<sup>1</sup>Guaranteed by design and characterization, not 100% tested in production.

<sup>2</sup> Measured from differential waveform

<sup>3</sup> Slew rate is measured through the Vswing voltage range centered around differential 0V. This results in a +/-150mV window around differential 0V.

<sup>4</sup> Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a +/-75mV window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations.

<sup>5</sup> Vcross is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

<sup>6</sup> The total variation of all Vcross measurements in any particular system. Note that this is a subset of Vcross\_min/max (Vcross absolute) allowed. The intent is to limit Vcross induced modulation by setting  $\Delta$ -Vcross to be smaller than Vcross absolute.

<sup>7</sup> At default SMBus settings.

<sup>8</sup> If driving a receiver with input terminations, the Vmax and Vmin values will be halved.

<sup>1</sup> Applies to all outputs, when driven by 9SQL4958 or equivalent

<sup>2</sup> Based on PCIe Base Specification Rev3.1a. These filters are different than Common Clock filters. See <http://www.pcisig.com> for latest specifications. 0.7ps is the Intel specified limit, which may differ from the PCI SIG limit.

<sup>3</sup> Sample size of at least 100K cycles. This figure extrapolates to 108ps pk-pk at 1M cycles for a BER of  $1^{-12}$ .

<sup>4</sup> For RMS values, additive jitter is calculated by solving the following equation for b [ $a^2 + b^2 = c^2$ ] where "a" is rms input jitter and "c" is rms total jitter.

<sup>5</sup> SRIS is not currently defined for PCIe Gen1 and Gen4.
