

FEATURES

Supply range

2.8 V to 15 V, ADR291

4.4 V to 15 V, ADR292

Supply current: 15 μ A maximum

Low noise: 8 μ V and 12 μ V p-p (0.1 Hz to 10 Hz)

High output current: 5 mA

Temperature range: -40°C to $+125^{\circ}\text{C}$

Pin-compatible with REF02/REF19x

APPLICATIONS

Portable instrumentation

Precision reference for 3 V and 5 V systems

Analog-to-digital and digital-to-analog converter reference

Solar-powered applications

Loop-current-powered instruments

GENERAL DESCRIPTION

The ADR291 and ADR292 are low noise, micropower precision voltage references that use an XFET[®] reference circuit. The new XFET architecture offers significant performance improvements over traditional band gap and buried Zener-based references. Improvements include one quarter the voltage noise output of band gap references operating at the same current, very low and ultralinear temperature drift, low thermal hysteresis, and excellent long-term stability.

The ADR291/ADR292 family is a series of voltage references providing stable and accurate output voltages from supplies as low as 2.8 V for the ADR291. Output voltage options are 2.5 V and 4.096 V for the ADR291 and ADR292, respectively.

Quiescent current is only 12 μ A, making these devices ideal for battery-powered instrumentation. Three electrical grades are available offering initial output accuracies of ± 2 mV, ± 3 mV, and ± 6 mV maximum for the ADR291, and ± 3 mV, ± 4 mV, and ± 6 mV maximum for the ADR292. Temperature

coefficients for the three grades are 8 ppm/ $^{\circ}\text{C}$, 15 ppm/ $^{\circ}\text{C}$, and 25 ppm/ $^{\circ}\text{C}$ maximum, respectively. Line regulation and load regulation are typically 30 ppm/V and 30 ppm/mA, maintaining the reference's overall high performance. For a device with 5.0 V output, refer to the ADR293 data sheet.

The ADR291 and ADR292 references are specified over the extended industrial temperature range of -40°C to $+125^{\circ}\text{C}$. Devices are available in the 8-lead SOIC, 8-lead TSSOP, and 3-lead TO-92 packages.

Table 1. ADR291/ADR292 Product

| Part No. | Output Voltage (V) | Initial Accuracy ($\pm\%$) | Temperature Coefficient (ppm/ $^{\circ}\text{C}$) Max |
|----------|--------------------|------------------------------|--|
| ADR291 | 2.500 | 0.08, 0.12, 0.24 | 8, 15, 25 |
| ADR292 | 4.096 | 0.07, 0.10, 0.15 | 8, 15, 25 |

ABSOLUTE MAXIMUM RATINGS

Remove power before inserting or removing units from their sockets.

Table 8.

| Parameter | Rating |
|---|-----------------|
| Supply Voltage | 18 V |
| Output Short-Circuit Duration to GND | Indefinite |
| Storage Temperature Range T, R, RU Packages | -65°C to +150°C |
| Operating Temperature Range ADR291/ADR292 | -40°C to +125°C |
| Junction Temperature Range T, R, RU Packages | -65°C to +125°C |
| Lead Temperature (Soldering, 60 sec) | 300°C |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 9. Package Types

| Package Type | θ_{JA}^1 | θ_{JC} | Unit |
|-------------------|-----------------|---------------|------|
| 8-Lead SOIC (R) | 158 | 43 | °C/W |
| 8-Lead TSSOP (RU) | 240 | 43 | °C/W |
| 3-Lead TO-92 (T) | 160 | - | °C/W |

¹ θ_{JA} is specified for worst-case conditions. For example, θ_{JA} is specified for a device in socket testing. In practice, θ_{JA} is specified for a device soldered in the circuit board.

Table 10. Other XFET Products

| Part Number | Nominal Output Voltage (V) | Package Type |
|------------------------|----------------------------|------------------|
| ADR420 | 2.048 | 8-Lead MSOP/SOIC |
| ADR421 | 2.50 | 8-Lead MSOP/SOIC |
| ADR423 | 3.0 | 8-Lead MSOP/SOIC |
| ADR425 | 5.0 | 8-Lead MSOP/SOIC |

ESD CAUTION

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

TERMINOLOGY

Line Regulation

Line regulation refers to the change in output voltage due to a specified change in input voltage. It includes the effects of self-heating. Line regulation is expressed as percent-per-volt, parts-per-million-per-volt, or microvolts-per-volt change in input voltage.

Load Regulation

The change in output voltage is due to a specified change in load current and includes the effects of self-heating. Load regulation is expressed in microvolts-per-milliampere, parts-per-million-per-milliampere, or ohms of dc output resistance.

Long-Term Stability

Long-term stability refers to the typical shift of output voltage at 25°C on a sample of parts subjected to a test of 1000 hours at 125°C.

$$\Delta V_{OUT} = V_{OUT}(t_0) - V_{OUT}(t_1)$$

$$\Delta V_{OUT} [\text{ppm}] = \frac{V_{OUT}(t_0) - V_{OUT}(t_1)}{V_{OUT}(t_0)} \times 10^6$$

where:

$V_{OUT}(t_0)$ = V_{OUT} at 25°C at Time 0.

$V_{OUT}(t_1)$ = V_{OUT} at 25°C after 1000 hours of operation at 125°C.

Temperature Coefficient

Temperature coefficient is the change of output voltage over the operating temperature change, normalized by the output voltage at 25°C, expressed in ppm/°C. The equation follows:

$$TCV_o [\text{ppm}/^\circ\text{C}] = \frac{V_o(T_2) - V_o(T_1)}{V_o(25^\circ\text{C}) \times (T_2 - T_1)} \times 10^6$$

where:

$V_{OUT}(25^\circ\text{C})$ = V_{OUT} at 25°C.

$V_{OUT}(T_1)$ = V_{OUT} at Temperature 1.

$V_{OUT}(T_2)$ = V_{OUT} at Temperature 2.

NC = no connect.

There are internal connections at NC pins that are reserved for manufacturing purposes. Users should not connect anything at the NC pins.

Thermal Hysteresis

Thermal hysteresis is defined as the change of output voltage after the device is cycled through temperatures from +25°C to -40°C, then to +85°C, and back to +25°C. This is a typical value from a sample of parts put through such a cycle.

$$V_{OUT-HYS} = V_{OUT}(25^\circ\text{C}) - V_{OUT_TC}$$

$$V_{OUT-HYS} [\text{ppm}] = \frac{V_{OUT}(25^\circ\text{C}) - V_{OUT_TC}}{V_{OUT}(25^\circ\text{C})} \times 10^6$$

where:

$V_{OUT}(25^\circ\text{C})$ = V_{OUT} at 25°C.

V_{OUT_TC} = V_{OUT} at 25°C after temperature cycle from +25°C to -40°C, then to +85°C, and back to +25°C.

THEORY OF OPERATION

The ADR291/ADR292 series of references uses a reference generation technique known as XFET (eXtra implanted junction FET). This technique yields a reference with low noise, low supply current, and very low thermal hysteresis.

The core of the XFET reference consists of two junction field effect transistors, one having an extra channel implant to raise its pinch-off voltage. By running the two JFETs at the same drain current, the difference in pinch-off voltage can be amplified and used to form a highly stable voltage reference. The intrinsic reference voltage is around 0.5 V with a negative temperature coefficient of about -120 ppm/K. This slope is essentially locked to the dielectric constant of silicon and can be closely compensated by adding a correction term generated in the same fashion as the proportional-to-temperature (PTAT) term used to compensate band gap references. Because most of the noise of a band gap reference comes from the compensation circuitry, the intrinsic temperature coefficient offers a significant advantage (being about 30 times lower), and therefore, requiring less correction resulting in much lower noise.

The simplified schematic in Figure 31 shows the basic topology of the ADR291/ADR292 series. The temperature correction term is provided by a current source with a value designed to be proportional to absolute temperature. The general equation is

$$V_{OUT} = \Delta V_P \left(\frac{R1 + R2 + R3}{R1} \right) + (I_{PTAT})(R3)$$

where:

ΔV_P is the difference in pinch-off voltage between the two FETs.
 I_{PTAT} is the positive temperature coefficient correction current.

The various versions of the ADR291/ADR292 family are created by on-chip adjustment of R1 and R3 to achieve 2.500 V or 4.096 V at the reference output.

The process used for the XFET reference also features vertical NPN and PNP transistors, the latter of which are used as output devices to provide a very low dropout voltage.

Figure 31. ADR291/ADR292 Simplified Schematic

DEVICE POWER DISSIPATION CONSIDERATIONS

The ADR291/ADR292 family of references is guaranteed to deliver load currents to 5 mA with an input voltage that ranges from 2.7 V to 15 V (minimum supply voltage depends on the output voltage chosen). When these devices are used in applications with large input voltages, care should be exercised to avoid exceeding the published specifications for maximum power dissipation or junction temperature that could result in premature device failure. Use the following formula to calculate maximum junction temperature or dissipation of a device:

$$P_D = \frac{T_J - T_A}{\theta_{JA}}$$

where

T_J and T_A are the junction and ambient temperatures, respectively.

P_D is the device power dissipation.

θ_{JA} is the device package thermal resistance.

BASIC VOLTAGE REFERENCE CONNECTIONS

References, in general, require a bypass capacitor connected from the V_{OUT} pin to the GND pin. The circuit in Figure 32 illustrates the basic configuration for the ADR291/ADR292 family of references. Note that the decoupling capacitors are not required for circuit stability.

Figure 32. Basic Voltage Reference Configuration

NOISE PERFORMANCE

The noise generated by the ADR291/ADR292 family of references is typically less than 12 µV p-p over the 0.1 Hz to 10 Hz band. The noise measurement is made with a band-pass filter made of a 2-pole high-pass filter with a corner frequency at 0.1 Hz and a 2-pole low-pass filter with a corner frequency at 10 Hz.

TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. Two components normally associated with this are the time it takes for the active circuits to settle and for the thermal gradients on the chip to stabilize. Figure 28 shows the turn-on settling time for the ADR291.

ADR291/ADR292

APPLICATIONS INFORMATION

HIGH VOLTAGE FLOATING CURRENT SOURCE

The circuit shown in Figure 33 can be used to generate a floating current source with minimal self-heating. This particular configuration operates on high supply voltages determined by the breakdown voltage of the N-channel JFET.

Figure 33. High Voltage Floating Current Source

KELVIN CONNECTIONS

In many portable instrumentation applications, the PC board area is directly related to cost; therefore, circuit interconnects are reduced to a minimal width. These narrow lines can cause large voltage drops if the voltage reference is required to provide load currents to various functions. In fact, circuit interconnects can exhibit a typical line resistance of 0.45 mΩ/square (1 oz. Cu, for example). Force and sense connections, also referred to as Kelvin connections, offer a convenient method of eliminating the effects of voltage drops in circuit wires. Load currents flowing through wiring resistance produce an error ($V_{\text{ERROR}} = R \times I_L$) at the load. However, the Kelvin connection shown in Figure 34 overcomes the problem by including the wiring resistance within the forcing loop of the op amp. Since the op amp senses the load voltage, the op amp loop control forces the output to compensate for the wiring error producing the correct voltage at the load.

Figure 34. Advantage of Kelvin Connection

LOW POWER, LOW VOLTAGE REFERENCE FOR DATA CONVERTERS

The ADR291/ADR292 family has a number of features that makes it ideally suited for use with analog-to-digital and digital-to-analog converters. Because of its low supply voltage, the ADR291 can be used with converters that run on 3 V supplies without having to add a higher supply voltage for the reference. The low quiescent current (12 μA maximum) and low noise, tight temperature coefficient, combined with the high accuracy of the ADR291/ADR292, make it ideal for low power applications such as handheld, battery-operated equipment.

One such ADC for which the ADR291 is well suited is the AD7701. Figure 35 shows the ADR291 used as the reference for this converter. The AD7701 is a 16-bit ADC with on-chip digital filtering intended for the measurement of wide dynamic range, low frequency signals such as those representing chemical, physical, or biological processes. It contains a charge balancing (Σ - Δ) ADC, calibration microcontroller with on-chip static RAM, a clock oscillator, and a serial communications port.

This entire circuit runs on ± 5 V supplies. The power dissipation of the AD7701 is typically 25 mW and, when

combined with the power dissipation of the ADR291 (60 μW), the entire circuit still consumes about 25 mW.

Figure 35. Low Power, Low Voltage Supply Reference for the AD7701

VOLTAGE REGULATOR FOR PORTABLE EQUIPMENT

The ADR291/ADR292 family of references is ideal for providing a stable, low cost, and low power reference voltage in portable equipment power supplies. Figure 36 shows how the ADR291 and ADR292 can be used in a voltage regulator that not only has low output noise (as compared to switch mode design) and low power, but also a very fast recovery after current surges. Some precautions should be taken in the selection of the output capacitors. Too high an ESR (effective series resistance) could endanger the stability of the circuit. A solid tantalum capacitor, 16 V or higher, and an aluminum electrolytic capacitor, 10 V or higher, are recommended for C1 and C2, respectively. Also, the path from the ground side of C1 and C2 to the ground side of R1 should be kept as short as possible.
