## Industrial Photovoltaic MOSFET Driver

### Description

The Broadcom<sup>®</sup> industrial ACPL-K308U photovoltaic driver is designed to drive high voltage MOSFETs. It consists of an AlGaAs infrared light-emitting diode (LED) input stage optically coupled to an output detector circuit. The detector consists of a high-speed photovoltaic diode array and a turn-off circuit. This photovoltaic driver turns on (contact closes) with a minimum input current of 5 mA through the input LED. It turns off (contact opens) with an input voltage of 0.8V or less.

The ACPL-K308U is available in the stretched SO-8 package outline footprint with a minimum of 8 mm (clearance/creepage). It is ideal for fast turn on and turn off in inrush current prevention and insulation resistance measurement and leakage current detection.

**Figure 1: Functional Diagram**

### Features

- 8-mm creepage and clearance in a compact SSO-8 package
- Operating temperature range:  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$
- Photovoltaic driver for high-voltage MOSFETs in a solid state relay application
- Open circuit voltage: 8.2V typical at  $I_F = 10\text{ mA}$
- Short circuit current: 70  $\mu\text{A}$  typical at  $I_F = 10\text{ mA}$
- Logic circuit compatibility
- Switching speed (typical): 50  $\mu\text{s}$  ( $T_{\text{ON}}$ ), 23  $\mu\text{s}$  ( $T_{\text{OFF}}$ ) at  $I_F = 10\text{ mA}$ ,  $C_L = 1\text{ nF}$
- Configurable to wide portfolio of high-voltage MOSFETs
- Galvanic isolation
- High input-to-output insulation voltage
- Safety and regulatory approvals
  - IEC/EN/DIN EN 60747-5-5, maximum working insulation voltage 1140  $V_{\text{PEAK}}$
  - 5000  $V_{\text{rms}}$  for 1 minute per UL1577
  - CSA component acceptance

### Applications

- Solid state relay module
- Inrush current prevention
- Insulation resistance measurement in battery system, solar PV inverters; EV charging system; motor winding insulation

## Application Information

The ACPL-K308U industrial photovoltaic (PV) driver is a device that is paired with MOSFETs to form basic building block of several types of application. It consists of an AlGaAs LED input that is optically coupled to a photovoltaic diode array. This becomes a voltage source with galvanic isolation. The advantage of photovoltaic driver is its simple design that does not require bias supply.

## Basic Construction

As shown in Figure 12, the input side of the PV driver is LED driven. A current limiting resistor is required to limit the current through the LED. Recommended input forward current is 5 mA to 10 mA. The LED is optically coupled through a photodiode stack (D1 to D12) consisting of 12 photodiodes connected in series. When current is driven into the light-emitting diode (LED) on the input side, the light from the LED generates photo current on the string of photodiodes to charge the gate of the MOSFETs, generating a photo-voltage proportional to the number of photodiodes, to switch and keep the power device on.

Figure 12: Basic Construction of Photovoltaic Driver

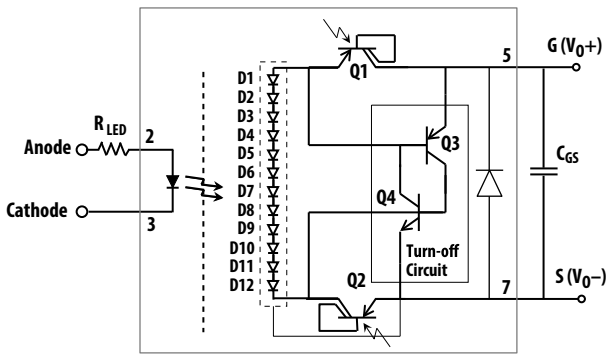

Figure 13: Photovoltaic Driver + Single External MOSFET

## PV Driver and MOSFET Configurations

The photovoltaic driver is a device that is combined with high voltage MOSFETs to form a solid-state relay. The photovoltaic driver can be configured with a single MOSFET or two MOSFETs (back-to-back) for bidirectional application. Pin 5 is connected to the Gate, and Pin 7 is connected to the Source. Figure 13 and Figure 14 are sample application circuits for the two configurations.

## Turn-Off Circuit

The photovoltaic driver has a built in turn-off circuit, which decreases the turn-off time. This circuit instantaneously discharges the gate capacitance of MOSFETs when the photovoltaic driver is turned off. The turn-off circuit is activated when the photovoltaic voltage is collapsing.

The sequence of operation of the turn-off circuit:

When LED is ON:

1. Q1 and Q2 are saturated.
2. SCR (Q3 and Q4) is disabled.
3. Photodiode array is connected to Gate and Source.

When LED is OFF:

1. Q1 and Q2 cease to conduct.
2. Photodiode array is disconnected from Gate and Source.
3. SCR (Q3 and Q4) is triggered and Gate capacitance (C<sub>GS</sub>) is discharged rapidly.

Figure 14: Photovoltaic Driver + Two Back-to-Back MOSFETs

## V<sub>OC</sub> and MOSFET V<sub>GS(TH)</sub>

ACPL-K308U has typical V<sub>OC</sub> of 8.2V and minimum V<sub>OC</sub> of 5.8V at 125°C. This is sufficient to drive most logic gate level MOSFETs, with threshold voltages V<sub>GS(TH)</sub> of 4V or less. The V<sub>OC</sub> has a typical temperature coefficient of -18 mV/°C. To serve as a guide in the design at different temperatures, Figure 15 shows the ACPL-K308U's minimum V<sub>OC</sub> vs. the MOSFET's maximum V<sub>GS(TH)</sub>.

Figure 15: V<sub>OC</sub> Minimum vs. MOSFET V<sub>GS(TH)</sub> Maximum

## Two PV Drivers in Series

For high-voltage MOSFETs that require higher V<sub>GS(TH)</sub>, two ACPL-K308U devices can be connected in series.

Figure 16 shows the connection for this configuration. Two PV drivers in series will give 2× higher V<sub>OC</sub> (Typical = 16V) compared with a single PV driver.

## Thermal Resistance Model for ACPL-K308U

The diagram of ACPL-K308U for measurement is shown in [Figure 17](#). Here, one die is heated first and the temperatures of all the dice are recorded after thermal equilibrium is reached. Then, the second die is heated and all the dice temperatures are recorded. With the known ambient temperature, the die junction temperature and power dissipation, the thermal resistance can be calculated. The thermal resistance calculation can be cast in matrix form. This yields a 2 by 2 matrix for our case of two heat sources.

$$\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} \cdot \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} = \begin{bmatrix} \Delta T_1 \\ \Delta T_2 \end{bmatrix}$$

$R_{12}$ : Thermal Resistance of Die1 due to heating of Die2.

$R_{21}$ : Thermal Resistance of Die2 due to heating of Die1.

$R_{22}$ : Thermal Resistance of Die2 due to heating of Die2.

$P_1$ : Power dissipation of Die1 (W).

$P_2$ : Power dissipation of Die2 (W).

$T_1$ : Junction temperature of Die1 due to heat from all dice (°C).

$T_2$ : Junction temperature of Die2 due to heat from all dice.

$T_A$ : Ambient temperature.

$\Delta T_1$ : Temperature difference between Die1 junction and ambient (°C).

$\Delta T_2$ : Temperature difference between Die2 junction and ambient (°C).

$$T_1 = R_{11} \times P_1 + R_{12} \times P_2 + T_A$$

$$T_2 = R_{21} \times P_1 + R_{22} \times P_2 + T_A$$
