5V, Rail-to-Rail I/O, Zero-Drift, Programmable Gain Instrumentation Amplifiers

FN8364  
Rev.2.02  
Jun 4, 2020

The [ISL28533](#), [ISL28534](#), [ISL28535](#), [ISL28633](#), [ISL28634](#), and [ISL28635](#) are 5V zero-drift rail-to-rail input/output Programmable Gain Instrumentation Amplifiers (PGIA). These instrumentation amplifiers feature low offset, low noise, low gain error and high CMRR. They are ideal for high precision applications over the wide industrial temperature range.

These instrumentation amplifiers are designed with a unique 2-bit, 3-state logic interface that allows up to 9 selectable gain settings. The ISL2853x single-ended output includes an additional uncommitted zero-drift amplifier, useful to buffer the REF input or used as a precision amplifier. The ISL2863x differential output amplifier includes a reference pin to set the common-mode output voltage to interface with differential input ADCs.

**Applications**

- Pressure and strain gauge transducers
- Weight scales
- Flow sensors
- Biometric: ECG/blood glucose
- Temperature sensors
- Test and measurement
- Data acquisition systems
- Low ohmic current sense

TABLE 1. KEY DIFFERENCES BETWEEN FAMILY OF PARTS

PART NUMBER	OUTPUT	ADDITIONAL UNCOMMITTED OP AMP
ISL28533/34/35	Single-ended	Yes
ISL28633/34/35	Differential	No

**Features**

- Ultra high precision front-end amplifier
- Zero-drift instrumentation amplifier
- Pin selectable 9 gain settings:  $G = 1$  to 1,000
- Rail-to-rail input/output
- Single-ended output (ISL28533, ISL28534, ISL28535)
- Differential output (ISL28633, ISL28634, ISL28635)
- RFI filtered inputs improve EMI rejection
- Single supply ..... 2.5V to 5.5V
- Dual supply .....  $\pm 1.25V$  to  $\pm 2.75V$
- Low input offset .....  $5\mu V$ , Maximum
- Low input offset drift .....  $50nV/^{\circ}C$ , Maximum
- High CMRR .....  $138dB$ ,  $G = 100$
- Low gain error .....  $<0.4\%$ , All Gains, Maximum
- Gain bandwidth ..... 2.3MHz
- Input voltage noise (0.1Hz to 10Hz) .....  $0.4\mu V_{p,p}$
- Operating temperature range .....  $-40^{\circ}C$  to  $+125^{\circ}C$

### NOTES:

1. Add “-T13” suffix for 2.5k unit or “-T7A” suffix for 250 unit Tape and Reel options. See [TB347](#) for details about reel specifications.
2. These Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
3. For Moisture Sensitivity Level (MSL), see device information page for [ISL28533](#), [ISL28534](#), [ISL28535](#), [ISL28633](#), [ISL28634](#), [ISL28635](#). For more information on MSL, see [TB363](#).

## Absolute Maximum Ratings

Supply Voltage V+ to V-	6V
Input Voltage V <sub>IN</sub> to GND	((V-) - 0.3V) to ((V+) + 0.3V)
Input Differential Voltage	V+ to V-
Input Current	5mA
Output Current I <sub>OUT</sub> (10s)	±40mA
Latch-Up	
Class 2 Level	100mA
ESD Rating	
Human Body Model	8kV
Machine Model	700V
Charged Device Model	2kV

## Thermal Information

Thermal Resistance (Typical)	$\theta_{JA}$ (°C/W)	$\theta_{JC}$ (°C/W)
14 Ld TSSOP (Notes 4, 5)	92	30
Maximum Storage Temperature Range	-65°C to +150°C	
Pb-Free Reflow Profile	see <a href="#">TB493</a>	

## Operating Conditions

Temperature Range	-40°C to +125°C
Maximum Junction Temperature	+140°C
Supply Voltage	2.5V (±1.25V) to 5.5V (±2.75V)

**CAUTION:** Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions can adversely impact product reliability and result in failures not covered by warranty.

### NOTES:

- $\theta_{JA}$  is measured with the component mounted on a high effective thermal conductivity test board in free air. See [TB379](#) for details.
- For  $\theta_{JC}$ , the "case temp" location is taken at the package top center.

## Applications Information

### Precision Sensor Amplifier

The ISL2853x and ISL2863x are a family of ultra high precision instrumentation amplifiers. These amplifiers feature zero drift circuitry that provide auto offset voltage correction and noise reduction, delivering very low offset voltage drift of 5nV/°C and a low 1/F noise frequency corner down in the sub Hz range. The instrumentation amplifier integrates precision matched resistors for the front gain stage and the differential second stage, providing very high gain accuracy and excellent CMRR. The precision performance makes these amplifiers ideal for analog sensor front-end, instrumentation and data acquisition applications such as weigh scales, flow sensors and shunt current sensing that require very low noise and high dynamic range.

### SINGLE-ENDED OUTPUT

The ISL28533, ISL28534 and ISL28535 family of parts are differential input, single-ended output instrumentation amplifiers using a three op amp architecture (see Figure 73). The first stage is differential input/differential output and is used to set the gain. The second stage is a difference amplifier, which is used to remove the common-mode voltage from the differential signal. With the integrated gain resistors and the programmable gains, these instrumentation amplifiers require no external components for gain setting and operation.

There is an additional uncommitted zero drift operational amplifier included on the chip. This can be used to drive the REF pin if needed to provide a low impedance to REF. The REF pin is used to shift the output DC reference. Note that on this device the REF input is a resistor that is part of the difference amplifier non-inverting input. To ensure good common-mode rejection in the output stage, the REF pin should be driven by a low impedance source such as the output of amplifier A4. Any parasitic resistance added to the REF pin degrades the common-mode rejection of the difference amplifier.

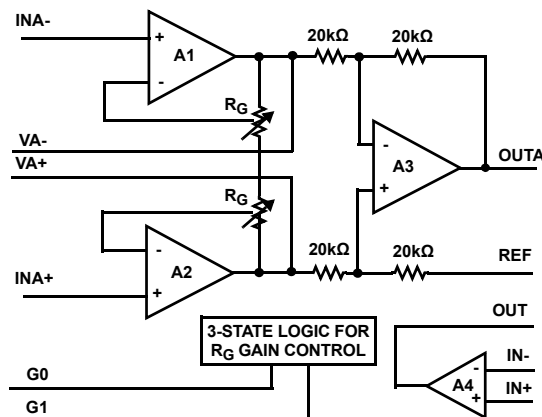

FIGURE 73. ISL2853x BLOCK DIAGRAM

### DIFFERENTIAL OUTPUT

The ISL28633, ISL28634 and ISL28635 family of parts are differential input, differential output instrumentation amplifiers and are ideal as a preamplifier/driver for differential input ADCs

(see Figure 74). With the integrated gain resistors and the programmable gains, these instrumentation amplifiers require no external components for gain setting and operation.

FIGURE 74. ISL2863x BLOCK DIAGRAM

The first stage amplifier is identical to the first stage in the ISL2853x family. The output stage is a difference amplifier, which is configured to provide differential output drive. The REF pin is also available on this device and can be used to provide a DC shift of the output signal. On this device the REF pin is a high impedance input of an operational amplifier. The voltage used to drive this pin can be developed using a resistor divider without the need of an additional buffer without penalty of CMRR degradation.

### RFI FILTER

The instrumentation amplifier inputs of the ISL2853x and ISL2863x have RFI filters for Electro Magnetic Interference (EMI) reduction. In EMI sensitive applications, the high frequency RF signal can appear as a rectified DC offset at the output of precision amplifiers. Because the gain of the precision front-end can be 100 or greater, it is critical not to amplify any conducted or radiated noise that may be present at the amplifier inputs. The RFI input is a 1kΩ, 3pF LPF with a corner frequency of approximately 50MHz (see Figure 75).

FIGURE 75. RFI FILTER INPUTS

### GAIN STAGE OUTPUT VA+/VA- PINS

The ISL2853x and ISL2863x instrumentation amplifiers include pinouts for the output of the differential gain stage. VA+ is referenced to the non-inverting input of the difference amplifier while VA- is referenced to the inverting input. These pins can be

used for measuring the input common-mode voltage for sensor feedback and health monitoring. The differential gain stage output pins VA+ and VA- buffers the input common-mode voltage while amplifying differential voltage. By tying two resistors across VA+ and VA-, the buffered input common-mode voltage is extracted at the midpoint of the resistors (see Figure 76). This voltage can be sent to an ADC for sensor monitoring or feedback control, improving the precision and accuracy of the sensor.

$VA+ = V_{cm} + V_{dm}/2$   
 $VA- = V_{cm} - V_{dm}/2$   
 $V_x = [(VA+) + (VA-)] / 2$   
 $V_x = V_{cm}$

FIGURE 76. COMMON-MODE SENSING WITH VA+/VA- PINS

**PROGRAMMABLE GAIN LOGIC**

The ISL2853x and ISL2863x feature a three-state logic interface for digital programming of the amplifier gain. This allows the PGIa’s gain to be changed without an external gain setting resistors, improving the gain accuracy and reducing component count.

The three-state logic pins have voltage levels for recognizing valid logic states to set the gain of the amplifier (see Figure 77). With three logic states per input, this allows nine gain settings with just two digital input pins (see Table 3).

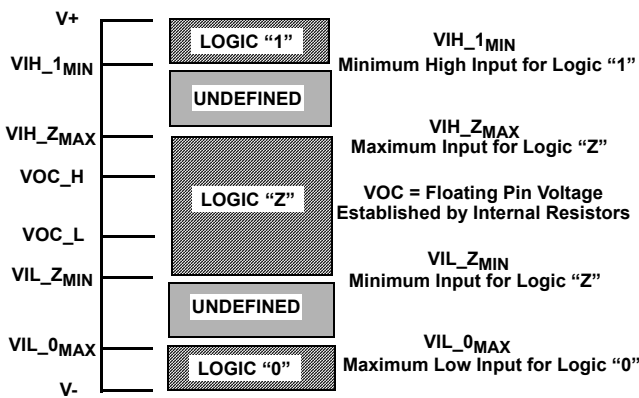

FIGURE 77. G0/G1 LOGIC THRESHOLD LEVELS

Logic states of the G0/G1 pins can be achieved by simple pin-strapping to the supply rails for logic HI/LOW, or may be left floating for logic Z. Internal resistors on the G0/G1 pins set the logic level to mid-supply for logic Z. Alternatively a microcontroller can be used to drive the pins HI/LOW or they may be left in a High-Z state. The VIH, VIL and logic Z threshold levels

are TTL/CMOS compatible for single 5V and 3V supplies. See Table 2 for logic threshold levels.

It is important to note that logic threshold levels are referenced to the V- negative supply rail of the amplifier. For dual supply operation of the instrumentation amplifier logic threshold levels are shifted by the magnitude of V-. Externally driven logic signals require level shifting to properly set amplifier gain.

TABLE 2. LOGIC THRESHOLD VALUES

G0/G1	PARAMETER	THRESHOLD VOLTAGE	+5VDC	+3VDC
1	VIH_1_MIN	0.8*Vs	4V	2.4V

1	Z	50	500	500
1	1	100	1000	1000

**GAIN SETTING WITH DCP**

For applications without a tri-state driver the alternative solution for programmable switching the 9 gain settings is to use a DCP. Using a Dual DCP implements the capability to select all 9 gains with an I<sup>2</sup>C/SPI bus interface, saving valuable GPIO lines. The ISL23328 is a dual 128 tap DCP that can switch the G0 and G1 pins with an I<sup>2</sup>C interface (see Figure 78). The wiper of the DCP can be swept from V+ to V- in 128 steps.

FIGURE 78. GAIN SWITCHING WITH ISL23328 DCP

## GAIN SWITCHING DELAY TIME

The G0 and G1 pins change the gain setting of the PGIA. For applications that must switch gains at high frequency, consider that there is a gain switching propagation delay of  $\sim 1\mu\text{s}$  before output response. The total response time for a gain change must also include the amplifier output settling time. See “Electrical Specifications” on [page 8](#) for output settling time.

## DUAL SUPPLY OPERATION

ISL2853x and ISL2863x typical applications utilize single supply operation. The single supply range is from 2.5V to 5V, but the amplifiers can also operate with split supplies from  $\pm 1.25\text{V}$  to  $\pm 2.5\text{V}$ . The G0 and G1 logic thresholds are referenced to the most negative supply rail (V-), therefore a logic level shifter is needed in split supply applications when the G0 and G1 pins are not strapped to the amplifier supply pins (i.e., when driven by a single supply logic device).

## POWER SUPPLY AND REF PIN SEQUENCING

As the REF pin in some applications is tied to a high accuracy voltage reference VREF (such as the ISL21090), proper care must be taken that the voltage at REF does not come up prior to supply voltages V+ and V-. The REF pin ESD protection diodes will be forward biased when the voltage at REF exceeds V+ or V- by more than 0.3V. For applications where REF must be present before V+ or V-, it is recommended to use the ISL2863x family of PGIA. As the REF pin is an very high impedance input, having a series resistance to limit the ESD diode current will not severely impact CMRR performance. Typically a 1k $\Omega$  resistor will adequately limit this current.

## COMMON-MODE INPUT RANGE

The 3-op amp instrumentation amplifier architecture amplifies differential input voltage. The common-mode voltage is removed by the difference amplifier at the second stage. Consideration of input common-mode and differential voltage must be taken to not saturate the output of the A1 and A2 amplifiers. This is a common mistake when input differential voltages plus the input  $V_{\text{CM}}$  combined is large enough to saturate the output. The PGIA features rail to rail output amplifiers to maximize output dynamic range thus signals VA+, VA- and VOUT+/VOUT- can drive near the supply rails. [Figures 17](#) through [20](#) give the typical input common-mode voltage range vs output voltage for different REF voltages.

## Application Circuits

Typical application circuits for bridge sensor health monitor and active shield guard driver are shown in [Figures 79](#) and [80](#).

### Sensor Health Monitor

A bridge type sensor uses four matched resistive elements to create a balanced differential circuit. The bridge can be a combination of discrete resistors and resistive sensors for a quarter, half and full bridge applications. The bridge is excited by a low noise, high accuracy voltage reference or current source on two legs. The other two legs are the differential signal whose output voltage change is analogous to changes in the sensed environment. In a bridge circuit, the common-mode voltage of the differential signal is at the mid point potential voltage of the bridge

excitation source. For example in a single supply system using a +5V reference for excitation, the common-mode voltage is +2.5V.

The concept of sensor health monitoring is to keep track of the bridge impedance within the data acquisition system. Changes in the environment, degradation over time or a faulty bridge resistive element will imbalance the bridge, causing measurement errors. Since the bridge differential output common-mode voltage is one-half the excitation voltage, by measuring this common mode the sensor impedance health can be monitored, for example through an ADC channel (see [Figure 79 on page 28](#)). While common-mode voltage can be measured directly off the bridge, this is not recommended because the bridge impedance is highly sensitive to any additional loading. Sensing off the legs directly can give an erroneous reading of the analog signal being measured. Since the VA+ and VA- pins buffer the input common-mode voltage, this provides a low impedance point to drive the ADC without using additional amplifiers. By continuously monitoring the common-mode voltage this gives an indication of sensor health.

### Active Shield Guard Drive

Sensors that operate at far distances from the signal conditioning circuits are subject to noise environments that reduce the signal to noise ratio into an amplifier. Differential signaling and shielded cables are a few techniques that are used to reduce noise from sensitive signal lines. Reducing noise that the instrumentation amplifier cannot reject (high frequency noise or common-mode voltage levels beyond supply rail) improves measuring accuracy. Shielded cables offer excellent rejection of noise coupling into signal lines. However, cable impedance mismatch to signal wires form a common-mode error into the amplifier. Driving the cable shield to a low impedance potential reduces the impedance mismatch. The cable shield is usually tied to chassis ground as it makes an excellent low impedance point and is easily accessible. However, this may not always be the best potential voltage to tie the shield to, in particular for single supply amplifiers.

In some data acquisition systems the sensor signal amplifiers are powered with dual supplies ( $\pm 5\text{V}$  or  $\pm 12\text{V}$ ). By tying the shield to analog ground 0V, this places the common-mode voltage of the shield right at the middle of the supply bias - where the amplifiers operate with the best CMR performance. With single supply amplifiers becoming more popular choice as a sensor amplifier, shield at 0V is now at the lower power supply rail of the amplifier - typically a common-mode voltage where the same CMR performance degrades. Tying the shield at common-mode voltage of mid supply rail is most applicable for high impedance sensor applications.

An alternative solution for an improved shield guard drive is to use the VA+ and VA- pins for sensing common-mode and driving the shield to this voltage (see [Figure 80 on page 28](#)). Using the VA+ and VA- pins generate a low impedance reference of the input common-mode voltage. Driving the shield to the input common-mode voltage reduces cable impedance mismatch and improves CMR performance in single supply sensor applications. For further buffering of the shield driver, the additional unused op amp on the ISL2853x products can be used, reducing the need of adding an external amplifier.

## Revision History

The revision history provided is for informational purposes only and is believed to be accurate, but not warranted. Please go to the web to make sure that you have the latest revision.

DATE	REVISION	CHANGE
Jun 4, 2020	2.02	Added Figures 21 and 22.
Apr 9, 2020	2.01	Updated Related Literature section Updated pin configurations Updated Figures 1 -4. Removed About Intersil Updated Disclaimer
Jan 21, 2017	2.00	Removed DAQ on a stick application note reference from pages 1 and 4. Added Table of differences on page 1. Updated "Ordering Information" on page 5 by adding tape and reel options to note. Updated "About Intersil" verbiage.
Nov 22, 2013	1.00	Ordering information table on page 5: Removed "coming soon" for ISL28535FVZ and ISL28635FVZ and Evaluation boards.
Sep 24, 2013	0.00	Initial Release

# Package Outline Drawing

M14.173

14 LEAD THIN SHRINK SMALL OUTLINE PACKAGE (TSSOP)

Rev 3, 10/09

**NOTES:**

1. Dimension does not include mold flash, protrusions or gate burrs. Mold flash, protrusions or gate burrs shall not exceed 0.15 per side.
2. Dimension does not include interlead flash or protrusion. Interlead flash or protrusion shall not exceed 0.25 per side.
3. Dimensions are measured at datum plane H.
4. Dimensioning and tolerancing per ASME Y14.5M-1994.
5. Dimension does not include dambar protrusion. Allowable protrusion shall be 0.80mm total in excess of dimension at maximum material condition. Minimum space between protrusion and adjacent lead is 0.07mm.
6. Dimension in ( ) are for reference only.
7. Conforms to JEDEC MO-153, variation AB-1.
