offload Engine is enabled in the receiver. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). The enhanced descriptor is not required if the Advanced Time Stamp and IPC Full Checksum Offload features are not enabled. In such case, you can use the 16 bytes descriptor to save 4 bytes of memory.

Table 31-62: EMAC_DMA0_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:2 (R/W)	DSL	Descriptor Skip Length. The `EMAC_DMA0_BUSMODE.DSL` bit specifies the number of 32-bit words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA, in Ring mode.
0 (R/W1S)	SWR	Software Reset. The `EMAC_DMA0_BUSMODE.SWR` bit, when set, directs the MAC DMA Controller to reset all MAC Subsystem internal registers and logic. It is cleared automatically after the reset operation has completed in all of the core clock domains. Read a 0 value in this bit before re-programming any register of the core. Note: The reset operation is completed only when all the resets in all the active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.

DMA Interrupt Enable Register

The EMAC_DMA0_IEN register enables (unmasks) EMAC DMA interrupts.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Normal Interrupt Summary Enable

Figure 31-31: EMAC_DMA0_IEN Register Diagram

Table 31-63: EMAC_DMA0_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	NIE	Normal Interrupt Summary Enable. The EMAC_DMA0_IEN.NIE bit, when set, enables a normal interrupt. When this bit is reset, a normal interrupt is disabled. This bit enables the following bits: EMAC_DMA0_STAT.TI, EMAC_DMA0_STAT.TU, EMAC_DMA0_STAT.RI, and EMAC_DMA0_STAT.ERI.
15 (R/W)	AIE	Abnormal Interrupt Summary Enable. The EMAC_DMA0_IEN.AIE bit, when set, enables an abnormal interrupt. When this bit is reset, an Abnormal Interrupt is disabled. This bit enables the following bits: EMAC_DMA0_STAT.TPS, EMAC_DMA0_STAT.TJT, EMAC_DMA0_STAT.OVF, EMAC_DMA0_STAT.RU, EMAC_DMA0_STAT.RPS, EMAC_DMA0_STAT.RWT, EMAC_DMA0_STAT.ETI, and EMAC_DMA0_STAT.FBI.

Table 31-63: EMAC_DMA0_IEN Register Fields (Continued)

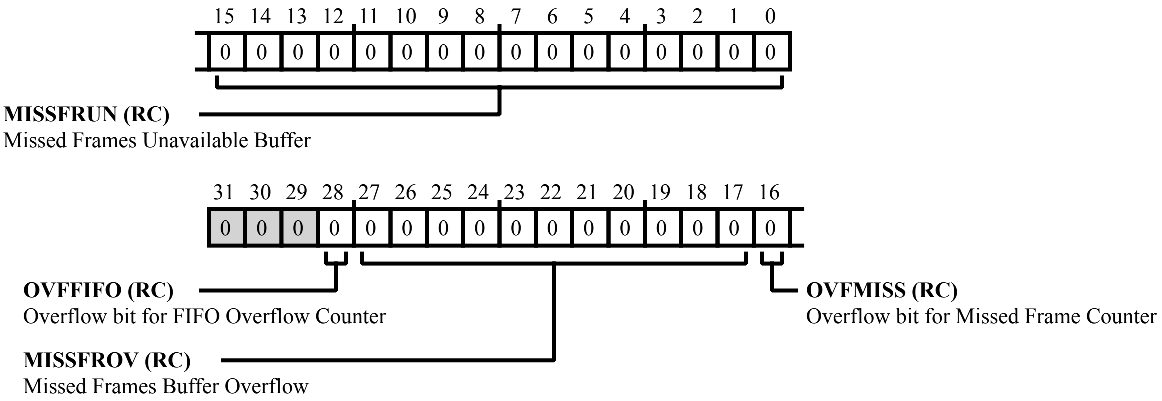
Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	ERE	Early Receive Interrupt Enable. The `EMAC_DMA0_IEN.ERE` bit, when set (and with `EMAC_DMA0_IEN.NIE` =1), enables the Early Receive Interrupt. When this bit is reset, Early Receive Interrupt is disabled.
13 (R/W)	FBE	Fatal Bus Error Enable. The `EMAC_DMA0_IEN.FBE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Fatal Bus Error Interrupt. When this bit is reset, Fatal Bus Error Enable Interrupt is disabled.
10 (R/W)	ETE	Early Transmit Interrupt Enable. The `EMAC_DMA0_IEN.ETE` bit, when this bit is set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Early Transmit Interrupt. When this bit is reset, Early Transmit Interrupt is disabled.
9 (R/W)	RWE	Receive WatchdogTimeout Enable. The `EMAC_DMA0_IEN.RWE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Receive Watchdog Timeout Interrupt. When this bit is reset, Receive Watchdog Timeout Interrupt is disabled.
8 (R/W)	RSE	Receive Stopped Enable. The `EMAC_DMA0_IEN.RSE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Receive Stopped Interrupt is enabled. When this bit is reset, Receive Stopped Interrupt is disabled.
7 (R/W)	RUE	Receive Buffer Unavailable Enable. The `EMAC_DMA0_IEN.RUE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Receive Buffer Unavailable Interrupt. When this bit is reset, the Receive Buffer Unavailable Interrupt is disabled.
6 (R/W)	RIE	Receive Interrupt Enable. The `EMAC_DMA0_IEN.RIE` bit, when set (and with `EMAC_DMA0_IEN.NIE` =1), enables the Receive Interrupt. When this bit is reset, Receive Interrupt is disabled.
5 (R/W)	UNE	Underflow Interrupt Enable. The `EMAC_DMA0_IEN.UNE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Transmit Underflow Interrupt. When this bit is reset, Underflow Interrupt is disabled.
4 (R/W)	OVE	Overflow Interrupt Enable. The `EMAC_DMA0_IEN.OVE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Receive Overflow Interrupt. When this bit is reset, Overflow Interrupt is disabled.

Table 31-63: EMAC_DMA0_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TJE	Transmit Jabber Timeout Enable. The `EMAC_DMA0_IEN.TJE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Transmit Jabber Timeout Interrupt. When this bit is reset, Transmit Jabber Timeout Interrupt is disabled.
2 (R/W)	TUE	Transmit Buffer Unavailable Enable. The `EMAC_DMA0_IEN.TUE` bit, when set (and with `EMAC_DMA0_IEN.NIE` =1), enables the Transmit Buffer Unavailable Interrupt. When this bit is reset, Transmit Buffer Unavailable Interrupt is disabled.
1 (R/W)	TSE	Transmit Stopped Enable. The `EMAC_DMA0_IEN.TSE` bit, when set (and with `EMAC_DMA0_IEN.AIE` =1), enables the Transmission Stopped Interrupt. When this bit is reset, Transmission Stopped Interrupt is disabled.
0 (R/W)	TIE	Transmit Interrupt Enable. The `EMAC_DMA0_IEN.TIE` bit, when set (and with `EMAC_DMA0_IEN.NIE` =1), enables the Transmit Interrupt. When this bit is reset, Transmit Interrupt is disabled.

DMA Missed Frame Register

The `EMAC_DMA0_MISS_FRM` register contains counters for EMAC DMA missed frames and buffer overflows.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
OVFFIFO (RC)
Overflow bit for FIFO Overflow Counter
MISSFROV (RC)
Missed Frames Buffer Overflow
OVFMISS (RC)
Overflow bit for Missed Frame Counter

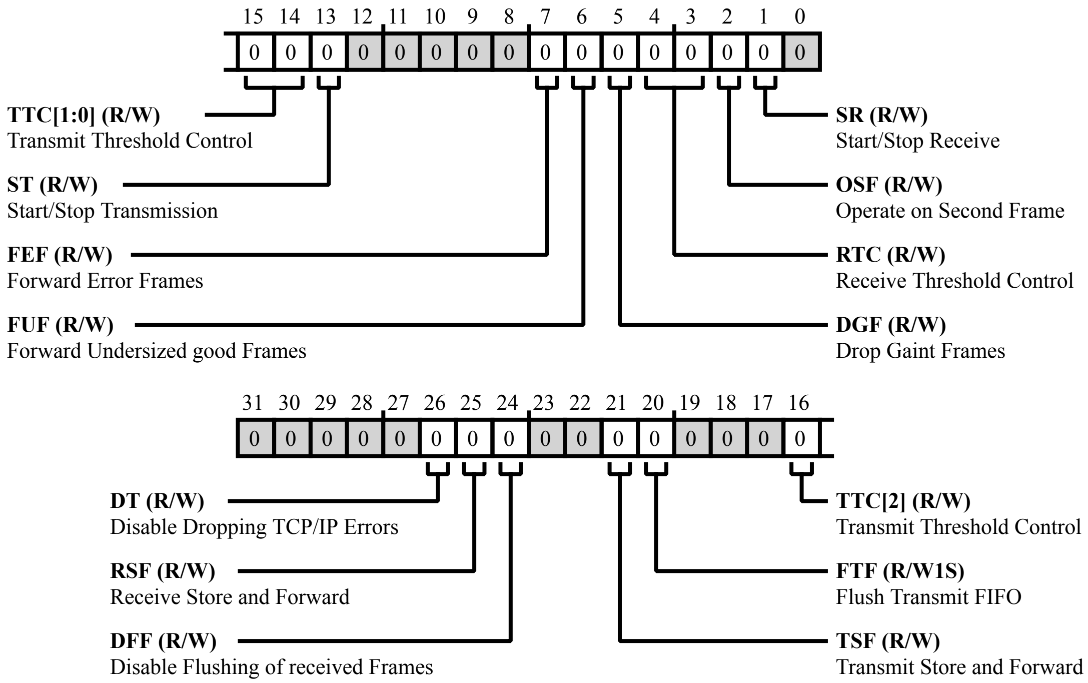
Figure 31-32: EMAC_DMA0_MISS_FRM Register Diagram

Table 31-64: EMAC_DMA0_MISS_FRM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28 (RC/NW)	OVFFIFO	Overflow bit for FIFO Overflow Counter. The `EMAC_DMA0_MISS_FRM.OVFFIFO` bit holds the overflow bit for FIFO Overflow Counter.
27:17 (RC/NW)	MISSFROV	Missed Frames Buffer Overflow. The `EMAC_DMA0_MISS_FRM.MISSFROV` bits indicate the number of frames missed by the application due to buffer overflow.
16 (RC/NW)	OVFMISS	Overflow bit for Missed Frame Counter. The `EMAC_DMA0_MISS_FRM.OVFMISS` bit holds the overflow bit for the Missed Frame Counter.
15:0 (RC/NW)	MISSFRUN	Missed Frames Unavailable Buffer. The `EMAC_DMA0_MISS_FRM.MISSFRUN` bits indicate the number of frames missed by the controller because of the Application Receive Buffer being unavailable.

DMA Operation Mode Register

The EMAC_DMA0_OPMODE register selects receive and transmit DMA operating modes.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
DT (R/W)
Disable Dropping TCP/IP Errors
RSF (R/W)
Receive Store and Forward
DFF (R/W)
Disable Flushing of received Frames
TTC[2] (R/W)
Transmit Threshold Control
FTF (R/W1S)
Flush Transmit FIFO
TSF (R/W)
Transmit Store and Forward

Figure 31-33: EMAC_DMA0_OPMODE Register Diagram

Table 31-65: EMAC_DMA0_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	DT	Disable Dropping TCP/IP Errors. The EMAC_DMA0_OPMODE.DT bit, when set, directs the core not to drop frames that only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is reset, all error frames are dropped if the EMAC_DMA0_OPMODE.FEF bit is reset.
25 (R/W)	RSF	Receive Store and Forward. The EMAC_DMA0_OPMODE.RSF bit, when set, directs the MFL only to read a frame from the Rx FIFO after the complete frame has been written to it, ignoring the EMAC_DMA0_OPMODE.RTC bits. When this bit is reset, the Rx FIFO operates in threshold mode, subject to the threshold specified by the EMAC_DMA0_OPMODE.RTC bits.
24 (R/W)	DFF	Disable Flushing of received Frames. The EMAC_DMA0_OPMODE.DFF bit, when set, directs the Rx DMA not to flush any frames because of the unavailability of receive descriptors/buffers as it does normally when this bit is reset.

Table 31-65: EMAC_DMA0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	TSF	Transmit Store and Forward. The `EMAC_DMA0_OPMODE.TSF` bit, when set, starts transmission when a full frame resides in the MFL Transmit FIFO. When this bit is set, the TTC values specified in Register 6[16:14] are ignored. This bit should be changed only when transmission is stopped.	
20 (R/W1S)	FTF	Flush Transmit FIFO. The `EMAC_DMA0_OPMODE.FTF` bit, when set, directs the transmit FIFO controller logic to reset to its default values and thus all data in the Tx FIFO is lost/flushed. This bit is cleared internally when the flushing operation is completed fully. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation completes only after emptying the Tx FIFO of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. In order to complete this flush operation, the PHY transmit clock is required to be active. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.	
16:14 (R/W)	TTC	Transmit Threshold Control. The `EMAC_DMA0_OPMODE.TTC` bits control the threshold level of the MFL Transmit FIFO. Transmission starts when the frame size within the MFL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the `EMAC_DMA0_OPMODE.TSF` bit is reset. The value =011 is not used.	
		0	64
		1	128
		2	192
		3	256
		4	40
		5	32
		6	24
		7	16

Table 31-65: EMAC_DMA0_OPMODE Register Fields (Continued)

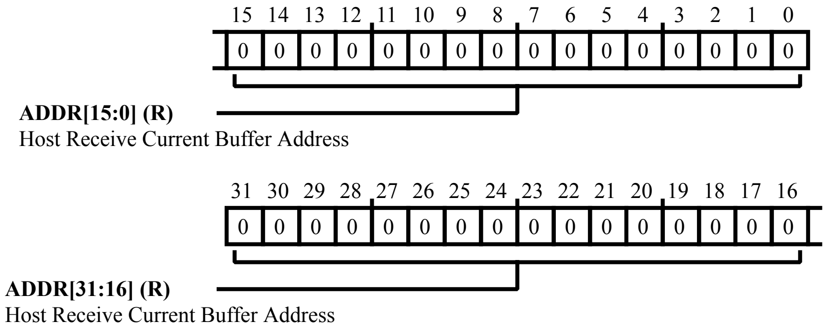
Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	ST	Start/Stop Transmission. The `EMAC_DMA0_OPMODE.ST` bit, when set, places transmission in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Transmit Descriptor List Address, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state, and the `EMAC_DMA0_STAT.TU` bit is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting the `EMAC_DMA0_TXDSC_CUR` address register, then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and becomes the current position when transmission is restarted. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.
7 (R/W)	FEF	Forward Error Frames. The `EMAC_DMA0_OPMODE.FEF` bit, when reset, directs the Rx FIFO to drop frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frames start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. When `EMAC_DMA0_OPMODE.FEF` bit is set, all frames except runt error frames are forwarded to the DMA. But when Rx FIFO overflows when a partial frame is written, then such frames are dropped even when `EMAC_DMA0_OPMODE.FEF` is set.
6 (R/W)	FUF	Forward Undersized good Frames. The `EMAC_DMA0_OPMODE.FUF` bit, when set, directs the Rx FIFO to forward Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC). When reset, the Rx FIFO drops all frames of less than 64 bytes, unless it is already transferred because of lower value of Receive Threshold (for example, `EMAC_DMA0_OPMODE.RTC` =01).
5 (R/W)	DGF	Drop Gaint Frames. The `EMAC_DMA0_OPMODE.DGF` bit, when set, the MAC drops the received giant frames in the Rx FIFO, that is, frames that are larger than the computed giant frame limit. When reset, the MAC does not drop the giant frames in the Rx FIFO.

Table 31-65: EMAC_DMA0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/W)	RTC	Receive Threshold Control. The `EMAC_DMA0_OPMODE.RTC` bits control the threshold level of the MFL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MFL Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically. These bits are valid only when the `EMAC_DMA0_OPMODE.RSF` bit is zero, and are ignored when the `EMAC_DMA0_OPMODE.RSF` bit is set to 1. The value =11 is not used.	
		0	64
		1	32
		2	96
		3	128
2 (R/W)	OSF	Operate on Second Frame. The `EMAC_DMA0_OPMODE.OSF` bit, when set, instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.	
1 (R/W)	SR	Start/Stop Receive. The `EMAC_DMA0_OPMODE.SR` bit, when set, places the Receive process in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by DMA Receive Descriptor List Address or the position retained when the Receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended, and the `EMAC_DMA0_STAT.RU` bit is set. The Start Receive command is effective only when reception has stopped. If the command was issued before setting `EMAC_DMA0_RXDSC_CUR` address register, DMA behavior is unpredictable. When this bit is cleared, Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.	

DMA Rx Buffer Current Register

The `EMAC_DMA0_RXBUF_CUR` register holds the pointer to the current receive DMA buffer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 31-66: EMAC_DMA0_RXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Buffer Address. The `EMAC_DMA0_RXBUF_CUR.ADDR` bit field points to the current Receive Buffer address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Descriptor List Address Register

The `EMAC_DMA0_RXDSC_ADDR` register holds the address for the DMA receive descriptor list. Writing to this Register is permitted only when reception is stopped. When stopped, this must be written to before the receive Start command is given. The processor can write to `EMAC_DMA0_RXDSC_ADDR` only when Rx DMA has stopped (`EMAC_DMA0_OPMODE.SR` bit =0). When stopped, it can be written with a new descriptor list address. When the processor sets the `EMAC_DMA0_OPMODE.SR` bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the `EMAC_DMA0_OPMODE.SR` bit is cleared to 0, the DMA takes the descriptor address where it was stopped earlier.

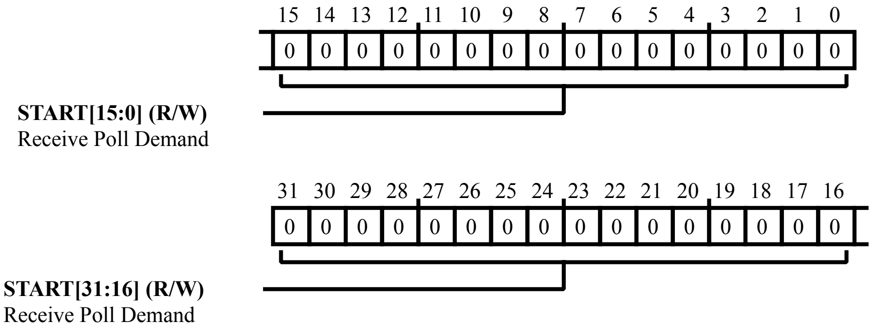
Figure 31-37: EMAC_DMA0_RXIWDOG Register Diagram

Table 31-69: EMAC_DMA0_RXIWDOG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RIWT	RI WatchDog Timer Count. The `EMAC_DMA0_RXIWDOG.RIWT` bit field indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watch-dog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when `EMAC_DMA0_STAT.RI` bit is set high because of automatic setting of `EMAC_DMA0_STAT.RI` as per RDES1[31] of any received frame.

DMA Rx Poll Demand register

The `EMAC_DMA0_RXPOLL` register directs the EMAC to poll the receive descriptor list.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Receive Poll Demand

Figure 31-38: EMAC_DMA0_RXPOLL Register Diagram

Table 31-70: EMAC_DMA0_RXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Receive Poll Demand. The `EMAC_DMA0_RXPOLL.START` bits, when written with any value, cause the DMA to read the current descriptor pointed to by the `EMAC_DMA0_RXDSC_CUR` register. If that descriptor is not available (owned by application), reception returns to the Suspended state, and the `EMAC_DMA0_STAT.RU` bit is asserted. If the descriptor is available, the Receive DMA returns to the active state.

DMA Status Register

The `EMAC_DMA0_STAT` register indicates EMAC DMA status.

Figure 31-39: EMAC_DMA0_STAT Register Diagram

Table 31-71: EMAC_DMA0_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	GLPII	GMAC LPI Interrupt. The `EMAC_DMA0_STAT.GLPII` bit indicates an interrupt event in the LPI logic of the MAC. To reset this bit to 1'b0, the software must read the corresponding registers in the DWC_gmac to get the exact cause of the interrupt and clear its source.

Table 31-71: EMAC_DMA0_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/NW)	TTI	Time Stamp Trigger Interrupt. The `EMAC_DMA0_STAT.TTI` bit indicates an interrupt event in the MAC core's Time Stamp Generator block. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear its source to reset this bit to =0. When this bit is high, the interrupt signal from the MAC is high.	
27 (R/NW)	MCI	MAC MMC Interrupt. The `EMAC_DMA0_STAT.MCI` bit reflects an interrupt event in the MMC module of the MAC core. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear the source of interrupt to make this bit as =0. The interrupt signal from the MAC is high when this bit is high.	
26 (R/NW)	GLI	Line Interface Interrupt. The `EMAC_DMA0_STAT.GLI` bit When set, this bit reflects any of the following interrupt events in the DWC_gmac interfaces	
25:23 (R/NW)	EB	Error Bits. The `EMAC_DMA0_STAT.EB` bits indicate the type of error that caused a Bus Error (for example, error response on the SCB interface). These bits are valid only when the `EMAC_DMA0_STAT.FBI` bit is set. This field does not generate an interrupt.	
		0	Error during data buffer access, write transfer, Rx DMA
		1	Error during data buffer access, write transfer, Tx DMA
		2	Error during data buffer access, read transfer, Rx DMA
		3	Error during data buffer access, read transfer, Tx DMA
		4	Error during descriptor access, write transfer, Rx DMA
		5	Error during descriptor access, write transfer, Tx DMA
		6	Error during descriptor access, read transfer, Rx DMA
		7	Error during descriptor access, read transfer, Tx DMA
22:20 (R/NW)	TS	Tx Process State. The `EMAC_DMA0_STAT.TS` bits indicate the transmit DMA state. This field does not generate an interrupt.	
		0	Stopped; Reset or Stop Tx Command Issued
		1	Running; Fetching Tx Transfer Descriptor
		2	Running; Waiting for Status
		3	Reading Data from Host Memory Buffer and Queuing It to Tx Buffer
		4	TIME_STAMP Write State

Table 31-71: EMAC_DMA0_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Reserved
		6	Suspended; Tx Descriptor Unavailable or Tx Buffer Underflow
		7	Closing Tx Descriptor
19:17 (R/NW)	RS	Rx Process State. The `EMAC_DMA0_STAT.RS` bits indicate the receive DMA state. This field does not generate an interrupt.	
		0	Stopped: Reset or Stop Rx Command Issued.
		1	Running: Fetching Rx Transfer Descriptor.
		2	Reserved
		3	Running: Waiting for Rx Packet
		4	Suspended: Rx Descriptor Unavailable
		5	Running: Closing Rx Descriptor
		6	TIME_STAMP Write State
		7	Running: Transferring Rx Packet Data from Rx Buffer to Host Memory
16 (R/W1C)	NIS	Normal Interrupt Summary. The value of the `EMAC_DMA0_STAT.NIS` bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: `EMAC_DMA0_STAT.TI`, `EMAC_DMA0_STAT.TU`, `EMAC_DMA0_STAT.RI`, and `EMAC_DMA0_STAT.ERI`. Only unmasked bits affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes `EMAC_DMA0_STAT.NIS` to be set is cleared.	
15 (R/W1C)	AIS	Abnormal Interrupt Summary. The value of the `EMAC_DMA0_STAT.AIS` bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: `EMAC_DMA0_IEN.TSE`, `EMAC_DMA0_IEN.TJE`, `EMAC_DMA0_IEN.OVE`, `EMAC_DMA0_IEN.UNE`, `EMAC_DMA0_IEN.RUE`, `EMAC_DMA0_IEN.RSE`, `EMAC_DMA0_IEN.RWE`, `EMAC_DMA0_IEN.ETE`, and `EMAC_DMA0_IEN.FBE`. Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit that causes `EMAC_DMA0_STAT.AIS` to be set is cleared.	
14 (R/W1C)	ERI	Early Receive Interrupt. The `EMAC_DMA0_STAT.ERI` bit indicates that the DMA had filled the first data buffer of the packet. The `EMAC_DMA0_STAT.RI` bit automatically clears this bit.	

Table 31-71: EMAC_DMA0_STAT Register Fields (Continued)

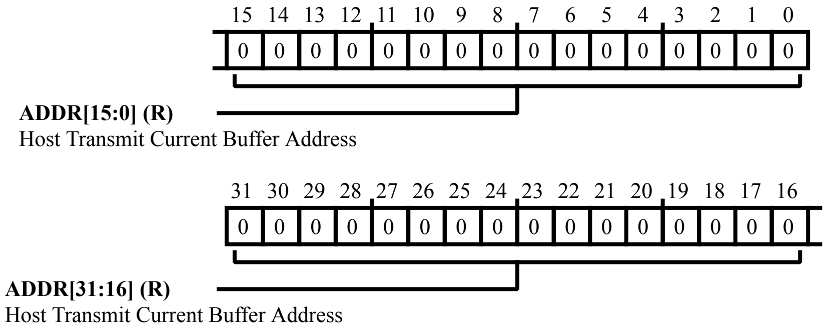
Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	FBI	Fatal Bus Error Interrupt. The `EMAC_DMA0_STAT.FBI` bit indicates that a bus error occurred, as detailed in the `EMAC_DMA0_STAT.EB` field. When this bit is set, the corresponding DMA engine disables all its bus accesses.
10 (R/W1C)	ETI	Early Transmit Interrupt. The `EMAC_DMA0_STAT.ETI` bit indicates that the frame to be transmitted was fully transferred to the MFL Transmit FIFO.
9 (R/W1C)	RWT	Receive WatchDog Timeout. The `EMAC_DMA0_STAT.RWT` bit is asserted when a frame with a length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
8 (R/W1C)	RPS	Receive Process Stopped. The `EMAC_DMA0_STAT.RPS` bit is asserted when the Receive Process enters the Stopped state.
7 (R/W1C)	RU	Receive Buffer Unavailable. The `EMAC_DMA0_STAT.RU` bit indicates that the Next Descriptor in the Receive List is owned by the application and cannot be acquired by the DMA. Receive Process is suspended. To resume processing Receive descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor was owned by the DMA.
6 (R/W1C)	RI	Receive Interrupt. The `EMAC_DMA0_STAT.RI` bit indicates the completion of frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.
5 (R/W1C)	UNF	Transmit Buffer Underflow. The `EMAC_DMA0_STAT.UNF` bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.
4 (R/W1C)	OVF	Receive Buffer Overflow. The `EMAC_DMA0_STAT.OVF` bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to application, the overflow status is set in RDES0[11].
3 (R/W1C)	TJT	Transmit Jabber Timeout. The `EMAC_DMA0_STAT.TJT` bit indicates that the Transmit Jabber Timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.

Table 31-71: EMAC_DMA0_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W1C)	TU	Transmit Buffer Unavailable. The `EMAC_DMA0_STAT.TU` bit indicates that the Next Descriptor in the Transmit List is owned by the application and cannot be acquired by the DMA. Transmission is suspended. The value in the `EMAC_DMA0_STAT.TS` bits explain the Transmit Process state transitions. To resume processing transmit descriptors, the application should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command.
1 (R/W1C)	TPS	Transmit Process Stopped. The `EMAC_DMA0_STAT.TPS` bit is set when the transmission is stopped.
0 (R/W1C)	TI	Transmit Interrupt. The `EMAC_DMA0_STAT.TI` bit indicates that frame transmission is finished and TDES1[31] is set in the First Descriptor.

DMA Tx Buffer Current Register

The `EMAC_DMA0_TXBUF_CUR` register holds the pointer to the current transmit DMA buffer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 31-72: EMAC_DMA0_TXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Current Buffer Address. The `EMAC_DMA0_TXBUF_CUR.ADDR` bit field points to the current Transmit Buffer Address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Descriptor List Address Register

The `EMAC_DMA0_TXDSC_ADDR` register holds the address for the DMA transmit descriptor list. The processor can write to this Register only when Tx DMA has stopped (`EMAC_DMA0_OPMODE.ST` bit =0). When stopped, this can be written with a new descriptor list address. When the processor sets the `EMAC_DMA0_OPMODE.ST` bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the `EMAC_DMA0_OPMODE.ST` bit is cleared to 0, then the DMA takes the descriptor address where it was stopped earlier.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Transmit Poll Demand. The EMAC_DMA0_TXPOLL.START bits, when written with any value, cause the DMA to read the current descriptor pointed to by EMAC_DMA0_TXDSC_CUR register. If that descriptor is not available (owned by application), transmission returns to the Suspend state, and the EMAC_DMA0_STAT.TU bit is asserted. If the descriptor is available, transmission resumes.

DMA Bus Mode Register

The `EMAC_DMA1_BUSMODE` register selects the DMA bus operating modes for EMAC DMA.

Fixed Burst
RPBL (R/W)
Receive Programmable Burst Length

Figure 31-44: EMAC_DMA1_BUSMODE Register Diagram

Table 31-76: EMAC_DMA1_BUSMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	AAL	Address Aligned Bursts. The `EMAC_DMA1_BUSMODE.AAL` bit, when set high and the FB bit equals 1, directs the SCB interface to generate all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffers start address) is not aligned, but subsequent bursts are aligned to the address.
24 (R/W)	PBL8	PBL * 8. The `EMAC_DMA1_BUSMODE.PBL8` bit, when set high, multiplies the PBL value programmed (bits [22:17] and bits [13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, and 32 beats depending on the PBL value.
23 (R/W)	USP	Use Separate PBL. The `EMAC_DMA1_BUSMODE.USP` bit, when set high, configures the Rx DMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to Tx DMA operations only.

Table 31-76: EMAC_DMA1_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22:17 (R/W)	RPBL	Receive Programmable Burst Length. The `EMAC_DMA1_BUSMODE.RPBL` bits indicate the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read/Write. The Rx DMA always attempts to burst as specified in RPBL every time it starts a Burst transfer on the host bus. RPBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.
16 (R/W)	FB	Fixed Burst. The `EMAC_DMA1_BUSMODE.FB` bit controls whether the SCB Master interface performs fixed burst transfers or not. See the `EMAC_DMA0_BMMODE.UNDEF` bit description for more information.
13:8 (R/W)	PBL	Programmable Burst Length. The `EMAC_DMA1_BUSMODE.PBL` bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read/Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable for Tx DMA transactions only. PBL-max limit = (FIFO size / 2) / 4. PBL-max limit (transmit) = 256 bytes / 2 /4 = 32. PBL-max limit (receive) = 128 bytes / 2 /4 = 16. Note that this PBL is at the DMA end. If PBL= 32 and if BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If `EMAC_DMA1_BUSMODE.PBL` =8, and if `EMAC_DMA0_BMMODE.BLEN16` is enabled, the max burst is limited to `EMAC_DMA0_BMMODE.BLEN8`. If `EMAC_DMA1_BUSMODE.PBL8` bit is set, the programmed PBL value is multiplied by 8 times internally. However, the result cannot be more than the above maximum limits specified above.
7 (R/W)	ATDS	Alternate Descriptor Size. The `EMAC_DMA1_BUSMODE.ATDS` bit, when set, increases the size of the alternate descriptor to 32 bytes (8 DWORDS). This is required when the Advanced Time Stamp feature or Full IPC Offload Engine is enabled in the receiver. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). The enhanced descriptor is not required if the Advanced Time Stamp and IPC Full Checksum Offload features are not enabled. In such case, you can use the 16 bytes descriptor to save 4 bytes of memory.

Table 31-76: EMAC_DMA1_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:2 (R/W)	DSL	Descriptor Skip Length. The `EMAC_DMA1_BUSMODE.DSL` bit specifies the number of 32-bit words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA, in Ring mode.

Channel 1 Credit Shaping Control Register

The `EMAC_DMA1_CHCBSCTL` register controls the credit-based shaper algorithm in the Traffic Manager for scheduling the frames for transmission. This register is present only when you select the Transmit Channel 1 in the AV mode.

ABPSSIE (R/W)
Average Bits Per Slot Interrupt Enable

Figure 31-45: EMAC_DMA1_CHCBSCTL Register Diagram

Table 31-77: EMAC_DMA1_CHCBSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	ABPSSIE	Average Bits Per Slot Interrupt Enable. When the `EMAC_DMA1_CHCBSCTL.ABPSSIE` bit is set, the MAC asserts an interrupt (sbd_intr_o or mci_intr_o) when the average bits per slot status is updated for Channel 1. When this bit is cleared, an interrupt is not asserted for such an event.
6:4 (R/W)	SLC	Slot Count. The `EMAC_DMA1_CHCBSCTL.SLC` bit field programs the number of slots (of duration 125 micro-sec) over which the average transmitted bits per slot (provided in the CBS Status register) are computed for Channel 1 when the credit-based shaper algorithm is enabled.
1 (R/W)	CC	Credit Control. The `EMAC_DMA1_CHCBSCTL.CC` bit, when reset, sets the accumulated credit parameter in the credit-based shaper algorithm logic to zero when there is positive credit and no frame to transmit in Channel 1.
0 (R/W)	CBSD	Credit based shaper disable. The `EMAC_DMA1_CHCBSCTL.CBSD` bit disables the credit-based shaper algorithm for Channel 1 traffic and makes the traffic management algorithm to strict priority for Channel 1 over Channel 0. When reset, the credit-based shaper algorithm schedules the traffic in Channel 1 for transmission.

Channel 1 Average Traffic Transmitted Register

The `EMAC_DMA1_CHCBSSTAT` register provides the average traffic transmitted in Channel 1. This register is present only when you select the Transmit Channel 1 in the AV mode.

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/NW)	ABSU	ABS Updated. The `EMAC_DMA1_CHCBSSTAT.ABSU` bit indicates that the MAC has updated the ABS value. This bit is cleared when the application reads the ABS value.
16:0 (R/NW)	ABS	Average Bits Per Slot. The `EMAC_DMA1_CHCBSSTAT.ABS` bit field contains the average transmitted bits per slot. This field is computed over programmed number of slots (`EMAC_DMA1_CHCBSCTL.SLC` bit field) for Channel 1 traffic. The maximum value is 0x30D4 for 100 Mbps and 0x1E848 for 1000 Mbps.

Channel 1 High Credit Value Register

The `EMAC_DMA1_CHHIC` register provides the maximum value that can be accumulated for Channel 1 in the credit parameter of the credit-based shaper algorithm. This register is present only when you select the Transmit Channel 1 in the AV mode.

RSN (R)
Reference Slot Number

Figure 31-50: EMAC_DMA1_CHSFCS Register Diagram

Table 31-82: EMAC_DMA1_CHSFCS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/NW)	RSN	Reference Slot Number. The `EMAC_DMA1_CHSFCS.RSN` bits, gives the current value of the reference slot number in DMA used for comparison checking.
1 (R/W)	ASC	Advance Slot Check. The `EMAC_DMA1_CHSFCS.ASC` bits, When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transmit descriptor is ---equal to the reference slot number given in Bits [19:16] -or- ahead of the reference slot number by up to two slots. This bit is applicable only when Bit 0 (ESC) is set.
0 (R/W)	ESC	Enable Slot Comparison. The `EMAC_DMA1_CHSFCS.ESC` bits,When set, this bit enables the checking of the slot numbers, programmed in the transmit descriptor, with the current reference given in Bits [19:16]. The DMA fetches the data from the corresponding buffer only when the slot number is equal to the reference slot number or is ahead of the reference slot number by one slot. When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed.

Channel 1 Send Slope Credit Value Register

The EMAC_DMA1_CHSSC register provides the bandwidth that is available for the AV traffic on other channels. This register is present only when you select the Transmit Channel 1 in the AV mode.

Normal Interrupt Summary Enable

Figure 31-52: EMAC_DMA1_IEN Register Diagram

Table 31-84: EMAC_DMA1_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	NIE	Normal Interrupt Summary Enable. The `EMAC_DMA1_IEN.NIE` bit, when set, enables a normal interrupt. When this bit is reset, a normal interrupt is disabled. This bit enables the following bits: `EMAC_DMA1_STAT.TI`, `EMAC_DMA1_STAT.TU`, `EMAC_DMA1_STAT.RI`, and `EMAC_DMA1_STAT.ERI`.
15 (R/W)	AIE	Abnormal Interrupt Summary Enable. The `EMAC_DMA1_IEN.AIE` bit, when set, enables an abnormal interrupt. When this bit is reset, an Abnormal Interrupt is disabled. This bit enables the following bits: `EMAC_DMA1_STAT.TPS`, `EMAC_DMA1_STAT.TJT`, `EMAC_DMA1_STAT.OVF`, `EMAC_DMA1_STAT.RU`, `EMAC_DMA1_STAT.RPS`, `EMAC_DMA1_STAT.RWT`, `EMAC_DMA1_STAT.ETI`, and `EMAC_DMA1_STAT.FBI`.

Table 31-84: EMAC_DMA1_IEN Register Fields (Continued)

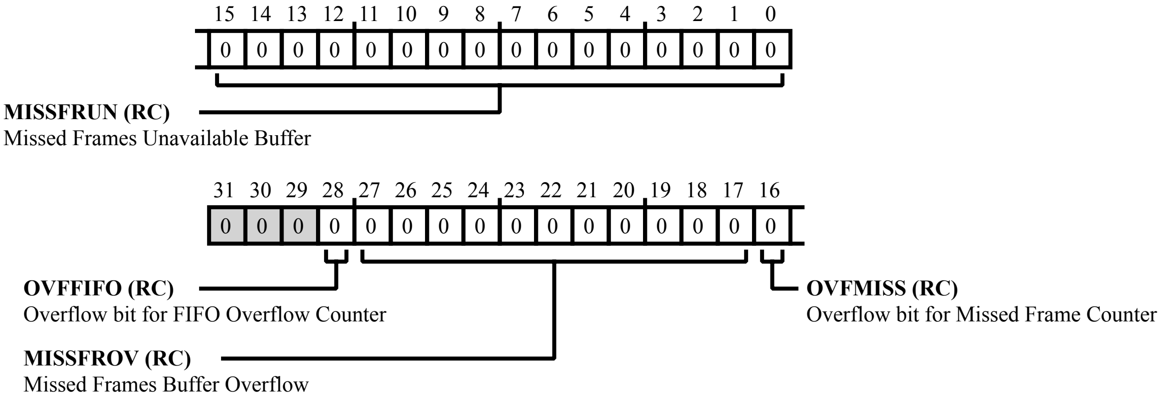
Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	ERE	Early Receive Interrupt Enable. The `EMAC_DMA1_IEN.ERE` bit, when set (and with `EMAC_DMA1_IEN.NIE` =1), enables the Early Receive Interrupt. When this bit is reset, Early Receive Interrupt is disabled.
13 (R/W)	FBE	Fatal Bus Error Enable. The `EMAC_DMA1_IEN.FBE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Fatal Bus Error Interrupt. When this bit is reset, Fatal Bus Error Enable Interrupt is disabled.
10 (R/W)	ETE	Early Transmit Interrupt Enable. The `EMAC_DMA1_IEN.ETE` bit, when this bit is set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Early Transmit Interrupt. When this bit is reset, Early Transmit Interrupt is disabled.
9 (R/W)	RWE	Receive Watchdog Timeout Enable. The `EMAC_DMA1_IEN.RWE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Receive Watchdog Timeout Interrupt. When this bit is reset, Receive Watchdog Timeout Interrupt is disabled.
8 (R/W)	RSE	Receive Stopped Enable. The `EMAC_DMA1_IEN.RSE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Receive Stopped Interrupt is enabled. When this bit is reset, Receive Stopped Interrupt is disabled.
7 (R/W)	RUE	Receive Buffer Unavailable Enable. The `EMAC_DMA1_IEN.RUE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Receive Buffer Unavailable Interrupt. When this bit is reset, the Receive Buffer Unavailable Interrupt is disabled.
6 (R/W)	RIE	Receive Interrupt Enable. The `EMAC_DMA1_IEN.RIE` bit, when set (and with `EMAC_DMA1_IEN.NIE` =1), enables the Receive Interrupt. When this bit is reset, Receive Interrupt is disabled.
5 (R/W)	UNE	Underflow Interrupt Enable. The `EMAC_DMA1_IEN.UNE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Transmit Underflow Interrupt. When this bit is reset, Underflow Interrupt is disabled.
4 (R/W)	OVE	Overflow Interrupt Enable. The `EMAC_DMA1_IEN.OVE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Receive Overflow Interrupt. When this bit is reset, Overflow Interrupt is disabled.

Table 31-84: EMAC_DMA1_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TJE	Transmit Jabber Timeout Enable. The `EMAC_DMA1_IEN.TJE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Transmit Jabber Timeout Interrupt. When this bit is reset, Transmit Jabber Timeout Interrupt is disabled.
2 (R/W)	TUE	Transmit Buffer Unavailable Enable. The `EMAC_DMA1_IEN.TUE` bit, when set (and with `EMAC_DMA1_IEN.NIE` =1), enables the Transmit Buffer Unavailable Interrupt. When this bit is reset, Transmit Buffer Unavailable Interrupt is disabled.
1 (R/W)	TSE	Transmit Stopped Enable. The `EMAC_DMA1_IEN.TSE` bit, when set (and with `EMAC_DMA1_IEN.AIE` =1), enables the Transmission Stopped Interrupt. When this bit is reset, Transmission Stopped Interrupt is disabled.
0 (R/W)	TIE	Transmit Interrupt Enable. The `EMAC_DMA1_IEN.TIE` bit, when set (and with `EMAC_DMA1_IEN.NIE` =1), enables the Transmit Interrupt. When this bit is reset, Transmit Interrupt is disabled.

DMA Missed Frame Register

The EMAC_DMA1_MISS_FRM register contains counters for EMAC DMA missed frames and buffer overflows.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

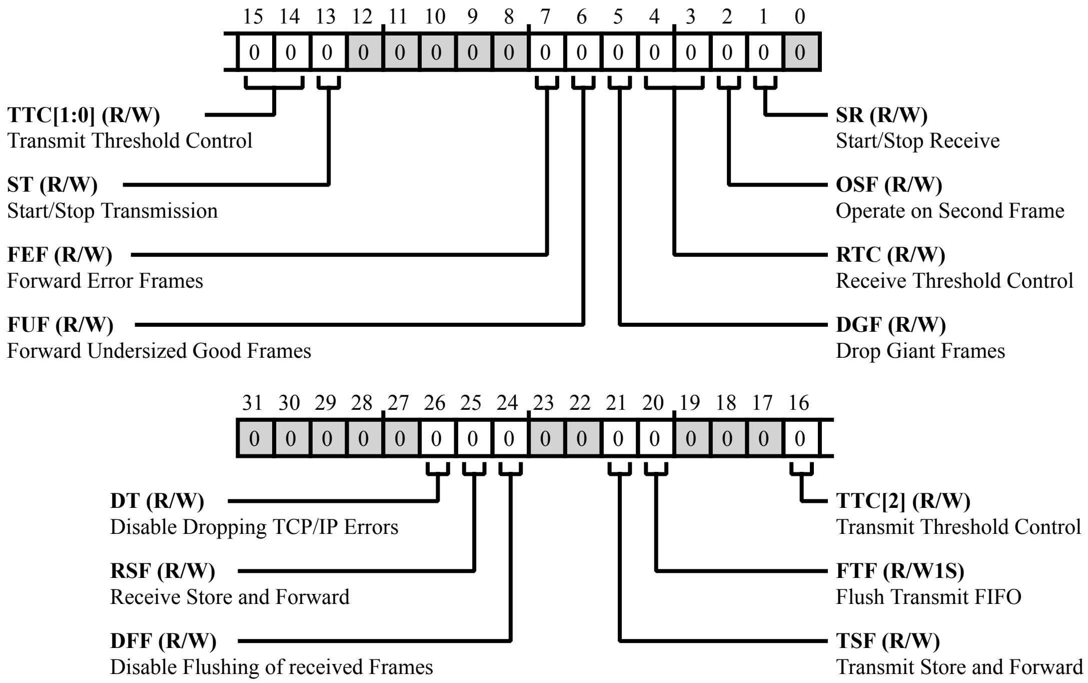
Bit No. (Access)	Bit Name	Description/Enumeration
28 (RC/NW)	OVFFIFO	Overflow bit for FIFO Overflow Counter. The EMAC_DMA1_MISS_FRM.OVFFIFO bit holds the overflow bit for FIFO Overflow Counter.
27:17 (RC/NW)	MISSFROV	Missed Frames Buffer Overflow. The EMAC_DMA1_MISS_FRM.MISSFROV bits indicate the number of frames missed by the application due to buffer overflow.
16 (RC/NW)	OVFMISS	Overflow bit for Missed Frame Counter. The EMAC_DMA1_MISS_FRM.OVFMISS bit holds the overflow bit for the Missed Frame Counter.
15:0 (RC/NW)	MISSFRUN	Missed Frames Unavailable Buffer. The EMAC_DMA1_MISS_FRM.MISSFRUN bits indicate the number of frames missed by the controller because of the Application Receive Buffer being unavailable.

DMA Operation Mode Register

The `EMAC_DMA1_OPMODE` register selects receive and transmit DMA operating modes.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

TSF (R/W)
Transmit Store and Forward

Figure 31-54: EMAC_DMA1_OPMODE Register Diagram

Table 31-86: EMAC_DMA1_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	DT	Disable Dropping TCP/IP Errors. The `EMAC_DMA1_OPMODE.DT` bit, when set, directs the core not to drop frames that only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is reset, all error frames are dropped if the `EMAC_DMA1_OPMODE.FEF` bit is reset.
25 (R/W)	RSF	Receive Store and Forward. The `EMAC_DMA1_OPMODE.RSF` bit, when set, directs the MFL only to read a frame from the Rx FIFO after the complete frame has been written to it, ignoring the `EMAC_DMA1_OPMODE.RTC` bits. When this bit is reset, the Rx FIFO operates in threshold mode, subject to the threshold specified by the `EMAC_DMA1_OPMODE.RTC` bits.
24 (R/W)	DFF	Disable Flushing of received Frames. The `EMAC_DMA1_OPMODE.DFF` bit, when set, directs the Rx DMA not to flush any frames because of the unavailability of receive descriptors/buffers as it does normally when this bit is reset.

Table 31-86: EMAC_DMA1_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	TSF	Transmit Store and Forward. The `EMAC_DMA1_OPMODE.TSF` bit, when set, starts transmission when a full frame resides in the MFL Transmit FIFO. When this bit is set, the TTC values specified in Register 6[16:14] are ignored. This bit should be changed only when transmission is stopped.	
20 (R/W1S)	FTF	Flush Transmit FIFO. The `EMAC_DMA1_OPMODE.FTF` bit, when set, directs the transmit FIFO controller logic to reset to its default values and thus all data in the Tx FIFO is lost/flushed. This bit is cleared internally when the flushing operation is completed fully. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation completes only after emptying the Tx FIFO of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. In order to complete this flush operation, the PHY transmit clock is required to be active. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.	
16:14 (R/W)	TTC	Transmit Threshold Control. The `EMAC_DMA1_OPMODE.TTC` bits control the threshold level of the MFL Transmit FIFO. Transmission starts when the frame size within the MFL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the `EMAC_DMA1_OPMODE.TSF` bit is reset. The value =011 is not used.	
		0	64
		1	128
		2	192
		3	256
		4	40
		5	32
		6	24
		7	16

Table 31-86: EMAC_DMA1_OPMODE Register Fields (Continued)

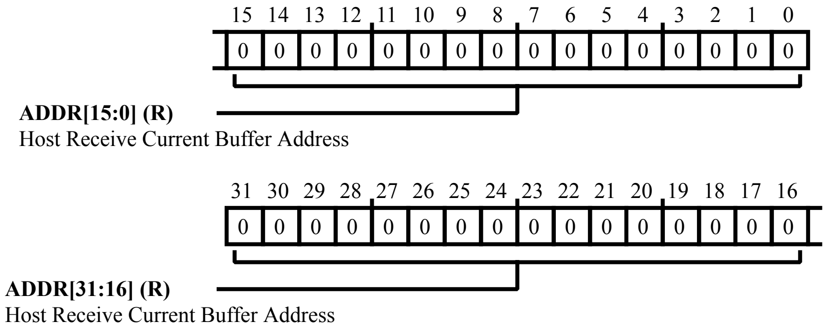
Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	ST	Start/Stop Transmission. The `EMAC_DMA1_OPMODE.ST` bit, when set, places transmission in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Transmit Descriptor List Address, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state, and the `EMAC_DMA1_STAT.TU` bit is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting the `EMAC_DMA1_TXDSC_CUR` address register, then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and becomes the current position when transmission is restarted. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.
7 (R/W)	FEF	Forward Error Frames. The `EMAC_DMA1_OPMODE.FEF` bit, when reset, directs the Rx FIFO to drop frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frames start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. When `EMAC_DMA1_OPMODE.FEF` bit is set, all frames except runt error frames are forwarded to the DMA. But when Rx FIFO overflows when a partial frame is written, then such frames are dropped even when `EMAC_DMA1_OPMODE.FEF` is set.
6 (R/W)	FUF	Forward Undersized Good Frames. The `EMAC_DMA1_OPMODE.FUF` bit, when set, directs the Rx FIFO to forward Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC). When reset, the Rx FIFO drops all frames of less than 64 bytes, unless it is already transferred because of lower value of Receive Threshold (for example, `EMAC_DMA1_OPMODE.RTC` =01).
5 (R/W)	DGF	Drop Giant Frames. The `EMAC_DMA1_OPMODE.DGF` bit, when set, the MAC drops the received giant frames in the Rx FIFO, that is, frames that are larger than the computed giant frame limit. When reset, the MAC does not drop the giant frames in the Rx FIFO.

Table 31-86: EMAC_DMA1_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/W)	RTC	Receive Threshold Control. The `EMAC_DMA1_OPMODE.RTC` bits control the threshold level of the MFL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MFL Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically. These bits are valid only when the `EMAC_DMA1_OPMODE.RSF` bit is zero, and are ignored when the `EMAC_DMA1_OPMODE.RSF` bit is set to 1. The value =11 is not used.	
		0	64
		1	32
		2	96
		3	128
2 (R/W)	OSF	Operate on Second Frame. The `EMAC_DMA1_OPMODE.OSF` bit, when set, instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.	
1 (R/W)	SR	Start/Stop Receive. The `EMAC_DMA1_OPMODE.SR` bit, when set, places the Receive process in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by DMA Receive Descriptor List Address or the position retained when the Receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended, and the `EMAC_DMA1_STAT.RU` bit is set. The Start Receive command is effective only when reception has stopped. If the command was issued before setting `EMAC_DMA1_RXDSC_CUR` address register, DMA behavior is unpredictable. When this bit is cleared, Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.	

DMA Rx Buffer Current Register

The EMAC_DMA1_RXBUF_CUR register holds the pointer to the current receive DMA buffer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

ADDR[31:16] (R)
Host Receive Current Buffer Address

Figure 31-55: EMAC_DMA1_RXBUF_CUR Register Diagram

Table 31-87: EMAC_DMA1_RXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Buffer Address. The `EMAC_DMA1_RXBUF_CUR.ADDR` bit field points to the current Receive Buffer address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Descriptor List Address Register

The `EMAC_DMA1_RXDSC_ADDR` register holds the address for the DMA receive descriptor list. Writing to this Register is permitted only when reception is stopped. When stopped, this must be written to before the receive Start command is given. The processor can write to `EMAC_DMA1_RXDSC_ADDR` only when Rx DMA has stopped (`EMAC_DMA1_OPMODE.SR` bit =0). When stopped, it can be written with a new descriptor list address. When the processor sets the `EMAC_DMA1_OPMODE.SR` bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the `EMAC_DMA1_OPMODE.SR` bit is cleared to 0, the DMA takes the descriptor address where it was stopped earlier.

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

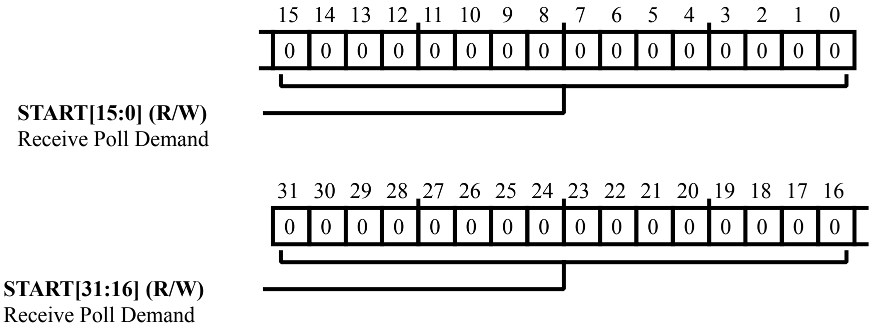
Figure 31-58: EMAC_DMA1_RXIWDOG Register Diagram

Table 31-90: EMAC_DMA1_RXIWDOG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RIWT	RI Watch Dog Timer Count. The `EMAC_DMA1_RXIWDOG.RIWT` bit field indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when `EMAC_DMA1_STAT.RI` bit is set high because of automatic setting of `EMAC_DMA1_STAT.RI` as per RDES1[31] of any received frame.

DMA Rx Poll Demand Register

The EMAC_DMA1_RXPOLL register directs the EMAC to poll the receive descriptor list.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
START[31:16] (R/W)
Receive Poll Demand

Figure 31-59: EMAC_DMA1_RXPOLL Register Diagram

Table 31-91: EMAC_DMA1_RXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Receive Poll Demand. The `EMAC_DMA1_RXPOLL.START` bits, when written with any value, cause the DMA to read the current descriptor pointed to by the `EMAC_DMA1_RXDSC_CUR` register. If that descriptor is not available (owned by application), reception returns to the Suspended state, and the `EMAC_DMA1_STAT.RU` bit is asserted. If the descriptor is available, the Receive DMA returns to the active state.

DMA Status Register

The `EMAC_DMA1_STAT` register indicates EMAC DMA status.

Figure 31-60: EMAC_DMA1_STAT Register Diagram

Table 31-92: EMAC_DMA1_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	GTMSI	MAC TMS Interrupt. MAC TMS Interrupt: The `EMAC_DMA1_STAT.GTMSI` bit indicates an interrupt event in the traffic manager and scheduler logic. To reset this bit, the software must read the corresponding registers (Channel Status Register) to get the exact cause of the interrupt and clear its source.

Table 31-92: EMAC_DMA1_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/NW)	TTI	Time Stamp Trigger Interrupt. The `EMAC_DMA1_STAT.TTI` bit indicates an interrupt event in the MAC core's Time Stamp Generator block. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear its source to reset this bit to =0. When this bit is high, the interrupt signal from the MAC is high.	
27 (R/NW)	MCI	MAC MMC Interrupt. The `EMAC_DMA1_STAT.MCI` bit reflects an interrupt event in the MMC module of the MAC core. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear the source of interrupt to make this bit as =0. The interrupt signal from the MAC is high when this bit is high.	
26 (R/NW)	GLI	Line Interface Interrupt. The `EMAC_DMA1_STAT.GLI` bit When set, this bit reflects any of the following interrupt events in the DWC_gmac interfaces	
25:23 (R/NW)	EB	Error Bits. The `EMAC_DMA1_STAT.EB` bits indicate the type of error that caused a Bus Error (for example, error response on the SCB interface). These bits are valid only when the `EMAC_DMA1_STAT.FBI` bit is set. This field does not generate an interrupt.	
		0	Error during data buffer access, write transfer, Rx DMA
		1	Error during data buffer access, write transfer, Tx DMA
		2	Error during data buffer access, read transfer, Rx DMA
		3	Error during data buffer access, read transfer, Tx DMA
		4	Error during descriptor access, write transfer, Rx DMA
		5	Error during descriptor access, write transfer, Tx DMA
		6	Error during descriptor access, read transfer, Rx DMA
		7	Error during descriptor access, read transfer, Tx DMA
22:20 (R/NW)	TS	Tx Process State. The `EMAC_DMA1_STAT.TS` bits indicate the transmit DMA state. This field does not generate an interrupt.	
		0	Stopped; Reset or Stop Tx Command Issued
		1	Running; Fetching Tx Transfer Descriptor
		2	Running; Waiting for Status
		3	Reading Data from Host Memory Buffer and Queuing It to Tx Buffer
		4	TIME_STAMP Write State

Table 31-92: EMAC_DMA1_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Reserved
		6	Suspended; Tx Descriptor Unavailable or Tx Buffer Underflow
		7	Closing Tx Descriptor
19:17 (R/NW)	RS	Rx Process State. The `EMAC_DMA1_STAT.RS` bits indicate the receive DMA state. This field does not generate an interrupt.	
		0	Stopped: Reset or Stop Rx Command Issued.
		1	Running: Fetching Rx Transfer Descriptor.
		2	Reserved
		3	Running: Waiting for Rx Packet
		4	Suspended: Rx Descriptor Unavailable
		5	Running: Closing Rx Descriptor
		6	TIME_STAMP Write State
		7	Running: Transferring Rx Packet Data from Rx Buffer to Host Memory
16 (R/W1C)	NIS	Normal Interrupt Summary. The value of the `EMAC_DMA1_STAT.NIS` bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: `EMAC_DMA1_STAT.TI`, `EMAC_DMA1_STAT.TU`, `EMAC_DMA1_STAT.RI`, and `EMAC_DMA1_STAT.ERI`. Only unmasked bits affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes `EMAC_DMA1_STAT.NIS` to be set is cleared.	
15 (R/W1C)	AIS	Abnormal Interrupt Summary. The value of the `EMAC_DMA1_STAT.AIS` bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: `EMAC_DMA1_IEN.TSE`, `EMAC_DMA1_IEN.TJE`, `EMAC_DMA1_IEN.OVE`, `EMAC_DMA1_IEN.UNE`, `EMAC_DMA1_IEN.RUE`, `EMAC_DMA1_IEN.RSE`, `EMAC_DMA1_IEN.RWE`, `EMAC_DMA1_IEN.ETE`, and `EMAC_DMA1_IEN.FBE`. Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit that causes `EMAC_DMA1_STAT.AIS` to be set is cleared.	
14 (R/W1C)	ERI	Early Receive Interrupt. The `EMAC_DMA1_STAT.ERI` bit indicates that the DMA had filled the first data buffer of the packet. The `EMAC_DMA1_STAT.RI` bit automatically clears this bit.	

Table 31-92: EMAC_DMA1_STAT Register Fields (Continued)

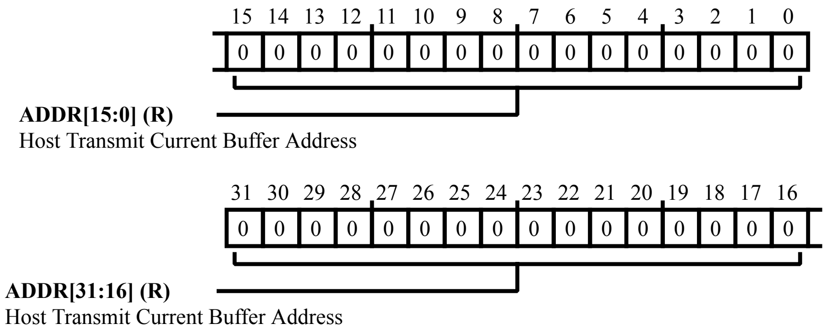
Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	FBI	Fatal Bus Error Interrupt. The `EMAC_DMA1_STAT.FBI` bit indicates that a bus error occurred, as detailed in the `EMAC_DMA1_STAT.EB` field. When this bit is set, the corresponding DMA engine disables all its bus accesses.
10 (R/W1C)	ETI	Early Transmit Interrupt. The `EMAC_DMA1_STAT.ETI` bit indicates that the frame to be transmitted was fully transferred to the MFL Transmit FIFO.
9 (R/W1C)	RWT	Receive WatchDog Timeout. The `EMAC_DMA1_STAT.RWT` bit is asserted when a frame with a length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
8 (R/W1C)	RPS	Receive Process Stopped. The `EMAC_DMA1_STAT.RPS` bit is asserted when the Receive Process enters the Stopped state.
7 (R/W1C)	RU	Receive Buffer Unavailable. The `EMAC_DMA1_STAT.RU` bit indicates that the Next Descriptor in the Receive List is owned by the application and cannot be acquired by the DMA. Receive Process is suspended. To resume processing Receive descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor was owned by the DMA.
6 (R/W1C)	RI	Receive Interrupt. The `EMAC_DMA1_STAT.RI` bit indicates the completion of frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.
5 (R/W1C)	UNF	Transmit Buffer Underflow. The `EMAC_DMA1_STAT.UNF` bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.
4 (R/W1C)	OVF	Receive Buffer Overflow. The `EMAC_DMA1_STAT.OVF` bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to application, the overflow status is set in RDES0[11].
3 (R/W1C)	TJT	Transmit Jabber Timeout. The `EMAC_DMA1_STAT.TJT` bit indicates that the Transmit Jabber Timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.

Table 31-92: EMAC_DMA1_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W1C)	TU	Transmit Buffer Unavailable. The `EMAC_DMA1_STAT.TU` bit indicates that the Next Descriptor in the Transmit List is owned by the application and cannot be acquired by the DMA. Transmission is suspended. The value in the `EMAC_DMA1_STAT.TS` bits explain the Transmit Process state transitions. To resume processing transmit descriptors, the application should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command.
1 (R/W1C)	TPS	Transmit Process Stopped. The `EMAC_DMA1_STAT.TPS` bit is set when the transmission is stopped.
0 (R/W1C)	TI	Transmit Interrupt. The `EMAC_DMA1_STAT.TI` bit indicates that frame transmission is finished and TDES1[31] is set in the First Descriptor.

DMA Tx Buffer Current Register

The `EMAC_DMA1_TXBUF_CUR` register holds the pointer to the current transmit DMA buffer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Host Transmit Current Buffer Address

Figure 31-61: EMAC_DMA1_TXBUF_CUR Register Diagram

Table 31-93: EMAC_DMA1_TXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Current Buffer Address. The `EMAC_DMA1_TXBUF_CUR.ADDR` bit field points to the current Transmit Buffer Address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Descriptor List Address Register

The `EMAC_DMA1_TXDSC_ADDR` register holds the address for the DMA transmit descriptor list. The processor can write to this Register only when Tx DMA has stopped (`EMAC_DMA1_OPMODE.ST` bit =0). When stopped, this can be written with a new descriptor list address. When the processor sets the `EMAC_DMA1_OPMODE.ST` bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the `EMAC_DMA1_OPMODE.ST` bit is cleared to 0, then the DMA takes the descriptor address where it was stopped earlier.

Table 31-96: EMAC_DMA1_TXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Transmit Poll Demand. The `EMAC_DMA1_TXPOLL.START` bits, when written with any value, cause the DMA to read the current descriptor pointed to by `EMAC_DMA1_TXDSC_CUR` register. If that descriptor is not available (owned by application), transmission returns to the Suspend state, and the `EMAC_DMA1_STAT.TU` bit is asserted. If the descriptor is available, transmission resumes.

DMA Bus Mode Register

The `EMAC_DMA2_BUSMODE` register selects the DMA bus operating modes for EMAC DMA.

Fixed Burst
RPBL (R/W)
Receive Programmable Burst Length

Figure 31-65: EMAC_DMA2_BUSMODE Register Diagram

Table 31-97: EMAC_DMA2_BUSMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	AAL	Address Aligned Bursts. The `EMAC_DMA2_BUSMODE.AAL` bit, when set high and the FB bit equals 1, directs the SCB interface to generate all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffers start address) is not aligned, but subsequent bursts are aligned to the address.
24 (R/W)	PBL8	PBL * 8. The `EMAC_DMA2_BUSMODE.PBL8` bit, when set high, multiplies the PBL value programmed (bits [22:17] and bits [13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, and 32 beats depending on the PBL value.
23 (R/W)	USP	Use Separate PBL. The `EMAC_DMA2_BUSMODE.USP` bit, when set high, configures the Rx DMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to Tx DMA operations only.

Table 31-97: EMAC_DMA2_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22:17 (R/W)	RPBL	Receive Programmable Burst Length. The `EMAC_DMA2_BUSMODE.RPBL` bits indicate the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read/Write. The Rx DMA always attempts to burst as specified in RPBL every time it starts a Burst transfer on the host bus. RPBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.
16 (R/W)	FB	Fixed Burst. The `EMAC_DMA2_BUSMODE.FB` bit controls whether the SCB Master interface performs fixed burst transfers or not. See the `EMAC_DMA0_BMMODE.UNDEF` bit description for more information.
13:8 (R/W)	PBL	Programmable Burst Length. The `EMAC_DMA2_BUSMODE.PBL` bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read/Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable for Tx DMA transactions only. PBL-max limit = (FIFO size / 2) / 4. PBL-max limit (transmit) = 256 bytes / 2 /4 = 32. PBL-max limit (receive) = 128 bytes / 2 /4 = 16. Note that this PBL is at the DMA end. If PBL= 32 and if BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If `EMAC_DMA2_BUSMODE.PBL` =8, and if `EMAC_DMA0_BMMODE.BLEN16` is enabled, the max burst is limited to `EMAC_DMA0_BMMODE.BLEN8`. If `EMAC_DMA2_BUSMODE.PBL8` bit is set, the programmed PBL value is multiplied by 8 times internally. However, the result cannot be more than the above maximum limits specified above.
7 (R/W)	ATDS	Alternate Descriptor Size. The `EMAC_DMA2_BUSMODE.ATDS` bit, when set, increases the size of the alternate descriptor to 32 bytes (8 DWORDS). This is required when the Advanced Time Stamp feature or Full IPC Offload Engine is enabled in the receiver. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). The enhanced descriptor is not required if the Advanced Time Stamp and IPC Full Checksum Offload features are not enabled. In such case, you can use the 16 bytes descriptor to save 4 bytes of memory.

Table 31-97: EMAC_DMA2_BUSMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:2 (R/W)	DSL	Descriptor Skip Length. The `EMAC_DMA2_BUSMODE.DSL` bit specifies the number of 32-bit words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA, in Ring mode.
0 (R/W1S)	SWR	Software Reset. The `EMAC_DMA2_BUSMODE.SWR` bit, when set, directs the MAC DMA Controller to reset all MAC Subsystem internal registers and logic. It is cleared automatically after the reset operation has completed in all of the core clock domains. Read a 0 value in this bit before re-programming any register of the core. Note: The reset operation is completed only when all the resets in all the active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.

Channel 2 Credit Shaping Control Register

The `EMAC_DMA2_CHCBSCTL` register controls the credit-based shaper algorithm in the Traffic Manager for scheduling the frames for transmission. This register is present only when you select the Transmit Channel 1 in the AV mode.

ABPSSIE (R/W)
Average bits per slot Interrupt Enable

Figure 31-66: EMAC_DMA2_CHCBSCTL Register Diagram

Table 31-98: EMAC_DMA2_CHCBSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	ABPSSIE	Average bits per slot Interrupt Enable. The `EMAC_DMA2_CHCBSCTL.ABPSSIE` bit asserts an interrupt (sbd_intr_o or mci_intr_o) when the average bits per slot status is updated for Channel 1. When this bit is cleared, interrupt is not asserted for such an event.
6:4 (R/W)	SLC	Slot Count. The `EMAC_DMA2_CHCBSCTL.SLC` bit field programs the number of slots (of duration 125 micro-sec) over which the average transmitted bits per slot (provided in the CBS Status register) need to be computed for Channel 1 when the credit-based shaper algorithm is enabled. The
1 (R/W)	CC	Credit Control. The `EMAC_DMA2_CHCBSCTL.CC` bit, when reset, sets the accumulated credit parameter in the credit-based shaper algorithm logic to zero when there is positive credit and no frame to transmit in Channel 1.
0 (R/W)	CBSD	Credit Based Shaper Disable. The `EMAC_DMA2_CHCBSCTL.CBSD` bit disables the credit-based shaper algorithm for Channel 1 traffic and makes the traffic management algorithm to strict priority for Channel 1 over Channel 0. When reset, the credit-based shaper algorithm schedules the traffic in Channel 1 for transmission.

Channel 2 Avg Traffic Transmitted Status Register

The `EMAC_DMA2_CHCBSSTAT` register provides the average traffic transmitted in Channel 1. This register is present only when you select the Transmit Channel 1 in the AV mode.

17 (R/NW)	ABSU	ABS Updated. The `EMAC_DMA2_CHCBSSTAT.ABSU` bits When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application reads the ABS value.
16:0 (R/NW)	ABS	Average Bits per Slot. The `EMAC_DMA2_CHCBSSTAT.ABS` bit field contains the average transmitted bits per slot. This field is computed over programmed number of slots (`EMAC_DMA2_CHCBSCTL.SLC` bit field) for Channel 1 traffic. The maximum value is 0x30D4 for 100 Mbps and 0x1E848 for 1000 Mbps.

Channel 2 High Credit Value Register

The `EMAC_DMA2_CHHIC` register provides the maximum value that can be accumulated for Channel 1 in the credit parameter of the credit-based shaper algorithm. This register is present only when you select the Transmit Channel 1 in the AV mode.

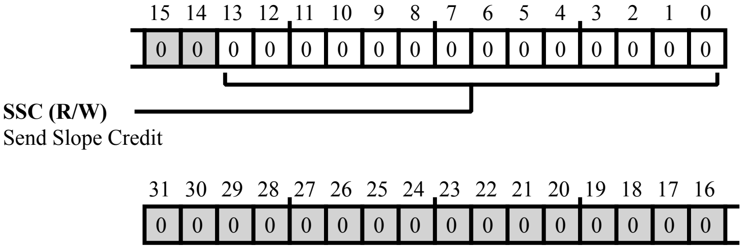
Table 31-103: EMAC_DMA2_CHSFCS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/NW)	RSN	Reference Slot number. The `EMAC_DMA2_CHSFCS.RSN` bits, gives the current value of the reference slot number in DMA used for comparison checking.
1 (R/W)	ASC	Advance Slot Check. The `EMAC_DMA2_CHSFCS.ASC` bits, When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transmit descriptor
0 (R/W)	ESC	Enable Slot Comparison. The `EMAC_DMA2_CHSFCS.ESC` bit enables the checking of the slot numbers, programmed in the transmit descriptor, with the current reference given in Bits [19:16]. The DMA fetches the data from the corresponding buffer only when the slot number is equal to the reference slot number or is ahead of the reference slot number by one slot. When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed.

Channel 2 Send Slope Credit Value Register

The `EMAC_DMA2_CHSSC` register provides the bandwidth that is available for the AV traffic on other channels. This register is present only when you select the Transmit Channel 1 in the AV mode.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	NIE	Normal Interrupt Summary Enable. The `EMAC_DMA2_IEN.NIE` bit, when set, enables a normal interrupt. When this bit is reset, a normal interrupt is disabled. This bit enables the following bits: `EMAC_DMA2_STAT.TI`, `EMAC_DMA2_STAT.TU`, `EMAC_DMA2_STAT.RI`, and `EMAC_DMA2_STAT.ERI`.
15 (R/W)	AIE	Abnormal Interrupt Summary Enable. The `EMAC_DMA2_IEN.AIE` bit, when set, enables an abnormal interrupt. When this bit is reset, an Abnormal Interrupt is disabled. This bit enables the following bits: `EMAC_DMA2_STAT.TPS`, `EMAC_DMA2_STAT.TJT`, `EMAC_DMA2_STAT.OVF`, `EMAC_DMA2_STAT.RU`, `EMAC_DMA2_STAT.RPS`, `EMAC_DMA2_STAT.RWT`, `EMAC_DMA2_STAT.ETI`, and `EMAC_DMA2_STAT.FBI`.

Table 31-105: EMAC_DMA2_IEN Register Fields (Continued)

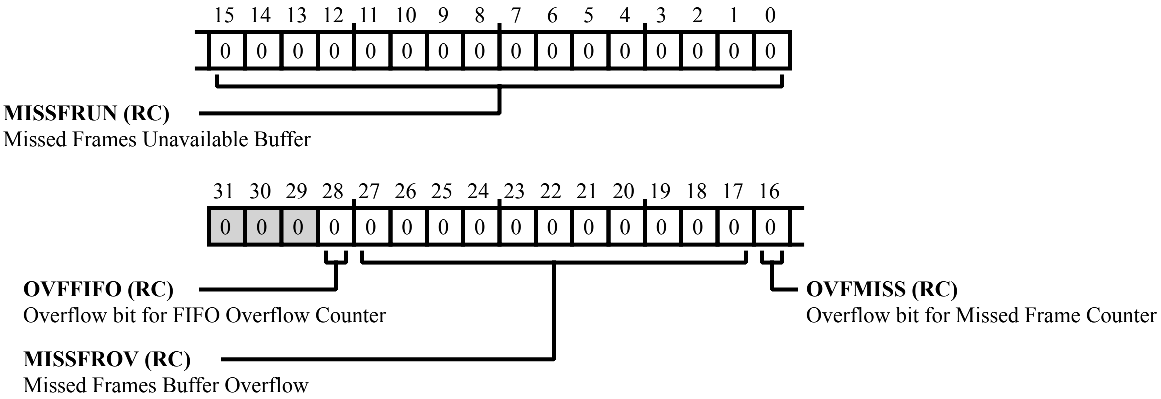
Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	ERE	Early Receive Interrupt Enable. The `EMAC_DMA2_IEN.ERE` bit, when set (and with `EMAC_DMA2_IEN.NIE` =1), enables the Early Receive Interrupt. When this bit is reset, Early Receive Interrupt is disabled.
13 (R/W)	FBE	Fatal Bus Error Enable. The `EMAC_DMA2_IEN.FBE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Fatal Bus Error Interrupt. When this bit is reset, Fatal Bus Error Enable Interrupt is disabled.
10 (R/W)	ETE	Early Transmit Interrupt Enable. The `EMAC_DMA2_IEN.ETE` bit, when this bit is set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Early Transmit Interrupt. When this bit is reset, Early Transmit Interrupt is disabled.
9 (R/W)	RWE	Receive Watchdog Timeout Enable. The `EMAC_DMA2_IEN.RWE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Receive Watchdog Timeout Interrupt. When this bit is reset, Receive Watchdog Timeout Interrupt is disabled.
8 (R/W)	RSE	Receive Stopped Enable. The `EMAC_DMA2_IEN.RSE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Receive Stopped Interrupt is enabled. When this bit is reset, Receive Stopped Interrupt is disabled.
7 (R/W)	RUE	Receive Buffer Unavailable Enable. The `EMAC_DMA2_IEN.RUE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Receive Buffer Unavailable Interrupt. When this bit is reset, the Receive Buffer Unavailable Interrupt is disabled.
6 (R/W)	RIE	Receive Interrupt Enable. The `EMAC_DMA2_IEN.RIE` bit, when set (and with `EMAC_DMA2_IEN.NIE` =1), enables the Receive Interrupt. When this bit is reset, Receive Interrupt is disabled.
5 (R/W)	UNE	Underflow Interrupt Enable. The `EMAC_DMA2_IEN.UNE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Transmit Underflow Interrupt. When this bit is reset, Underflow Interrupt is disabled.
4 (R/W)	OVE	Overflow Interrupt Enable. The `EMAC_DMA2_IEN.OVE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Receive Overflow Interrupt. When this bit is reset, Overflow Interrupt is disabled.

Table 31-105: EMAC_DMA2_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TJE	Transmit Jabber Timeout Enable. The `EMAC_DMA2_IEN.TJE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Transmit Jabber Timeout Interrupt. When this bit is reset, Transmit Jabber Timeout Interrupt is disabled.
2 (R/W)	TUE	Transmit Buffer Unavailable Enable. The `EMAC_DMA2_IEN.TUE` bit, when set (and with `EMAC_DMA2_IEN.NIE` =1), enables the Transmit Buffer Unavailable Interrupt. When this bit is reset, Transmit Buffer Unavailable Interrupt is disabled.
1 (R/W)	TSE	Transmit Stopped Enable. The `EMAC_DMA2_IEN.TSE` bit, when set (and with `EMAC_DMA2_IEN.AIE` =1), enables the Transmission Stopped Interrupt. When this bit is reset, Transmission Stopped Interrupt is disabled.
0 (R/W)	TIE	Transmit Interrupt Enable. The `EMAC_DMA2_IEN.TIE` bit, when set (and with `EMAC_DMA2_IEN.NIE` =1), enables the Transmit Interrupt. When this bit is reset, Transmit Interrupt is disabled.

DMA Missed Frame Register

The EMAC_DMA2_MISS_FRM register contains counters for EMAC DMA missed frames and buffer overflows.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

TSF (R/W)
Transmit Store and Forward

Figure 31-75: EMAC_DMA2_OPMODE Register Diagram

Table 31-107: EMAC_DMA2_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	DT	Disable Dropping TCP/IP Errors. The `EMAC_DMA2_OPMODE.DT` bit, when set, directs the core not to drop frames that only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is reset, all error frames are dropped if the `EMAC_DMA2_OPMODE.FEF` bit is reset.
25 (R/W)	RSF	Receive Store and Forward. The `EMAC_DMA2_OPMODE.RSF` bit, when set, directs the MFL only to read a frame from the Rx FIFO after the complete frame has been written to it, ignoring the `EMAC_DMA2_OPMODE.RTC` bits. When this bit is reset, the Rx FIFO operates in threshold mode, subject to the threshold specified by the `EMAC_DMA2_OPMODE.RTC` bits.
24 (R/W)	DFF	Disable Flushing of Received Frames. The `EMAC_DMA2_OPMODE.DFF` bit, when set, directs the Rx DMA not to flush any frames because of the unavailability of receive descriptors/buffers as it does normally when this bit is reset.

Table 31-107: EMAC_DMA2_OPMODE Register Fields (Continued)

<table>
<tr><th>Bit No.
(Access)</th><th>Bit Name</th><th colspan="2">Description/Enumeration</th></tr>
<tr><td>21
(R/W)</td><td>TSF</td><td colspan="2">Transmit Store and Forward.
The <code>EMAC_DMA2_OPMODE.TSF</code> bit, when set, starts transmission when a full frame resides in the MFL Transmit FIFO. When this bit is set, the TTC values specified in Register 6[16:14] are ignored. This bit should be changed only when transmission is stopped.</td></tr>
<tr><td>20
(R/W1S)</td><td>FTF</td><td colspan="2">Flush Transmit FIFO.
The <code>EMAC_DMA2_OPMODE.FTF</code> bit, when set, directs the transmit FIFO controller logic to reset to its default values and thus all data in the Tx FIFO is lost/flushed. This bit is cleared internally when the flushing operation is completed fully. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation completes only after emptying the Tx FIFO of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. In order to complete this flush operation, the PHY transmit clock is required to be active. This field cleared to 1b0 by the core (Self Clear). The application cannot clear this type of field, and a register write of 1b0 to this bit has no effect on this field.</td></tr>
<tr><td rowspan="9">16:14
(R/W)</td><td rowspan="9">TTC</td><td colspan="2">Transmit Threshold Control.
The <code>EMAC_DMA2_OPMODE.TTC</code> bits control the threshold level of the MFL Transmit FIFO. Transmission starts when the frame size within the MFL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the <code>EMAC_DMA2_OPMODE.TSF</code> bit is reset. The value =011 is not used.</td></tr>
<tr><td>0</td><td>64</td></tr>
<tr><td>1</td><td>128</td></tr>

</table>

Table 31-107: EMAC_DMA2_OPMODE Register Fields (Continued)

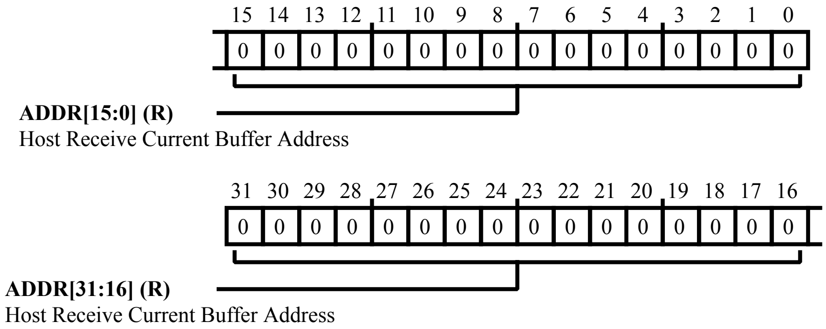
Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	ST	Start/Stop Transmission. The `EMAC_DMA2_OPMODE.ST` bit, when set, places transmission in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Transmit Descriptor List Address, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state, and the `EMAC_DMA2_STAT.TU` bit is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting the `EMAC_DMA2_TXDSC_CUR` address register, then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and becomes the current position when transmission is restarted. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.
7 (R/W)	FEF	Forward Error Frames. The `EMAC_DMA2_OPMODE.FEF` bit, when reset, directs the Rx FIFO to drop frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frames start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. When `EMAC_DMA2_OPMODE.FEF` bit is set, all frames except runt error frames are forwarded to the DMA. But when Rx FIFO overflows when a partial frame is written, then such frames are dropped even when `EMAC_DMA2_OPMODE.FEF` is set.
6 (R/W)	FUF	Forward Undersized good Frames. The `EMAC_DMA2_OPMODE.FUF` bit, when set, directs the Rx FIFO to forward Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC). When reset, the Rx FIFO drops all frames of less than 64 bytes, unless it is already transferred because of lower value of Receive Threshold (for example, `EMAC_DMA2_OPMODE.RTC` =01).
5 (R/W)	DGF	Drop Giant Frames. The `EMAC_DMA2_OPMODE.DGF` bit, when set, the MAC drops the received giant frames in the Rx FIFO, that is, frames that are larger than the computed giant frame limit. When reset, the MAC does not drop the giant frames in the Rx FIFO.

Table 31-107: EMAC_DMA2_OPMODE Register Fields (Continued)

<table>
<tr><th>Bit No.
(Access)</th><th>Bit Name</th><th colspan="2">Description/Enumeration</th></tr>
<tr><td rowspan="5">4:3
(R/W)</td><td rowspan="5">RTC</td><td colspan="2">Receive Threshold Control.
The <code>EMAC_DMA2_OPMODE.RTC</code> bits control the threshold level of the MFL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MFL Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically. These bits are valid only when the <code>EMAC_DMA2_OPMODE.RSF</code> bit is zero, and are ignored when the <code>EMAC_DMA2_OPMODE.RSF</code> bit is set to 1. The value =11 is not used.</td></tr>
<tr><td>0</td><td>64</td></tr>
<tr><td>1</td><td>32</td></tr>
<tr><td>2</td><td>96</td></tr>
<tr><td>3</td><td>128</td></tr>
<tr><td>2
(R/W)</td><td>OSF</td><td colspan="2">Operate on Second Frame.
The <code>EMAC_DMA2_OPMODE.OSF</code> bit, when set, instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.</td></tr>
<tr><td>1
(R/W)</td><td>SR</td><td colspan="2">Start/Stop Receive.
The <code>EMAC_DMA2_OPMODE.SR</code> bit, when set, places the Receive process in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by DMA Receive Descriptor List Address or the position retained when the Receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended, and the <code>EMAC_DMA2_STAT.RU</code> bit is set.
The Start Receive command is effective only when reception has stopped. If the command was issued before setting <code>EMAC_DMA2_RXDSC_CUR</code> address register, DMA behavior is unpredictable. When this bit is cleared, Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.</td></tr>
</table>

DMA Rx Buffer Current Register

The `EMAC_DMA2_RXBUF_CUR` register holds the pointer to the current receive DMA buffer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 31-108: EMAC_DMA2_RXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Receive Current Buffer Address. The `EMAC_DMA2_RXBUF_CUR.ADDR` bit field points to the current Receive Buffer address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Rx Descriptor List Address Register

The `EMAC_DMA2_RXDSC_ADDR` register holds the address for the DMA receive descriptor list. Writing to this Register is permitted only when reception is stopped. When stopped, this must be written to before the receive Start command is given. The processor can write to `EMAC_DMA2_RXDSC_ADDR` only when Rx DMA has stopped (`EMAC_DMA2_OPMODE.SR` bit =0). When stopped, it can be written with a new descriptor list address. When the processor sets the `EMAC_DMA2_OPMODE.SR` bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the `EMAC_DMA2_OPMODE.SR` bit is cleared to 0, the DMA takes the descriptor address where it was stopped earlier.

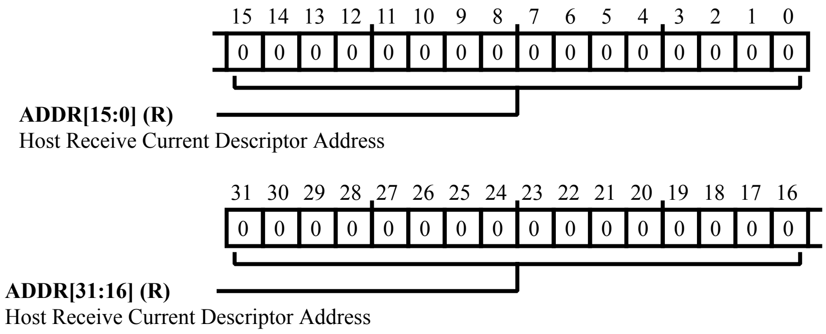
Table 31-109: EMAC_DMA2_RXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Start of Receive List. The `EMAC_DMA2_RXDSC_ADDR.VALUE` bit field contains the base address of the First Descriptor in the Receive Descriptor list. The LSB bits [1:0] for the 32bit bus width are ignored and are taken as all-zero by the DMA internally. Therefore, these LSB bits are Read-Only (RO).

DMA Rx Descriptor Current Register

The `EMAC_DMA2_RXDSC_CUR` register contains the current DMA receive descriptor.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

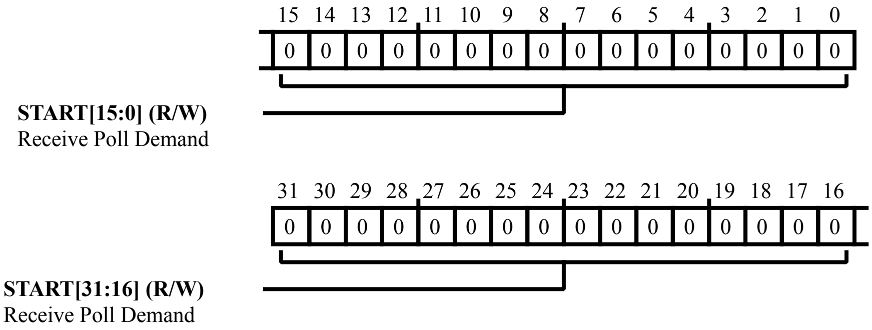
Figure 31-79: EMAC_DMA2_RXIWDOG Register Diagram

Table 31-111: EMAC_DMA2_RXIWDOG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RIWT	RI WatchDog Timer Count. The `EMAC_DMA2_RXIWDOG.RIWT` bit field indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watch-dog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when `EMAC_DMA2_STAT.RI` bit is set high because of automatic setting of `EMAC_DMA2_STAT.RI` as per RDES1[31] of any received frame.

DMA Rx Poll Demand register

The EMAC_DMA2_RXPOLL register directs the EMAC to poll the receive descriptor list.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

START[31:16] (R/W)
Receive Poll Demand

Figure 31-80: EMAC_DMA2_RXPOLL Register Diagram

Table 31-112: EMAC_DMA2_RXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Receive Poll Demand. The `EMAC_DMA2_RXPOLL.START` bits, when written with any value, cause the DMA to read the current descriptor pointed to by the `EMAC_DMA2_RXDSC_CUR` register. If that descriptor is not available (owned by application), reception returns to the Suspended state, and the `EMAC_DMA2_STAT.RU` bit is asserted. If the descriptor is available, the Receive DMA returns to the active state.

DMA Status Register

The `EMAC_DMA2_STAT` register indicates EMAC DMA status.

Figure 31-81: EMAC_DMA2_STAT Register Diagram

Table 31-113: EMAC_DMA2_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	GTMSI	MAC TMS Interrupt. The `EMAC_DMA2_STAT.GTMSI` bit indicates an interrupt event in the traffic manager and scheduler logic. To reset this bit, the software must read the corresponding registers (Channel Status Register) to get the exact cause of the interrupt and clear its source.

Table 31-113: EMAC_DMA2_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/NW)	TTI	Time Stamp Trigger Interrupt. The `EMAC_DMA2_STAT.TTI` bit indicates an interrupt event in the MAC core's Time Stamp Generator block. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear its source to reset this bit to =0. When this bit is high, the interrupt signal from the MAC is high.	
27 (R/NW)	MCI	MAC MMC Interruptl. The `EMAC_DMA2_STAT.MCI` bit reflects an interrupt event in the MMC module of the MAC core. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear the source of interrupt to make this bit as =0. The interrupt signal from the MAC is high when this bit is high.	
26 (R/NW)	GLI	Line Interface Interrupt. The `EMAC_DMA2_STAT.GLI` bit When set, this bit reflects any of the following interrupt events in the DWC_gmac interfaces	
25:23 (R/NW)	EB	Error Bits. The `EMAC_DMA2_STAT.EB` bits indicate the type of error that caused a Bus Error (for example, error response on the SCB interface). These bits are valid only when the `EMAC_DMA2_STAT.FBI` bit is set. This field does not generate an interrupt.	
		0	Error during data buffer access, write transfer, Rx DMA
		1	Error during data buffer access, write transfer, Tx DMA
		2	Error during data buffer access, read transfer, Rx DMA
		3	Error during data buffer access, read transfer, Tx DMA
		4	Error during descriptor access, write transfer, Rx DMA
		5	Error during descriptor access, write transfer, Tx DMA
		6	Error during descriptor access, read transfer, Rx DMA
		7	Error during descriptor access, read transfer, Tx DMA
22:20 (R/NW)	TS	Tx Process State. The `EMAC_DMA2_STAT.TS` bits indicate the transmit DMA state. This field does not generate an interrupt.	
		0	Stopped; Reset or Stop Tx Command Issued
		1	Running; Fetching Tx Transfer Descriptor
		2	Running; Waiting for Status
		3	Reading Data from Host Memory Buffer and Queuing It to Tx Buffer
		4	TIME_STAMP Write State

Table 31-113: EMAC_DMA2_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Reserved
		6	Suspended; Tx Descriptor Unavailable or Tx Buffer Underflow
		7	Closing Tx Descriptor
19:17 (R/NW)	RS	Rx Process State. The `EMAC_DMA2_STAT.RS` bits indicate the receive DMA state. This field does not generate an interrupt.	
		0	Stopped: Reset or Stop Rx Command Issued.
		1	Running: Fetching Rx Transfer Descriptor.
		2	Reserved
		3	Running: Waiting for Rx Packet
		4	Suspended: Rx Descriptor Unavailable
		5	Running: Closing Rx Descriptor
		6	TIME_STAMP Write State
		7	Running: Transferring Rx Packet Data from Rx Buffer to Host Memory
16 (R/W1C)	NIS	Normal Interrupt Summary. The value of the `EMAC_DMA2_STAT.NIS` bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: `EMAC_DMA2_STAT.TI`, `EMAC_DMA2_STAT.TU`, `EMAC_DMA2_STAT.RI`, and `EMAC_DMA2_STAT.ERI`. Only unmasked bits affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes `EMAC_DMA2_STAT.NIS` to be set is cleared.	
15 (R/W1C)	AIS	Abnormal Interrupt Summary. The value of the `EMAC_DMA2_STAT.AIS` bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: `EMAC_DMA2_IEN.TSE`, `EMAC_DMA2_IEN.TJE`, `EMAC_DMA2_IEN.OVE`, `EMAC_DMA2_IEN.UNE`, `EMAC_DMA2_IEN.RUE`, `EMAC_DMA2_IEN.RSE`, `EMAC_DMA2_IEN.RWE`, `EMAC_DMA2_IEN.ETE`, and `EMAC_DMA2_IEN.FBE`. Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit that causes `EMAC_DMA2_STAT.AIS` to be set is cleared.	
14 (R/W1C)	ERI	Early Receive Interrupt. The `EMAC_DMA2_STAT.ERI` bit indicates that the DMA had filled the first data buffer of the packet. The `EMAC_DMA2_STAT.RI` bit automatically clears this bit.	

Table 31-113: EMAC_DMA2_STAT Register Fields (Continued)

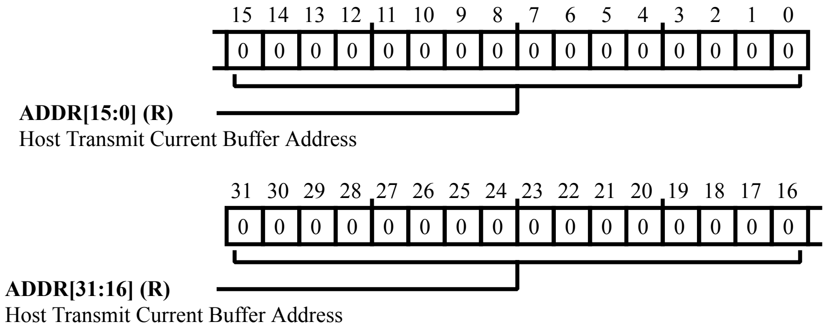
Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	FBI	Fatal Bus Error Interrupt. The `EMAC_DMA2_STAT.FBI` bit indicates that a bus error occurred, as detailed in the `EMAC_DMA2_STAT.EB` field. When this bit is set, the corresponding DMA engine disables all its bus accesses.
10 (R/W1C)	ETI	Early Transmit Interrupt. The `EMAC_DMA2_STAT.ETI` bit indicates that the frame to be transmitted was fully transferred to the MFL Transmit FIFO.
9 (R/W1C)	RWT	Receive WatchDog Timeout. The `EMAC_DMA2_STAT.RWT` bit is asserted when a frame with a length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
8 (R/W1C)	RPS	Receive Process Stopped. The `EMAC_DMA2_STAT.RPS` bit is asserted when the Receive Process enters the Stopped state.
7 (R/W1C)	RU	Receive Buffer Unavailable. The `EMAC_DMA2_STAT.RU` bit indicates that the Next Descriptor in the Receive List is owned by the application and cannot be acquired by the DMA. Receive Process is suspended. To resume processing Receive descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor was owned by the DMA.
6 (R/W1C)	RI	Receive Interrupt. The `EMAC_DMA2_STAT.RI` bit indicates the completion of frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.
5 (R/W1C)	UNF	Transmit Buffer Underflow. The `EMAC_DMA2_STAT.UNF` bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.
4 (R/W1C)	OVF	Receive Buffer Overflow. The `EMAC_DMA2_STAT.OVF` bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to application, the overflow status is set in RDES0[11].
3 (R/W1C)	TJT	Transmit Jabber Timeout. The `EMAC_DMA2_STAT.TJT` bit indicates that the Transmit Jabber Timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.

Table 31-113: EMAC_DMA2_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W1C)	TU	Transmit Buffer Unavailable. The `EMAC_DMA2_STAT.TU` bit indicates that the Next Descriptor in the Transmit List is owned by the application and cannot be acquired by the DMA. Transmission is suspended. The value in the `EMAC_DMA2_STAT.TS` bits explain the Transmit Process state transitions. To resume processing transmit descriptors, the application should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command.
1 (R/W1C)	TPS	Transmit Process Stopped. The `EMAC_DMA2_STAT.TPS` bit is set when the transmission is stopped.
0 (R/W1C)	TI	Transmit Interrupt. The `EMAC_DMA2_STAT.TI` bit indicates that frame transmission is finished and TDES1[31] is set in the First Descriptor.

DMA Tx Buffer Current Register

The `EMAC_DMA2_TXBUF_CUR` register holds the pointer to the current transmit DMA buffer.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Table 31-114: EMAC_DMA2_TXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	ADDR	Host Transmit Current Buffer Address. The `EMAC_DMA2_TXBUF_CUR.ADDR` bit field points to the current Transmit Buffer Address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset.

DMA Tx Descriptor List Address Register

The `EMAC_DMA2_TXDSC_ADDR` register holds the address for the DMA transmit descriptor list. The processor can write to this Register only when Tx DMA has stopped (`EMAC_DMA2_OPMODE.ST` bit =0). When stopped, this can be written with a new descriptor list address. When the processor sets the `EMAC_DMA2_OPMODE.ST` bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the `EMAC_DMA2_OPMODE.ST` bit is cleared to 0, then the DMA takes the descriptor address where it was stopped earlier.

Transmit Poll Demand

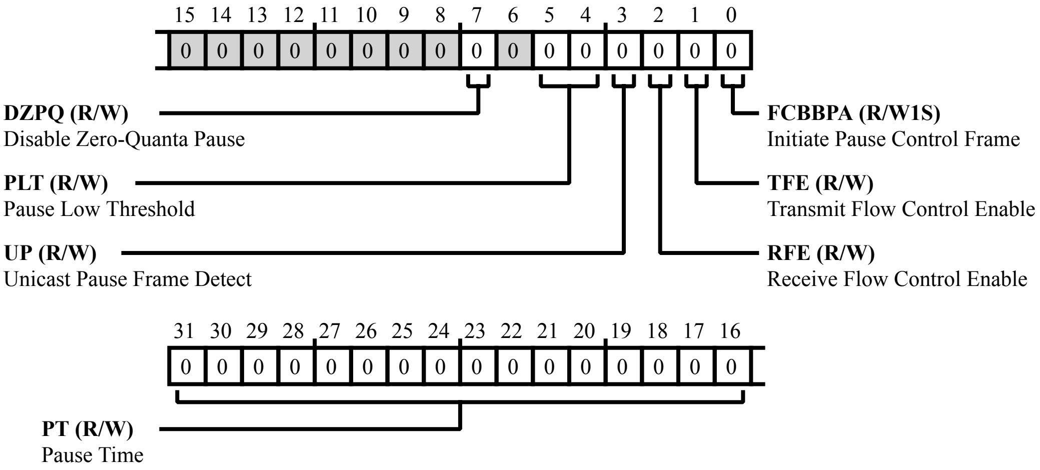
Figure 31-85: EMAC_DMA2_TXPOLL Register Diagram

Table 31-117: EMAC_DMA2_TXPOLL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	START	Transmit Poll Demand. The `EMAC_DMA2_TXPOLL.START` bits, when written with any value, cause the DMA to read the current descriptor pointed to by `EMAC_DMA2_TXDSC_CUR` register. If that descriptor is not available (owned by application), transmission returns to the Suspend state, and the `EMAC_DMA2_STAT.TU` bit is asserted. If the descriptor is available, transmission resumes.

FLow Control Register

The EMAC_FLOWCTL register controls EMAC flow control features.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PT (R/W)
Pause Time

Figure 31-86: EMAC_FLOWCTL Register Diagram

Table 31-118: EMAC_FLOWCTL Register Fields

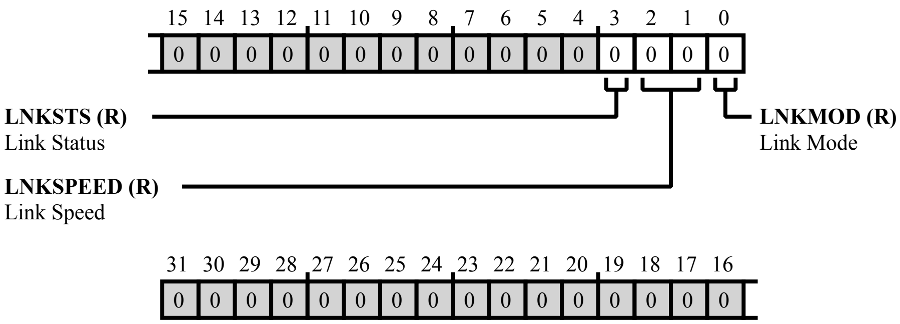
Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	PT	Pause Time. The EMAC_FLOWCTL.PT bits hold the value to be used in the Pause Time field in the transmit control frame.
7 (R/W)	DZPQ	Disable Zero-Quanta Pause. The EMAC_FLOWCTL.DZPQ bit disables the automatic generation of the Zero-Quanta Pause frames on the de-assertion of the flow-control signal from the FIFO layer
5:4 (R/W)	PLT	Pause Low Threshold. The EMAC_FLOWCTL.PLT bit configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause frame.
3 (R/W)	UP	Unicast Pause Frame Detect. The EMAC_FLOWCTL.UP bit, when set, directs the MAC to detect the Pause frames with the station's unicast address specified in EMAC_ADDR0_HI and EMAC_ADDR0_LO address registers. This bit also directs the MAC to the detect Pause frames with the unique multicast address. When this bit is reset, the MAC will detect only a Pause frame with the unique multicast address specified in the 802.3x standard.

Table 31-118: EMAC_FLOWCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	RFE	Receive Flow Control Enable. The `EMAC_FLOWCTL.RFE` bit, when set, directs the MAC to decode the received Pause frame and disable its transmitter for a specified (Pause Time) time. When this bit is reset, the decode function of the Pause frame is disabled.
1 (R/W)	TFE	Transmit Flow Control Enable. In Full-Duplex mode, when the `EMAC_FLOWCTL.TFE` bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In Half-Duplex mode, when this bit is set, the MAC enables the back pressure operation. When this bit is reset, the back pressure feature is disabled.
0 (R/W1S)	FCBBPA	Initiate Pause Control Frame. The `EMAC_FLOWCTL.FCBBPA` bit initiates a Pause Control frame in Full-Duplex mode and activates the back pressure function in Half-Duplex mode if TFE bit is set. In Full-Duplex mode, this bit should be read as =0 before writing to the `EMAC_FLOWCTL` register. To initiate a Pause control frame, the Application must set this bit to =1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to =0. The `EMAC_FLOWCTL` register should not be written to until this bit is cleared. In Half-Duplex mode, when this bit is set (and `EMAC_FLOWCTL.TFE` is set), the back pressure is asserted by the MAC Core. During back pressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. The `EMAC_FLOWCTL.FCBBPA` bit is logically OR'ed with the flow control input signal for the back pressure function. When the MAC is configured to Full-Duplex mode, the back pressure function is automatically disabled.

RGMII Control and Status Register

The `EMAC_GIGE_CTLSTAT` register indicates the status signals received from the PHY through the SGMII, RGMII, or SMII interface.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

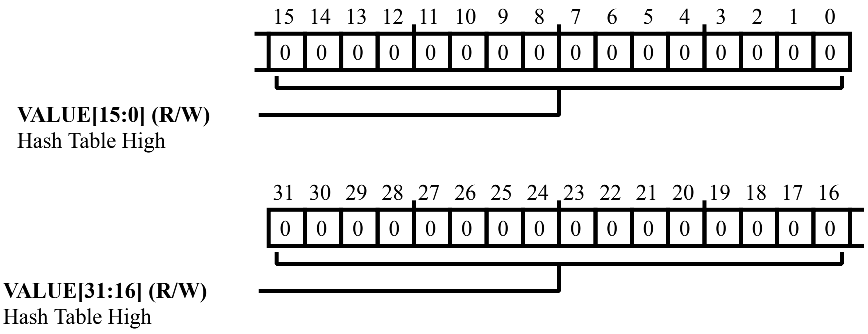
Figure 31-87: EMAC_GIGE_CTLSTAT Register Diagram

Table 31-119: EMAC_GIGE_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/NW)	LNKSTS	Link Status. The `EMAC_GIGE_CTLSTAT.LNKSTS` bit indicates that the link is up between the local PHY and the remote PHY. When cleared, this bit indicates that the link is down between the local PHY and the remote PHY.
2:1 (R/NW)	LNKSPEED	Link Speed. The `EMAC_GIGE_CTLSTAT.LNKSPEED` bit indicates the current speed of the link.
0 (R/NW)	LNKMOD	Link Mode. The `EMAC_GIGE_CTLSTAT.LNKMOD` bit indicates whether the current mode of link operation is half duplex or full duplex.

Hash Table High Register

The `EMAC_HASHTBL_HI` register contains the upper 32 bits of the hash table.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VALUE[31:16] (R/W)
Hash Table Low

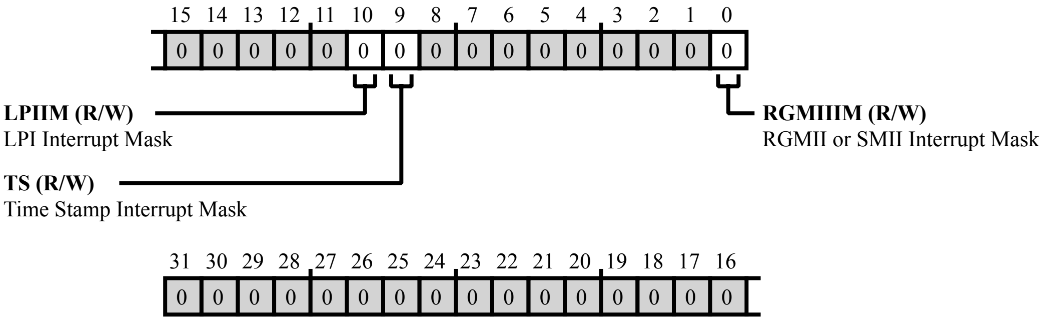
Figure 31-89: EMAC_HASHTBL_LO Register Diagram

Table 31-121: EMAC_HASHTBL_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Hash Table Low. The `EMAC_HASHTBL_LO.VALUE` bits contain the lower 32 bits of Hash table.

Interrupt Mask Register

The EMAC_IMSK register enables (unmasks) EMAC interrupts.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LPIIM (R/W)
LPI Interrupt Mask
TS (R/W)
Time Stamp Interrupt Mask
RGMIIIM (R/W)
RGMII or SMII Interrupt Mask
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 31-90: EMAC_IMSK Register Diagram

Table 31-122: EMAC_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	LPIIM	LPI Interrupt Mask. The EMAC_IMSK.LPIIM bit, When set, disables the assertion of the interrupt signal because of the setting of the LPI Interrupt Status bit in Interrupt Status Register.
9 (R/W)	TS	Time Stamp Interrupt Mask. The EMAC_IMSK.TS bit, when set, disables the assertion of the interrupt signal, which is generated when the EMAC_ISTAT.TS bit is set.
0 (R/W)	RGMIIIM	RGMII or SMII Interrupt Mask. The EMAC_IMSK.RGMIIIM bit, When set, disables the assertion of the interrupt signal because of the setting of the RGMII Interrupt Status bit in Interrupt Status Register.

MMC IPC Rx Interrupt Mask Register

The `EMAC_IPC_RXIMSK` register enables (unmasks) MMC IPC receive interrupts.

Figure 31-91: EMAC_IPC_RXIMSK Register Diagram

Table 31-123: EMAC_IPC_RXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	ICMPERROCT	Rx ICMP Error Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.ICMPERROCT` bit, when set, masks the interrupt when the `EMAC_RXICMP_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
28 (R/W)	ICMPGOCT	Rx ICMP (Good) Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.ICMPGOCT` bit, when set, masks the interrupt when the `EMAC_RXICMP_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
27 (R/W)	TCPERROCT	Rx TCP Error Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.TCPERROCT` bit, when set, masks the interrupt when the `EMAC_RXTCP_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
26 (R/W)	TCPGOCT	Rx TCP (Good) Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.TCPGOCT` bit, when set, masks the interrupt when the `EMAC_RXTCP_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
25 (R/W)	UDPERROCT	Rx UDP Error Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.UDPERROCT` bit, when set, masks the interrupt when the `EMAC_RXUDP_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
24 (R/W)	UDPGOCT	Rx UDP (Good) Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.UDPGOCT` bit, when set, masks the interrupt when the `EMAC_RXUDP_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
23 (R/W)	V6NOPAYOCT	Rx IPv6 No Payload Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V6NOPAYOCT` bit, when set, masks the interrupt when the `EMAC_RXIPV6_NOPAY_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
22 (R/W)	V6HDERROCT	Rx IPv6 Header Error Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V6HDERROCT` bit, when set, masks the interrupt when the `EMAC_RXIPV6_HDR_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
21 (R/W)	V6GOCT	Rx IPv6 (Good) Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V6GOCT` bit, when set, masks the interrupt when the `EMAC_RXIPV6_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.

Table 31-123: EMAC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	V4UDSBLOCT	Rx IPv4 UDS Disable Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4UDSBLOCT` bit, when set, masks the interrupt when the `EMAC_RXIPV4_UDSBL_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
19 (R/W)	V4FRAGOCT	Rx IPv4 Fragmented Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4FRAGOCT` bit, when set, masks the interrupt when the `EMAC_RXIPV4_FRAG_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
18 (R/W)	V4NOPAYOCT	Rx IPv4 No Payload Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4NOPAYOCT` bit, when set, masks the interrupt when the `EMAC_RXIPV4_NOPAY_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
17 (R/W)	V4HDERROCT	Rx IPv4 Header Error Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4HDERROCT` bit, when set, masks the interrupt when the `EMAC_RXIPV4_HDR_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
16 (R/W)	V4GOCT	Rx IPv4 (Good) Octets Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4GOCT` bit, when set, masks the interrupt when the `EMAC_RXIPV4_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
13 (R/W)	ICMPERRFRM	Rx ICMP Error Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.ICMPERRFRM` bit, when set, masks the interrupt when the `EMAC_RXICMP_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
12 (R/W)	ICMPGFRM	Rx ICMP (Good) Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.ICMPGFRM` bit, when set, masks the interrupt when the `EMAC_RXICMP_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
11 (R/W)	TCPERRFRM	Rx TCP Error Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.TCPERRFRM` bit, when set, masks the interrupt when the `EMAC_RXTCP_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
10 (R/W)	TCPGFRM	Rx TCP (Good) Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.TCPGFRM` bit, when set, masks the interrupt when the `EMAC_RXTCP_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.

Table 31-123: EMAC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	UDPERRFRM	Rx UDP Error Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.UDPERRFRM` bit, when set, masks the interrupt when the `EMAC_RXUDP_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
8 (R/W)	UDPGFRM	Rx UDP (Good) Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.UDPGFRM` bit, when set, masks the interrupt when the `EMAC_RXUDP_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
7 (R/W)	V6NOPAYFRM	Rx IPv6 No Payload Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V6NOPAYFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV6_NOPAY_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
6 (R/W)	V6HDERRFRM	Rx IPv6 Header Error Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V6HDERRFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV6_HDR_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
5 (R/W)	V6GFRM	Rx IPv6 (Good) Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V6GFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV6_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
4 (R/W)	V4UDSBLFRM	Rx IPv4 UDS Disable Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4UDSBLFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV4_UDSBL_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
3 (R/W)	V4FRAGFRM	Rx IPv4 Fragmented Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4FRAGFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV4_FRAG_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
2 (R/W)	V4NOPAYFRM	Rx IPv4 No Payload Frame Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4NOPAYFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV4_NOPAY_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
1 (R/W)	V4HDERRFRM	Rx IPv4 Header Error Frame Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4HDERRFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV4_HDR_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.

Table 31-123: EMAC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	V4GFRM	Rx IPv4 (Good) Frames Count Half/Full Mask. The `EMAC_IPC_RXIMSK.V4GFRM` bit, when set, masks the interrupt when the `EMAC_RXIPV4_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.

MMC IPC Rx Interrupt Register

The `EMAC_IPC_RXINT` register indicates status of MMC IPC receive interrupts.

Figure 31-92: EMAC_IPC_RXINT Register Diagram

Table 31-124: EMAC_IPC_RXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/NW)	ICMPERROCT	Rx ICMP Error Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.ICMPERROCT` bit is set when the `EMAC_RXICMP_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
28 (R/NW)	ICMPGOCT	Rx ICMP (Good) Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.ICMPGOCT` bit is set when the `EMAC_RXICMP_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
27 (R/NW)	TCPERROCT	Rx TCP Error Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.TCPERROCT` bit is set when the `EMAC_RXTCP_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
26 (R/NW)	TCPGOCT	Rx TCP (Good) Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.TCPGOCT` bit is set when the `EMAC_RXTCP_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
25 (R/NW)	UDPERROCT	Rx UDP Error Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.UDPERROCT` bit is set when the `EMAC_RXUDP_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
24 (R/NW)	UDPGOCT	Rx UDP (Good) Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.UDPGOCT` bit is set when the `EMAC_RXUDP_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
23 (R/NW)	V6NOPAYOCT	Rx IPv6 No Payload Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V6NOPAYOCT` bit is set when the `EMAC_RXIPV6_NOPAY_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
22 (R/NW)	V6HDERROCT	Rx IPv6 Header Error Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V6HDERROCT` bit is set when the `EMAC_RXIPV6_HDR_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
21 (R/NW)	V6GOCT	Rx IPv6 (Good) Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V6GOCT` bit is set when the `EMAC_RXIPV6_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
20 (R/NW)	V4UDSBLOCT	Rx IPv4 UDS Disable Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4UDSBLOCT` bit is set when the `EMAC_RXIPV4_UDSBL_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.

Table 31-124: EMAC_IPC_RXINT Register Fields (Continued)

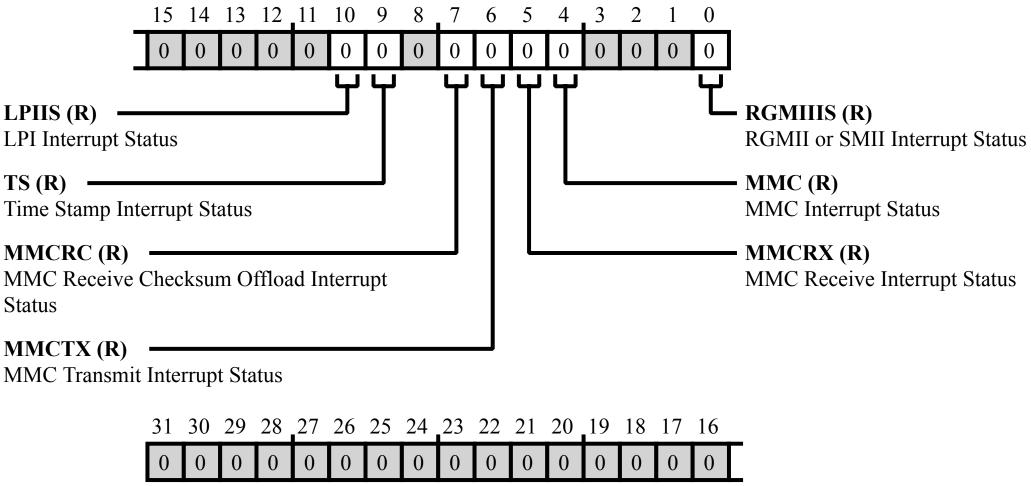
Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/NW)	V4FRAGOCT	Rx IPv4 Fragmented Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4FRAGOCT` bit is set when the `EMAC_RXIPV4_FRAG_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
18 (R/NW)	V4NOPAYOCT	Rx IPv4 No Payload Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4NOPAYOCT` bit set when the `EMAC_RXIPV4_NOPAY_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
17 (R/NW)	V4HDERROCT	Rx IPv4 Header Error Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4HDERROCT` bit is set when the `EMAC_RXIPV4_HDR_ERR_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
16 (R/NW)	V4GOCT	Rx IPv4 (Good) Octets Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4GOCT` bit is set when the `EMAC_RXIPV4_GD_OCT` counter reaches half the maximum value, and also when it reaches the maximum value.
13 (R/NW)	ICMPERRFRM	Rx ICMP Error Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.ICMPERRFRM` bit is set when the `EMAC_RXICMP_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
12 (R/NW)	ICMPGFRM	Rx ICMP (Good) Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.ICMPGFRM` bit is set when the `EMAC_RXICMP_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
11 (R/NW)	TCPERRFRM	Rx TCP Error Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.TCPERRFRM` bit is set when the `EMAC_RXTCP_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
10 (R/NW)	TCPGFRM	Rx TCP (Good) Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.TCPGFRM` bit is set when the `EMAC_RXTCP_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
9 (R/NW)	UDPERRFRM	Rx IDP Error Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.UDPERRFRM` bit is set when the `EMAC_RXUDP_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
8 (R/NW)	UDPGFRM	Rx UDP (Good) Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.UDPGFRM` bit is set when the `EMAC_RXUDP_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.

Table 31-124: EMAC_IPC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	V6NOPAYFRM	Rx IPv6 No Payload Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V6NOPAYFRM` bit is set when the `EMAC_RXIPV6_NOPAY_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
6 (R/NW)	V6HDERRFRM	Rx IPv6 Header Error Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V6HDERRFRM` bit is set when the `EMAC_RXIPV6_HDR_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
5 (R/NW)	V6GFRM	Rx IPv6 (Good) Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V6GFRM` bit is set when the `EMAC_RXIPV6_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
4 (R/NW)	V4UDSBLFRM	Rx IPv4 UDS Disable Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4UDSBLFRM` bit is set when the `EMAC_RXIPV4_UDSBL_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
3 (R/NW)	V4FRAGFRM	Rx IPv4 Fragmented Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4FRAGFRM` bit is set when the `EMAC_RXIPV4_FRAG_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
2 (R/NW)	V4NOPAYFRM	Rx IPv4 No Payload Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4NOPAYFRM` bit is set when the `EMAC_RXIPV4_NOPAY_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
1 (R/NW)	V4HDERRFRM	Rx IPv4 Header Error Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4HDERRFRM` bit is set when the `EMAC_RXIPV4_HDR_ERR_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.
0 (R/NW)	V4GFRM	Rx IPv4 (Good) Frames Count Half/Full Interrupt. The `EMAC_IPC_RXINT.V4GFRM` bit is set when the `EMAC_RXIPV4_GD_FRM` counter reaches half the maximum value, and also when it reaches the maximum value.

Interrupt Status Register

The EMAC_ISTAT register indicates EMAC interrupt status.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LPIIS (R)
LPI Interrupt Status
TS (R)
Time Stamp Interrupt Status
MMCRC (R)
MMC Receive Checksum Offload Interrupt Status
MMCTX (R)
MMC Transmit Interrupt Status
RGMIIIS (R)
RGMII or SMII Interrupt Status
MMC (R)
MMC Interrupt Status
MMCRX (R)
MMC Receive Interrupt Status
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Figure 31-93: EMAC_ISTAT Register Diagram

Table 31-125: EMAC_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/NW)	LPIIS	LPI Interrupt Status. The `EMAC_ISTAT.LPIIS` bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver.
9 (R/NW)	TS	Time Stamp Interrupt Status. The `EMAC_ISTAT.TS` bit is set when: There is an overflow in the `EMAC_TM_SEC` register, or The `EMAC_TM_STMPSTAT.ATSTS` bit is asserted. The `EMAC_ISTAT.TS` bit is cleared on reading the byte 0 of the `EMAC_TM_STMPSTAT` register.
7 (R/NW)	MMCRC	MMC Receive Checksum Offload Interrupt Status. The `EMAC_ISTAT.MMCRC` bit is set high whenever an interrupt is generated in the `EMAC_IPC_RXINT`. This bit is cleared when all the bits in this interrupt register are cleared.
6 (R/NW)	MMCTX	MMC Transmit Interrupt Status. The `EMAC_ISTAT.MMCTX` bit is set high whenever an interrupt is generated in the `EMAC_MMC_TXINT` register. This bit is cleared when all the bits in this interrupt register are cleared.

Table 31-125: EMAC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/NW)	MMCRX	MMC Receive Interrupt Status. The `EMAC_ISTAT.MMCRX` bit is set high whenever an interrupt is generated in the `EMAC_MMC_RXINT` register. This bit is cleared when all the bits in this interrupt register are cleared.
4 (R/NW)	MMC	MMC Interrupt Status. The `EMAC_ISTAT.MMC` bit is set high whenever any of `EMAC_ISTAT` bits [7:5] is set (=1) and is cleared only when all of these bits are cleared (=0).
0 (R/NW)	RGMIIIS	RGMII or SMII Interrupt Status. The `EMAC_ISTAT.RGMIIIS` bit is set because of any change in value of the Link Status of RGMII interface.

Layer3 and Layer4 Control Register

The `EMAC_L3L4_CTL` register controls the operations of the filter 0 of Layer 3 and Layer 4. This register is reserved if the Layer 3 and Layer 4 Filtering feature is not selected during core configuration.

Figure 31-94: EMAC_L3L4_CTL Register Diagram

Table 31-126: EMAC_L3L4_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	L4DPIM	Layer 4 Destination Port Inverse Matching. The `EMAC_L3L4_CTL.L4DPIM` bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching.
20 (R/W)	L4DPM	Layer 4 Destination Port Matching. The `EMAC_L3L4_CTL.L4DPM` bit indicates that the Layer 4 Destination Port number field is enabled for matching.
19 (R/W)	L4SPIM	Layer 4 Source Port Inverse Matching. The `EMAC_L3L4_CTL.L4SPIM` bit indicates that the Layer 4 Source Port number field is enabled for inverse matching.
18 (R/W)	L4SPM	Layer 4 Source Port Matching. The `EMAC_L3L4_CTL.L4SPM` bit indicates that the Layer 4 Source Port number field is enabled for matching.

Table 31-126: EMAC_L3L4_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	L4PEN	Layer 4 Filtering Enable. The `EMAC_L3L4_CTL.L4PEN` bit indicates that source and destination port number fields for UDP (TCP) frames are used for matching.
15:11 (R/W)	L3HDBM	Layer 3 Destination Address Bits Mask. The `EMAC_L3L4_CTL.L3HDBM` bits are the number of lower bits of IP destination Address that are masked for matching in the IPv4 frames.
10:6 (R/W)	L3HSBM	Layer 3 Source Address Bits Mask. The `EMAC_L3L4_CTL.L3HSBM` bit are the number of lower bits of IP source address that are masked for matching in the IPv4 frames.
5 (R/W)	L3DAIM	Layer 3 Destination Address Inverse Matching. The `EMAC_L3L4_CTL.L3DAIM` bit indicates that the Layer 3 IP destination address field is enabled for inverse matching.
4 (R/W)	L3DAM	Layer 3 Destination Address Matching. The `EMAC_L3L4_CTL.L3DAM` bit indicates that Layer 3 IP destination address field is enabled for matching.
3 (R/W)	L3SAIM	Layer 3 Source Address Inverse Matching. The `EMAC_L3L4_CTL.L3SAIM` bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching.
2 (R/W)	L3SAM	Layer 3 Source Address Matching. The `EMAC_L3L4_CTL.L3SAM` bit indicates that the Layer 3 IP Source Address field is enabled for matching.
0 (R/W)	L3PEN	Layer 3 Enabled. The `EMAC_L3L4_CTL.L3PEN` bit indicates that layer 3 source or destination address matching is enabled for IPV6 (IPV4) frames.

Layer 3 Address0 Register

The `EMAC_L3_ADDR0` register tells For IPv4 frames, the Layer 3 Address 0 Register 0 contains the 32-bit IP Source Address field.

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A0	Layer 3 Address 0 Field. The `EMAC_L3_ADDR0.L3A0` bits, When Bit 0 (L3PEN0) and Bit 2 (L3SAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN0) and Bit 4 (L3DAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN0) is reset and Bit 2 (L3SAM0) is set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with the IP Source Address field in the IPv4 frames.

Layer 3 Address1 Register

The `EMAC_L3_ADDR1` register tells For IPv4 frames, the Layer 3 Address 1 Register 0 contains the 32-bit IP Source Address field.

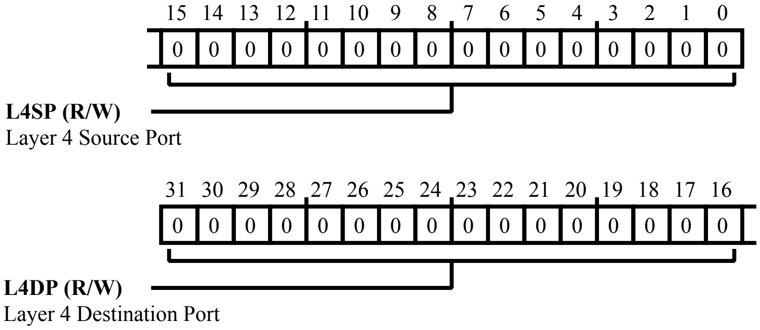
31:0 (R/W)	L3A3	Layer 3 Address 3 Field. The `EMAC_L3_ADDR3.L3A3` bits, When Bit 0 (L3PEN0) and Bit 2 (L3SAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN0) and Bit 4 (L3DAM0) are set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with Bits [31:0] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN0) is reset and Bit 2 (L3SAM0) is set in Register 256 (Layer 3 and Layer 4 Control Register 0), this field contains the value to be matched with the IP Source Address field in the IPv4 frames.

Layer 4 Address Register

The `EMAC_L4_ADDR` register contains Layer 4 Port number field. It contains the 16-bit Source and Destination Port numbers of the TCP or UDP frame.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

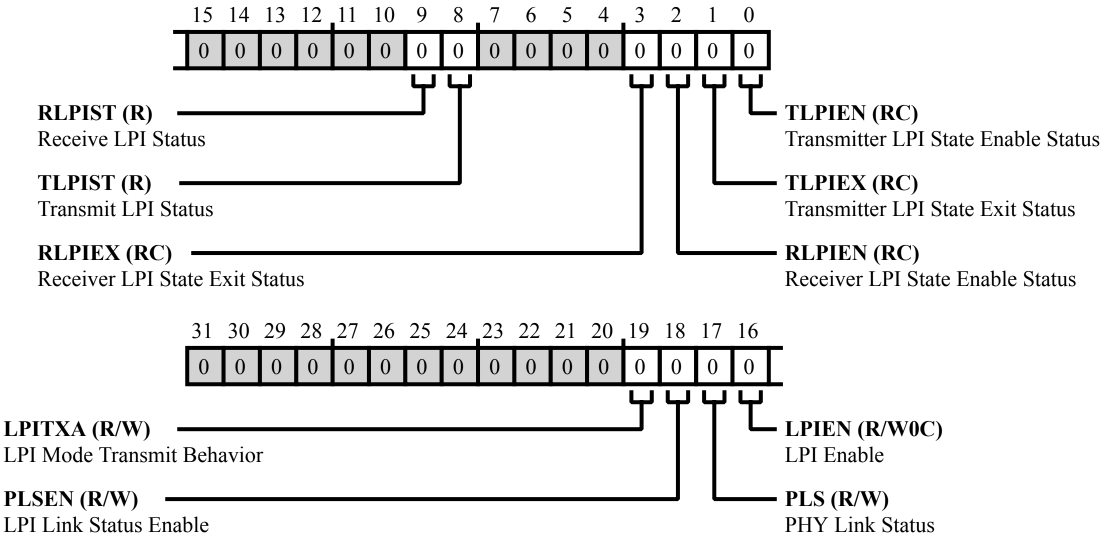
Figure 31-99: EMAC_L4_ADDR Register Diagram

Table 31-131: EMAC_L4_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	L4DP	Layer 4 Destination Port. When `EMAC_L3L4_CTL.L4PEN` is reset and `EMAC_L3L4_CTL.L4DPM` is set, the `EMAC_L4_ADDR.L4DP` bit field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 frames. When `EMAC_L3L4_CTL.L4PEN` and `EMAC_L3L4_CTL.L4DPM` are set, the `EMAC_L4_ADDR.L4DP` bit field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 frames.
15:0 (R/W)	L4SP	Layer 4 Source Port. When `EMAC_L3L4_CTL.L4PEN` is reset and `EMAC_L3L4_CTL.L4DPM` is set, the `EMAC_L4_ADDR.L4SP` bit field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 frames. When `EMAC_L3L4_CTL.L4PEN` and `EMAC_L3L4_CTL.L4DPM` are set, the `EMAC_L4_ADDR.L4SP` bit field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 frames.

Low Power Idle Control and Status Register

The `EMAC_LPI_CTLSTAT` register controls the behavior of EMAC0 for LPI mode and reports status.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

PLS (R/W)
PHY Link Status

Figure 31-100: EMAC_LPI_CTLSTAT Register Diagram

Table 31-132: EMAC_LPI_CTLSTAT Register Fields

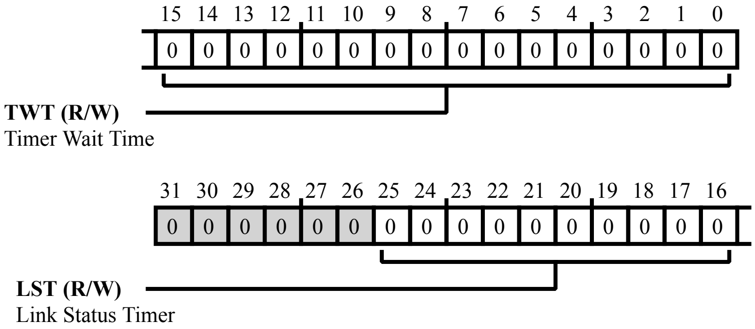
Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	LPITXA	LPI Mode Transmit Behavior. The `EMAC_LPI_CTLSTAT.LPITXA` bit controls the behavior of the MAC when it is entering or exiting of the LPI mode on the transmit side.
18 (R/W)	PLSEN	LPI Link Status Enable. The `EMAC_LPI_CTLSTAT.PLSEN` bit enables the link status received on the RGMII receive paths to be used for activating the LPI LS timer.
17 (R/W)	PLS	PHY Link Status. The `EMAC_LPI_CTLSTAT.PLS` bit indicates the link status of the PHY
16 (R/W0C)	LPIEN	LPI Enable. The `EMAC_LPI_CTLSTAT.LPIEN` bit instructs the MAC Transmitter to enter the LPI state. When reset, this bit instructs the MAC to exit the LPI state and resume normal transmission.
9 (R/NW)	RLPIST	Receive LPI Status. The `EMAC_LPI_CTLSTAT.RLPIST` bit indicates that the MAC is receiving the LPI pattern on the GMII or MII interface.

Table 31-132: EMAC_LPI_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
8 (R/NW)	TLPIST	Transmit LPI Status. The `EMAC_LPI_CTLSTAT.TLPIST` bit indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface.
3 (RC/NW)	RLPIEX	Receiver LPI State Exit Status. The `EMAC_LPI_CTLSTAT.RLPIEX` bit indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register.
2 (RC/NW)	RLPIEN	Receiver LPI State Enable Status. The `EMAC_LPI_CTLSTAT.RLPIEN` bit indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register.
1 (RC/NW)	TLPIEX	Transmitter LPI State Exit Status. The `EMAC_LPI_CTLSTAT.TLPIEX` bit indicates that the MAC transmitter has exited the LPI state after the program has cleared the `EMAC_LPI_CTLSTAT.LPIEN` bit and the LPI TW Timer has expired. This bit is cleared by a read into this register.
0 (RC/NW)	TLPIEN	Transmitter LPI State Enable Status. The `EMAC_LPI_CTLSTAT.TLPIEN` bit indicates that the MAC Transmitter has entered the LPI state due to the setting of the `EMAC_LPI_CTLSTAT.LPIEN` bit. This bit is cleared by a read into this register.

Low Power Idle Timeout Register

The EMAC_LPI_TMRSCTL controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
LST (R/W)
Link Status Timer

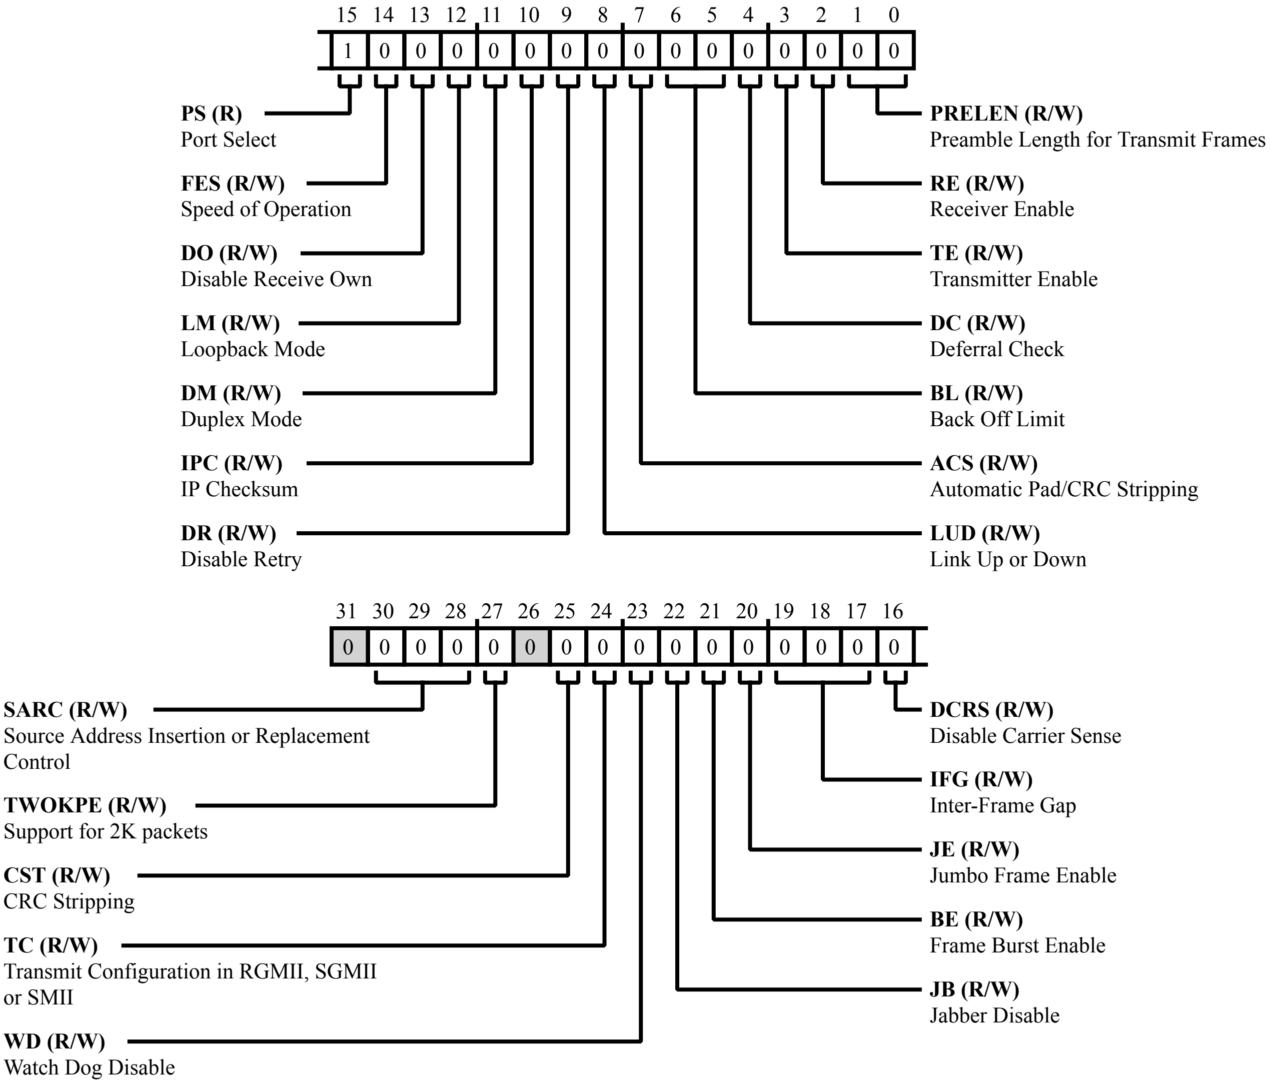
Figure 31-101: EMAC_LPI_TMRSCTL Register Diagram

Table 31-133: EMAC_LPI_TMRSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/W)	LST	Link Status Timer. The `EMAC_LPI_TMRSCTL.LST` bit, specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY.
15:0 (R/W)	TWT	Timer Wait Time. The `EMAC_LPI_TMRSCTL.TWT` bit, specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission.

MAC Configuration Register

The `EMAC_MACCFG` register configures MAC features.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Jabber Disable

Figure 31-102: EMAC_MACCFG Register Diagram

Table 31-134: EMAC_MACCFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:28 (R/W)	SARC	Source Address Insertion or Replacement Control. The `EMAC_MACCFG.SARC` bit, controls the source address insertion or replacement for all transmitted frames.

Table 31-134: EMAC_MACCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	TWOKPE	Support for 2K packets. The `EMAC_MACCFG.TWOKPE` bit, IEEE 802.3as Support for 2K Packets When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets.	
25 (R/W)	CST	CRC Stripping. The `EMAC_MACCFG.CST` bit, when set, directs the MAC to strip the last 4 bytes (FCS) of all frames of Ether type (Type field of frame greater than 0x0600) and drop these bytes before forwarding the frame to the application.	
24 (R/W)	TC	Transmit Configuration in RGMII, SGMII or SMII. The `EMAC_MACCFG.TC` bit, enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII port.	
23 (R/W)	WD	Watch Dog Disable. The `EMAC_MACCFG.WD` bit, when set, disables the watchdog timer on the receiver, and can receive frames of up to 16,384 bytes. When this bit is reset, the MAC allows no more than 2,048 bytes (10,240 if `EMAC_MACCFG.JE` is set high) of the frame being received and cuts off any bytes received after that.	
22 (R/W)	JB	Jabber Disable. The `EMAC_MACCFG.JB` bit, when set, disables the jabber timer on the transmitter, and can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if `EMAC_MACCFG.JE` is set high) during transmission.	
21 (R/W)	BE	Frame Burst Enable. The `EMAC_MACCFG.BE` bit, allows frame bursting during transmission in the GMII half-duplex mode.	
20 (R/W)	JE	Jumbo Frame Enable. The `EMAC_MACCFG.JE` bit, when set, directs the MAC to allow Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames).	
19:17 (R/W)	IFG	Inter-Frame Gap. The `EMAC_MACCFG.IFG` bits control the minimum inter-frame gap between frames during transmission. Note that in Half-Duplex mode, the minimum gap can be configured for 64 bit times (`EMAC_MACCFG.IFG` =100) only. Lower values are not considered.	
		0	96 bit times
		1	88 bit times
		2	80 bit times
		3	72 bit times
		4	64 bit times

Table 31-134: EMAC_MACCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	56 bit times
		6	48 bit times
		7	40 bit times
16 (R/W)	DCRS	Disable Carrier Sense. The `EMAC_MACCFG.DCRS` bit, when set, makes the MAC transmitter ignore the CRS signal during frame transmission in Half-Duplex mode. This request results in no errors generated due to Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors due to Carrier Sense and will even abort the transmissions.	
15 (R/NW)	PS	Port Select. The `EMAC_MACCFG.PS` bit selects between GMII and MII as: 0=GMII (1000 Mbps) and 1=MII (10/100 Mbps). This bit is read-only with the appropriate value in the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, and R_W in the default 10/100/1000 Mbps configuration.	
14 (R/W)	FES	Speed of Operation. The `EMAC_MACCFG.FES` bit indicates the Ethernet speed as 10 Mbps (bit =0) or 100 Mbps (bit =1).	
13 (R/W)	DO	Disable Receive Own. The `EMAC_MACCFG.DO` bit, when set, disables MAC reception of frames when MAC is transmitting in Half-Duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in Full-Duplex mode.	
12 (R/W)	LM	Loopback Mode. The `EMAC_MACCFG.LM` bit, when set, directs the MAC to operate in internal loop back mode. (The media independent interface pins are not driven or sampled.)	
11 (R/W)	DM	Duplex Mode. The `EMAC_MACCFG.DM` bit, when set, directs the MAC to operate in a Full-Duplex mode where it can transmit and receive simultaneously.	
10 (R/W)	IPC	IP Checksum. The `EMAC_MACCFG.IPC` bit, when set, directs the MAC to calculate the 16-bit one's complement of the one's complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 25-26 or 29-30 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The `EMAC_MACCFG.IPC` bit, when set, enables IPv4 checksum checking for received frame payloads' TCP/UDP/ICMP headers. When this bit is reset, the Checksum Offload Engine function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared.	

Table 31-134: EMAC_MACCFG Register Fields (Continued)

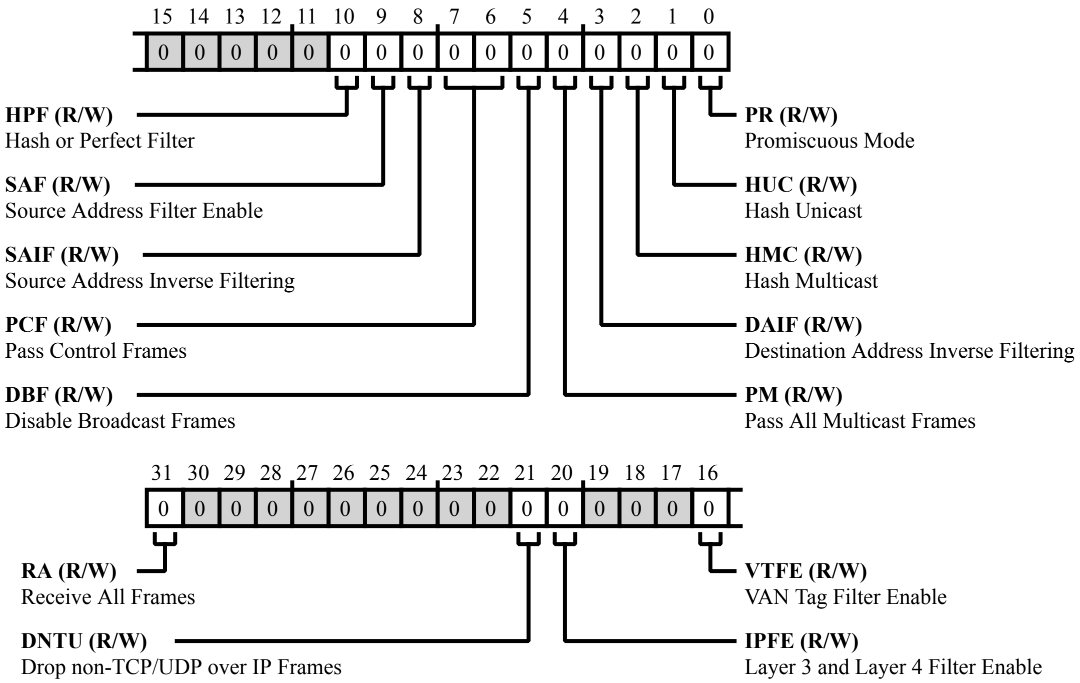
Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	DR	Disable Retry. The `EMAC_MACCFG.DR` bit, when set, directs the MAC to attempt only 1 transmission. When a collision occurs on the media independent interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status. When the `EMAC_MACCFG.DR` bit is reset, the MAC attempts retries based on the settings of BL. This bit is applicable only to Half-Duplex mode.	
		0	Retry enabled
		1	Retry disabled
8 (R/W)	LUD	Link Up or Down. The `EMAC_MACCFG.LUD` bit, indicates whether the link is up or down during the transmission of configuration in the RGMII, SGMII, or SMII interface: 0 means Link down and 1 means Link Up	
7 (R/W)	ACS	Automatic Pad/CRC Stripping. The `EMAC_MACCFG.ACS` bit, when set, directs the MAC to strip the Pad/FCS field on incoming frames only if the length fields value is less than or equal to 1,500 bytes. All received frames with length field greater than or equal to 1,501 bytes are passed to the application without stripping the Pad/FCS field. When the `EMAC_MACCFG.ACS` bit is reset, the MAC passes all incoming frames to the Host unmodified.	
6:5 (R/W)	BL	Back Off Limit. The `EMAC_MACCFG.BL` bit selects the back-off limit, determining the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only to Half-Duplex mode.The random integer r takes the value in the range: 0 less-than-equal-to r less-than 2^k Where k is the minimum of n (number of transmission attempts) or a limit value.	
		0	k = min (n, 10)
		1	k = min (n, 8)
		2	k = min (n, 4)
		3	k = min (n, 1)

Table 31-134: EMAC_MACCFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	DC	Deferral Check. The `EMAC_MACCFG.DC` bit, when set, enables the deferral check function in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status when the transmit state machine is deferred for more than 24,288 bit times in 10/100-Mbps mode. If the Jumbo frame mode is enabled in 10/100-Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active CRS (carrier sense) signal. Defer time is not cumulative. If the transmitter defers for 10,000 bit times, then transmits, collides, backs off, and then has to defer again after completion of back-off, the deferral timer resets to 0 and restarts. When the `EMAC_MACCFG.DC` bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in Half-Duplex mode.
3 (R/W)	TE	Transmitter Enable. The `EMAC_MACCFG.TE` bit, when set, enables the transmit state machine of the MAC for transmission. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and will not transmit any further frames.
2 (R/W)	RE	Receiver Enable. The `EMAC_MACCFG.RE` bit, when set, enables the receiver state machine of the MAC for receiving frames. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames.
1:0 (R/W)	PRELEN	Preamble Length for Transmit Frames. The `EMAC_MACCFG.PRELEN` bit, control the number of preamble bytes that are added to the beginning of every Transmit frame.

MAC Rx Frame Filter Register

The `EMAC_MACFRMFILT` register controls receive frame filter features.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
HPF (R/W)
Hash or Perfect Filter
SAF (R/W)
Source Address Filter Enable
SAIF (R/W)
Source Address Inverse Filtering
PCF (R/W)
Pass Control Frames
DBF (R/W)
Disable Broadcast Frames
PR (R/W)
Promiscuous Mode
HUC (R/W)
Hash Unicast
HMC (R/W)
Hash Multicast
DAIF (R/W)
Destination Address Inverse Filtering
PM (R/W)
Pass All Multicast Frames

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
RA (R/W)
Receive All Frames
DNTU (R/W)
Drop non-TCP/UDP over IP Frames
VTFE (R/W)
VAN Tag Filter Enable
IPFE (R/W)
Layer 3 and Layer 4 Filter Enable

Figure 31-103: EMAC_MACFRMFILT Register Diagram

Table 31-135: EMAC_MACFRMFILT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	RA	Receive All Frames. The `EMAC_MACFRMFILT.RA` bit, when set, directs the MAC Receiver module to pass to the Application all frames received irrespective of whether they pass the address filter. The result of the DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver module passes to the Application only those frames that pass the DA address filter.
21 (R/W)	DNTU	Drop non-TCP/UDP over IP Frames. The `EMAC_MACFRMFILT.DNTU` bit, enables the MAC to drop the non-TCP or UDP over IP frames. The MAC forward only those frames that are processed by the Layer 4 filter. When reset, this bit enables the MAC to forward all non-TCP or UDP over IP frames.
20 (R/W)	IPFE	Layer 3 and Layer 4 Filter Enable. The `EMAC_MACFRMFILT.IPFE` bit, enables the MAC to drop frames that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect.

Table 31-135: EMAC_MACFRMFILT Register Fields (Continued)

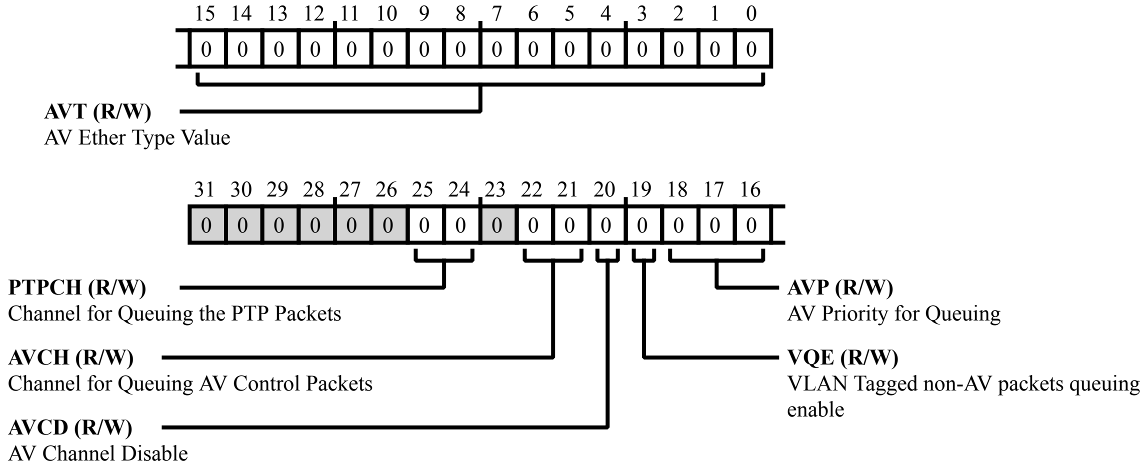
Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	VTFE	VAN Tag Filter Enable. The `EMAC_MACFRMFILT.VTFE` bit, enables the MAC to drop VLAN tagged frames that do not match the VLAN Tag comparison.	
10 (R/W)	HPF	Hash or Perfect Filter. The `EMAC_MACFRMFILT.HPF` bit. when set, configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by `EMAC_MACFRMFILT.HMC` or `EMAC_MACFRMFILT.HUC` bits. When `EMAC_MACFRMFILT.HPF` is low and either the `EMAC_MACFRMFILT.HUC` bit or `EMAC_MACFRMFILT.HMC` bit is set, the frame is passed only if it matches the Hash filter.	
9 (R/W)	SAF	Source Address Filter Enable. When the `EMAC_MACFRMFILT.SAF` bit, is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the frame.	
8 (R/W)	SAIF	Source Address Inverse Filtering. WHen the `EMAC_MACFRMFILT.SAIF` bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA Address filter.	
7:6 (R/W)	PCF	Pass Control Frames. The `EMAC_MACFRMFILT.PCF` bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). Note that the processing of PAUSE control frames depends only on the value of the `EMAC_FLOWCTL.RFE` bit.	
		0	Pass no control frames All control frames are filtered from reaching the application.
		1	Pass no PAUSE frames All control frames are passed to the application (even if the fail the address filter), except for PAUSE frames.
		2	Pass all control frames All control frames are passed to the application (even if the fail the address filter).
		3	Pass address filtered control frames All control frames that pass the address filter are passed to the application.
5 (R/W)	DBF	Disable Broadcast Frames. The `EMAC_MACFRMFILT.DBF` bit, when set, directs the AFM module to filter all incoming broadcast frames. When this bit is reset, the AFM module passes all received broadcast frames.	
		0	AFM module passes all received broadcast frames
		1	AFM module filters all incoming broadcast frames

Table 31-135: EMAC_MACFRMFILT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	PM	Pass All Multicast Frames. The `EMAC_MACFRMFILT.PM` bit, when set, indicates that all received frames with a multicast destination address (first bit in the destination address field is =1) are passed. When this bit is reset, filtering of multicast frame depends on `EMAC_MACFRMFILT.HMC` bit.
3 (R/W)	DAIF	Destination Address Inverse Filtering. The `EMAC_MACFRMFILT.DAIF` bit, when set, directs the Address Check block to operate in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When this bit is reset, normal filtering of frames is performed.
2 (R/W)	HMC	Hash Multicast. The `EMAC_MACFRMFILT.HMC` bit, when set, directs the EMAC to perform destination address filtering of received multicast frames according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for multicast frames, that is, the MAC compares the DA field with the values programmed in the `EMAC_ADDR0_HI` and `EMAC_ADDR0_LO` address registers.
1 (R/W)	HUC	Hash Unicast. The `EMAC_MACFRMFILT.HUC` bit, when set, directs the EMAC to perform destination address filtering of unicast frames according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in the `EMAC_ADDR0_HI` and `EMAC_ADDR0_LO` address registers.
0 (R/W)	PR	Promiscuous Mode. The `EMAC_MACFRMFILT.PR` bit, when set, directs the Address Filter module to pass all incoming frames regardless of its destination or source address. The DA Filter Fails status bits of the Receive Status Word is always cleared when `EMAC_MACFRMFILT.PR` is set.

AV MAC Control Register

The EMAC_MAC_AVCTL register controls the AV traffic by identifying the AV traffic and queuing it to appropriate channel. This register is present only when you select the AV feature during core configuration.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
AVT (R/W)
AV Ether Type Value
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PTPCH (R/W)
Channel for Queuing the PTP Packets
AVCH (R/W)
Channel for Queuing AV Control Packets
AVCD (R/W)
AV Channel Disable
AVP (R/W)
AV Priority for Queuing
VQE (R/W)
VLAN Tagged non-AV packets queuing enable

Figure 31-104: EMAC_MAC_AVCTL Register Diagram

Table 31-136: EMAC_MAC_AVCTL Register Fields

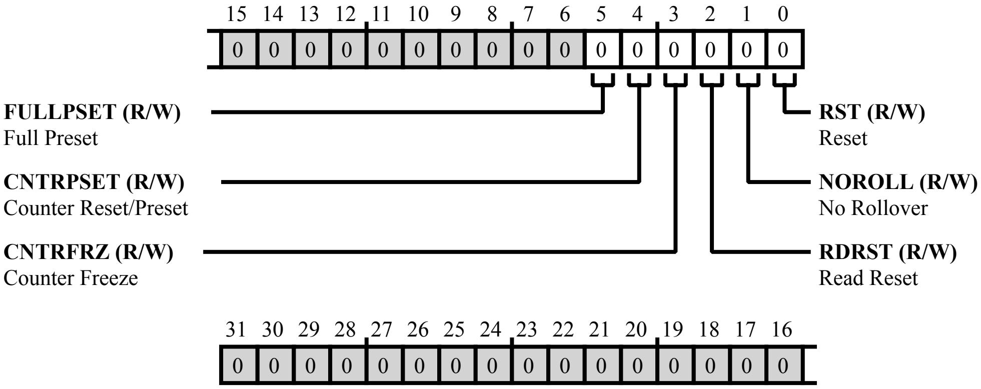
Bit No. (Access)	Bit Name	Description/Enumeration
25:24 (R/W)	PTPCH	Channel for Queuing the PTP Packets. The `EMAC_MAC_AVCTL.PTPCH` bit, specifies the channel on which the untagged PTP packets, sent over the Ethernet payload and not over IPv4 or IPv6, are queued.
22:21 (R/W)	AVCH	Channel for Queuing AV Control Packets. The `EMAC_MAC_AVCTL.AVCH` bit, specifies the channel on which the received untagged AV control packets are queued.
20 (R/W)	AVCD	AV Channel Disable. The `EMAC_MAC_AVCTL.AVCD` bit, When this bit is set, the MAC forwards all packets to the default Channel 0 and the values programmed in the AVP, AVCH, and PTPCH fields are ignored. This bit is reserved and read-only if Channel 1 or Channel 2 receive paths are not selected during core configuration.
19 (R/W)	VQE	VLAN Tagged non-AV packets queuing enable. The `EMAC_MAC_AVCTL.VQE` bit, When this bit is set, the MAC also queues non-AV VLAN tagged packets into the available channels according to the value of the AVP bits. This bit is reserved and read-only if Channel 1 and Channel 2 Receive paths are not selected during core configuration.

Table 31-136: EMAC_MAC_AVCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18:16 (R/W)	AVP	AV Priority for Queuing. The `EMAC_MAC_AVCTL.AVP` bit, The value programmed in these bits control the receive channel (0, 1, or 2) to which an AV packet with a given priority must be queued.
15:0 (R/W)	AVT	AV Ether Type Value. The `EMAC_MAC_AVCTL.AVT` bit, contains the value that is compared with the EtherType field of the incoming (tagged or untagged) Ethernet frame to detect an AV packet.

MMC Control Register

The EMAC_MMC_CTL register selects the MMC operating mode.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 31-105: EMAC_MMC_CTL Register Diagram

Table 31-137: EMAC_MMC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	FULLPSET	Full Preset. The EMAC_MMC_CTL.FULLPSET bit, when =0 (and EMAC_MMC_CTL.CNTRPSET =1), presets all MMC counters to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When EMAC_MMC_CTL.FULLPSET =1 (and EMAC_MMC_CTL.CNTRPSET =1), all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.
4 (R/W)	CNTRPSET	Counter Reset/Preset. The EMAC_MMC_CTL.CNTRPSET bit, when set, initializes all counters or presets counters to almost full or almost half as per EMAC_MMC_CTL.FULLPSET. The EMAC_MMC_CTL.CNTRPSET bit is cleared automatically after 1 clock cycle. This bit along with bit5 is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.
3 (R/W)	CNTRFRZ	Counter Freeze. The EMAC_MMC_CTL.CNTRFRZ bit, when set, freezes all the MMC counters to their current value. None of the MMC counters are updated due to any transmitted or received frame, until this bit is reset to 0. If any MMC counter is read with the EMAC_MMC_CTL.RDRST bit set, then that counter is also cleared in this mode.

Table 31-137: EMAC_MMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	RDRST	Read Reset. The `EMAC_MMC_CTL.RDRST` bit, when set, resets the MMC counters to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.
1 (R/W)	NOROLL	No Rollover. The `EMAC_MMC_CTL.NOROLL` bit, when set, prevents counter rolls over to 0 after reaching max.
0 (R/W)	RST	Reset. The `EMAC_MMC_CTL.RST` bit, when set, resets all counters. This bit is cleared automatically after 1 clock cycle.

MMC Rx Interrupt Mask Register

The `EMAC_MMC_RXIMSK` register enables (unmasks) MMC receive interrupts.

Table 31-138: EMAC_MMC_RXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	CTLFIM	Rx Control Frame Counter Interrupt Mask. The `EMAC_MMC_RXIMSK.CTLFIM` bit, masks the interrupt when the rxctrlframes_g counter reaches half of the maximum value or the maximum value.
24 (R/W)	RCVERRFIM	Rx Error Frame Counter Interrupt Mask. The `EMAC_MMC_RXIMSK.RCVERRFIM` bit,masks the interrupt when the rxrcverror counter reaches half of the maximum value or the maximum value.
23 (R/W)	WATCHERR	Rx Watch Dog Error Count Half/Full Mask. The `EMAC_MMC_RXIMSK.WATCHERR` bit, when set, masks the interrupt when `EMAC_RXWDOG_ERR` counter reaches full or half.
22 (R/W)	VLANFRGB	Rx VLAN Frames (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.VLANFRGB` bit, when set, masks the interrupt when `EMAC_RXVLANFRM_GB` counter reaches full or half.
21 (R/W)	FIFOOV	Rx FIFO Overflow Count Half/Full Mask. The `EMAC_MMC_RXIMSK.FIFOOV` bit, when set, masks the interrupt when `EMAC_RXFIFO_OVF` counter reaches full or half.
20 (R/W)	PAUSEFRM	Rx Pause Frames Count Half/Full Mask. The `EMAC_MMC_RXIMSK.PAUSEFRM` bit, when set, masks the interrupt when `EMAC_RXPAUSEFRM` counter reaches full or half.
19 (R/W)	OUTRANGE	Rx Out Of Range Type Count Half/Full Mask. The `EMAC_MMC_RXIMSK.OUTRANGE` bit, when set, masks the interrupt when `EMAC_RXOORTYPE` counter reaches full or half.
18 (R/W)	LENERR	Rx Length Error Count Half/Full Mask. The `EMAC_MMC_RXIMSK.LENERR` bit, when set, masks the interrupt when `EMAC_RXLEN_ERR` counter reaches full or half.
17 (R/W)	UCASTG	Rx Unicast Frames (Good) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.UCASTG` bit, when set, masks the interrupt when `EMAC_RXUCASTFRM_G` counter reaches full or half.
16 (R/W)	R1024TOMAX	Rx 1024-to-max Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.R1024TOMAX` bit, when set, masks the interrupt when `EMAC_RX1024TOMAX_GB` counter reaches full or half.
15 (R/W)	R512TO1023	Rx 512-to-1023 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.R512TO1023` bit, when set, masks the interrupt when `EMAC_RX512TO1023_GB` counter reaches full or half.
14 (R/W)	R256TO511	Rx 255-to-511 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.R256TO511` bit, when set, masks the interrupt when `EMAC_RX256TO511_GB` counter reaches full or half.

Table 31-138: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	R128TO255	Rx 128-to-255 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.R128TO255` bit, when set, masks the interrupt when `EMAC_RX128TO255_GB` counter reaches full or half.
12 (R/W)	R65TO127	Rx 65-to-127 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.R65TO127` bit, when set, masks the interrupt when `EMAC_RX65TO127_GB` counter reaches full or half.
11 (R/W)	R64	Rx 64 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.R64` bit, when set, masks the interrupt when `EMAC_RX64_GB` counter reaches full or half.
10 (R/W)	OSIZEG	Rx Oversize (Good) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.OSIZEG` bit, when set, masks the interrupt when `EMAC_RXOSIZE_G` counter reaches full or half.
9 (R/W)	USIZEG	Rx Undersize (Good) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.USIZEG` bit, when set, masks the interrupt when `EMAC_RXUSIZE_G` counter reaches full or half.
8 (R/W)	JABERR	Rx Jabber Error Count Half/Full Mask. The `EMAC_MMC_RXIMSK.JABERR` bit, when set, masks the interrupt when `EMAC_RXJAB_ERR` counter reaches full or half.
7 (R/W)	RUNTERR	Rx Runt Error Count Half/Full Mask. The `EMAC_MMC_RXIMSK.RUNTERR` bit, when set, masks the interrupt when `EMAC_RXRUNT_ERR` counter reaches full or half.
6 (R/W)	ALIGNERR	Rx Alignment Error Count Half/Full Mask. The `EMAC_MMC_RXIMSK.ALIGNERR` bit, when set, masks the interrupt when `EMAC_RXALIGN_ERR` counter reaches full or half.
5 (R/W)	CRCERR	Rx CRC Error Count Half/Full Mask. The `EMAC_MMC_RXIMSK.CRCERR` bit, when set, masks the interrupt when `EMAC_RXCRC_ERR` counter reaches full or half.
4 (R/W)	MCASTG	Rx Multicast Frames (Good) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.MCASTG` bit, when set, masks the interrupt when `EMAC_RXMCASTFRM_G` counter reaches full or half.
3 (R/W)	BCASTG	Rx Broadcast Frames (Good) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.BCASTG` bit, when set, masks the interrupt when `EMAC_RXBCASTFRM_G` counter reaches full or half.

Table 31-138: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	OCTCNTG	Rx Octet Count (Good) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.OCTCNTG` bit, when set, masks the interrupt when `EMAC_RXOCTCNT_G` counter reaches full or half.
1 (R/W)	OCTCNTGB	Rx Octet Count (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.OCTCNTGB` bit, when set, masks the interrupt when `EMAC_RXOCTCNT_GB` counter reaches half or full.
0 (R/W)	FRCNTGB	Rx Frame Count (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_RXIMSK.FRCNTGB` bit, when set, masks the interrupt when `EMAC_RXFRMCNT_GB` counter reaches half or full.

MMC Rx Interrupt Register

The `EMAC_MMC_RXINT` register indicates status of MMC receive interrupts.

FIFOOVF (R)
Rx FIFO Overflow Count Half/Full
R1024TOMAX (R)
Rx 1024-to-max Octets (Good/Bad) Count Half/Full
UCASTG (R)
Rx Unicast Frames (Good) Count Half/Full
LENERR (R)
Rx Length Error Count Half/Full
OUTRANGE (R)
Rx Out Of Range Type Count Half/Full
PAUSEFR (R)
Rx Pause Frames Count Half/Full

Figure 31-107: EMAC_MMC_RXINT Register Diagram

Table 31-139: EMAC_MMC_RXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (RC/NW)	RXCTLFIS	Rx Control Frame Counter Interrupt Status. The `EMAC_MMC_RXINT.RXCTLFIS` bit is set when the rxctrlframes_g counter reaches half of the maximum value or the maximum value.
24 (RC/NW)	RXRCVERRFIS	Rx Error Frame Counter Interrupt Status. The `EMAC_MMC_RXINT.RXRCVERRFIS` bit is set when the rxrcverror counter reaches half of the maximum value or the maximum value.
23 (R/NW)	WDOGERR	Rx Watch Dog Error Count Half/Full. The `EMAC_MMC_RXINT.WDOGERR` bit is set when the `EMAC_RXWDOG_ERR` counter reaches full or half.
22 (R/NW)	VLANFRGB	Rx VLAN Frames (Good/Bad) Count Half/Full. The `EMAC_MMC_RXINT.VLANFRGB` bit is set when `EMAC_RXVLANFRM_GB` counter reaches full or half.
21 (R/NW)	FIFOOVF	Rx FIFO Overflow Count Half/Full. The `EMAC_MMC_RXINT.FIFOOVF` bit is set when `EMAC_RXFIFO_OVF` counter reaches full or half.
20 (R/NW)	PAUSEFR	Rx Pause Frames Count Half/Full. The `EMAC_MMC_RXINT.PAUSEFR` bit is set when `EMAC_RXPAUSEFRM` counter reaches full or half.
19 (R/NW)	OUTRANGE	Rx Out Of Range Type Count Half/Full. The `EMAC_MMC_RXINT.OUTRANGE` bit is set when `EMAC_RXOORTYPE` counter reaches full or half.
18 (R/NW)	LENERR	Rx Length Error Count Half/Full. The `EMAC_MMC_RXINT.LENERR` bit is set when `EMAC_RXLEN_ERR` counter reaches full or half.
17 (R/NW)	UCASTG	Rx Unicast Frames (Good) Count Half/Full. The `EMAC_MMC_RXINT.UCASTG` bit is set when `EMAC_RXUCASTFRM_G` counter reaches full or half.
16 (R/NW)	R1024TOMAX	Rx 1024-to-max Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_RXINT.R1024TOMAX` bit is set when `EMAC_RX1024TOMAX_GB` counter reaches full or half.
15 (R/NW)	R512TO1023	Rx 512-to-1023 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_RXINT.R512TO1023` bit is set when `EMAC_RX512TO1023_GB` counter reaches full or half.
14 (R/NW)	R256TO511	Rx 255-to-511 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_RXINT.R256TO511` bit is set when `EMAC_RX256TO511_GB` counter reaches full or half.

Table 31-139: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/NW)	R128TO255	Rx 128-to-255 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_RXINT.R128TO255` bit is set when `EMAC_RX128TO255_GB` counter reaches full or half.
12 (R/NW)	R65TO127	Rx 65-to-127 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_RXINT.R65TO127` bit is set when `EMAC_RX65TO127_GB` counter reaches full or half.
11 (R/NW)	R64	Rx 64 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_RXINT.R64` bit is set when `EMAC_RX64_GB` counter reaches full or half.
10 (R/NW)	OSIZEG	Rx Oversize (Good) Count Half/Full. The `EMAC_MMC_RXINT.OSIZEG` bit is set when `EMAC_RXOSIZE_G` counter reaches full or half.
9 (R/NW)	USIZEG	Rx Undersize (Good) Count Half/Full. The `EMAC_MMC_RXINT.USIZEG` bit is set when `EMAC_RXUSIZE_G` counter reaches full or half.
8 (R/NW)	JABERR	Rx Jabber Error Count Half/Full. The `EMAC_MMC_RXINT.JABERR` bit is set when `EMAC_RXJAB_ERR` counter reaches full or half.
7 (R/NW)	RUNTERR	Rx Runt Error Count Half/Full. The `EMAC_MMC_RXINT.RUNTERR` bit is set when `EMAC_RXRUNT_ERR` counter reaches full or half.
6 (R/NW)	ALIGNERR	Rx Alignment Error Count Half/Full. The `EMAC_MMC_RXINT.ALIGNERR` bit is set when `EMAC_RXALIGN_ERR` counter reaches full or half
5 (R/NW)	CRCERR	Rx CRC Error Counter Half/Full. The `EMAC_MMC_RXINT.CRCERR` bit is set when `EMAC_RXCRC_ERR` counter reaches full or half.
4 (R/NW)	MCASTG	Rx Multicast Count (Good) Half/Full. The `EMAC_MMC_RXINT.MCASTG` bit is set when `EMAC_RXMCASTFRM_G` counter reaches full or half.
3 (R/NW)	BCASTG	Rx Broadcast Count (Good) Half/Full. The `EMAC_MMC_RXINT.BCASTG` bit is set when `EMAC_RXBCASTFRM_G` counter reaches full or half.

Table 31-139: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/NW)	OCTCNTG	Octet Count (Good) Half/Full. The `EMAC_MMC_RXINT.OCTCNTG` bit is set when `EMAC_RXOCTCNT_G` counter reaches full or half.
1 (R/NW)	OCTCNTGB	Octet Count (Good/Bad) Half/Full. The `EMAC_MMC_RXINT.OCTCNTGB` bit is set when `EMAC_RXOCTCNT_GB` counter reaches half or full.
0 (R/NW)	FRCNTGB	Frame Count (Good/Bad) Half/Full. The `EMAC_MMC_RXINT.FRCNTGB` bit is set when `EMAC_RXFRMCNT_GB` counter reaches half or full.

MMC TX Interrupt Mask Register

The EMAC_MMC_TXIMSK register enables (unmasks) MMC transmit interrupts.

Figure 31-108: EMAC_MMC_TXIMSK Register Diagram

Table 31-140: EMAC_MMC_TXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	OSZGFIM	Tx Oversize Good Frame Count Interrupt Mask. The `EMAC_MMC_TXIMSK.OSZGFIM` bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value.
24 (R/W)	VLANFRG	Tx VLAN Frames (Good) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.VLANFRG` bit, when set, masks the interrupt when `EMAC_TXVLANFRM_G` counter reaches full or half.
23 (R/W)	PAUSEFRM	Tx Pause Frames Count Half/Full Mask. The `EMAC_MMC_TXIMSK.PAUSEFRM` bit, when set, masks the interrupt when `EMAC_TXPAUSEFRM` counter reaches full or half.
22 (R/W)	EXCESSDEF	Tx Excess Deferred Count Half/Full Mask. The `EMAC_MMC_TXIMSK.EXCESSDEF` bit, when set, masks the interrupt when `EMAC_TXEXCESSDEF` counter reaches full or half.
21 (R/W)	FRCNTG	Tx Frame Count (Good) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.FRCNTG` bit, when set, masks the interrupt when `EMAC_TXFRMCNT_G` counter reaches full or half.
20 (R/W)	OCTCNTG	Tx Octet Count (Good) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.OCTCNTG` bit, when set, masks the interrupt when `EMAC_TXOCTCNT_G` counter reaches full or half.
19 (R/W)	CARRERR	Tx Carrier Error Count Half/Full Mask. The `EMAC_MMC_TXIMSK.CARRERR` bit, when set, masks the interrupt when `EMAC_TXCARR_ERR` counter reaches full or half.
18 (R/W)	EXCESSCOL	Tx Excess collision Count Half/Full Mask. The `EMAC_MMC_TXIMSK.EXCESSCOL` bit, when set, masks the interrupt when `EMAC_TXEXCESSCOL` counter reaches full or half.
17 (R/W)	LATECOL	Tx Late Collision Count Half/Full Mask. The `EMAC_MMC_TXIMSK.LATECOL` bit, when set, masks the interrupt when `EMAC_TXLATECOL` counter reaches full or half.
16 (R/W)	DEFERRED	Tx Deferred Count Half/Full Mask. The `EMAC_MMC_TXIMSK.DEFERRED` bit, when set, masks the interrupt when `EMAC_TXDEFERRED` counter reaches full or half.
15 (R/W)	MULTCOLG	Tx Multiple Collisions (Good) Count Mask. The `EMAC_MMC_TXIMSK.MULTCOLG` bit, when set, masks the interrupt when `EMAC_TXMULTCOL_G` counter reaches full or half.
14 (R/W)	SNGCOLG	Tx Single Collision (Good) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.SNGCOLG` bit, when set, masks the interrupt when `EMAC_TXSNGCOL_G` counter reaches full or half.

Table 31-140: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	UNDERR	Tx Underflow Error Count Half/Full Mask. The `EMAC_MMC_TXIMSK.UNDERR` bit, when set, masks the interrupt when `EMAC_TXUNDR_ERR` counter reaches full or half.
12 (R/W)	BCASTGB	Tx Broadcast Frames (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.BCASTGB` bit, when set, masks the interrupt when `EMAC_TXBCASTFRM_GB` counter reaches full or half.
11 (R/W)	MCASTGB	Tx Multicast Frames (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.MCASTGB` bit, when set, masks the interrupt when `EMAC_TXMCASTFRM_GB` counter reaches full or half.
10 (R/W)	UCASTGB	Tx Unicast Frames (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.UCASTGB` bit, when set, masks the interrupt when `EMAC_TXUCASTFRM_GB` counter reaches full or half.
9 (R/W)	T1024TOMAX	Tx 1024-to-max Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.T1024TOMAX` bit, when set, masks the interrupt when `EMAC_TX1024TOMAX_GB` counter reaches full or half.
8 (R/W)	T512TO1023	Tx 512-to-1023 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.T512TO1023` bit, when set, masks the interrupt when `EMAC_TX512TO1023_GB` counter reaches full or half.
7 (R/W)	T256TO511	Tx 256-to-511 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.T256TO511` bit, when set, masks the interrupt when `EMAC_TX256TO511_GB` counter reaches full or half.
6 (R/W)	T128TO255	Tx 128-to-255 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.T128TO255` bit, when set, masks the interrupt when `EMAC_TX128TO255_GB` counter reaches full or half.
5 (R/W)	T65TO127	Tx 65-to-127 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.T65TO127` bit, when set, masks the interrupt when `EMAC_TX65TO127_GB` counter reaches full or half.
4 (R/W)	T64	Tx 64 Octets (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.T64` bit, when set, masks the interrupt when `EMAC_TX64_GB` counter reaches full or half.
3 (R/W)	MCASTG	Tx Multicast Frames (Good) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.MCASTG` bit, when set, masks the interrupt when `EMAC_TXMCASTFRM_G` counter reaches full or half.

Table 31-140: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	BCASTG	Tx Broadcast Frames (Good) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.BCASTG` bit, when set, masks the interrupt when `EMAC_TXBCASTFRM_G` counter reaches full or half.
1 (R/W)	FRCNTGB	Tx Frame Count (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.FRCNTGB` bit, when set, masks the interrupt when `EMAC_TXFRMCNT_GB` counter reaches full or half.
0 (R/W)	OCTCNTGB	Tx Octet Count (Good/Bad) Count Half/Full Mask. The `EMAC_MMC_TXIMSK.OCTCNTGB` bit, when set, masks the interrupt when `EMAC_TXOCTCNT_GB` counter reaches full or half.

MMC Tx Interrupt Register

The `EMAC_MMC_TXINT` register indicates status of MMC transmit interrupts.

Table 31-141: EMAC_MMC_TXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (RC/NW)	TXOSIZEGFIS	Tx Oversize Good Frame Count Interrupt Status. The `EMAC_MMC_TXINT.TXOSIZEGFIS` bit is set when the txoversize_g counter reaches half of the maximum value or the maximum value.
24 (R/NW)	VLANFRGB	Tx VLAN Frames (Good) Count Half/Full. The `EMAC_MMC_TXINT.VLANFRGB` bit is set when `EMAC_TXVLANFRM_G` counter reaches full or half.
23 (R/NW)	PAUSEFRM	Tx Pause Frames Count Half/Full. The `EMAC_MMC_TXINT.PAUSEFRM` bit is set when `EMAC_TXPAUSEFRM` counter reaches full or half.
22 (R/NW)	EXCESSDEF	Tx Excess Deferred Count Half/Full. The `EMAC_MMC_TXINT.EXCESSDEF` bit is set when `EMAC_TXEXCESSDEF` counter reaches full or half.
21 (R/NW)	FRCNTG	Tx Frame Count (Good) Count Half/Full. The `EMAC_MMC_TXINT.FRCNTG` bit is set when `EMAC_TXFRMCNT_G` counter reaches full or half.
20 (R/NW)	OCTCNTG	Tx Octet Count (Good) Count Half/Full. The `EMAC_MMC_TXINT.OCTCNTG` bit is set when `EMAC_TXOCTCNT_G` counter reaches full or half.
19 (R/NW)	CARRERR	Tx Carrier Error Count Half/Full. The `EMAC_MMC_TXINT.CARRERR` bit is set when `EMAC_TXCARR_ERR` counter reaches full or half.
18 (R/NW)	EXCESSCOL	Tx Excess Collision Count Half/Full. The `EMAC_MMC_TXINT.EXCESSCOL` bit is set when `EMAC_TXEXCESSCOL` counter reaches full or half.
17 (R/NW)	LATECOL	Tx Late Collision Count Half/Full. The `EMAC_MMC_TXINT.LATECOL` bit is set when `EMAC_TXLATECOL` counter reaches full or half.
16 (R/NW)	DEFERRED	Tx Deferred Count Half/Full. The `EMAC_MMC_TXINT.DEFERRED` bit is set when `EMAC_TXDEFERRED` counter reaches full or half.
15 (R/NW)	MULTCOLG	Tx Multiple collision (Good) Count Half/Full. The `EMAC_MMC_TXINT.MULTCOLG` bit is set when `EMAC_TXMULTCOL_G` counter reaches full or half.
14 (R/NW)	SNGCOLG	Tx Single Collision (Good) Count Half/Full. The `EMAC_MMC_TXINT.SNGCOLG` bit is set when `EMAC_TXSNGCOL_G` counter reaches full or half.

Table 31-141: EMAC_MMC_TXINT Register Fields (Continued)

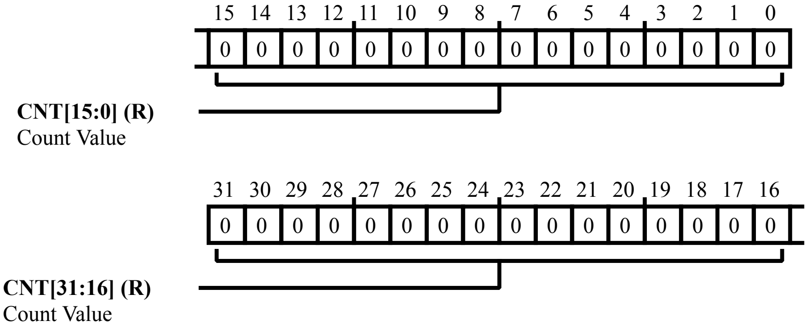
Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/NW)	UNDERR	Tx Underflow Error Count Half/Full. The `EMAC_MMC_TXINT.UNDERR` bit is set when `EMAC_TXUNDR_ERR` counter reaches full or half.
12 (R/NW)	BCASTGB	Tx Broadcast Frames (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.BCASTGB` bit is set when `EMAC_TXBCASTFRM_GB` counter reaches full or half.
11 (R/NW)	MCASTGB	Tx Multicast Frames (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.MCASTGB` bit is set when `EMAC_TXMCASTFRM_GB` counter reaches full or half.
10 (R/NW)	UCASTGB	Tx Unicast Frames (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.UCASTGB` bit is set when `EMAC_TXUCASTFRM_GB` counter reaches full or half.
9 (R/NW)	T1024TOMAX	Tx 1024-to-max Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.T1024TOMAX` bit is set when `EMAC_TX1024TOMAX_GB` counter reaches full or half.
8 (R/NW)	T512TO1023	Tx 512-to-1023 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.T512TO1023` bit is set when `EMAC_TX512TO1023_GB` counter reaches full or half.
7 (R/NW)	T256TO511	Tx 256-to-511 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.T256TO511` bit is set when `EMAC_TX256TO511_GB` counter reaches full or half.
6 (R/NW)	T128TO255	Tx 128-to-255 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.T128TO255` bit is set when `EMAC_TX128TO255_GB` counter reaches full or half.
5 (R/NW)	T65TO127	Tx 65-to-127 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.T65TO127` bit is set when `EMAC_TX65TO127_GB` counter reaches full or half.
4 (R/NW)	T64	Tx 64 Octets (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.T64` bit is set when `EMAC_TX64_GB` counter reaches full or half.
3 (R/NW)	MCASTG	Tx Multicast Frames (Good) Count Half/Full. The `EMAC_MMC_TXINT.MCASTG` bit is set when `EMAC_TXMCASTFRM_G` counter reaches full or half.

Table 31-141: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/NW)	BCASTG	Tx Broadcast Frames (Good) Count Half/Full. The `EMAC_MMC_TXINT.BCASTG` bit is set when `EMAC_TXBCASTFRM_G` counter reaches full or half.
1 (R/NW)	FRCNTGB	Tx Frame Count (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.FRCNTGB` bit is set when `EMAC_TXFRMCNT_GB` counter reaches full or half.
0 (R/NW)	OCTCNTGB	Tx Octet Count (Good/Bad) Count Half/Full. The `EMAC_MMC_TXINT.OCTCNTGB` bit is set when `EMAC_TXOCTCNT_GB` counter reaches full or half.

Rx 1024- to Max-Byte Frames (Good/Bad) Register

The EMAC_RX1024TOMAX_GB register contains a count of the number of good and bad frames received with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 31-164: EMAC_SMI_ADDR Register Diagram

Table 31-196: EMAC_SMI_ADDR Register Fields

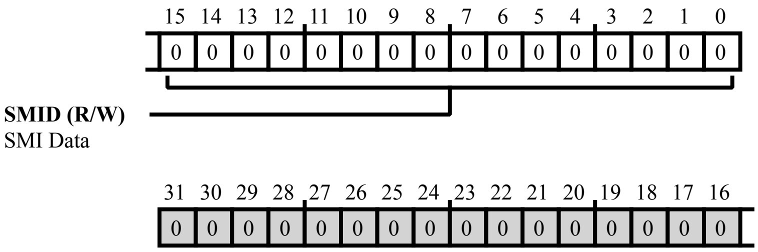
Bit No. (Access)	Bit Name	Description/Enumeration	
15:11 (R/W)	PA	Physical Layer Address. The `EMAC_SMI_ADDR.PA` bits select the PHY. This field tells which of the 32 possible PHY devices are being accessed.	
10:6 (R/W)	SMIR	SMI Register Address. The `EMAC_SMI_ADDR.SMIR` bits select the desired Station Management Interface register in the selected PHY device.	
5:2 (R/W)	CR	Clock Range. The `EMAC_SMI_ADDR.CR` bits select the Clock Range, determining the frequency of the MDC clock as per the SCLK0_0 frequency. The suggested range of SCLK0_0 frequency applicable for each value below (when Bit[5] =0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. When the MSB of this field is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when SCLK0_0=100 MHz and you program these bits to b#1010, the resulting MDC clock is 12.5 MHz, which is outside the limit of IEEE 802.3 specified range. Use the values shown only if the interface chips support faster MDC clocks.	
		0	MDC Clock= SCLK0_0/42 (for SCLK0_0=60-100MHz)
		1	MDC Clock= SCLK0_0/62 (for SCLK0_0=100-125 MHz)
		2	MDC Clock= SCLK0_0/16 (for SCLK0_0=20-35 MHz)

Table 31-196: EMAC_SMI_ADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	MDC Clock= SCLK0_0/26 (for SCLK0_0=35-60 MHz)
		8	MDC Clock= SCLK0_0/4
		9	MDC Clock= SCLK0_0/6
		10	MDC Clock= SCLK0_0/8
		11	MDC Clock= SCLK0_0/10
		12	MDC Clock= SCLK0_0/12
		13	MDC Clock= SCLK0_0/14
		14	MDC Clock= SCLK0_0/16
		15	MDC Clock= SCLK0_0/18
1 (R/W)	SMIW	SMI Write. The `EMAC_SMI_ADDR.SMIW` bit, when set, tells the PHY this is a Write operation using the Station Management Interface Data register. If this bit is not set, this is a Read operation.	
0 (R/W1S)	SMIB	SMI Busy. The `EMAC_SMI_ADDR.SMIB` bit should read low (=0) before writing to the `EMAC_SMI_ADDR` and `EMAC_SMI_DATA` registers. This bit must also =0 during a Write to `EMAC_SMI_ADDR`. During a PHY register access, this bit is set (=1) by the Application to indicate that a Read or Write access is in progress. The `EMAC_SMI_DATA` register should be kept valid until this bit is cleared by the MAC during a PHY Write operation. `EMAC_SMI_DATA` is invalid until this bit is cleared by the MAC during a PHY Read operation. The `EMAC_SMI_ADDR` should not be written to until this bit is cleared.	

SMI Data Register

The EMAC_SMI_DATA register contains the station management interface data.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

31:0 (R/W)	VALUE	Time Value.

Time Stamp Control Register

The `EMAC_TM_CTL` register controls time stamp generation and update. The `EMAC_TM_CTL.SNAPTYPSEL`, `EMAC_TM_CTL.TSMSTRENA`, and `EMAC_TM_CTL.TSEVNTENA` bits work together to decide the set of PTP packet types for which snapshot needs to be taken. (Encoding shown in table.)

SNAPTYPSEL()	TSMSTRENA	TSEVNTENA	Messages for which snapshot is taken
00	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	X	X	SYNC, Delay_Req

Figure 31-169: EMAC_TM_CTL Register Diagram

Table 31-201: EMAC_TM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28 (R/W)	ATSEN3	Auxiliary Snapshot 3 Enable. The `EMAC_TM_CTL.ATSEN3` bit, controls capturing the Auxiliary Snapshot Trigger 3
27 (R/W)	ATSEN2	Auxiliary Snapshot 2 Enable. The `EMAC_TM_CTL.ATSEN2` bit, controls capturing the Auxiliary Snapshot Trigger 2
26 (R/W)	ATSEN1	Auxiliary Snapshot 1 Enable. The `EMAC_TM_CTL.ATSEN1` bit, controls capturing the Auxiliary Snapshot Trigger 1

Table 31-201: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	ATSEN0	Auxiliary Snapshot 0 Enable. The `EMAC_TM_CTL.ATSEN0` bit, controls capturing the Auxiliary Snapshot Trigger 0	
24 (R/W)	ATSFC	Auxiliary Time Stamp FIFO Clear. The `EMAC_TM_CTL.ATSFC` bit, when set, resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is cleared, auxiliary snapshots gets stored in the FIFO.	
18 (R/W)	TSENMACADDR	Time Stamp Enable MAC Address. The `EMAC_TM_CTL.TSENMACADDR` bit, when set, uses the DA MAC address (that matches the `EMAC_ADDR0_LO` and `EMAC_ADDR0_HI` registers) to filter the PTP frames when PTP is sent directly over Ethernet.	
		0	Disable PTP MAC address filter
		1	Enable PTP MAC address filter
17:16 (R/W)	SNAPTYPSEL	Snapshot Type Select. The `EMAC_TM_CTL.SNAPTYPSEL` bits along with bit 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken. (See the table in the `EMAC_TM_CTL` register description.)	
15 (R/W)	TSMSTRENA	Time Stamp Master (Frames) Enable. The `EMAC_TM_CTL.TSMSTRENA` bit, when set, takes the snapshot for messages relevant to master node only else snapshot is taken for PTP messages relevant to slave node.	
		0	Enable Snapshot for Slave Messages
		1	Enable Snapshot for Master Messages
14 (R/W)	TSEVNTENA	Time Stamp Event (PTP Frames) Enable. The `EMAC_TM_CTL.TSEVNTENA` bit, when set, takes the time stamp snapshot for PTP event messages only (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all PTP messages except Announce, Management, and Signaling.	
		0	Enable Time Stamp for All Messages
		1	Enable Time Stamp for Event Messages Only

Table 31-201: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TSIPV4ENA	Time Stamp IPV4 (PTP Frames) Enable. The `EMAC_TM_CTL.TSIPV4ENA` bit, when set, directs the EMAC receiver to process the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default.	
		0	Disable Time Stamp for PTP Over IPv4 Frames
		1	Enable Time Stamp for PTP Over IPv4 Frames
12 (R/W)	TSIPV6ENA	Time Stamp IPV6 (PTP Frames) Enable. The `EMAC_TM_CTL.TSIPV6ENA` bit, when set, directs the EMAC receiver to process PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets.	
		0	Disable Time Stamp for PTP Over IPv6 frames
		1	Enable Time Stamp for PTP Over IPv6 Frames
11 (R/W)	TSIPENA	Time Stamp IP Enable. The `EMAC_TM_CTL.TSIPENA` bit, when set, directs the EMAC receiver to process the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores PTP over Ethernet packets.	
		0	Disable PTP Over Ethernet Frames
		1	Enable PTP Over Ethernet Frames
10 (R/W)	TSVER2ENA	Time Stamp VER2 (Snooping) Enable. The `EMAC_TM_CTL.TSVER2ENA` bit, when set, processes the PTP packets using the 1588 version 2 format (enables PTP packet snooping for VER2) else processed using the version 1 format.	
		0	Disable packet snooping for V2 frames
		1	Enable packet snooping for V2 frames
9 (R/W)	TSCTRLSSR	Time Stamp Control Nanosecond Rollover. The `EMAC_TM_CTL.TSCTRLSSR` bit, when set, rolls over the `EMAC_TM_NSEC` register after 0x3B9A_C9FF value (10^9-1) and increments the `EMAC_TM_SEC` register. When reset, the roll over value of `EMAC_TM_NSEC` register is 0x7FFF_FFFF. The nanosecond increment has to be programmed correctly depending on the PTP reference clock frequency and this bit value.	
		0	Roll Over Nanosecond After 0x7FFFFFFF
		1	Roll Over Nanosecond After 0x3B9AC9FF

Table 31-201: EMAC_TM_CTL Register Fields (Continued)

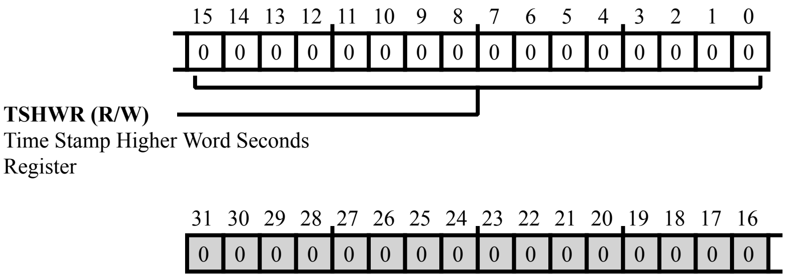
Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	TSENALL	Time Stamp Enable All (Frames). The `EMAC_TM_CTL.TSENALL` bit, when set, enables the time stamp snapshot for all frames received by the core.	
		0	Disable timestamp for all frames
		1	Enable timestamp for all frames
5 (R/W1S)	TSADDREG	Time Stamp Addend Register Update. The `EMAC_TM_CTL.TSADDREG` bit, when set, updates the contents of the `EMAC_TM_ADDEND` register for fine correction. This bit is cleared when the update is completed. This bit should be zero before setting it.	
4 (R/W1S)	TSTRIG	Time Stamp (Target Time) Trigger Enable. The `EMAC_TM_CTL.TSTRIG` bit, when set, generates the time stamp interrupt when the System Time becomes greater than the value written in Time Stamp Target Time Seconds register. This bit is reset after the generation of the Time Stamp Trigger Interrupt.	
		1	Interrupt (TS) if system time is greater than target time register
3 (R/W1S)	TSUPDT	Time Stamp (System Time) Update. The `EMAC_TM_CTL.TSUPDT` bit, when set, updates (adds/subtracts) the system time with the value specified in the `EMAC_TM_SECUPDT` and `EMAC_TM_NSECUPDT` registers. This bit should read =0 before updating it. This bit is reset when the update is completed in hardware. The `EMAC_TM_NSEC` register is not updated.	
		1	System time updated with Time stamp register values
2 (R/W1S)	TSINIT	Time Stamp (System Time) Initialize. The `EMAC_TM_CTL.TSINIT` bit, when set, initializes (over-writes) the system time with the value specified in the `EMAC_TM_SECUPDT` and `EMAC_TM_NSECUPDT` registers. This bit should read =0 before updating it. This bit is reset when the initialization is complete. Only the `EMAC_TM_NSEC` register can be initialized.	
		1	System time initialized with Time stamp register values
1 (R/W)	TSCFUPDT	Time Stamp (System Time) Fine/Coarse Update. The `EMAC_TM_CTL.TSCFUPDT` bit, when set, indicates that the system time update is done using the fine correction method. When reset, it indicates the system time correction to be done using Coarse method.	
		0	Use Coarse Correction Method for System Time Update
		1	Use Fine Correction Method for System Time Update

Table 31-201: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	TSENA	Time Stamp (PTP) Enable. The `EMAC_TM_CTL.TSENA` bit, when set, enables PTP module for time stamping transmitted and received frames. It also enables System Time which is used for time stamping the frames. Programs should initialize the System Time after setting this bit.	
		0	Disable PTP Module
		1	Enable PTP Module

Time Stamp High Second Register

The EMAC_TM_HISEC register contains the upper 32 bits of the seconds field of the system time.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

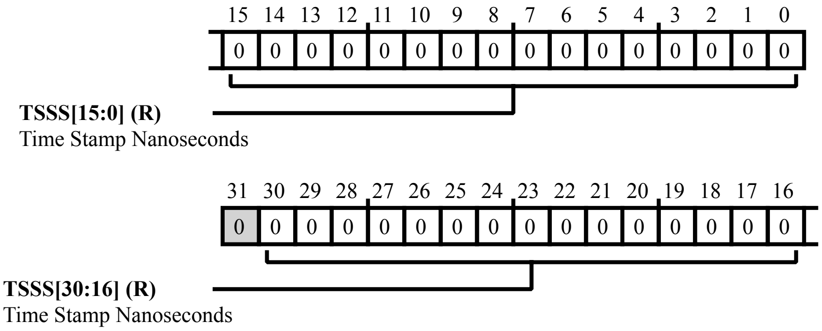
Figure 31-170: EMAC_TM_HISEC Register Diagram

Table 31-202: EMAC_TM_HISEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TSHWR	Time Stamp Higher Word Seconds Register. The EMAC_TM_HISEC.TSHWR bit field contains the most significant 16-bits of the time stamp seconds value. The register is directly written to initialize the value. This register is incremented when there is an overflow from the 32-bits of the EMAC_TM_SEC register.

Time Stamp Nanoseconds Register

The `EMAC_TM_NSEC` register contains the nanoseconds field of the system time.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TSSS[30:16] (R)
Time Stamp Nanoseconds

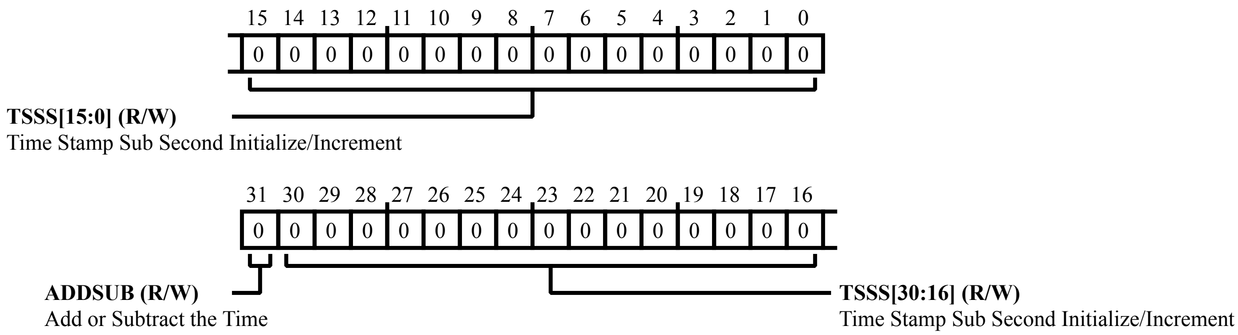
Figure 31-171: EMAC_TM_NSEC Register Diagram

Table 31-203: EMAC_TM_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:0 (R/NW)	TSSS	Time Stamp Nanoseconds. The value in the `EMAC_TM_NSEC.TSSS` bit field has the nanosecond representation of time, with an accuracy of 0.46 nanosecond. (When `EMAC_TM_CTL.TSCTRLSSR` is set, each bit represents 1 ns and the maximum value will be 0x3B9A_C9FF, after which it rolls-over to zero).

Time Stamp Nanoseconds Update Register

The `EMAC_TM_NSECUPDT` register contains the low 32 bits to be added to, subtracted from, or written to the nanoseconds field of the system time.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Time Stamp Sub Second Initialize/Increment
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ADDSUB (R/W)
Add or Subtract the Time
TSSS[30:16] (R/W)
Time Stamp Sub Second Initialize/Increment

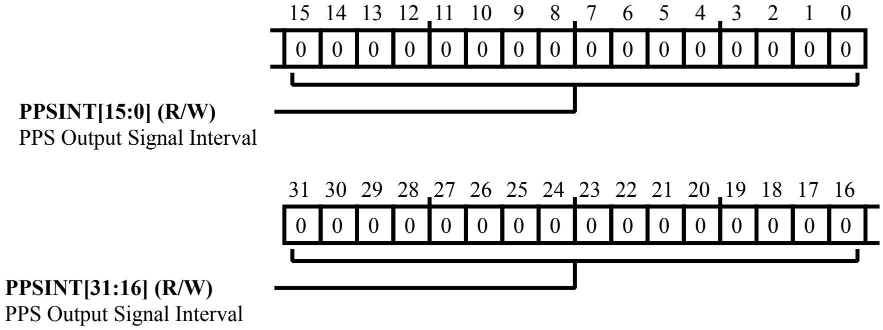
Figure 31-172: EMAC_TM_NSECUPDT Register Diagram

Table 31-204: EMAC_TM_NSECUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ADDSUB	Add or Subtract the Time. The `EMAC_TM_NSECUPDT.ADDSUB` bit, when set, subtracts the time value with the contents of the update registers. When this bit is reset, the time value is added with the contents of the update registers.
30:0 (R/W)	TSSS	Time Stamp Sub Second Initialize/Increment. The value in the `EMAC_TM_NSECUPDT.TSSS` bit field indicates the time, in nanoseconds, to be initialized or added to or subtracted from the system time nanoseconds.

Time Stamp PPS Interval Register

The `EMAC_TM_PPS0INTVL` register contains the interval value for the time between rising edges (period) of PPS output.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PPSINT[15:0] (R/W)
PPS Output Signal Interval
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PPSINT[31:16] (R/W)
PPS Output Signal Interval

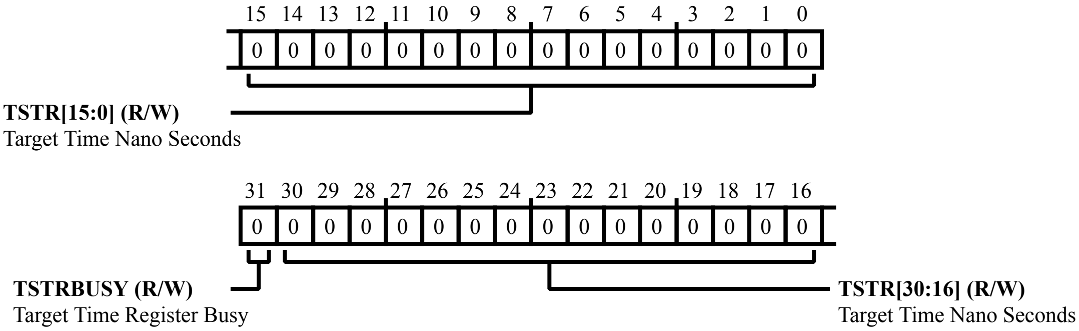
Figure 31-173: EMAC_TM_PPS0INTVL Register Diagram

Table 31-205: EMAC_TM_PPS0INTVL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Interval. The `EMAC_TM_PPS0INTVL.PPSINT` bits store the interval between the rising edges of PPS signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20ns), and desired interval between rising edges of PPS signal output is 100ns (that is, 5 units of sub-second increment value), then you should program value 4 (5-1) in this register.

Time Stamp Target Time Nanoseconds Register

The EMAC_TM_PPS0NTGTM register contains the high 32 bits of the target nanoseconds field for comparison to the corresponding system time field.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TSTR[15:0] (R/W)
Target Time Nano Seconds
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TSTRBUSY (R/W)
Target Time Register Busy
TSTR[30:16] (R/W)
Target Time Nano Seconds

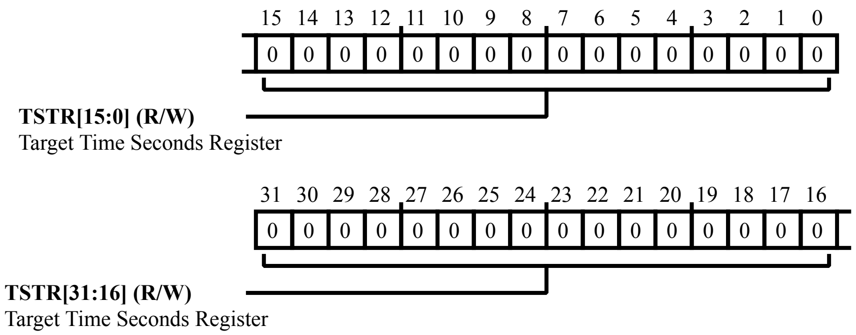
Figure 31-174: EMAC_TM_PPS0NTGTM Register Diagram

Table 31-206: EMAC_TM_PPS0NTGTM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	TSTRBUSY	Target Time Register Busy. The EMAC_TM_PPS0NTGTM.TSTRBUSY bit is set when Flexible PPS is enabled and the PPS Frequency Control bit field in the PPS Control register is programmed to 0001, 0010 or 0100. Programming the PPS Frequency Control bit field to 0001, 0010 or 0100, instructs the core to synchronize the EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers to the PTP clock domain. The EMAC clears this bit after synchronizing the EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers to the PTP clock domain The application must not update the EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.
30:0 (R/W)	TSTR	Target Time Nano Seconds. The EMAC_TM_PPS0NTGTM.TSTR bit field stores the time in (signed) nanoseconds. When the value of the time stamp matches the both EMAC_TM_PPS0TGTM and EMAC_TM_NSEC registers, based on the Target Time Register Mode bit field in the PPS control register, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when the Target Time Register Mode bit field is set. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.

Time Stamp Target Time Seconds Register

The `EMAC_TM_PPS0TGTM` register contains the high 32 bits of the target seconds field for comparison to the corresponding system time field.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

PPSINT[31:16] (R/W)
PPS Output Signal Width

Figure 31-188: EMAC_TM_PPS3WIDTH Register Diagram

Table 31-220: EMAC_TM_PPS3WIDTH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Width. The `EMAC_TM_PPS3WIDTH.PPSINT` bits store the interval between a rising edge and the next falling edge (width) of PPS output in terms of units of sub second increment value. Program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns) and the desired width of the PPS signal output is 60 ns (3 units of sub-second increment value), program the value 2 (3-1) in this register.

PPS Control Register

The `EMAC_TM_PPSCTL` register controls the interval of PPS output.

When the `EMAC_TM_PPSCTL.PPSEN` bit is disabled (=0, fixed PPS output), the PPS Frequency Control (PPSCTL0) bits control the behavior of the PPS output signal. The default value of PPSCTRL is 0000 and the PPS output is 1 pulse every second. For other values of PPSCTRL, the PPS output becomes a generated clock. (See bit enumerations for frequencies.) In the binary rollover mode, the PPS output has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. This behavior is because of the non-linear toggling of the bits in the digital rollover mode in System Time - Nanoseconds Register.

When the `EMAC_TM_PPSCTL.PPSEN` bit is enabled (=1, flexible PPS output), the PPS Frequency Control bits function as PPSCMD. (See bit enumerations for commands.) Programming these bits with a non-zero value instructs the core to initiate an event. After the command is transferred or synchronized to the PTP clock domain, these bits gets cleared automatically. Software should ensure that these bits are programmed only when they are all-zero.

30:29 (R/W)	TRGTMODSEL3	Target Time Register Mode for PPS3. The `EMAC_TM_PPSCTL.TRGTMODSEL3` bits indicates the Target Time registers mode for PPS3 output signal.

Table 31-221: EMAC_TM_PPSCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/W1S)	PPSCMD3	Flexible PPS3 Output Control. The `EMAC_TM_PPSCTL.PPSCMD3` bits controls the flexible PPS3 output signal.	
22:21 (R/W)	TRGTMODSEL2	Target Time Register Mode for PPS2. The `EMAC_TM_PPSCTL.TRGTMODSEL2` bits indicates the Target Time registers mode for PPS2 output signal.	
18:16 (R/W1S)	PPSCMD2	Flexible PPS2 Output Control. The `EMAC_TM_PPSCTL.PPSCMD2` bits controls the flexible PPS3 output signal.	
14:13 (R/W)	TRGTMODSEL1	Target Time Register Mode for PPS1. The `EMAC_TM_PPSCTL.TRGTMODSEL1` bits indicates the Target Time registers mode for PPS1 output signal.	
10:8 (R/W1S)	PPSCMD1	Flexible PPS1 Output Control. The `EMAC_TM_PPSCTL.PPSCMD1` bits controls the flexible PPS1 output signal.	
6:5 (R/W)	TRGTMODSEL0	Target Time Register Mode. The `EMAC_TM_PPSCTL.TRGTMODSEL0` bits select the target time register mode.	
		0	Interrupt Only The Target Time registers are programmed only for interrupt event generation.
		1	Reserved
		2	Interrupt and PPS Start/Stop The Target Time registers are programmed for interrupt event and for starting or stopping the PPS output signal generation.
		3	PPS Start/Stop Only The Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.
4 (R/W)	PPSEN	Enable the flexible PPS output mode. The `EMAC_TM_PPSCTL.PPSEN` bit enables PPS operation. When set low, the PPS Frequency Control field controls frequency of Fixed PPS output. When set high, PPS Frequency Control field is used to command Flexible PPS output.	

Table 31-221: EMAC_TM_PPSCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W)	PPSCTL0	PPS Frequency Control. When the `EMAC_TM_PPSCTL.PPSEN` bit is disabled (=0, fixed PPS output), the `EMAC_TM_PPSCTL.PPSCTL0` bits control the behavior of the PPS output signal. When the `EMAC_TM_PPSCTL.PPSEN` bit is enabled (=1, flexible PPS output), the `EMAC_TM_PPSCTL.PPSCTL0` bits function as PPSCMD. (See bit enumerations for PPS output frequency, rollover, and PPS commands.) Programming these bits with a non-zero value instructs the core to initiate an event. After the command is transferred or synchronized to the PTP clock domain, these bits gets cleared automatically. Software should ensure that these bits are programmed only when they are all-zero. All values not shown in the bit enumerations are reserved. For more information about the `EMAC_TM_PPSCTL.PPSCTL0` bits, see the pulse-per-second functional description.

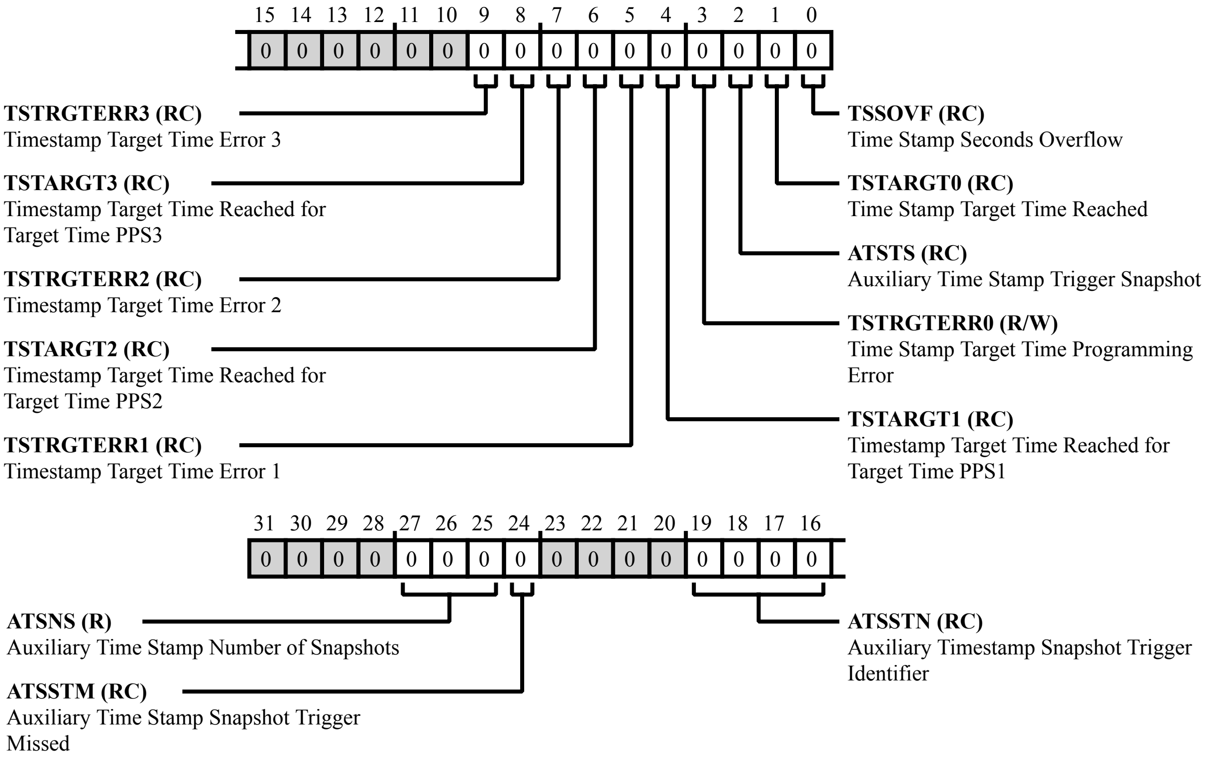
Table 31-223: EMAC_TM_SECUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSS	Time Stamp Second Initialize/Update. The value in the `EMAC_TM_SECUPDT.TSS` bit field indicates the time, in seconds, to be initialized or added to or subtracted from the system time seconds.

Time Stamp Status Register

The `EMAC_TM_STMPSTAT` register contains the PTP status.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
TSTRGTERR3 (RC)
Timestamp Target Time Error 3
TSTARGT3 (RC)
Timestamp Target Time Reached for Target Time PPS3
TSTRGTERR2 (RC)
Timestamp Target Time Error 2
TSTARGT2 (RC)
Timestamp Target Time Reached for Target Time PPS2
TSTRGTERR1 (RC)
Timestamp Target Time Error 1
TSSOVF (RC)
Time Stamp Seconds Overflow
TSTARGT0 (RC)
Time Stamp Target Time Reached
ATSTS (RC)
Auxiliary Time Stamp Trigger Snapshot
TSTRGTERR0 (R/W)
Time Stamp Target Time Programming Error
TSTARGT1 (RC)
Timestamp Target Time Reached for Target Time PPS1
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
ATSNS (R)
Auxiliary Time Stamp Number of Snapshots
ATSSTM (RC)
Auxiliary Time Stamp Snapshot Trigger Missed
ATSSTN (RC)
Auxiliary Timestamp Snapshot Trigger Identifier

Figure 31-192: EMAC_TM_STMPSTAT Register Diagram

Table 31-224: EMAC_TM_STMPSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:25 (R/NW)	ATSNS	Auxiliary Time Stamp Number of Snapshots. The `EMAC_TM_STMPSTAT.ATSNS` bits indicate the number of Snapshots available in the FIFO. A value of 4 (100) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 000) when the Auxiliary snapshot FIFO clear bit is set.
24 (RC/NW)	ATSSTM	Auxiliary Time Stamp Snapshot Trigger Missed. The `EMAC_TM_STMPSTAT.ATSSTM` bit is set when the Auxiliary time stamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot was not stored in the FIFO.
19:16 (RC/NW)	ATSSTN	Auxiliary Timestamp Snapshot Trigger Identifier. The `EMAC_TM_STMPSTAT.ATSSTN` bit identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable.

Table 31-224: EMAC_TM_STMPSTAT Register Fields (Continued)

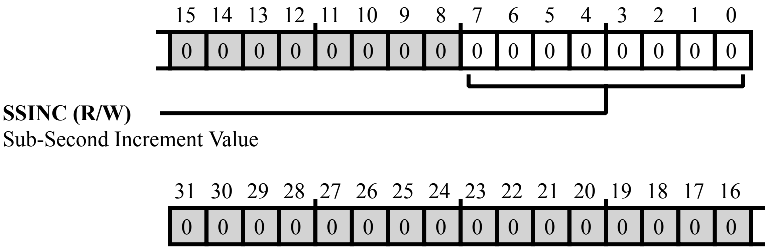
Bit No. (Access)	Bit Name	Description/Enumeration
9 (RC/NW)	TSTRGTERR3	Timestamp Target Time Error 3. The `EMAC_TM_STMPSTAT.TSTRGTERR3` bit when set the target time being programmed in PPS3 Target Time High Register and PPS3 Target Time Low Register, is already elapsed.
8 (RC/NW)	TSTARGT3	Timestamp Target Time Reached for Target Time PPS3. The `EMAC_TM_STMPSTAT.TSTARGT3` bit indicates that the value of system time is greater than or equal to the value specified in PPS3 Target Time High Register and PPS3 Target Time Low Register.
7 (RC/NW)	TSTRGTERR2	Timestamp Target Time Error 2. The `EMAC_TM_STMPSTAT.TSTRGTERR2` bit when set the target time being programmed in PPS2 Target Time High Register and PPS2 Target Time Low Register, is already elapsed.
6 (RC/NW)	TSTARGT2	Timestamp Target Time Reached for Target Time PPS2. The `EMAC_TM_STMPSTAT.TSTARGT2` bit indicates that the value of system time is greater than or equal to the value specified in PPS2 Target Time High Register and PPS2 Target Time Low Register.
5 (RC/NW)	TSTRGTERR1	Timestamp Target Time Error 1. The `EMAC_TM_STMPSTAT.TSTRGTERR1` bit when set the target time being programmed in PPS1 Target Time High Register and PPS1 Target Time Low Register, is already elapsed.
4 (RC/NW)	TSTARGT1	Timestamp Target Time Reached for Target Time PPS1. The `EMAC_TM_STMPSTAT.TSTARGT1` bit indicates that the value of system time is greater than or equal to the value specified in PPS1 Target Time High Register and PPS1 Target Time Low Register.
3 (R/W)	TSTRGTERR0	Time Stamp Target Time Programming Error. The `EMAC_TM_STMPSTAT.TSTRGTERR0` bit is set when the target time, which is being programmed in the `EMAC_TM_SEC` and `EMAC_TM_NSEC` registers, has already elapsed. This bit is cleared when read by the application.
2 (RC/NW)	ATSTS	Auxiliary Time Stamp Trigger Snapshot. The `EMAC_TM_STMPSTAT.ATSTS` bit is set high when the auxiliary snapshot is written to the FIFO.
1 (RC/NW)	TSTARGT0	Time Stamp Target Time Reached. The `EMAC_TM_STMPSTAT.TSTARGT0` bit, when set, indicates the value of system time has reached or passed the value specified in the `EMAC_TM_PPS0TGTM` and `EMAC_TM_NSEC` registers.

Table 31-224: EMAC_TM_STMPSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (RC/NW)	TSSOVF	Time Stamp Seconds Overflow. The `EMAC_TM_STMPSTAT.TSSOVF` bit, when set, indicates that the seconds value of the time stamp (when supporting PTP version 2 format) has overflowed beyond 0xFFFF_FFFF.

Time Stamp Sub Second Increment Register

The EMAC_TM_SUBSEC register contains the value by which the system time nano second is incremented.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
SSINC (R/W)
Sub-Second Increment Value
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

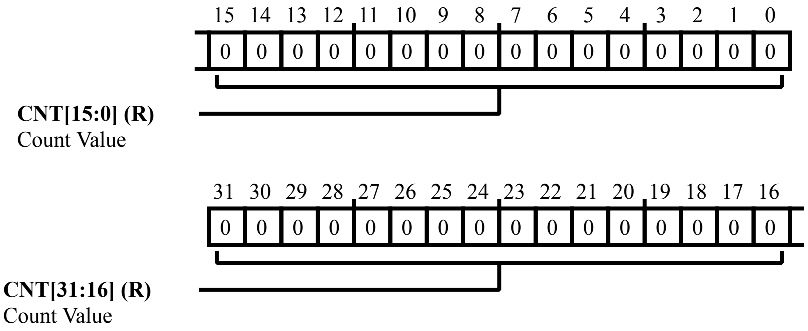
Figure 31-193: EMAC_TM_SUBSEC Register Diagram

Table 31-225: EMAC_TM_SUBSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SSINC	Sub-Second Increment Value. The value in the `EMAC_TM_SUBSEC.SSINC` bits is accumulated every PTP clock cycle with the contents of the nanosecond register. For example, when PTP clock is 50 MHz (period is 20 ns), the processor should program 20 (0x14) when the EMAC_TM_NSEC register has an accuracy of 1 ns (`EMAC_TM_CTL.TSCTRLSSR` bit is set). When `EMAC_TM_CTL.TSCTRLSSR` is clear, the EMAC_TM_NSEC register has a resolution of ~0.465ns. In this case, the processor should program a value of 43 (0x2B) that is derived by 20ns/0.465.

Tx 1024- to Max-Byte Frames (Good/Bad) Register

The `EMAC_TX1024TOMAX_GB` register contains the count of the number of good and bad frames transmitted with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
VTHM (R/W)
VLAN Tag Hash Table Match Enable
ESVL (R/W)
Enable S-VLAN
ETV (R/W)
Enable Tag VLAN Comparison
VTIM (R/W)
VLAN Tag Inverse Match Enable

Figure 31-220: EMAC_VLANTAG Register Diagram

Table 31-252: EMAC_VLANTAG Register Fields

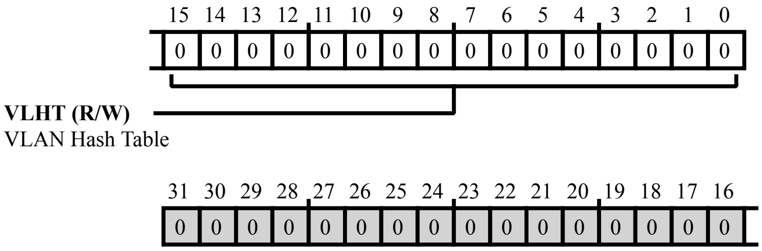
Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	VTHM	VLAN Tag Hash Table Match Enable. The EMAC_VLANTAG.VTHM bit, When set, the most significant four bits of the VLAN tags CRC are used to index the content of VLAN Hash Table Register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table.
18 (R/W)	ESVL	Enable S-VLAN. The EMAC_VLANTAG.ESVL bit, When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.
17 (R/W)	VTIM	VLAN Tag Inverse Match Enable. The EMAC_VLANTAG.VTIM bit, enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched.
16 (R/W)	ETV	Enable Tag VLAN Comparison. The EMAC_VLANTAG.ETV bit, when set, directs the EMAC to use a 12-bit VLAN identifier, rather than the complete 16-bit VLAN tag, for comparison and filtering. Bits[11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. When this bit is reset, all 16 bits of the received VLAN frame's fifteenth and sixteenth bytes are used for comparison.

Table 31-252: EMAC_VLANTAG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VL	VLAN Tag Id Receive Frames. The `EMAC_VLANTAG.VL` bits contain the 802.1Q VLAN tag to identify VLAN frames, and is compared to the fifteenth and sixteenth bytes of the frames being received for VLAN frames. Bits[15:13] are the User Priority, Bit[12] is the Canonical Format Indicator (CFI) and bits[11:0] are the VLAN tag's VLAN Identifier (VID) field. When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and sixteenth bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 to be VLAN frames.

VLAN Hash Table Register

The `EMAC_VLAN_HSHTBL` register contains the VLAN hash table



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
CSVL (R/W)
C-VLAN or S-VLAN
VLP (R/W)
VLAN Priority Control
VLC (R/W)
VLAN Tag Control in Transmit Frames

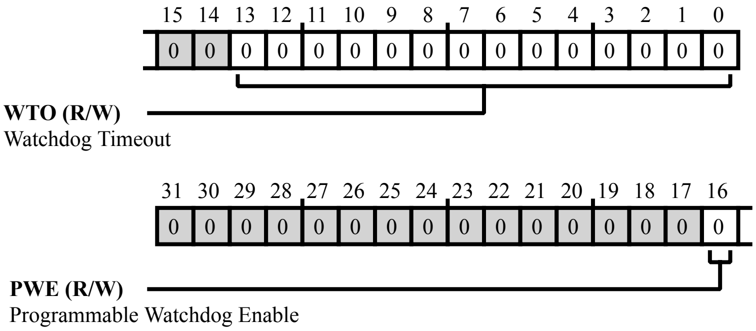
Figure 31-222: EMAC_VLAN_INCL Register Diagram

Table 31-254: EMAC_VLAN_INCL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	CSVL	C-VLAN or S-VLAN. The `EMAC_VLAN_INCL.CSVL` bit, When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted frames.
18 (R/W)	VLP	VLAN Priority Control. The `EMAC_VLAN_INCL.VLP` bit, When this bit is set, the control Bits [17:16] are used for VLAN deletion, insertion, or replacement
17:16 (R/W)	VLC	VLAN Tag Control in Transmit Frames. The `EMAC_VLAN_INCL.VLC` bit, 2'b00:No VLAN tag deletion, insertion, or replacement 2'b01:VLAN tag deletion. The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted frames with VLAN tags. 2'b10:VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the frame after inserting the Type value (0x8100/0x88a8) in bytes 13 and 14. This operation is performed on all transmitted frames, irrespective of whether they already have a VLAN tag. 2'b11:VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted frames (Bytes 13 and 14 are 0x8100/0x88a8).
15:0 (R/W)	VLT	VLAN Tag for Transmit Frames. The `EMAC_VLAN_INCL.VLT` bit, contains the value of the VLAN tag to be inserted or replaced.

Watchdog Timeout Register

The `EMAC_WDOG_TIMOUT` register controls the watchdog timeout for received frames.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
PWE (R/W)
Programmable Watchdog Enable

Figure 31-223: EMAC_WDOG_TIMOUT Register Diagram

Table 31-255: EMAC_WDOG_TIMOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	PWE	Programmable Watchdog Enable. The `EMAC_WDOG_TIMOUT.PWE` bit, When this bit is set and Bit 23 (WD) of Register 0 (MAC Configuration Register) is reset, the WTO field (Bits[13:0]) is used as watchdog timeout for a received frame.
13:0 (R/W)	WTO	Watchdog Timeout. The `EMAC_WDOG_TIMOUT.WTO` bit, When Bit 16 (PWE) is set and Bit 23 (WD) of Register 0 (MAC Configuration Register) is reset, this field is used as watchdog timeout for a received frame. If the length of a received frame exceeds the value of this field, such frame is terminated and declared as an error frame.

32 Sinus Cardinalis (SINC) Filter

The sinus cardinalis (SINC) filter module processes four independent sigma-delta bit streams by applying a pair of SINC filters to each stream. A SINC filter converts the bit stream from a sigma-delta front-end modulator into a digital word representing the signal level presented to the modulator.

The filter consists of a set of integration and decimation stages implemented directly in logic for efficient execution. The SINC filter supports capture of current or voltage feedback signals from an isolating analog-to-digital converter (ADC). Each modulator bit stream connects to two SINC filters: a primary filter for controlling feedback; a secondary filter for overcurrent detection. The SINC module includes four filter channels and two modulator clock generators.

SINC Filter Features

The SINC features include:

- Four-bit stream filter channels for current or voltage feedback signal processing
- Each channel includes two SINC filter pairs:
  - A primary filter for feedback signal processing
  - A secondary filter for overload detection
- Up to two modulator clock sources with phase control options
- Configuration of SINC filter channels according to a modulator clock selection
- Programmable order and decimation rates
- Primary filters:
  - Programmable bias and gain with output saturation
  - Dedicated direct memory access (DMA) channels with data interleaving and programmable data ready output triggers
- Secondary filters:
  - Detecting a fault when signals exceed amplitude and duration values

  - Registers preserving the eight most recent samples before a fault event
- Multiple interrupt trigger sources for overload fault and data overflow events

SINC Functional Description

The SINC filter has the following functionality:

Digital filter

The filter removes the modulator sample clock and recovers a digital value of the sampled signal.

DC gain and data resolution

The DC gain of the digital filter is a function of the order and decimation rate.

Frequency response

The frequency response of the filter depends on the order, decimation rate, and modulator clock frequency.

Output scaling

The output scaling and postprocessing functions embedded in the SINC filter blocks differ, depending on the function.

ADSP-SC58x SINC Register List

The SINC filter module processes four independent sigma-delta bit streams by applying a pair of SINC filters to each stream. A SINC filter converts the bit stream from a sigma-delta front-end modulator into a digital word representing the signal level presented to the modulator. Each modulator bit stream connects to two SINC filters: a primary filter for controlling feedback, and a secondary filter for overcurrent detection. A set of registers governs SINC operations. For more information on SINC functionality, see the SINC register descriptions.

SINC Definitions

To make the best use of the SINC, it is useful to understand the following terms.

Decimation

Decimation is the process of discarding samples from a data stream.

Decimation Rate

The decimation rate is the ratio of the filter input data rate to the filter output data rate.

Filter Order

The SINC filter order is the number of integration and decimation stages in the filter.

Modulator Order

The modulator order is the number of comparator and integrator stages in a sigma-delta modulator.

Sigma-Delta Modulator

The sigma-delta modulator is an oversampling analog-to-digital conversion circuit that generates a digital bit stream whose pulse density is proportional to the analog voltage presented to the input.

Figure 32-1: SINC Block Diagram

The block diagram shows four SINC filter pairs (SINC0–3), one modulator clock source, and one bank of control registers (units). The module accepts four sigma-delta bit streams from the GPIO input pins and directs the modulator clock source of GROUP 0 to the GPIO output pin. A pulse-width modulation (PWM) signal synchronizes the modulator clock to optimize system performance. Each SINC filter pair includes the primary filter, secondary filter, DMA interface, and overload limit detection functions.

The primary SINC filter transmits its data to memory using DMA. The secondary SINC filter generates overload signals, which can be routed through the trigger routing unit (TRU) to trip a PWM modulator and generate an interrupt request.

The SINC filter pairs are assigned to control unit 0, where multiple channels of current or voltage-feedback share common filter parameters. The primary filters generate high-resolution signals for closing the feedback control loop. The secondary filters are for rapid-overload fault detection, require lower resolution, but a faster response. The primary and secondary filters have programmable order and decimation rates. The primary filters also have the programmable output gain stage, while the secondary filters have the programmable overload limit thresholds.

To use the primary and secondary filters, set up the filter parameters once, prior to using the filters. The feedback control algorithm reads the data from the primary filter directly from memory. A PWM interrupt request signal can generate the algorithm timing signal, or the SINC module generates a data trigger. The data history of the secondary filter is saved in buffer registers once an overload fault signal is detected. The data history supports fault diagnostics.

SINC Architectural Concepts

The architecture of the SINC includes the following:

- Digital Filter
- DC Gain and Data Resolution
- Frequency Response
- Output Scaling

Digital Filter

The SINC filter has a transfer function that lends itself to an implementation in digital logic, using a series of summation and decimation functions. The filter removes the modulator sample clock and recovers a digital value of the sampled signal. The filter design matches a bipolar SD modulator. The design produces a 50% pulse density for a 0V input, over 50% for positive inputs and less than 50% for negative inputs.

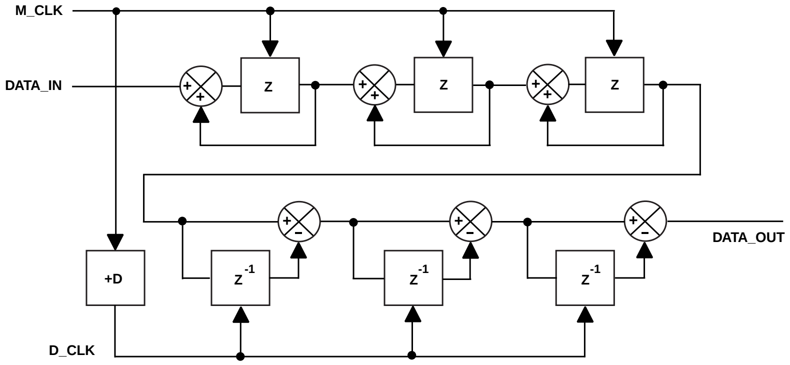

Figure 32-2: SINC Digital Filter

The digital filter is a set of accumulators driven by the modulator clock (`M_CLK`), followed by a set of differentiators driven by the decimation clock (`D_CLK`). The input accumulators convert the input bit stream into a multibyte word, while the output differentiators derive the average 1's density of the bit stream. The number of accumulator and differentiator stages can be three or four, depending on the order of the filter. The DC gain and bandwidth of the filter are functions of the filter order (`O`) and the decimation rate (`D`), which is the ratio of the modulator to the decimation clock.

The calculation of the transfer function of the SINC filter includes the product of the transfer functions for the accumulators and differentiators, and in the `z` domain. The following equation gives the calculation:

$$H(z) = \left[\frac{1}{D} \text{ x } \frac{1 - z^{-D}}{1 - z^{-1}}\right]^{O}$$

DC Gain and Data Resolution

The DC gain of the digital filter is a function of the order and decimation rate. At 100% ones density input, each accumulator stage counts `D` pulses, and the gain of the filter is given as follows:

$$G_{dc} = D^{o}$$

The higher the decimation rate, the higher the resolution of the output data. The number of usable data bits is a function of the `SNR`; the ***Filter Order versus Decimation*** table shows `ENOB` versus the decimation rate.

Table 32-5: ENOB versus Decimation

Decimation		4	5	6	7	8	16	32	64	128	256
O = 3	SNR (dB)	6.42	11.47	16.41	20.57	23.55	35.02	48.59	62.26	76.46	89.59
	ENOB	0.8	1.6	2.4	3.1	3.6	5.5	7.8	10.0	12.4	14.6
O = 4	SNR (dB)	9.08	14.77	19.78	23.41	25.9	38.05	51.29	64.67	79.15	
	ENOB	1.2	2.1	3.1	3.6	4.0	6.0	8.2	10.4	12.8	

Notes: ENOB versus order and decimation rate.

Test conditions are for a 1.22 kHz tone and a 10 MHz modulator.

Frequency Response

The frequency response of the filter depends on the order, decimation rate, and modulator clock frequency, f_M. The equation is obtained by substituting $e^{j \text{ x } Ts}$ for `z` in the transfer function, where `Ts` is the period of the modulator clock:

$$H\left(e^{j\frac{\omega}{f_M}}\right) = \left[\frac{1}{D} \times \frac{\sin\left(D\frac{\omega}{2f_M}\right)}{\sin\left(\frac{\omega}{2f_M}\right)} \times e^{-j(D-1)\frac{\omega}{2f_M}}\right]^{O}$$

The filter has a linear phase response with a constant group delay given by:

$$\tau_d = \left(\frac{D-1}{2}\right)\frac{O}{f_M}$$

The ***Frequency Response*** plots show zeros at multiples the decimation frequency, where the `sin` term in the numerator goes to zero. This response makes it possible to remove some PWM ripple components from the motor current waveform by matching the decimation frequency to the PWM switching frequency. There are some limitations at lower PWM frequencies based on available decimation rates. High decimation rates limit the bandwidth of the control loop because of the phase delay, which is 3π radians at the decimation frequency.

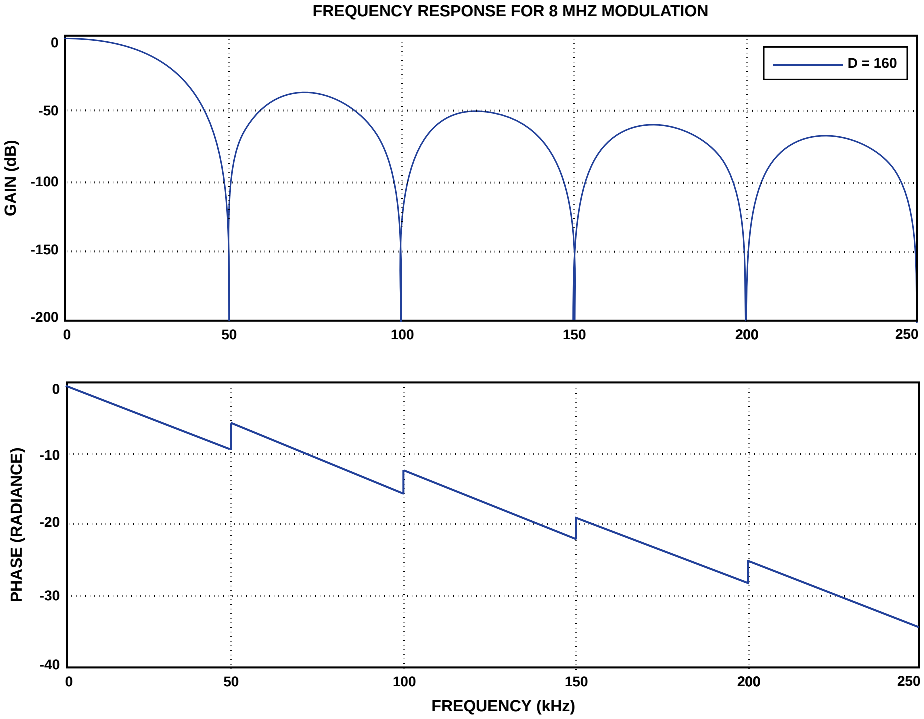

Figure 32-5: Frequency Response

Output Scaling

The output scaling and postprocessing functions embedded in the SINC filter blocks differ, depending on the function. The primary filter used for feedback signal processing includes the output bias and scaling blocks to present a 16-bit signed integer to the control code. The scaling is required at decimation rates higher than 32 to keep the lower 16 bits of the output word.

The secondary filter supports overload detection functions. The secondary filter can detect signals crossing maximum and minimum thresholds. It has a glitch filter that only accepts faults with a minimum number of counts (`c`) within a certain count window (`w`). The secondary filter has no output scaling, so the minimum and maximum values in the overload registers must be calculated from the DC gain of the secondary filter. The response time to a step input is approximately 2 x O decimation clock cycles.

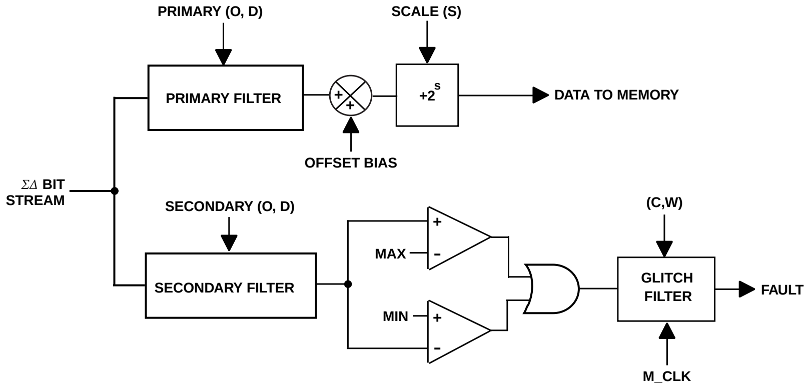

Figure 32-4: Output Scaling

SINC Operating Modes

The SINC filter module has only one operating mode. The module generates the clock source for a sigma-delta modulator analog front end and filters the output data stream for the modulator. The primary SINC filter transfers its data to memory through DMA. The secondary SINC filter output generates an overload trigger signal that the SINC filter module can use as a PWM trip signal. The SINC control registers enable the module and set up the modulator clock sources, filter parameters, DMA transfers, and interrupts masks, as described in SINC Programming Model.

For self-testing purposes, the SINC data inputs can be driven by bit streams transferred from the SPORT0A port through DMA from a slave memory space (typically M4 main memory). The following programming selections are required to enable SINC self-test mode:

- [3:0] – set each bit to 1 for each SINC channel to be selected for test. If 1, the SINC channel input will be driven by the SPORT, not the associated GPIO.
- Enable filters to route SPORT data to SINC unit with the write: `*pREG_TESYS1_SINC_TEST = 0xf`
- The SINC unit must be configured as follows.
  - Timer Group 0; MCLK0
- The SPORT (A) must be configured as follows.
  - External Clock
  - 16 bit data recommended
  - No multichannel mode
  - Enable SPORT0_A in transmit mode, external clock, internal FS, and I2S Mode `*pREG_SPORT0_CTL_A = 0x021548f1`
- Any data transmitted on SPORT0 Data A channel is sent to SINC block.

SINC Data Transfer Modes

The only mode of data transfer between the primary SINC filter and memory is through DMA (See Primary DMA Configuration and Data Interrupts for more information. Reading the history registers for the secondary filter is the only way to transfer data between the secondary SINC filter and memory. See Overload Detection for more information.

SINC Signal Modes

The SINC filter has an interrupt request signal and a number of triggers and status signals to indicate system events and errors.

- Primary data transfer trigger:

  The SINC filter can generate a trigger after a user-specified number of primary output sets are transferred to memory. There is one trigger source for each filter group. See Primary DMA Configuration and Data Interrupts for more information.

- Secondary data overload trigger:

  The SINC filter can generate a trigger when one of the secondary filters detects an overload condition. There is one trigger source for each secondary filter. See Overload Detection for more information.

- SINC status bits:

  The SINC status bits indicate secondary filter overload errors, primary filter saturation errors, primary filter transfer count exceeded, and primary filter data buffer errors.

  - Secondary filter overload errors:

    A number of status bits indicate the type of error and the filter channel when a secondary filter detects an overload condition. The status bits `SINC_STAT.GLIM0` and `SINC_STAT.GLIM1` indicate the control group of the secondary filter that detected the overload. The status bits `SINC_STAT.MAX0` through `SINC_STAT.MAX3` indicate when the error a maximum limit on one of the secondary filter channels is passed, causing the error. The status bits `SINC_STAT.MIN0` through `SINC_STAT.MIN3` indicate when a minimum limit on one of the secondary filter channels is passed, causing the error.

  - Primary filter data saturation errors:

    A number of status bits indicate the group and filter channel when the SINC filter detects data saturation . The status bits `SINC_STAT.GSAT0` and `SINC_STAT.GSAT1` indicate the filter control group when the SINC filter detects data saturation. The status bits `SINC_STAT.PSAT0` through `SINC_STAT.PSAT3` indicate a primary filter channel that detects data saturation.

  - Primary filter transfer count exceeded:

    The status bits `SINC_STAT.PCNT0` and `SINC_STAT.PCNT1` are set every time a specified number of primary filter data sets for that filter group are transferred to memory. The primary filter data set for a group is the data for all the channels in the group. The specified number of data sets is the value in the

`SINC_LEVEL0.PCNT`-`SINC_LEVEL1.PCNT` bits. Write 1 to clear the bits before the next data transfer to generate a trigger.

- Primary filter data buffer errors:

  A number of status bits indicate data buffer errors. The status bits `SINC_STAT.FOVF0` and `SINC_STAT.FOVF1` indicate the filter control group when there is a SINC data buffer overflow. This error occurs when a third sample is presented to the buffer before the first sample transfers to memory. The status bits `SINC_STAT.PFAB0` and `SINC_STAT.PFAB1` indicate the filter group when an error occurs while writing the data to memory.

- SINC status interrupt request:

  There is a single SINC filter interrupt request output that can indicate secondary filter overload errors, primary filter data saturation, or primary filter data buffer overrun. There is one interrupt mask bit for each of these conditions per filter group. See Interrupt Masking for more information.

SINC Event Control

The SINC provides status and error bits through different registers to signal the core about its state and various error conditions that occur during its operation. These conditions include:

- Interrupt status related to data overload, data saturation, data FIFO fault conditions
- Error status related to SINC operations
- History status (which do not generate interrupts) related to data FIFO operations

SINC Interrupt Signals

The interrupt request and trigger signals to the SINC filter module include:

- One interrupt request signal, SINC_STAT, triggered by fault events, such as detected overload limits and data transfer errors. Manage interrupt request generation with the masking bits in the `SINC_CTL` register:

  - Bits `SINC_CTL.ELIM0`-`SINC_CTL.ELIM1` can enable (unmask) interrupt request generation on overload faults when the `SINC_STAT.GLIM0`-`SINC_STAT.GLIM1` bit is set, respectively.
  - Bits `SINC_CTL.ESAT0`-`SINC_CTL.ESAT1` can mask interrupt request generation on data saturation faults when the `SINC_STAT.GSAT0`-`SINC_STAT.GSAT1` bit is set, respectively.
  - Bits `SINC_CTL.EFOVF0`-`SINC_CTL.EFOVF1` can mask interrupt request generation on data buffer overruns when the `SINC_STAT.FOVF0`-`SINC_STAT.FOVF1` bit is set, respectively.

  The fault bits in the `SINC_STAT` register must be cleared to clear the interrupt request.

- Two data count triggers, one trigger per each control group. The SINC filter module regularly uses the data count triggers to generate a software interrupt request or trigger an event. First, set the `SINC_CTL.EPCNT0` or `SINC_CTL.EPCNT1` masking bit to enable the data count trigger. Then, the TRU must assign the data count master (`SINC0_DATA0-1`) to an interrupt request input.

- Four overload triggers, one trigger per each channel. The SINC filter module can use overload triggers to trip the appropriate PWM block in the case of a fault. The overload trigger is always enabled, and the TRU must assign the masters (`SINC0_P0_OVLD` through `SINC0_P4_OVLD`) to the appropriate PWM trip input slave (`PWMn_TRIP_TRIGn`).

SINC Status and Error Signals

The status and error signals related to SINC operations are as follows:

- `SINC_STAT` signals:
  - The amplitude and duration limit error signals for secondary SINC filters: `SINC_STAT.MAX0` through `SINC_STAT.MAX3`, `SINC_STAT.MIN0` through `SINC_STAT.MIN3`, and `SINC_STAT.GLIM0-SINC_STAT.GLIM1`.
  - The output saturation error signals for primary SINC filters: `SINC_STAT.MAX0` through `SINC_STAT.MAX3`, `SINC_STAT.MIN0` through `SINC_STAT.MIN3`, and `SINC_STAT.GLIM0-SINC_STAT.GLIM1`.
  - The output FIFO overflow error signals for primary SINC filters: `SINC_STAT.FOVF0` and `SINC_STAT.FOVF1`.
  - The output count error signals for primary SINC filters: `SINC_STAT.PCNT0` and `SINC_STAT.PCNT1`.
  - The SCB fabric-related error signals for primary SINC filters: `SINC_STAT.PFAB0-SINC_STAT.PFAB1`.
- `SINC_CLK` signals:
  - The phase shift signals for SINC modulator clocks: `SINC_CLK.MREQ0-SINC_CLK.MREQ1`.
- `SINC_HIS_STAT` signals:
  - The history saved signals for secondary SINC filters: `SINC_HIS_STAT.P0HISPTR` through `SINC_HIS_STAT.P3HISPTR`, which indicate that the data history of the filter is saved in buffer registers due to a detected overload error signal.

SINC Programming Model

The pin multiplexer enables the device input and output pins and connects the signals to the SINC module. Decide the filter grouping in advance. The filter parameters are defined according to the control register group.

Follow these steps to configure the filters:

1. Define the primary and secondary filter parameters by setting the appropriate bits in the control register for each filter channel group.

2. Set the upper and lower overload limits to maximum for each channel to avoid overload trips due to the filter startup transient.
3. Define the modulator clock frequency and startup mode.
4. Enable the SINC channels and assign them to the selected group of control registers.

Set the running overload limits after the filter settles, which is (order × decimation) modulator clock cycles after startup. When the filters are running, the module transfers its data to data RAM on the dedicated DMA channels. Once configured, the control registers do not need accessing, but the status and some data buffer registers typically are read after fault events.

In general, adjusting filter parameters during operation leads to unpredictable results. However, programs can write to the trigger and interrupt mask registers, as well as to the secondary threshold level registers during operation.

The DC gain of the converter subsystem depends on the gain of the input modulator (G_M), filter order (`O`), and decimation rate (`D`). The primary filter has an output binary scalar (`S`) to fit data into a 16-bit range:

$$G_M = 0.625 \times (D^O \div 2^S)$$

SINC Programming Concepts

Using the features and event control for the SINC to their greatest potential requires an understanding of some SINC-related concepts:

- Channel Configuration
- Trigger Masking
- Interrupt Masking
- Modulator Clock
- Filter Configuration
- Primary Filter Parameters
- Primary DMA Configuration and Data Interrupts
- Secondary Filter Parameters
- Overload Detection

Channel Configuration

The control bits, `SINC_CTL.EN0` through `SINC_CTL.EN3`, configure SINC module channels. These control bits enable or disable the selected SINC filter channel and assign the channel to control register group 0.

Trigger Masking

The SINC module has one data count trigger. The module can use the data count trigger to generate a software interrupt regularly or trigger an event. First, set the `SINC_CTL.EPCNT0` masking bit to enable the data count trigger. Then, the TRU must assign the data count master (`SINC_DATn`) to an interrupt input.

There are also four overload triggers, one trigger per each channel. The SINC module can use overload triggers to trip the appropriate PWM block when there is a fault. The overload trigger is always enabled, and the TRU must assign the masters (`SINC0_Pn_OVLD`) to the appropriate PWM trip input slave (`PWMn_TRIP_TRIGn`).

Interrupt Masking

The SINC filter can generate a `SINC_STAT` interrupt signal when triggered by fault events, such as detected overload limits or data transfer errors.

Enable (unmask) interrupt generation with the `SINC_CTL` register bits:

- The `SINC_CTL.ELIM0` bit can enable interrupt generation on overload faults when the `SINC_STAT.GLIM0` bit is set.
- The `SINC_CTL.ESAT0` bit can enable interrupt generation on data saturation faults when the `SINC_STAT.GSAT0` bit is set.
- The `SINC_CTL.EFOVF0` bit can enable interrupt generation on data buffer overruns when the `SINC_STAT.FOVF0` bit is set.

The fault bits in the `SINC_STAT` register must be cleared to clear the interrupt.

Modulator Clock

The SINC filter has one modulator clock source. The clock source can be set with an output frequency in the range of 1–20 MHz. The SINC module uses bits in the `SINC_CLK` register to control the modulator clock output, frequency, and phase. The SINC module uses the `SINC_CLK.MCEN0` bit field to enable the modulator clock and control the startup behavior of the clock. Start the clock immediately or enable the clock on the first rising edge of an external trigger connected to the `SINC0_SYNCn` input of the module. This action synchronizes the modulator clock with a PWM waveform source by routing a `PWMn_SYNC` master to the `SINC0_SYNC0` slave using the TRU.

The target frequency is in the range and derived from `SCLK0_0` using an integer divisor in the `SINC_CLK.MDIV0` bits. Write to the `SINC_CLK.MREQ0` bit to adjust the phase of the clock. This adjustment lengthens the next clock period by the number of `SCLK0_0` periods stored in the respective `SINC_CLK.MADJ0` bit field. The `SINC_CLK.MREQ0` bit is cleared automatically once the adjustment is complete.

Filter Configuration

Configure the primary and secondary filter parameters by setting the appropriate bits in the `SINC_RATE0`, `SINC_LEVEL0`, and `SINC_BIAS0` control registers. Configure the DMA transfers by setting the appropriate bits in the `SINC_PHEAD0` and `SINC_PTAIL0` registers. Set the maximum and minimum levels for overload detection in the four limit registers, `SINC_LIMIT0` – `SINC_LIMIT3`. Set the overload filtering parameters in the `SINC_LEVEL0` register.

Primary Filter Parameters

Set the primary filter to the 3rd or 4th order by the `SINC_LEVEL0.PORD` bit assigned to the channel. Set the decimation rate for the primary filter using the `SINC_RATE0.PDEC` bits assigned to the channel. Valid decimation rates are in the range 4–256. Set the phase of the primary filter output relative to the number of modulator clocks after enabling the filter using the `SINC_RATE0.PADJ` bits assigned to the channel. Valid `SINC_RATE0.PADJ` values are in the range 0 to `SINC_RATE0.PDEC` – 1.

The raw filter output is a 32-bit wide integer, has an offset added, and is scaled to a 16-bit number before transfer to memory. Store the 32-bit two's compliment offset value in the `SINC_BIAS0` register of the channel. Set the binary scale factor by a mantissa in the range 4–32 stored in the `SINC_LEVEL0.PSCALE` bits. The output is a valid 16-bit signed number. If the number is outside of the valid range, the output is saturated to 0x8000 or 0x7FFF, while the `SINC_STAT.PSAT0` or `SINC_STAT.GSAT0` fault bit (according to the channel group) is set.

Primary DMA Configuration and Data Interrupts

Transfer the primary SINC filter outputs to a circular buffer in data memory using DMA. The output from the primary filter is interleaved with outputs from other primary filters. The interleaving order is from the lowest to the highest numbered filter.

The SINC module stores the circular buffer head address in the `SINC_PHEAD0` register of the channel. It stores the tail address in the `SINC_PTAIL0` register of the channel. The data address wraps around to the head address after the tail address is reached. The head and tail addresses must be 16-bit aligned and can be set to the same address. The `SINC_PPTR0` register of the channel is a read-only register that contains the address of the most recent primary SINC filter data. If there is an overflow condition in the SINC filter output data FIFO due to a delay DMA transfer, the `SINC_STAT.FOVF0` fault bit (according to the channel group) is set.

A SINC data trigger can be generated after a user-specified number of primary filter outputs (data transfers) completes. Specify the data count value by the `SINC_LEVEL0.PCNT` bits assigned to the channel, and the trigger is generated every `SINC_LEVEL0.PCNT` + 1 data transfers.

The ***SINC Data Buffer Organization*** figure shows the SINC data buffer organization. In the figure, `SINC_OUT_0_M[n]` is the data for the n th most recent sample in the m th channel in the filter group 0, and n = 0 is the most recent data.

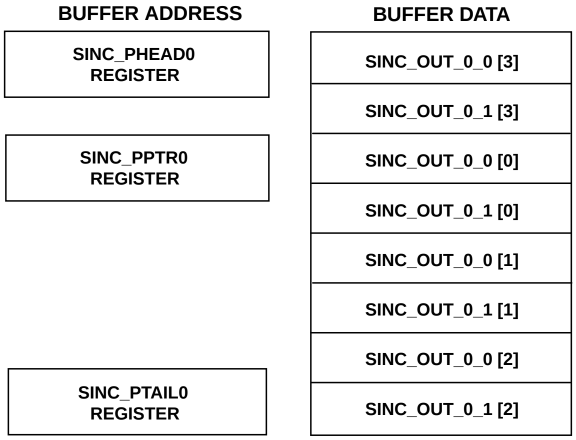

Figure 32-5: SINC Data Buffer Organization

Secondary Filter Parameters

Set the secondary filter to the 3rd or 4th order by the `SINC_LEVEL0.SORD` bit assigned to the channel. Set the decimation rate for the secondary filter using the `SINC_RATE0.SDEC` bits assigned to the channel. The secondary filter outputs are limited to 16-bit values. Limit the decimation rate according to the filter order:

- Valid decimation rates are in the range 4–40 for the 3rd order filters
- Valid decimation rates are in the range of 4–16 for the 4th order filters

Set the phase of the primary filter output relative to the number of modulator clocks after using the `SINC_RATE0.PADJ` and `SINC_RATE0.SDEC` bits to enable the filter. Valid `SINC_RATE0.PADJ` values are in the range 0 to – 1.

Overload Detection

The function of the secondary SINC filter is to detect AC current overload conditions and set up the upper and lower limit detection thresholds. There are event count filters on the overload detector outputs to reject short-term transients, if desired. Define the overload thresholds in four 32-bit registers `SINC_LIMIT0`, according to the channel number. Each register contains the 16-bit `SINC_LIMIT0.LMAX` and `SINC_LIMIT0.LMIN` overload threshold values. The SINC filter module detects an overload condition when the secondary filter output exceeds the threshold for a minimum number of counts (`SINC_LEVEL0.LCNT`) within the detection window (`SINC_LEVEL0.LWIN`). When the SINC filter module detects an overload condition, the appropriate `SINC0_Px_OVLD` trigger is generated, and the `SINC_STAT.GLIM0` fault bit is set.

The SINC filter module saves the eight most recent data samples for the secondary filter in a local circular buffer to support diagnostics after a fault is triggered. Since 16-bit data is saved, only four buffer registers are required per channel. For example, the `SINC_P1SEC_HIST[n]`[0–3] registers store the eight most recent 16-bit secondary filter outputs from channel 1. The `SINC_HIS_STAT` register contains four pointers (`SINC_HIS_STAT.P0HISPTR` through `SINC_HIS_STAT.P3HISPTR`) to the buffer location of the most recent secondary current samples, per channel.

ADSP-SC58x SINC Register Descriptions

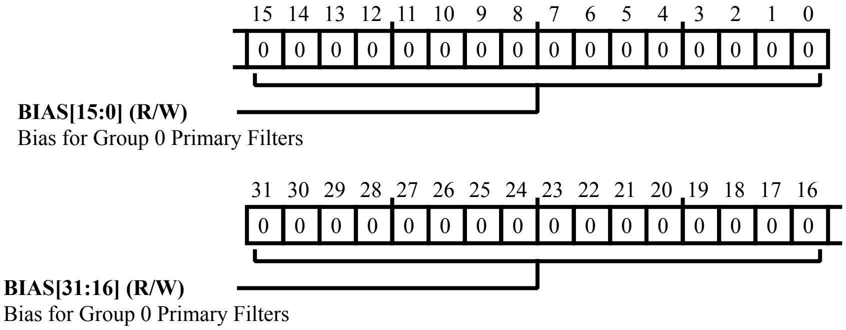
SINC (SINC) contains the following registers.

Table 32-6: ADSP-SC58x SINC Register List

Name	Description
`SINC_BIAS0`	Bias for Group 0 Register
`SINC_BIAS1`	Bias for Group 1 Register
`SINC_CLK`	Clock Control Register
`SINC_CTL`	Control Register
`SINC_HIS_STAT`	History Status Register
`SINC_LEVEL0`	Level Control for Group 0 Register
`SINC_LEVEL1`	Level Control for Group 1 Register
`SINC_LIMIT0`	(Amplitude) Limits for Secondary Filter 0 Register
`SINC_LIMIT1`	(Amplitude) Limits for Secondary Filter 1 Register
`SINC_LIMIT2`	(Amplitude) Limits for Secondary Filter 2 Register
`SINC_LIMIT3`	(Amplitude) Limits for Secondary Filter 3 Register
`SINC_P0SEC_HIST[n]`	Pair 0 Secondary (Filter) History n Register
`SINC_P1SEC_HIST[n]`	Pair 1 Secondary (Filter) History n Register
`SINC_P2SEC_HIST[n]`	Pair 2 Secondary (Filter) History n Register
`SINC_P3SEC_HIST[n]`	Pair 3 Secondary (Filter) History n Register
`SINC_PHEAD0`	Primary (Filters) Head for Group 0 Register
`SINC_PHEAD1`	Primary (Filters) Head for Group 1 Register
`SINC_PPTR0`	Primary (Filters) Pointer for Group 0 Register
`SINC_PPTR1`	Primary (Filters) Pointer for Group 1 Register
`SINC_PTAIL0`	Primary (Filters) Tail for Group 0 Register
`SINC_PTAIL1`	Primary (Filters) Tail for Group 1 Register
`SINC_RATE0`	Rate Control for Group 0 Register
`SINC_RATE1`	Rate Control for Group 1 Register
`SINC_STAT`	Status Register

Bias for Group 0 Register

The SINC_BIAS0 register controls an output bias added to primary SINC filters of group 0.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

		1	Enable
28 (R/W)	EFOVF1	Enable FIFO Overflow for Group 1. The `SINC_CTL.EFOVF1` bit enables (unmasks) the SINC_STAT interrupt request on data FIFO overflow conditions if this bit and status bit `SINC_STAT.FOVF1` are set (=1). The `SINC_STAT.FOVF1` bit is set (=1) when the group 1 output data FIFO overflows due to delayed SCB fabric ready response.	
		0	Disable
		1	Enable
15 (R/W)	ELIM0	Enable Limit for Group 0. The `SINC_CTL.ELIM0` bit enables (unmasks) the SINC_STAT interrupt request on overload conditions if this bit and status bit `SINC_STAT.GLIM0` are set (=1).	
		0	Disable
		1	Enable
14 (R/W)	ESAT0	Enable Saturation for Group 0. The `SINC_CTL.ESAT0` bit enables (unmasks) the SINC_STAT interrupt request on output saturation conditions if this bit and status bit `SINC_STAT.GSAT0` are set (=1).	
		0	Disable
		1	Enable
13 (R/W)	EPCNT0	Enable Primary Count for Group 0. The `SINC_CTL.EPCNT0` bit enables a trigger event on each SINC_DATA0 interrupt request if this bit and status bit `SINC_STAT.PCNT0` are set (=1).	
		0	Disable
		1	Enable

		0	Disable
		1	Reserved
		2	Enable and Assign to Group 0
		3	Reserved

History Status Register

The `SINC_HIS_STAT` provides status for data histories of secondary SINC filters, in the corresponding history buffer registers. The SINC history buffer registers save the most recent filter samples once an overload fault signal is detected.

Table 32-12: SINC_LEVEL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	PORD	Primary (Filter) Order. The `SINC_LEVEL0.PORD` bit determines the order for group 1 primary filters.	
		0	Third Order
		1	Fourth Order

Table 32-12: SINC_LEVEL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PSCALE	Primary (Filter) Scaling. The `SINC_LEVEL0.PSCALE` bits specify the scaling applied to the output of group 0 primary filters, prior to DMA transfer to memory. The valid value is between 4 to 32. The SINC integrator, decimator, and bias adjustment produce an integer value up to 32 bits wide. The range of a full-scale signal of a bit stream filtered by a primary SINC filter is approximately (BIAS +- ((0.625 * `SINC_RATE0.PDEC`) ^ order)). The value requires about (ln2(`SINC_RATE0.PDEC`) * order) bits of precision (where 'order' is 3 or 4, as specified by the `SINC_LEVEL0.PORD` bit. This bit field specifies the bit position of the intermediate value, which is transferred on the MSB of 16-bit DMA sample. Thus, the intermediate value is right-shifted by (`SINC_LEVEL0.PSCALE` - 16) bits if `SINC_LEVEL0.PSCALE` >= 16, or left-shifted by (16 - `SINC_LEVEL0.PSCALE`) bits if `SINC_LEVEL0.PSCALE` < 16. If `SINC_LEVEL0.PSCALE` >= 16, thus selecting a right shift, the shifted value is rounded up (as if 0.5 * LSB is added) before truncation. Rounding is not necessary for a left shift. If the scaled and rounded value exceeds the range of a signed 16-bit number, the sample is saturated (to 0x8000 or 0x7FFF), and the corresponding saturation status bit (`SINC_STAT.PSAT3`, `SINC_STAT.PSAT2`, `SINC_STAT.PSAT1`, or `SINC_STAT.PSAT0` is set.
23:16 (R/W)	PCNT	Primary (Filter) Count. The `SINC_LEVEL0.PCNT` bits specify the modulo number of outputs for group 0 primary filters. The number must be one less than a desired modulo. Each time the number of outputs specified by this bit filed is transferred, the `SINC_STAT.PCNT0` status bit is set (=1). When the `SINC_STAT.PCNT0` bit is set (unless masked), it causes a TRU trigger. For example: 8'h00 written to the `SINC_LEVEL0.PCNT` bit field sets bit `SINC_STAT.PCNT0` to 1 after every primary SINC filter output is transferred. 8'hFF written to the `SINC_LEVEL0.PCNT` bit field sets bit `SINC_STAT.PCNT0` to 1 after every 256 primary SINC filter outputs transferred.
14 (R/W)	SORD	Secondary (Filter) Order Select. The `SINC_LEVEL0.SORD` bit determines the order for group 0 secondary filters. 0 Third Order 1 Fourth Order

Table 32-12: SINC_LEVEL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13:11 (R/W)	LCNT	(Excursion) Limit Count. The `SINC_LEVEL0.LCNT` bits specify the number (count) of output excursions beyond the amplitude specified for group 0 secondary filters. The number of excursions greater than specified by registers `SINC_LIMIT3`, `SINC_LIMIT2`, `SINC_LIMIT2`, and `SINC_LIMIT0` is perceived as an overload and sets (=1) a corresponding MAX or MIN bit in the `SINC_STAT` register. The valid count is between 1 to 8. If the count is greater than `SINC_LEVEL0.LWIN`, the bit fields behavior is as it is equal to `SINC_LEVEL0.LWIN`. See `SINC_LEVEL0.LWIN` for details. The valid count must be one less than a desired count: =000 require one excursion above the amplitude limit =111 require eight excursions above the amplitude limit.
10:8 (R/W)	LWIN	(Excursion) Limit Window. The `SINC_LEVEL0.LWIN` bits specify the window size for excursion checking for group 0 secondary filters. The window size is the number of the most recent outputs to be included in a measurement specified by the `SINC_LEVEL0.LCNT` bits. The valid value must be one less than a desired count (1 to 8), meaning the valid value is 0 to 7.

Level Control for Group 1 Register

The SINC_LEVEL1 register controls output scaling and count, excursion limit and window, as well as orders for primary and secondary SINC filters assigned to group 1.

29:24 (R/W)	PSCALE	Primary (Filter) Scaling. The `SINC_LEVEL1.PSCALE` bits specify the scaling applied to the output of group 1 primary filters, prior to DMA transfer to memory. The valid value is between 4 to 32. The SINC integrator, decimator, and bias adjustment produce an integer value up to 32 bits wide. The range of a full-scale signal of a bit stream filtered by a primary SINC filter is approximately (BIAS +- ((0.625 * `SINC_RATE1.PDEC`) ^ order)). The value requires about (ln2(`SINC_RATE1.PDEC`) * order) bits of precision (where 'order' is 3 or 4, as specified by the `SINC_LEVEL1.PORD` bit. This bit field specifies the bit position of the intermediate value, which is transferred on the MSB of 16-bit DMA sample. Thus, the intermediate value is right-shifted by (`SINC_LEVEL1.PSCALE` - 16) bits if `SINC_LEVEL1.PSCALE` >= 16, or left-shifted by (16 - `SINC_LEVEL1.PSCALE`) bits if `SINC_LEVEL1.PSCALE` < 16. If `SINC_LEVEL1.PSCALE` >= 16, thus selecting a right shift, the shifted value is rounded up (as if 0.5 * LSB is added) before truncation. Rounding is not necessary for a left shift. If the scaled and rounded value exceeds the range of a signed 16-bit number, the sample is saturated (to 0x8000 or 0x7FFF), and the corresponding saturation status bit (`SINC_STAT.PSAT3`, `SINC_STAT.PSAT2`, `SINC_STAT.PSAT1`, or `SINC_STAT.PSAT0` is set.
23:16 (R/W)	PCNT	Primary (Filter) Count. The `SINC_LEVEL1.PCNT` bits specify the modulo number of outputs for group 1 primary filters. The number must be one less than a desired modulo. Each time the number of outputs specified by this bit filed is transferred, the `SINC_STAT.PCNT1` status bit is set (=1). When the `SINC_STAT.PCNT1` bit is set (unless masked), it causes a TRU trigger. For example: 8'h00 written to the `SINC_LEVEL1.PCNT` bit field sets bit `SINC_STAT.PCNT1` to 1 after every primary SINC filter output is transferred. 8'hFF written to the `SINC_LEVEL1.PCNT` bit field sets bit `SINC_STAT.PCNT1` to 1 after every 256 primary SINC filter outputs transferred.
14 (R/W)	SORD	Secondary (Filter) Order. The `SINC_LEVEL1.SORD` bit determines the order for group 1 secondary filters. The `SINC_LEVEL1.SORD` bit determines the order for group 1 secondary filters. 0 Third Order 1 Fourth Order

Table 32-13: SINC_LEVEL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13:11 (R/W)	LCNT	(Excursion) Limit Count. The `SINC_LEVEL1.LCNT` bits specify the number (count) of output excursions beyond the amplitude specified for group 1 secondary filters. The number of excursions greater than specified by registers `SINC_LIMIT3`, `SINC_LIMIT2`, `SINC_LIMIT2`, and `SINC_LIMIT0` is perceived as an overload and sets (=1) a corresponding MAX or MIN bit in the `SINC_STAT` register. The valid count is between 1 to 8. If the count is greater than `SINC_LEVEL1.LWIN`, the bit fields behavior is as it is equal to `SINC_LEVEL1.LWIN`. See `SINC_LEVEL1.LWIN` for details. The valid count must be one less than a desired count: =000 require one excursion above the amplitude limit =111 require eight excursions above the amplitude limit.
10:8 (R/W)	LWIN	(Excursion) Limit Window. The `SINC_LEVEL1.LWIN` bits specify the window size for excursion checking for group 1 secondary filters. The window size is the number of the most recent outputs to be included in a measurement specified by the `SINC_LEVEL1.LCNT` bits. The valid value must be one less than a desired count (1 to 8), meaning the valid value is 0 to 7.

(Amplitude) Limits for Secondary Filter 0 Register

15:0 (R/W)	LMIN	Limit Minimum for Secondary Filter 3. The `SINC_LIMIT3.LMIN` bits specify the output signal conditions for the secondary SINC filter 3. In conjunction with bits LCNT and LWIN in register `SINC_LEVEL1` or `SINC_LEVEL0`, this bit field specifies conditions for an associated minimum limit warning bit in register `SINC_STAT`.

Pair 0 Secondary (Filter) History n Register

The `SINC_P0SEC_HIST[n]` read-only register provides the eight most recent samples produced by secondary SINC filter 0. The 16-bit samples are stored in the 32-bit register in circular manner, starting with the low-order field of the first `SINC_P0SEC_HIST[n]` register. The stored values, one compared to the limit, count, and window settings, set the `SINC_STAT.MAX0` and `SINC_STAT.MIN0` bits.

Table 32-20: SINC_P2SEC_HIST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	HI	High Data Word. The `SINC_P2SEC_HIST[n].HI` bits provide the 16-bit sample in the most significant half of the 32- bit register.
15:0 (R/NW)	LO	Low Data Word. The `SINC_P2SEC_HIST[n].LO` bits provide the 16-bit sample in the least significant half of the 32- bit register.

Pair 3 Secondary (Filter) History n Register

The `SINC_P3SEC_HIST[n]` read-only register provides the eight most recent samples produced by secondary SINC filter 3. The 16-bit samples are stored in the 32-bit register in circular manner, starting with the low-order field of the first `SINC_P3SEC_HIST[n]` register. The stored values, compared to the limit, count, and window settings, set the `SINC_STAT.MAX3` and `SINC_STAT.MIN3` bits.

Table 32-24: SINC_PPTR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	PPTR	Primary (Filter) Pointer. The `SINC_PPTR0.PPTR` bits hold the address for the last memory location of the most recent set of primary SINC filter results (group 0). The address is incremented once all of the primary SINC filter data (assigned to group 0 and associated to a particular time stamp) is successfully presented to the system fabric. Memory locations beyond the location reported by this register may be partially updated, so the entire circular buffer is not considered valid. Note that in real-time operation, due to fabric latency, write data may be in flight on the system fabric after the point when this bit field is updated. Thus, the write data may not be observed in memory until it has transited the fabric.

Primary (Filters) Pointer for Group 1 Register

The `SINC_PPTR1` read-only register points to a circular buffer holding the most recent results of primary SINC filters, according to control group 1 assignments.

Figure 32-27: SINC_RATE0 Register Diagram

Table 32-28: SINC_RATE0 Register Fields

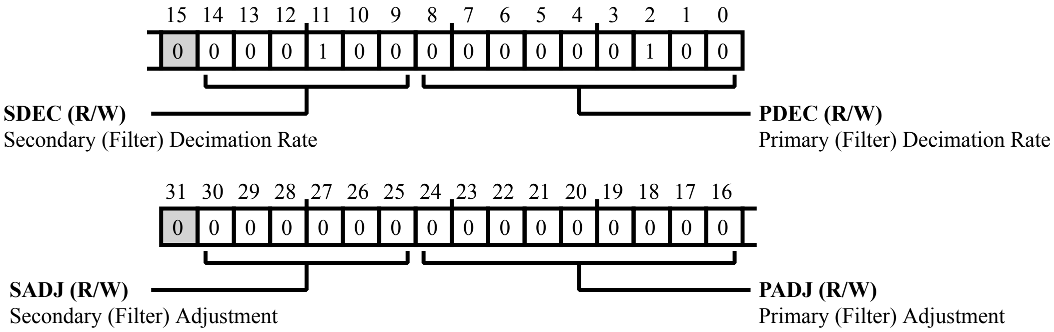
Bit No. (Access)	Bit Name	Description/Enumeration
30:25 (R/W)	SADJ	Secondary (Filter) Adjustment. The `SINC_RATE0.SADJ` bits provide the phase adjustment for the decimated output of group 0 secondary filters. The valid adjustment is between 0 and (`SINC_RATE0.SDEC` - 1), in modulator clock cycles, relative to the time the filter is enabled in the `SINC_CTL` register. The secondary SINC filter calculates an output in modulator clock cycle equivalent to ((`SINC_RATE0.SDEC` * n) - `SINC_RATE0.SADJ`), where n is an integer > 1. This bit field can be changed while the filter is running and takes effect after the next decimation sample is generated. The effect of the change requires time to ripple through the filter: a number of output sample periods is equal to the filter order.
24:16 (R/W)	PADJ	Primary (Filter) Adjustment. The `SINC_RATE0.PADJ` bits provide the phase adjustment for the decimated output of group 0 primary filters. The valid adjustment is between 0 and (`SINC_RATE0.PDEC` - 1), in modulator clock cycles, relative to the time the filter is enabled in the `SINC_CTL` register. The primary SINC filter calculates an output in modulator clock cycle equivalent to ((`SINC_RATE0.PDEC` * n) - `SINC_RATE0.PADJ`), where n is an integer > 1. This bit field can be changed while the filter is running and takes effect after the next decimation sample is generated. The effect of the change requires time to ripple through the filter: a number of output sample periods is equal to the filter order.

Table 32-28: SINC_RATE0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14:9 (R/W)	SDEC	Secondary (Filter) Decimation Rate. The `SINC_RATE0.SDEC` bits provide the decimation rate for group 0 secondary filters. The valid range depends on the SINC order selected. If the third order (`SINC_LEVEL0.SORD` = 0), the valid range is 4 to 40. If the forth order (`SINC_LEVEL0.SORD` = 1), the valid rate is 4 to 16.
8:0 (R/W)	PDEC	Primary (Filter) Decimation Rate. The `SINC_RATE0.PDEC` bits provide the decimation rate for group 0 primary filters. The valid rate is 256 to 4.

Rate Control for Group 1 Register

The `SINC_RATE1` register controls phase adjustments and decimation rates for primary and secondary SINC filters assigned to group 1.



15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Figure 32-29: SINC_STAT Register Diagram

Table 32-30: SINC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	GLIM1	Group 1 Limit Status. The `SINC_STAT.GLIM1` indicates status for an amplitude and duration limit of secondary SINC filters assigned to group 1. This bit is set (=1) if any limit specified by registers `SINC_LIMIT3`, `SINC_LIMIT2`, `SINC_LIMIT1`, or `SINC_LIMIT0`, within the duration count and window specified by bits `SINC_LEVEL0.LCNT` and `SINC_LEVEL0.LWIN` are exceeded. To identify the offending secondary SINC filter, examine the filters status bits `SINC_STAT.MAX3`, `SINC_STAT.MAX2`, `SINC_STAT.MAX1`, `SINC_STAT.MAX0`, `SINC_STAT.MIN3`, `SINC_STAT.MIN2`, `SINC_STAT.MIN1` and `SINC_STAT.MAX0` according to the group 1 assignments in the `SINC_CTL` register.	
		0	Not Exceeded
		1	Exceeded
30 (R/NW)	GSAT1	Group 1 Saturation Status. The `SINC_STAT.GSAT1` indicates status for the output saturation bit of primary SINC filters assigned to group 1. The bit is set (=1) if any filter of group 1 has its saturation status bit set (=1). To identify the offending SINC primary filter, examine bits `SINC_STAT.PSAT3`, `SINC_STAT.PSAT2`, `SINC_STAT.PSAT1`, and `SINC_STAT.PSAT0` according to the group 1 assignments specified by the `SINC_CTL.EN3`, `SINC_CTL.EN2`, `SINC_CTL.EN1`, and `SINC_CTL.EN0` bits.	
		0	Not Set
		1	Set
29 (R/W1C)	PCNT1	Primary (Filter) Count for Group 1 Status. The `SINC_STAT.PCNT1` indicates status for the output count of primary SINC filters assigned to group 1. The bit is set (=1) each time the modulo number of outputs (specified by the `SINC_LEVEL1.PCNT` bits) has been transferred for each primary SINC filter assigned to group 1. Each count in `SINC_LEVEL1.PCNT` corresponds to one complete set or vector of samples from all SINC filter pairs assigned to group 1. For example, if group 1 is assigned three SINC filters pairs 0, 1, and 3, and `SINC_LEVEL1.PCNT` is set to 5, then this status bit is set after the transfer of every 5th complete sample vector, comprising 3 x 5= 15 data samples. This bit asserts when the memory transfer on the system SCB fabric is complete, and a valid SCB write data response is received by the SINC filter unit. If this status bit and bit `SINC_CTL.EPCNT1` are set (=1), the SINC_DATA1 trigger is asserted. Write 1 to clear.	
		0	Not Reached
		1	Reached

Table 32-30: SINC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W1C)	FOVF1	FIFO Overflow for Group 1 Status. The `SINC_STAT.FOVF1` indicates status for the data output FIFO bit of primary SINC filters assigned to group 1. This bit is set (= 1) if the output FIFO for any filter in group 1 overflows due to slow SCB fabric response. The FIFO for each primary SINC filter contains two data sample locations. An overflow occurs if a third data sample is generated before the first sample's data is transferred into the SCB fabric write data channel. After any overflow signaled by this bit occurs, all further SCB transmissions generated by group 1 are UNSPECIFIED until all SINC filters of the group are shut down and restarted. Clearing this status bit (=0) alone is not sufficient to re-sync the DMA stream. Write 1 to clear. If this status bit and bit `SINC_CTL.EFOVF1` are set (=1), the SINC_STAT interrupt is asserted.	
		0	No Overflow
		1	Overflow
27 (R/W1C)	PFAB1	Primary (Filter) Fabric Error for Group 1 Status. The `SINC_STAT.PFAB1` indicates error status for the output of any primary SINC filter assigned to group 1. The bit is set (=1) if the SCB fabric provides a write error response for a filter output transfer associated with group 1, or if an overrun occurs for a filter in group 1. An interrupt is requested whenever this bit =1 (not maskable).	
		0	Disabled
		1	Enabled
23 (R/W1C)	PSAT3	Primary (Filter) 3 Saturation Status. The `SINC_STAT.PSAT3` bit indicates whether the primary SINC filter 3 requires saturation.	
		0	Not Saturated
		1	Saturated
22 (R/W1C)	PSAT2	Primary (Filter) 2 Saturation Status. The `SINC_STAT.PSAT2` bit indicates whether the primary SINC filter 2 requires saturation.	
		0	Not Saturated
		1	Saturated

Table 32-30: SINC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W1C)	PSAT1	Primary (Filter) 1 Saturation Status. The `SINC_STAT.PSAT1` bit indicates whether the primary SINC filter 1 requires saturation.	
		0	Not Saturated
		1	Saturated
20 (R/W1C)	PSAT0	Primary (Filter) 0 Saturation Status. The `SINC_STAT.PSAT0` bit indicates whether the primary SINC filter 0 requires saturation.	
		0	Not Saturated
		1	Saturated
19 (R/W1C)	MAX3	Maximum for Secondary Filter 3 Status. The `SINC_STAT.MAX3` bit indicates whether the output of the secondary SINC filter 3 exceeded its maximum amplitude and duration level. This bit is set (=1) if the limit is exceeded. The amplitude limit is specified by the `SINC_LIMIT3.LMAX` bits. The duration limit is specified in terms of an excursion count and window for the filter group to which the filter is assigned by the `SINC_CTL.EN3` bits. For group 0, the duration limit is `SINC_LEVEL0.LCNT` counts within a window of `SINC_LEVEL0.LWIN` samples. For group 1, the duration limit is `SINC_LEVEL1.LCNT` counts within a window of `SINC_LEVEL1.LWIN` samples.	
		0	Not Exceeded
		1	Exceeded
18 (R/W1C)	MAX2	Maximum for Secondary Filter 2 Status. The `SINC_STAT.MAX2` bit indicates whether the output of the secondary SINC filter 2 exceeded its maximum amplitude and duration level. This bit is set (=1) if the limit is exceeded. The amplitude limit is specified by the `SINC_LIMIT2.LMAX` bits. The duration limit is specified in terms of an excursion count and window for the filter group to which the filter is assigned by the `SINC_CTL.EN2` bits. For group 0, the duration limit is `SINC_LEVEL0.LCNT` counts within a window of `SINC_LEVEL0.LWIN` samples. For group 1, the duration limit is `SINC_LEVEL1.LCNT` counts within a window of `SINC_LEVEL1.LWIN` samples.	
		0	Not Exceeded
		1	Exceeded

Table 32-30: SINC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	MAX1	Maximum for Secondary Filter 1 Status. The `SINC_STAT.MAX1` bit indicates whether the output of the secondary SINC filter 0 exceeded its maximum amplitude and duration level. This bit is set (=1) if the limit is exceeded. The amplitude limit is specified by the `SINC_LIMIT1.LMAX` bits. The duration limit is specified in terms of an excursion count and window for the filter group to which the filter is assigned by the `SINC_CTL.EN1` bits. For group 0, the duration limit is `SINC_LEVEL0.LCNT` counts within a window of `SINC_LEVEL0.LWIN` samples. For group 1, the duration limit is `SINC_LEVEL1.LCNT` counts within a window of `SINC_LEVEL1.LWIN` samples.	
		0	Not Exceeded
		1	Exceeded
16 (R/W1C)	MAX0	Maximum for Secondary Filter 0 Status. The `SINC_STAT.MAX0` bit indicates whether the output of the secondary SINC filter 0 exceeded its maximum amplitude and duration level. This bit is set (=1) if the limit is exceeded. The amplitude limit is specified by the `SINC_LIMIT0.LMAX` bits. The duration limit is specified in terms of an excursion count and window for the filter group to which the filter is assigned by the `SINC_CTL.EN0` bits. For group 0, the duration limit is `SINC_LEVEL0.LCNT` counts within a window of `SINC_LEVEL0.LWIN` samples. For group 1, the duration limit is `SINC_LEVEL1.LCNT` counts within a window of `SINC_LEVEL1.LWIN` samples.	
		0	Not Exceeded
		1	Exceeded

Table 32-30: SINC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	GLIM0	Group 0 Limit Status. The `SINC_STAT.GLIM0` indicates status for an amplitude and duration limit of secondary SINC filters assigned to group 0. This bit is set (=1) if any limit specified by registers `SINC_LIMIT3`, `SINC_LIMIT2`, `SINC_LIMIT1`, or `SINC_LIMIT0`, within the duration count and window specified by bits `SINC_LEVEL1.LCNT` and `SINC_LEVEL1.LWIN` are exceeded. To identify the offending secondary SINC filter, examine the filters status bits `SINC_STAT.MAX3`, `SINC_STAT.MAX2`, `SINC_STAT.MAX1`, `SINC_STAT.MAX0`, `SINC_STAT.MIN3`, `SINC_STAT.MIN2`, `SINC_STAT.MIN1` and `SINC_STAT.MAX0` according to the group 0 assignments in the `SINC_CTL` register.	
		0	Not Exceeded
		1	Exceeded
14 (R/NW)	GSAT0	Group 0 Saturation Status. The `SINC_STAT.GSAT0` indicates status for the output saturation bit of primary SINC filters assigned to group 0. The bit is set (=1) if any filter of group 0 has its saturation status bit set (=1). To identify the offending SINC primary filter, examine bits `SINC_STAT.PSAT3`, `SINC_STAT.PSAT2`, `SINC_STAT.PSAT1`, and `SINC_STAT.PSAT0` according to the group 0 assignments specified by the `SINC_CTL.EN3`, `SINC_CTL.EN2`, `SINC_CTL.EN1`, and `SINC_CTL.EN0` bits.	
		0	Not Set
		1	Set
13 (R/W1C)	PCNT0	Primary (Filter) Count for Group 0 Status. The `SINC_STAT.PCNT0` indicates status for the output count of primary SINC filters assigned to group 0. The bit is set (=1) each time the modulo number of outputs (specified by the `SINC_LEVEL0.PCNT` bits) has been transferred for each primary SINC filter assigned to group 0. Each count in `SINC_LEVEL0.PCNT` corresponds to one complete set or vector of samples from all SINC filter pairs assigned to group 1. For example, if group 0 is assigned three SINC filters pairs 0, 1, and 3, and `SINC_LEVEL0.PCNT` is set to 5, then this status bit is set after the transfer of every 5th complete sample vector, comprising 3 x 5= 15 data samples. This bit asserts when the memory transfer on the system SCB fabric is complete, and a valid SCB write data response is received by the SINC filter unit. If this status bit and bit `SINC_CTL.EPCNT0` are set (=1), the SINC_DATA0 trigger is asserted. Write 1 to clear.	
		0	Not Reached
		1	Reached

Table 32-30: SINC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1C)	FOVF0	FIFO Overflow for Group 0 Status. The `SINC_STAT.FOVF0` indicates status for the data output FIFO bit of primary SINC filters assigned to group 0. This bit is set (= 1) if the output FIFO for any filter in group 0 overflows due to slow SCB fabric response. The FIFO for each primary SINC filter contains two data sample locations. An overflow occurs if a third data sample is generated before the first sample's data is transferred into the SCB fabric write data channel. After any overflow signaled by this bit occurs, all further SCB transmissions generated by group 1 are UNSPECIFIED until all SINC filters of the group are shut down and restarted. Clearing this status bit (=0) alone is not sufficient to re-sync the DMA stream. Write 1 to clear. If this status bit and bit `SINC_CTL.EFOVF0` are set (=1), the SINC_STAT interrupt is asserted.	
		0	No Overflow
		1	Overflow
11 (R/W1C)	PFAB0	Primary (Filter) Fabric Error for Group 0 Status. The `SINC_STAT.PFAB0` indicates error status for the output of any primary SINC filter assigned to group 0. The bit is set (=1) if the SCB fabric provides a write error response for a filter output transfer associated with group 0, or if an overrun occurs for a filter in group 0. An interrupt is requested whenever this bit is =1 (not maskable).	
		0	Disabled
		1	Enabled
3 (R/W1C)	MIN3	Minimum for Secondary Filter 3 Status. The `SINC_STAT.MIN3` bit indicates whether the output of the secondary SINC filter 3 exceeded its minimum amplitude and duration level. This bit is set (=1) if the limit is exceeded. The amplitude limit is specified by the `SINC_LIMIT3.LMIN` bits. The duration limit is specified in terms of an excursion count and window for the filter group to which the filter is assigned by the `SINC_CTL.EN3` bits. For group 0, the duration limit is `SINC_LEVEL0.LCNT` counts within a window of `SINC_LEVEL0.LWIN` samples. For group 1, the duration limit is `SINC_LEVEL1.LCNT` counts within a window of `SINC_LEVEL1.LWIN` samples.	
		0	Not Exceeded
		1	Exceeded

Table 32-30: SINC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W1C)	MIN2	Minimum for Secondary Filter 2 Status. The `SINC_STAT.MIN2` bit indicates whether the output of the secondary SINC filter 2 exceeded its minimum amplitude and duration level. This bit is set (=1) if the limit is exceeded. The amplitude limit is specified by the `SINC_LIMIT2.LMIN` bits. The duration limit is specified in terms of an excursion count and window for the filter group to which the filter is assigned by the `SINC_CTL.EN2` bits. For group 0, the duration limit is `SINC_LEVEL0.LCNT` counts within a window of `SINC_LEVEL0.LWIN` samples. For group 1, the duration limit is `SINC_LEVEL1.LCNT` counts within a window of `SINC_LEVEL1.LWIN` samples. 0 Not Exceeded 1 Exceeded
1 (R/W1C)	MIN1	Minimum for Secondary Filter 1 Status. The `SINC_STAT.MIN1` bit indicates whether the output of the secondary SINC filter 1 exceeded its minimum amplitude and duration level. This bit is set (=1) if the limit is exceeded. The amplitude limit is specified by the `SINC_LIMIT1.LMIN` bits. The duration limit is specified in terms of an excursion count and window for the filter group to which the filter is assigned by the `SINC_CTL.EN1` bits. For group 0, the limit is `SINC_LEVEL0.LCNT` counts within a window of `SINC_LEVEL0.LWIN` samples. For group 1, the limit is `SINC_LEVEL1.LCNT` counts within a window of `SINC_LEVEL1.LWIN` samples. 0 Not Exceeded 1 Exceeded

33 Digital Audio Interface (DAI)

The Digital Audio Interfaces (DAIn) are comprised of groups of identical peripherals and their respective Signal Routing Units (SRUn). The SRU connects inputs and outputs of the DAI peripherals with each other and to the external pins. This configuration allows peripherals to be interconnected to accomodate a wide variety of systems without making external pin connections.

In a typical processor, static (multiplexed) pins are assigned to specific peripherals. When certain peripherals are not required for an application, these pins are unnecessary and expensive. The pins may need to be defined as high or low to prevent any illegal conditions. The signal routing units on the SHARC processors addresses this situation by controlling a number of general-purpose pins which can be assigned flexibly (a virtual connectivity between peripherals) depending on system requirements. This virtual connectivity includes pin buffers and routing logic (multiplexer). It also allows the SHARC processors to include an arbitrary number and variety of peripherals while retaining high levels of compatibility without increasing pin count.

SRU Features

The SRU has the following features and capabilities.

- Flexible connections that can be made through software and during run time; no hard-wiring is required.
- At reset, a default routing scheme is already programmed.
- Connectivity can be made internally between peripherals, externally between pin buffers, or a mix of both.
- Status of the pin buffers can be programmed for conditional execution or interrupts.
- Some pin buffers allow control of signal polarity changes.
- No fan-out limitation, a peripheral or pin buffer output that can be routed to multiple peripheral or pin buffer inputs.
- Two independent routing systems are availablethe DAI0 and the DAI1. Signals can't be interconnected between both routing units with the exception of the following modules under some specific scenarios.
    - The precision clock generator (PCG)
    - A pair of DAI pin buffers from each DAI unit
    - Asynchronous Sample Rate Converter (ASRC) data for daisy chaining across the DAI units

NOTE: The 349–ball CSP BGA package has 2 x 14 DAI pins bonded off-chip (DAIx_PIN01 through DAIx_PIN12, DAIx_PIN19 and DAIx_PIN20).

Functional Description

The fundamental timing clock of the DAI modules is SCLK0_0.

The DAI Block Diagram shows how the DAI pin buffers are connected through the SRUn. This configuration allows for flexible signal routing.

The DAI units are comprised of four primary blocks:

- Peripherals (A/B/C) associated with DAIn
- Signal Routing Units (SRUn)
- DAIn I/O pin buffers
- Miscellaneous buffers

The peripherals shown in ***DAI Functional Block Diagram*** can have up to three connections (if master or slave capable); one acts as a signal input, one as a signal output and the third as an output enable. The SRUs are based on a group of multiplexers which are controlled by registers to establish the desired interconnections. The DAI pin buffers have three signals which are used for input and output to or from off-chip and the third for output enable.

The miscellaneous buffers have an input and an output and are used for group interconnection.

The figures are a simplified representation of a DAI system. In a real representation, the SRU and DAI would show several types of data being routed from several sources including the following:

- Serial ports (SPORT)
- Precision clock generators (PCG)
- Asynchronous sample rate converters (SRC)
- S/PDIF transmitter
- S/PDIF receiver
- DAI interrupts (miscellaneous)

ADSP-SC58x DAI Register List

The Digital Audio Interfaces (DAIn) contain groups of identical peripherals which can be connected internally between peripherals, externally between pin buffers, or a mix of both. This module contains the following registers.

Table 33-1: ADSP-SC58x DAI Register List

DAI Signal Naming Conventions

The peripherals associated with the DAI do not have any dedicated I/O pins for off-chip communication. Instead, the I/O pin is only accessible in the chip internally and is known as an *internal node*. Every internal node of a DAI peripheral (input or output) is given a unique mnemonic. The convention is to begin the name with an identifier for the peripheral that the signal is coming to or from, followed by the function of the signal.

A number is included if the DAI contains more than one peripheral type (for example, serial ports), or if the peripheral has more than one signal that performs this function (for example, serial ports). The mnemonic always ends with *_I* if the signal is an input, or with *_O* if the signal is an output. An example is shown in the ***Example DAI Mnemonics*** figure.

Figure 33-3: Example DAI Mnemonics

I/O Pin Buffers

Within the context of the SRU, physical connections to the DAI pins are replaced by a logical interface known as a *pin buffer*. This three terminal active device is capable of sourcing or sinking output current when its driver is enabled, and passing external input signals when disabled. Each pin has an input, an output, and an enable as shown in the ***Pin Buffer Example*** figure. The inputs and the outputs are defined with respect to the pin, similar to a peripheral device. This naming convention is consistent with the SRU naming convention.

Pin Buffer Signals

The pin buffer is based on three signals shown in the ***Pin Buffer Example*** figure and described in the following sections.

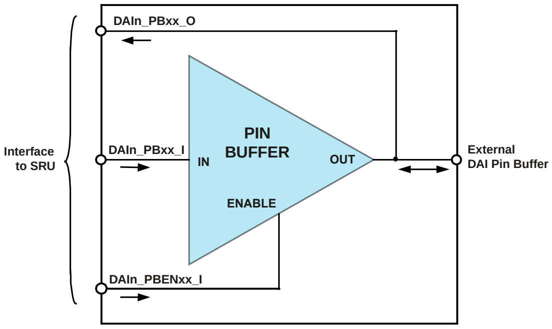

Figure 33-4: Pin Buffer Example

Pin Buffer Input Signal

A pin buffer input (`DAIn_PBxx_I`) is driven as an output from the processor when the pin buffer enable is set (=1). Each physical pin (connected to a bonded pad) can be connected through the SRU to any of the outputs of the DAI peripherals, based on the bit field values. The SRU can also be used to route signals that control the pins in other ways. Many signals can be configured for use as control signals.

Pin Buffer Enable Signal

When a pin buffer enable (`DAIn_PBENxx_I`) is set (=1), the signal present at the corresponding pin buffer input (`DAIn_PBxx_I`) is driven off-chip as an output. When a pin buffer enable is cleared (=0), the signal present at the corresponding pin buffer input is ignored. The pin enable control registers activate the drive buffer for each of the DAI pins. When the pins are not enabled (driven), they can be used as inputs. There are two options to control the pin buffer enable signal; setting the level high for a static solution, or connecting the dedicated peripheral's pin buffer output enable signal to its pin buffer, which automatically enables the pin buffer.

Pin Buffer Input Level State

The DAI pads are provided with an input enable signal (IE). The signal is used to ensure that the input path (`DAI_PBxx_O`) is pushed to a known state (versus a floating state in case of no external drivers on the DAI pad). This state can be considered as an AND gate of the pad signal with the IE as shown in the pin buffer figure. The IE signal is controlled from the PAD logic (`PADS_DAIx_IE` register) and is provided at a granularity at each DAI pin. (Refer to the GP port chapter.) Every DAI pin can be individually controlled depending on whether the pin is used in a system or not. The PADS register controlling the IE signal must have a reset value of 0 and hence all the pin buffer inputs are (`DAI_PBxx_O`) gated to 0.

NOTE: In previous SHARC products, this default value was 1 due to a weak pull-up.

Once the PADS module register is programmed to enable the IE signal on the used DAI pin buffers, the pin-buffer outputs its signal on `DAI_PBxx_O`. The programming model needs to enable all used DAI pin buffers. For unused DAI pin-buffers (no external system connection), keep the corresponding IE-bit at a disabled state.

Pin Buffer Functions

Pin buffers can be configured as inputs or outputs as described in the following sections.

Pin Buffers as Signal Input

When the DAI pin is used only as an input, connect the corresponding pin buffer enable to logic low as shown in the ***Pin Buffer as Input*** figure. This configuration disables the buffer amplifier and allows an off-chip source to drive the value present on the DAI pin and at the pin buffer output. When the pin buffer enable (for example, `DAI_PBEN0.PB01`) is cleared (= 0), the pin buffer output (`DAIn_PBxx_O`) is the signal driven onto the DAI pin by an external source, and the pin buffer input signal (`DAIn_PBxx_I`) is not used.

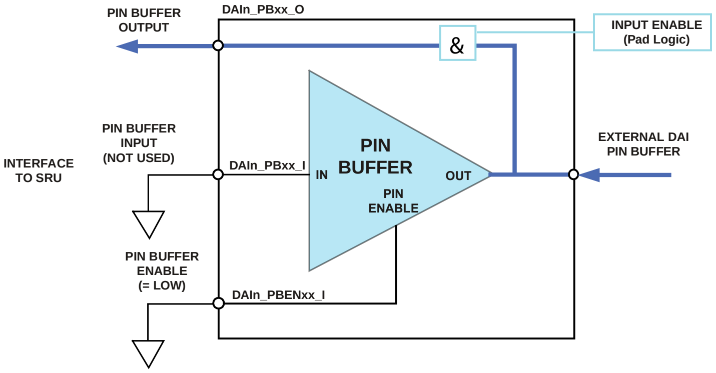

Figure 33-5: Pin Buffer as Input

NOTE: Whether programmed as input or output, a DAI buffer input always routes the same signal to an output internally. The DAI also has an additional programming requirement when it is configured as input. The corresponding pin must be enabled in the `PADS_DAIx_IE` register. The `DAI_PB01_O` pin cannot be routed as an input source for clock (Group A signals) and frame sync (Group C). For more information, see DAI Routing Capabilities.

Pin Buffers As Signal Output

In a typical embedded system, most pins are designated as either inputs or outputs when the circuit is designed, even though they can be used in either direction. Each of the DAI pins can be used as either an output or an input. Although the direction of a DAI pin is set simply by writing to a memory-mapped register, most often the direction of the pin is dictated by the designated use of that pin.

When the DAI pin is used only as an output, connect the corresponding pin buffer enable to logic high as shown in the ***Pin Buffer as Output*** figure. This configuration enables the buffer amplifier to operate as a current source and to drive the value present at the pin buffer input onto the DAI pin and off-chip. When the pin buffer enable bits are set (in the `DAIn_PBxx_I` registers) (=1), the pin buffer output (`DAIn_PBxx_O`) is the same signal as the pin buffer input (`DAIn_PBxx_I`), and this signal is driven as an output.

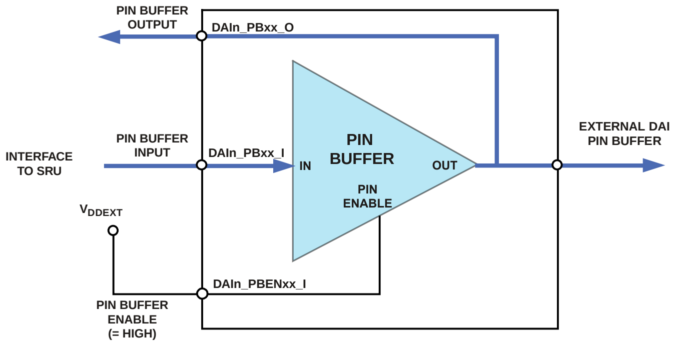

Figure 33-6: Pin Buffer as Output

DAI Pin Buffer Status

The signal levels on the DAI pins can be read with the `DAI_PIN_STAT` registers.

DAIn Peripherals

There are two categories of peripherals associated with the DAI units. These are described in the following sections.

Output Signals With Pin Buffer Enable Control

Many peripherals within the DAIn that have bidirectional pins generate a corresponding pin enable signal. Typically, the settings within the control registers of a peripheral determine if a bidirectional pin is an input or an output. The pin is then driven accordingly.

Though most peripherals are capable of operating bidirectionally, it is not required that all of the `_I` and `_O` signals of a peripheral be connected to the pin buffer. If the system design only uses a signal in one direction, it is simpler to connect the pin buffer accordingly.

NOTE: All available pin buffer output enables must be routed to their pin buffer input enable signals in cases where data streaming connections are used. This arrangement guarantees timing requirements.

NOTE: In some cases, it is necessary to use a peripheral's dedicated pin buffer enable signal instead of static levels. For example, SPORT TDM mode requires the SPORT's dedicated data pin buffer enable signal to be used for the SPORT's data pin to three-state the data pins on inactive channels.

Output Signals Without Pin Buffer Enable Control

Some peripherals have signal outputs without an automated pin buffer control enable signal. The operation of these peripherals is simplified. The routing to a DAIn pin buffer enable input requires a static high from the SRUn. In order to disable the pin buffer output, software must clear the pin buffer enable input accordingly.

Signal Routing Units (SRUs)

The following sections provide details specific to the SRUs.

Cross Mode Connections

The DAI allows a few signals to be interconnected across DAI units (see Figure 33-2 Digital Audio Interconnect Unit). These connections are commonly referred as *cross mode connections*. These cross mode connections are useful for the system designer to share signals across both DAI's so that synchronization can be achieved on the peripheral modules across DAI0 and DAI1.

NOTE: The 349-ball CSP BGA package has 2 x 14 DAI pins bonded off-chip and continues to support 2 x 20 pin buffers for internal routings.

Shared Clock. This cross mode connection (see Figure 33-7 Cross Connect Clock Example) can be used to share a clock signal cross DAIs. `DAI0_PIN03` and `DAI1_PIN03` can be used to share clock signal across DAI. When DAI0_PIN03 is configured as input clock pin then this clock signal is available in Group A of both DAIs. This source signal is `DAI0_PB03_O` in group A of DAI 0 and `DAI1_CRS_PB03_O` in group A of DAI1.

Peripherals routed through DAI0 like PCG A and SPORT 0A can use `DAI0_PB03_O` as the input clock signal. Peripherals routed through DAI1 like PCG C, SPORT 4A can use `DAI1_CRS_PB03` as the input clock signal. Similarly when `DAI1_PIN03` is configured as the input clock pin, then this clock signal is available as `DAI1_PB03_O` in group A of DAI1 and `DAI0_CRS_PB03` in group A of DAI0.

Shared Frame Sync. This cross mode connection can be used to share a frame sync signal cross DAIs. `DAI0_PIN04` and `DAI1_PIN04` can be used to share the frame sync signal across the DAIs. When `DAI0_PIN04` is configured as the input frame sync pin then this frame sync signal is available in Group C of both DAIs. This source signal is `DAI0_PB04_O` in group C of DAI 0 and `DAI1_CRS_PB04_O` in group C of DAI1.

Peripherals on DAI0 like SPORT 0A can use `DAI0_PB04_O` as the input frame sync signal. The peripherals on DAI1 like SPORT 4A can use `DAI1_CRS_PB04` as the input sync signal. Similarly when `DAI1_PIN04` is configured as input frame sync pin, then this frame sync signal is available as `DAI1_PB04_O` in group A of DAI1 and `DAI0_CRS_PB04` in group C of DAI0.

Shared Pin Buffer. This cross mode connection can be used to connect input signal on `DAI0_PIN03`, `DAI0_PIN04`, `DAI1_PIN03` and `DAI1_PIN04` to other DAI pins across DAI. When `DAI0_PIN03` and `DAI0_PIN04` are configured as input signals. These signals can be routed to the pin buffers of DAI1 in Group D using `DAI1_CRS_PIN03` and `DAI1_CRS_PIN04`. When `DAI1_PIN03` and `DAI1_PIN04` are configured as input signals they can be routed to the pin buffers of DAI0 in Group D using `DAI0_CRS_PIN03` and `DAI0_CRS_PIN04` signals.

PCGs and Pin Buffers. This cross mode connection (see Figure 33-8 Cross Connect PCG Example) can be used to connect PCG output signals of one DAI to pin buffers of other DAI. For example, PCG C outputs of DAI 1 can be connected to pin buffers of DAI 0 using `PCG0_CRS_CLKC_O` of Group D.

ASRC TDM and Data Signal. This cross mode connection is available in Group B (Data Signals). This allows programs to connect the Data and TDM signals of SRC3 and SRC 7 across DAIs so that eight SRCs can be daisy chained for TDM 16 operation. For example `SRC3_DAT_OP_O` and `SRC3_TDM_IP_O` of DAI0 are available as `SRC3_CRS_DAT_OP_O` and `SRC3_CRS_IP_O` in DAI1 so that DAI0 SRC3 can be connected to DAI1's SRC for daisy chaining.

Signal Routing Matrix by Groups

The SRU is similar to a set of patch bays, which contain a bank of inputs and a bank of outputs. For each input (destination), there is a set of permissible output (source) options. Outputs can feed to any number of inputs in parallel, but every input must be patched to exactly one valid output source. Together, the set of inputs and outputs are called a group. The signal's inputs and outputs that comprise each group all serve similar purposes. They are compatible such that almost any output-to-input patch makes functional sense. With the grouping, the multiplexing scheme becomes highly efficient since it does not make sense (for example) to route a frame sync signal to a data signal.

The SRU for the DAI contains six groups named A through F. Each group routes a unique set of signals with a specific purpose:

- Group A routes clock signals
- Group B routes serial data signals
- Group C routes frame sync signals
- Group D routes pin signals
- Group E routes miscellaneous signals
- Group F routes pin output enable signals

Together, the six groups of the SRU include all of the inputs and outputs of the DAI peripherals, a number of additional signals from the core, and all of the connections to the DAI pins.

NOTE: It is not possible to connect a signal in one group directly to a signal in a different group (analogous to wiring from one patch bay to another). However, group D (DAI) is largely devoted to routing in this vein.

DAI Group Routing

Each group has a unique encoding for its associated output signals and a set of configuration registers. For example, DAI group A is used to route clock signals. The memory-mapped group A registers, `DAI_CLK0` through `DAI_CLK5`, contain bit fields corresponding to the clock inputs of various peripherals. The values written to these bit fields specify a signal source that is an output from another peripheral. All of the possible encodings represent sources that are clock signals (or at least could be clock signals in some systems). The ***Example DAI Group A Multiplexing (DAI_CLKx)*** diagrams the input signals that are controlled by the group A registers. All bit fields in the SRU configuration registers correspond to inputs. The value written to the bit field specifies the signal source. This value is also an output from some other component within the SRU.

The SRU is similar to a set of patch bays. Each bay routes a distinct set of outputs to compatible inputs. These connections are implemented as a set of memory-mapped registers with a bit field for each input. The outputs are implemented as a set of bit encodings. Conceptually, a patch cord is used to connect an output to an input. In the SRU, a bit pattern that is associated with a signal output (shown in the ***Example DAI Group A Multiplexing (DAI_CLKx)*** figure) is written to a bit field corresponding to a signal input.

The same encoding can be written to any number of bit fields in the same group. It is not possible to run out of patch points for an output signal.

Figure 33-9: Example DAI Group A Multiplexing (DAIn_CLKx)

Just as group A routes clock signals, each of the other groups route a collection of compatible signals. Group B routes serial data streams while group C routes frame sync signals. All of the groups have an encoding that allow a signal to flow from a pin output to the input being specified by the bit field.

Group D routes signals to pins so that they may be driven off-chip (required to route a signal to the pin input). Group F routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input. The input of one pin can be patched to the output of another pin, allowing board-level routing under software control.

Rules for SRU Connections

There are two rules which apply to all routing:

1. One source (output node) can drive different destinations (input nodes).
2. One destination (input node) can only be assigned to one source (output node).

As an example from the ***Example DAI Group A Multiplexing (DAI_CLKx)*** figure:

- `DAI0_CRS_PB03_O` is routed to `SPT0_ACLK_I`
- `DAI0_CRS_PB03_O` is routed to `SPT0_BCLK_I`
- `SPT4_ACLK_O` is routed to `SPT3_ACLK_I`

NOTE: Inputs may only be connected to outputs.

Miscellaneous Buffers and Functions

The SRU group E provides miscellaneous buffers used for group interconnect.

DAI group E connections are slightly different from the others in that the inputs and outputs being routed vary considerably in function. This group routes control signals and provides a means of connecting signals between groups.

In the ***DAI MISCAx SRU Signal Connections*** table, the `DAIn_MISCAx_I` signals appear as inputs in group E (also connected to the DAI interrupt logic), but do not directly feed any peripheral. Rather, the `MISCAx_O` signals reappear as outputs in group F.

Table 33-3: DAI MISCAx SRU Signal Connections

MISCA Source	DAI Connection	MISCA Destination
	Group E	DAIn_MISCA5-0_I
DAIn_MISCA5-0_O	Group F	

Additional connections among groups provide a great amount of utility. Since the output groups F (DAI) dictate pin direction, these few signal paths enable a number of possible uses and connections for the DAI pins. Other examples include:

- A pin input can be patched to another pin's enable, allowing an off-chip signal to gate an output from the processor.
- Any of the DAI pins can be used as interrupt sources or general-purpose I/O (GPIO) signals.

In summary, the SRU enables many possible functional changes, both within the processor as well as externally. Used creatively, it allows system designers to radically change functionality at run time, and to potentially reuse circuit boards across many products.

DAI Routing Capabilities

This section describes the routing options to aid in designing a system using the DAI units. The Cross Mode Connections section provides information on connecting signals across DAI0 and DAI1. The DAI Default Routing section provides diagrams that show how that DAIs connect at default. The DAI Group tables provide the source signals and selections codes. Finally, the ADSP-SC58x DAI Register Descriptions provides information about configuring destinations.

The ***DAI Routing Capabilities*** tables provide an overview of the different routing capabilities for the DAI unit. For information on an individual peripherals routing, see the "SRU Programming" section of the specific peripheral chapter.

Table 33-4: DAI0 Routing Capabilities

SPORT7B–4A (clock, FS, data, TDV) MISCA5-0	Logic level high Logic level low	F-Pin Buffer Enable	DAI1 Pin Buffer Enable 20–1

NOTE: For DAI sources (Group A, clocks) and (Group C, FS) only DAI pin buffer 2 through 20 can be used (DAI pin buffer 1 is no longer available and replaced by DAI CRS buffer for the other DAI).

DAI Default Routing

When the processor comes out of reset, the SPORT junctions are bidirectional to the DAI pin buffers. This configuration allows systems to use the SPORTs as either master or slave (without changing the routing scheme). Therefore, programs only need to use the SPORT control register settings to configure master or slave operations. Note that all DAI inputs which are not routed by default are tied to signal low.

NOTE: All DAI input buffers which are not routed by default are driven low and all DAI pin buffer enable signals are driven low.

Figure 33-13: DAI1 Default Routing Pins 09-20

Unused DAI Connections

The SRUs have a default general-purpose routing scheme which can be modified to accomodate any number of different system designs. Regardless of the system design, it is good practice to tie all unused inputs to a high or low level to reduce dynamic power consumption.

Un-Bonded DAI Buffers

Some product variants have some DAI pin buffer not bonded off-chip. Note thee un bonded-DAI buffers can continued to be used for internal signal routing purposes (for example exchange CLK/FS/data between DAI buffers).

DAI Operating Modes

Some buffers allow polarity changes, described as follows.

DAI Pin Buffer Polarity

As shown in the ***Pin Buffer Polarity*** figure, the DAI pin buffer 20-19 can change the polarity of the input signal if the corresponding control bits (`DAI_PIN4.INV20`, `DAI_PIN4.INV19`) are set. These bits can be set during run time and the buffer should not loopback to itself.

DAI Miscellaneous Buffer Polarity

As shown in the ***Pin Buffer Polarity*** figure, the A5-4 miscellaneous buffers can change the polarity of the input signal if the corresponding control bits (`DAI_MISC1.IN5`, `DAI_MISC1.IN4`) are set. Both buffers are not connected to the DAI interrupt latch register. These bits can be set during run time.

Figure 33-16: DAI System Interrupt Controller

The DAI has its own system interrupt controllers that indicate to the core when DAI audio peripheral-related events have occurred. Since audio events generally occur infrequently relative to the SHARC core, the DAI interrupt controller reduces all of its interrupts onto two interrupt signals within the core's primary interrupt systems. One interrupt is mapped with DAI low priority. The second interrupt is mapped with DAI high priority. This configuration allows programs to broadly indicate priority. In this way, the DAI SIC provides 32 independently configurable sources or channels. The output bus interrupt signals are logically OR'ed into one interrupt line and fed to the interrupt controller logic of the core.

Three registers are used to configure the DAI interrupt controller. Each of the 32 interrupt sources can be independently configured to trigger on a rising edge, falling edge, both edges, or neither edge of an incoming signal. All DAI interrupt control registers are memory-mapped registers and are accessed through the peripheral bus.

Interrupt Sources

The DAI's five peripheral sources are multiplexed into 32 interrupt sources and are labeled DAI_INT31-0 (*DAI Interrupt Sources* table).

NOTE: There are two naming conventions. The DAI interrupt controller register bits are labeled DAI_31-0_INT. Their corresponding SRU routing signals are labeled DAI_INT_31-0_I.

Table 33-6: DAI Interrupt Sources

Interrupt Source	Description	Signal Response
DAI_INT2–0, DAI_INT4	S/PDIF RX, 4 channels	Event
DAI_INT2–0, DAI_INT4	S/PDIF RX, 4 channels	Waveform
DAI_INT21–18	ASRC, 4 channels	
DAI_INT31–22	Miscellaneous, S/PDIF TX, 9 channels	

Interrupt Latch Priority Option

The `DAI_IMSK_PRI` register specifies the priority for the DAI interrupt channels. DAI system interrupt controller has a pair of interrupt latch registers, `DAI_IRPTL_H` and `DAI_IRPTL_L`. The configuration of the `DAI_IMSK_PRI` register also determines the interrupt latch mapping for a particular DAI interrupt. When a DAI interrupt is configured as low priority (`DAI_IMSK_PRI` bit cleared, default setting), interrupts are mapped to the DAI_INTR_IRQL signal and when an interrupt occurs, the corresponding bit of the `DAI_IRPTL_L` register is set. When a DAI interrupt is configured as high priority (`DAI_IMSK_PRI` bit set), interrupts are mapped to the DAI_INTR_IRQH signal and the interrupt is latched to the `DAI_IRPTL_H` register. The low priority DAI interrupt (INTR_DAI_IRQL) and high priority DAI interrupt (INTR_DAI_IRQH) are connected to the SEC and GIC.

Interrupt Mask for Waveforms

The `DAI_IMSK_RE` and `DAI_IMSK_FE` registers allow programs to mask or unmask interrupts for specific edges of a signal mapped to the channel. It can be configured for rising edges, falling edges, both rising and falling edges, or neither rising nor falling edges by masking them separately. Signals from the SRU can be used to generate interrupts. For example, when the `DAI_IMSK_FE.MISCINT9` bit is set to one, any falling edge signals from the external channel generate an interrupt and the interrupt latch is set.

Interrupt Mask for Events

The system interrupt controller needs information about a peripheral's interrupt sources that correspond to event signals (see the ***DAI Interrupt Sources*** table). As a result, the rising edge is used as an interrupt source only. For DAI peripherals marked as events, programs may unmask an interrupt source on the rising edge only.

Shadow Interrupt Register

The DAI interrupt controller has shadow registers to simplify debug activities since these registers do not manipulate status control. Any read of the shadow registers (`DAI_IRPTL_HS`, `DAI_IRPTL_LS`), provides the same data as a read of the `DAI_IRPTL_H` and `DAI_IRPTL_L` registers. However, reads of the DAI shadow registers do not change the interrupt acknowledge status to the core interrupt controller.

Interrupt Service

The interrupt acknowledge operates differently when multiple channels are multiplexed into one interrupt output signal. When an interrupt from the DAI must be serviced, any of the two interrupt service routines (INTR_DAI_IRQL, INTR_DAI_IRQH) must query the SIC to determine the source(s). Sources can be any one or more of the DAI channels (DAI_INT31-0).

- When the `DAI_IRPTL_H` register is read, the high priority latched interrupts are cleared.
- When the `DAI_IRPTL_L` register is read, the low priority latched interrupts are cleared.

If an interrupt occurs in the same cycle as a latch register is cleared, the clear mechanism has lower priority and the new interrupt is registered.

Signal Routing Unit Effect Latency

After the DAIy registers are configured the effect latency is 2 *SCLK0* cycles minimum and 3 *SCLK0* cycles maximum.

DAI Programming Model

As discussed in the previous sections, the signal routing unit is controlled by writing values that provide a plug-in tool in CCES so that configuring the SRU is done graphically. Analog Devices offers macros that are included with the CrossCore or VisualDSP++ tools, greatly easing code development in the SRU.

There is a macro that has been created to connect peripherals used in a DAI configuration. This code can be used in both assembly and C code. See the INCLUDE file SRU.H. In practice the macro is provided and forms the style `SRU(source_O, destination_I)` for DAI0 and `SRU2(source_O, destination_I)` for DAI1. Example appears as: `SRU(DAI0_PB12_O, SPT0_ACLK_I); or SRU2(DAI1_PB14_O, SPT4_ACLK_I);`

Debug Features

The following section describes the feature that can be used to help in debugging the DAI.

Loopback Routing

The SPORT serial peripheral supports an internal loopback mode. If the loopback bit for each peripheral is enabled, it connects the transmitter with the receiver block internally (does not signal off-chip). The SRU can be used for this purpose. The ***Loopback Routing*** table describes the different possible routings based on the peripheral.

NOTE: The peripheral's loopback mode for debug is independent from both of the signal routing units.

Table 33-7: Loopback Routing

Peripheral	Loopback Mode	SRU1–0 Internal Routing for Loopback	SRU1–0 External Routing for Loopback
SPORT	Yes	SPTx_xx_O → SPTx_xx_I	SPTx_xx_O → DAIn_PBxx_I DAIn_PBxx_O → SPTx_xx_I
S/PDIF Tx/Rx	No	SPDIFn_TX_O → SPDIFn_RX_I	SPDIFn_TX_O → DAI_PBxx_I DAI_PBxx_O → SPDIFn_RX_I
SRC	No	SRCx_DAT_OP_O → SRCx_DAT_IP_I	SRCx_DAT_OP_O → DAI_PBxx_I DAI_PBxx_O → SRCx_DAT_IP_I

DAI Sources Overview

The following tables provide information of the various DAI sources sorted by group. The shaded cells in the tables denote connection to the other DAI.

DAI0 Group A – Clock Routing Source Signals

The group A clock sources are listed in the following table. The Group A clock destinations are configured using Clock Routing Control Register 0 through Clock Routing Control Register 5 .

Table 33-8: DAI0 Group A – Clock Routing

DAI1 Group A – Clock Routing Source Signals

The group A clock routing signal sources are listed in the following table. The Group A clock destinations are configured using Clock Routing Control Register 0 through Clock Routing Control Register 5 .

Table 33-14: DAI1 Group A – Clock Routing Signals

Selection Code	Source Signal	Description (Source Selection)
00000 (0x0)	DAI1_CRS_PB03_O	Pin Buffer 3 (DAI0)
00001 (0x1)	DAI1_PB02_O	Pin Buffer 2
00010 (0x2)	DAI1_PB03_O	Pin Buffer 3
00011 (0x3)	DAI1_PB04_O	Pin Buffer 4
00100 (0x4)	DAI1_PB05_O	Pin Buffer 5
00101 (0x5)	DAI1_PB06_O	Pin Buffer 6
00110 (0x6)	DAI1_PB07_O	Pin Buffer 7
00111 (0x7)	DAI1_PB08_O	Pin Buffer 8
01000 (0x8)	DAI1_PB09_O	Pin Buffer 9
01001 (0x9)	DAI1_PB10_O	Pin Buffer 10
01010 (0xA)	DAI1_PB11_O	Pin Buffer 11
01011 (0xB)	DAI1_PB12_O	Pin Buffer 12
01100 (0xC)	DAI1_PB13_O	Pin Buffer 13
01101 (0xD)	DAI1_PB14_O	Pin Buffer 14
01110 (0xE)	DAI1_PB15_O	Pin Buffer 15
01111 (0xF)	DAI1_PB16_O	Pin Buffer 16
10000 (0x10)	DAI1_PB17_O	Pin Buffer 17
10001 (0x11)	DAI1_PB18_O	Pin Buffer 18
10010 (0x12)	DAI1_PB19_O	Pin Buffer 19

DAI Destination Registers Overview

The tables in DAI Routing Capabilities provide high level descriptions that illustrate source (output) connections to destinations (inputs) depending on the routing groups A through F. This sections lists the various input fields (INx) which are described in detail in the ADSP-SC58x DAI Register Descriptions section.

Table 33-20: Clock Destination Registers (Group A)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_CLK0	IN0	SPT0_ACLK_I	SPT4_ACLK_I	SPORT0A or SPORT4A Clock
	IN1	SPT0_BCLK_I	SPT4_BCLK_I	SPORT0B or SPORT4B Clock
	IN2	SPT1_ACLK_I	SPT5_ACLK_I	SPORT1A or SPORT5A Clock
	IN3	SPT1_BCLK_I	SPT5_BCLK_I	SPORT1B or SPORT5B Clock
	IN4	SPT2_ACLK_I	SPT6_ACLK_I	SPORT2A or SPORT6A Clock
	IN5	SPT2_BCLK_I	SPT6_BCLK_I	SPORT2B or SPORT6B Clock
DAI_CLK1	IN0	SRC0_CLK_IP_I	SRC4_CLK_IP_I	SRC0 or SRC4 Clock Input
	IN1	SRC0_CLK_OP_I	SRC4_CLK_OP_I	SRC0 or SRC4 Clock Output
	IN2	SRC1_CLK_IP_I	SRC5_CLK_IP_I	SRC1 or SRC5 Clock Input
	IN3	SRC1_CLK_OP_I	SRC5_CLK_OP_I	SRC1 or SRC5 Clock Output
	IN4	SRC2_CLK_IP_I	SRC6_CLK_IP_I	SRC2 or SRC6 Clock Input
	IN5	SRC2_CLK_OP_I	SRC6_CLK_OP_I	SRC2 or SRC6 Clock Output
DAI_CLK2	IN0	SRC3_CLK_IP_I	SRC7_CLK_IP_I	SRC3 or SRC7 Clock Input
	IN1	SRC3_CLK_OP_I	SRC7_CLK_OP_I	SRC3 or SRC7 Clock Output
	IN2	SPDIF0_TX_CLK_I	SPDIF1_TX_CLK_I	SPDIF0 or SPDIF1 TX Clock
DAI_CLK3	IN5	SPDIF0_TX_HFCLK_I	SPDIF1_TX_HFCLK_I	SPDIF0 or SPDIF1 TX HF Clock
DAI_CLK4	IN0	PCG0_EXTCLKA_I	PCG0_EXTCLKC_I	PCG0 External Clock A or C
	IN1	PCG0_EXTCLKB_I	PCG0_EXTCLKD_I	PCG0 External Clock B or D
	IN3	SPDIF0_TX_EXT_SYNC_I	SPDIF1_TX_EXT_SYNC_I	SPDIF0 or SPDIF1 TX External Sync
	IN4	PCG0_SYNC_CLKA_I	PCG0_SYNC_CLKC_I	PCG0 Sync Clock A or C
	IN5	PCG0_SYNC_CLKB_I	PCG0_SYNC_CLKD_I	PCG0 Sync Clock B or D

Table 33-20: Clock Destination Registers (Group A) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_CLK5	IN0	SPT3_ACLK_I	SPT7_ACLK_I	SPORT3A or SPORT 7A Clock
	IN1	SPT3_BCLK_I	SPT7_BCLK_I	SPORT3B or SPORT 7B Clock

Table 33-21: Data Destination Registers (Group B)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_DAT0	IN0	SPT0_AD0_I	SPT4_AD0_I	SPORT0A or SPORT4A Primary Data
	IN1	SPT0_AD1_I	SPT4_AD1_I	SPORT0A or SPORT4A Secondary Data
	IN2	SPT0_BD0_I	SPT4_BD0_I	SPORT0B or SPORT4B Primary Data
	IN3	SPT0_BD1_I	SPT4_BD1_I	SPORT0B or SPORT4B Secondary Data
	IN4	SPT1_AD0_I	SPT5_AD0_I	SPORT1A or SPORT5A Primary Data
DAI_DAT1	IN0	SPT1_AD1_I	SPT5_AD1_I	SPORT1A or SPORT5A Secondary Data
	IN1	SPT1_BD0_I	SPT5_BD0_I	SPORT1B or SPORT5B Primary Data
	IN2	SPT1_BD1_I	SPT5_BD1_I	SPORT1B or SPORT5B Secondary Data
	IN3	SPT2_AD0_I	SPT6_AD0_I	SPORT2A or SPORT6A Primary Data
	IN4	SPT2_AD1_I	SPT6_AD1_I	SPORT2A or SPORT6A Secondary Data
DAI_DAT2	IN0	SPT2_BD0_I	SPT6_BD0_I	SPORT2B or SPORT6B Primary Data
	IN1	SPT2_BD1_I	SPT6_BD1_I	SPORT2B or SPORT6B Secondary Data
	IN2	SRC0_DAT_IP_I	SRC4_DAT_IP_I	SRC0 or SRC4 Data
	IN3	SRC1_DAT_IP_I	SRC5_DAT_IP_I	SRC1 or SRC5 Data
	IN4	SRC2_DAT_IP_I	SRC6_DAT_IP_I	SRC2 or SRC6 Data

Table 33-21: Data Destination Registers (Group B) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_DAT3	IN0	SRC3_DAT_IP_I	SRC7_DAT_IP_I	SRC3 or SRC7 Data
	IN1	SRC0_DAT_TDM_OP_I	SRC4_DAT_TDM_OP_I	SRC0 or SRC4 TDM output port
	IN2	SRC1_DAT_TDM_OP_I	SRC5_DAT_TDM_OP_I	SRC1 or SRC5 TDM Output port Data
	IN3	SRC2_DAT_TDM_OP_I	SRC6_DAT_TDM_OP_I	SRC2 or SRC6 TDM Output port Data
	IN4	SRC3_DAT_TDM_OP_I	SRC7_DAT_TDM_OP_I	SRC3 or SRC7 TDM Output port Data
DAI_DAT4	IN0	SPDIF0_TX_DAT_I	SPDIF1_TX_DAT_I	SPDIF0 or SPDIF1 serial transmitter Data
DAI_DAT5	IN4	SPDIF0_RX_I	SPDIF1_RX_I	SPDIF0 or SPDIF1 receiver bi-phase Data
DAI_DAT6	IN0	SPT3_AD0_I	SPT7_AD0_I	SPORT3A or SPORT7A Primary Data
	IN1	SPT3_AD1_I	SPT7_AD1_I	SPORT3A or SPORT7A Secondary Data
	IN2	SPT3_BD0_I	SPT7_BD0_I	SPORT3B or SPORT7B Primary Data
	IN3	SPT3_BD1_I	SPT7_BD1_I	SPORT3B or SPORT7B Secondary Data
	IN4	Reserved	Reserved	

Table 33-22: Frame Sync Destination Registers (Group C)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_FS0	IN0	SPT0_AFS_I	SPT4_AFS_I	SPORT0A or SPORT4A Frame Sync
	IN1	SPT0_BFS_I	SPT4_BFS_I	SPORT0B or SPORT4B Frame Sync
	IN2	SPT1_AFS_I	SPT5_AFS_I	SPORT1A or SPORT5A Frame Sync
	IN3	SPT1_BFS_I	SPT5_BFS_I	SPORT1B or SPORT5B Frame Sync
	IN4	SPT2_AFS_I	SPT6_AFS_I	SPORT2A or SPORT6A Frame Sync
	IN5	SPT2_BFS_I	SPT6_BFS_I	SPORT2B or SPORT6B Frame Sync
DAI_FS1	IN0	SRC0_FS_IP_I	SRC4_FS_IP_I	SRC0 or SRC4 Frame Sync Input
	IN1	SRC0_FS_OP_I	SRC4_FS_OP_I	SRC0 or SRC4 Frame Sync Output
	IN2	SRC1_FS_IP_I	SRC5_FS_IP_I	SRC1 or SRC5 Frame Sync Input
	IN3	SRC1_FS_OP_I	SRC5_FS_OP_I	SRC1 or SRC5 Frame Sync Output
	IN4	SRC2_FS_IP_I	SRC6_FS_IP_I	SRC2 or SRC6 Frame Sync Input

Table 33-22: Frame Sync Destination Registers (Group C) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
	IN5	SRC2_FS_OP_I	SRC6_FS_OP_I	SRC2 or SRC6 Frame Sync Output
DAI_FS2	IN0	SRC3_FS_IP_I	SRC7_FS_IP_I	SRC3 or SRC7 Frame Sync Input
	IN1	SRC3_FS_OP_I	SRC7_FS_OP_I	SRC3 or SRC7 Frame Sync Output
	IN2	SPDIF0_TX_FS_I	SPDIF1_TX_FS_I	SPDIF0 or SPDIF1 Transmit Frame Sync
DAI_FS4	IN0	SPT3_AFS_I	SPT7_AFS_I	SPORT3A or SPORT7A Frame Sync
	IN1	SPT3_BFS_I	SPT7_BFS_I	SPORT3B or SPORT7B Frame Sync

Table 33-23: Pin Buffer Assignment Destination Registers (Group D)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_PIN0	IN0	DAI0_PB01_I	DAI1_PB01_I	Pin Buffer 1
	IN1	DAI0_PB02_I	DAI1_PB02_I	Pin Buffer 2
	IN2	DAI0_PB03_I	DAI1_PB03_I	Pin Buffer 3
	IN3	DAI0_PB04_I	DAI1_PB04_I	Pin Buffer 4
DAI_PIN1	IN0	DAI0_PB05_I	DAI1_PB05_I	Pin Buffer 5
	IN1	DAI0_PB06_I	DAI1_PB06_I	Pin Buffer 6
	IN2	DAI0_PB07_I	DAI1_PB07_I	Pin Buffer 7
	IN3	DAI0_PB08_I	DAI1_PB08_I	Pin Buffer 8
DAI_PIN2	IN0	DAI0_PB09_I	DAI1_PB09_I	Pin Buffer 9
	IN1	DAI0_PB10_I	DAI1_PB10_I	Pin Buffer 10
	IN2	DAI0_PB11_I	DAI1_PB11_I	Pin Buffer 11
	IN3	DAI0_PB12_I	DAI1_PB12_I	Pin Buffer 12
DAI_PIN3	IN0	DAI0_PB13_I	DAI1_PB13_I	Pin Buffer 13
	IN1	DAI0_PB14_I	DAI1_PB14_I	Pin Buffer 14
	IN2	DAI0_PB15_I	DAI1_PB15_I	Pin Buffer 15
	IN3	DAI0_PB16_I	DAI1_PB16_I	Pin Buffer 16
DAI_PIN4	IN0	DAI0_PB17_I	DAI1_PB17_I	Pin Buffer 17
	IN1	DAI0_PB18_I	DAI1_PB18_I	Pin Buffer 18
	IN2	DAI0_PB19_I	DAI1_PB19_I	Pin Buffer 19
	IN3	DAI0_PB20_I	DAI1_PB20_I	Pin Buffer 20
	IN4	INV_DAI0_PB19_I	INV_DAI1_PB19_I	Inverted Pin Buffer 19

Table 33-23: Pin Buffer Assignment Destination Registers (Group D) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
	IN5	INV_DAI0_PB20_I	INV_DAI1_PB20_I	Inverted Pin Buffer 20

Table 33-24: Pin Buffer Enable Destination Registers (Group E)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_PBEN0	IN0	DAI0_PBEN01_I	DAI1_PBEN01_I	Pin Buffer 1 Enable
	IN1	DAI0_PBEN02_I	DAI1_PBEN02_I	Pin Buffer 2 Enable
	IN2	DAI0_PBEN03_I	DAI1_PBEN03_I	Pin Buffer 3 Enable
	IN3	DAI0_PBEN04_I	DAI1_PBEN04_I	Pin Buffer 4 Enable
	IN4	DAI0_PBEN05_I	DAI1_PBEN05_I	Pin Buffer 5 Enable
DAI_PBEN1	IN0	DAI0_PBEN06_I	DAI1_PBEN06_I	Pin Buffer 6 Enable
	IN1	DAI0_PBEN07_I	DAI1_PBEN07_I	Pin Buffer 7 Enable
	IN2	DAI0_PBEN08_I	DAI1_PBEN08_I	Pin Buffer 8 Enable
	IN3	DAI0_PBEN09_I	DAI1_PBEN09_I	Pin Buffer 9 Enable
	IN4	DAI0_PBEN10_I	DAI1_PBEN10_I	Pin Buffer 10 Enable
DAI_PBEN2	IN0	DAI0_PBEN11_I	DAI1_PBEN11_I	Pin Buffer 11 Enable
	IN1	DAI0_PBEN12_I	DAI1_PBEN12_I	Pin Buffer 12 Enable
	IN2	DAI0_PBEN13_I	DAI1_PBEN13_I	Pin Buffer 13 Enable
	IN3	DAI0_PBEN14_I	DAI1_PBEN14_I	Pin Buffer 14 Enable
	IN4	DAI0_PBEN15_I	DAI1_PBEN15_I	Pin Buffer 15 Enable
DAI_PBEN3	IN0	DAI0_PBEN16_I	DAI1_PBEN16_I	Pin Buffer 16 Enable
	IN1	DAI0_PBEN17_I	DAI1_PBEN17_I	Pin Buffer 17 Enable
	IN2	DAI0_PBEN18_I	DAI1_PBEN18_I	Pin Buffer 18 Enable
	IN3	DAI0_PBEN19_I	DAI1_PBEN19_I	Pin Buffer 19 Enable
	IN4	DAI0_PBEN20_I	DAI1_PBEN20_I	Pin Buffer 20 Enable

The the ***Miscellaneous Control Registers*** table, DAI_MISCAx_I is an alias name for DAI_INT_x_I.

Table 33-25: Miscellaneous Control Destination Registers (Group F)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_MISC0	IN6	DAI0_MISCA0_I/ DAI0_INT_6_I	DAI1_MISCA0_I/ DAI1_INT_6_I	DAIx miscellaneous A0 input, or DAIx interrupt 28

Table 33-25: Miscellaneous Control Destination Registers (Group F) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
	IN7	DAI0_MISCA1_I/ DAI0_INT_7_I	DAI1_MISCA1_I/ DAI1_INT_7_I	DAIx miscellaneous A1 input, or DAIx interrupt 29
	IN8	DAI0_MISCA2_I/ DAI0_INT_8_I	DAI1_MISCA2_I/ DAI1_INT_8_I	DAIx miscellaneous A2 input, or DAIx interrupt 30
	IN9	DAI0_MISCA3_I/ DAI0_INT_9_I	DAI1_MISCA3_I/ DAI1_INT_9_I	DAIx miscellaneous A3 input, or DAIx interrupt 31
	IN10	DAI0_MISCA4_I	DAI1_MISCA4_I	DAIx miscellaneous A4 input
	IN11	DAI0_MISCA5_I	DAI1_MISCA5_I	DAIx miscellaneous A5 input
	INV10	DAI0_INV_MISCA4_I	DAI1_INV_MISCA4_I	DAIx inverted miscellaneous A4 input
	INV11	DAI0_INV_MISCA5_I	DAI1_INV_MISCA5_I	DAIx inverted miscellaneous A5 input
DAI_MISC1	IN0	DAI0_INT_0	DAI1_INT_0	DAIx interrupt 22
	IN1	DAI0_INT_1	DAI1_INT_1	DAIx interrupt 23
	IN2	DAI0_INT_2	DAI1_INT_2	DAIx interrupt 24
	IN3	DAI0_INT_3	DAI1_INT_3	DAIx interrupt 25
	IN4	DAI0_INT_4	DAI1_INT_4	DAIx interrupt 26
	IN5	DAI0_INT_5	DAI1_INT_5	DAIx interrupt 27

The ***Interrupt Events*** table presents the information for the following registers.

- DAI_IMSK_PRI (Core Interrupt Priority Assignment) register
- DAI_IMSK_FE (Falling-Edge Interrupt Mask) and DAI_IMSK_RE (Rising-Edge Interrupt Mask) registers
- DAI_IRPTL_H (High-Priority Interrupt Latch) and DAI_IRPTL_L (Low-Priority Interrupt Latch) registers
- DAI_IRPTL_HS (Shadow High Interrupt Latch) and DAI_IRPTL_LS (Shadow Low Interrupt Latch) registers

Table 33-26: Interrupt Events

Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
