## Introduction

The Atmel ${ }^{\circledR}$ ATmega32A is a low-power CMOS 8-bit microcontroller based on the AVR ${ }^{\circledR}$ enhanced RISC architecture. By executing powerful instructions in a single clock cycle, the ATmega32A achieves throughputs close to 1 MIPS per MHz. This empowers system designer to optimize the device for power consumption versus processing speed.

## Features

- High-performance, Low-power Atmel AVR 8-bit Microcontroller
- Advanced RISC Architecture
- 131 Powerful Instructions - Most Single-clock Cycle Execution
- $32 \times 8$ General Purpose Working Registers
- Fully Static Operation
- Up to 16MIPS Throughput at 16 MHz
- On-chip 2-cycle Multiplier
- High Endurance Non-volatile Memory segments
- 32Kbytes of In-System Self-programmable Flash program memory
- 1024Bytes EEPROM
- 2Kbytes Internal SRAM
- Write/Erase cycles: 10,000 Flash/100,000 EEPROM
- Data retention: 20 years at $85^{\circ} \mathrm{C} / 100$ years at $25^{\circ} \mathrm{C}^{(1)}$
- Optional Boot Code Section with Independent Lock Bits
- In-System Programming by On-chip Boot Program
- True Read-While-Write Operation
- Programming Lock for Software Security
- JTAG (IEEE std. 1149.1 Compliant) Interface
- Boundary-scan Capabilities According to the JTAG Standard
- Extensive On-chip Debug Support
- Programming of Flash, EEPROM, Fuses and Lock Bits through the JTAG Interface
- Atmel QTouch ${ }^{\circledR}$ library support
- Capacitive touch buttons, sliders and wheels
- Atmel QTouch and QMatrix acquisition
- Up to 64 sense channels
- Peripheral Features
- Two 8-bit Timer/Counters with Separate Prescalers and Compare Modes
- One 16-bit Timer/Counter with Separate Prescaler, Compare Mode, and Capture Mode
- Real Time Counter with Separate Oscillator
- Four PWM Channels
- 8-channel, 10-bit ADC
- 8 Single-ended Channels
- 7 Differential Channels in TQFP Package Only
- 2 Differential Channels with Programmable Gain at 1x, 10x, or $200 x$
- Byte-oriented Two-wire Serial Interface
- Programmable Serial USART
- Master/Slave SPI Serial Interface
- Programmable Watchdog Timer with On-chip Oscillator
- On-chip Analog Comparator
- Special Microcontroller Features
- Power-on Reset and Programmable Brown-out Detection
- Internal Calibrated RC Oscillator
- External and Internal Interrupt Sources
- Six Sleep Modes: Idle, ADC Noise Reduction, Power-save, Power-down, Standby, and Extended Standby
- I/O and Packages
- 32 Programmable I/O Lines
- 40-pin PDIP, 44-lead TQFP, and 44-pad QFN/MLF
- Operating Voltages
- $2.7-5.5 \mathrm{~V}$
- Speed Grades
- $0-16 \mathrm{MHz}$
- Power Consumption at $1 \mathrm{MHz}, 3 \mathrm{~V}, 25^{\circ} \mathrm{C}$
- Active: 0.6 mA
- Idle Mode: 0.2mA
- Power-down Mode: < $1 \mu \mathrm{~A}$

## 1. Description

The AVR core combines a rich instruction set with 32 general purpose working registers. All the 32 registers are directly connected to the Arithmetic Logic Unit (ALU), allowing two independent registers to be accessed in one single instruction executed in one clock cycle. The resulting architecture is more code efficient while achieving throughputs up to ten times faster than conventional CISC microcontrollers.

The ATmega32A provides the following features: 32Kbytes of In-System Programmable Flash Program memory with Read-While-Write capabilities, 1024bytes EEPROM, 2048bytes SRAM, 32 general purpose I/O lines, 32 general purpose working registers, a JTAG interface for Boundary-scan, On-chip Debugging support and programming, three flexible Timer/Counters with compare modes, Internal and External Interrupts, a serial programmable USART, a byte oriented Two-wire Serial Interface, an 8-channel, 10-bit ADC with optional differential input stage with programmable gain (TQFP package only), a programmable Watchdog Timer with Internal Oscillator, an SPI serial port, and six software selectable power saving modes. The Idle mode stops the CPU while allowing the USART, Two-wire interface, A/D Converter, SRAM, Timer/Counters, SPI port, and interrupt system to continue functioning. The Power-down mode saves the register contents but freezes the Oscillator, disabling all other chip functions until the next External Interrupt or Hardware Reset. In Power-save mode, the Asynchronous Timer continues to run, allowing the user to maintain a timer base while the rest of the device is sleeping. The ADC Noise Reduction mode stops the CPU and all I/O modules except Asynchronous Timer and ADC, to minimize switching noise during ADC conversions. In Standby mode, the crystal/resonator Oscillator is running while the rest of the device is sleeping. This allows very fast start-up combined with low-power consumption. In Extended Standby mode, both the main Oscillator and the Asynchronous Timer continue to run.

The device is manufactured using Atmel's high density nonvolatile memory technology. The On-chip ISP Flash allows the program memory to be reprogrammed in-system through an SPI serial interface, by a conventional nonvolatile memory programmer, or by an On-chip Boot program running on the AVR core. The boot program can use any interface to download the application program in the Application Flash memory. Software in the Boot Flash section will continue to run while the Application Flash section is updated, providing true Read-While-Write operation. By combining an 8-bit RISC CPU with In-System Self-Programmable Flash on a monolithic chip, the Atmel ATmega32A is a powerful microcontroller that provides a highly-flexible and cost-effective solution to many embedded control applications.

The Atmel AVR ATmega32A is supported with a full suite of program and system development tools including: C compilers, macro assemblers, program debugger/simulators, in-circuit emulators, and evaluation kits.

## 2. Configuration Summary

| Features | ATmega32A |
| :---: | :---: |
| Pin count | 44 |
| Flash (KB) | 32 |
| SRAM (KB) | 2 |
| EEPROM (KB) | 1 |
| General Purpose I/O pins | 32 |
| SPI | 1 |
| TWI ( ${ }^{2} \mathrm{C}$ ) | 1 |
| USART | 1 |
| ADC | 10-bit, up to 76.9 ksps (15ksps at max resolution) |
| ADC channels | 8 |
| AC propagation delay | Typ 400ns |
| 8-bit Timer/Counters | 2 |
| 16-bit Timer/Counters | 1 |
| PWM channels | 4 |
| RC Oscillator | +/-3\% |
| VREF Bandgap |  |
| Operating voltage | 2.7-5.5V |
| Max operating frequency | 16 MHz |
| Temperature range | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| JTAG | Yes |

## 3. Ordering Information

| Speed (MHz) | Power Supply | Ordering Code ${ }^{(2)}$ | Package ${ }^{(1)}$ | Operational Range |
| :---: | :--- | :--- | :--- | :--- |
| 16 |  | ATmega32A-AU | 44 A |  |
|  |  | ATmega32A-AUR ${ }^{(3)}$ | 44 A |  |
|  | $2.7-5.5 \mathrm{~V}$ | ATmega32A-PU | 40 P 6 | Industrial $\left(-40^{\circ} \mathrm{C}\right.$ to $\left.85^{\circ} \mathrm{C}\right)$ |
|  |  | 44 M 1 |  |  |
|  |  | ATmega32A-MUR ${ }^{(3)}$ | 44 M 1 |  |
|  |  | 44 A |  |  |
|  |  | ATmega32A-ANR | 44 A |  |
|  |  | ATmega32A-MN | 44 M 1 | Extended $\left(-40^{\circ} \mathrm{C} \text { to } 105^{\circ} \mathrm{C}\right)^{(4)}$ |
|  |  | ATmega32A-MNR ${ }^{(3)}$ | 44 M 1 |  |

## Note:

1. This device can also be supplied in wafer form. Please contact your local Atmel sales office for detailed ordering information and minimum quantities.
2. Pb -free packaging complies to the European Directive for Restriction of Hazardous Substances (RoHS directive). Also Halide free and fully Green.
3. Tape and Reel
4. See characterization specifications at $105^{\circ} \mathrm{C}$

## Package Type

44A 44 -lead, $10 \times 10 \times 1.0 \mathrm{~mm}$, Thin Profile Plastic Quad Flat Package (TQFP)
40P6 40-pin, 0.600" Wide, Plastic Dual Inline Package (PDIP)
44M1 44 -pad, $7 \times 7 \times 1.0 \mathrm{~mm}$, Quad Flat No-Lead/Micro Lead Frame Package (QFN/MLF)

## 4. Block Diagram

## 5. Pin Configurations

Figure 5-1. Pinout TQFP ATmega32A

Figure 5-2. Pinout PDIP ATmega32A

## 5.1. $\quad V_{C C}$

Digital supply voltage.

### 5.2. GND

Ground.

### 5.3. PortA (PA7:PA0)

Port A serves as the analog inputs to the A/D Converter.

Port A also serves as an 8-bit bi-directional I/O port, if the A/D Converter is not used. Port pins can provide internal pull-up resistors (selected for each bit). The Port A output buffers have symmetrical drive characteristics with both high sink and source capability. When pins PA0 to PA7 are used as inputs and are externally pulled low, they will source current if the internal pull-up resistors are activated. The Port A pins are tristated when a reset condition becomes active, even if the clock is not running.

### 5.4. Port B (PB7:PB0)

Port B is an 8-bit bi-directional I/O port with internal pull-up resistors (selected for each bit). The Port B output buffers have symmetrical drive characteristics with both high sink and source capability. As inputs, Port B pins that are externally pulled low will source current if the pull-up resistors are activated. The Port $B$ pins are tristated when a reset condition becomes active, even if the clock is not running.

Port B also serves the functions of various special features of the ATmega32A as listed in Alternate Functions of Port B.

## Related Links

Alternate Functions of Port B on page 81

### 5.5. Port C (PC7:PC0)

Port C is an 8-bit bi-directional I/O port with internal pull-up resistors (selected for each bit). The Port C output buffers have symmetrical drive characteristics with both high sink and source capability. As inputs, Port C pins that are externally pulled low will source current if the pull-up resistors are activated. The Port C pins are tri-stated when a reset condition becomes active, even if the clock is not running. If the JTAG interface is enabled, the pull-up resistors on pins PC5(TDI), PC3(TMS) and PC2(TCK) will be activated even if a reset occurs.

The TD0 pin is tristated unless TAP states that shift out data are entered.
Port C also serves the functions of the JTAG interface and other special features of the ATmega32A as listed in Alternate Functions of Port C.

## Related Links

Alternate Functions of Port C on page 84

### 5.6. Port D (PD7:PDO)

Port D is an 8-bit bi-directional I/O port with internal pull-up resistors (selected for each bit). The Port D output buffers have symmetrical drive characteristics with both high sink and source capability. As inputs, Port D pins that are externally pulled low will source current if the pull-up resistors are activated. The Port D pins are tristated when a reset condition becomes active, even if the clock is not running.

Port D also serves the functions of various special features of the ATmega32A as listed in Alternate Functions of Port D.

## Related Links

Alternate Functions of Port D on page 86

### 5.7. RESET

Reset input. A low level on this pin for longer than the minimum pulse length will generate a reset, even if the clock is not running. The minimum pulse length is given in System and Reset Characteristics. Shorter pulses are not guaranteed to generate a reset.

## Related Links

System and Reset Characteristics on page 363

### 5.8. XTAL1

Input to the inverting Oscillator amplifier and input to the internal clock operating circuit.

### 5.9. XTAL2

Output from the inverting Oscillator amplifier.
5.10. $\quad \mathrm{AV}_{\mathrm{CC}}$
$A V_{C C}$ is the supply voltage pin for Port $A$ and the $A / D$ Converter. It should be externally connected to $V_{C C}$, even if the $A D C$ is not used. If the $A D C$ is used, it should be connected to $V_{c c}$ through a low-pass filter.

### 5.11. AREF

AREF is the analog reference pin for the A/D Converter.

## 6. Resources

A comprehensive set of development tools, application notes and datasheets are available for download on http://www.atmel.com/avr.

## 7. Data Retention

Reliability Qualification results show that the projected data retention failure rate is much less than 1 PPM over 20 years at $85^{\circ} \mathrm{C}$ or 100 years at $25^{\circ} \mathrm{C}$.

## 8. About Code Examples

This datasheet contains simple code examples that briefly show how to use various parts of the device. These code examples assume that the part specific header file is included before compilation. Be aware that not all C compiler vendors include bit definitions in the header files and interrupt handling in C is compiler dependent. Please confirm with the C compiler documentation for more details.

## 9. Capacitive Touch Sensing

The Atmel QTouch Library provides a simple to use solution to realize touch sensitive interfaces on most Atmel AVR microcontrollers. The QTouch Library includes support for the QTouch and QMatrix ${ }^{\circledR}$ acquisition methods.

Touch sensing can be added to any application by linking the appropriate Atmel QTouch Library for the AVR Microcontroller. This is done by using a simple set of APIs to define the touch channels and sensors, and then calling the touch sensing APl's to retrieve the channel information and determine the touch sensor states.

The QTouch Library is FREE and downloadable from the Atmel website at the following location: www.atmel.com/qtouchlibrary. For implementation details and other information, refer to the Atmel QTouch Library User Guide - also available for download from the Atmel website.

## 10. AVR CPU Core

### 10.1. Overview

This section discusses the Atmel AVR core architecture in general. The main function of the CPU core is to ensure correct program execution. The CPU must therefore be able to access memories, perform calculations, control peripherals, and handle interrupts.

Figure 10-1. Block Diagram of the AVR MCU Architecture

In order to maximize performance and parallelism, the AVR uses a Harvard architecture - with separate memories and buses for program and data. Instructions in the Program memory are executed with a single level pipelining. While one instruction is being executed, the next instruction is pre-fetched from the Program memory. This concept enables instructions to be executed in every clock cycle. The Program memory is In -System Reprogrammable Flash memory.

The fast-access Register File contains $32 \times 8$-bit general purpose working registers with a single clock cycle access time. This allows single-cycle Arithmetic Logic Unit (ALU) operation. In a typical ALU operation, two operands are output from the Register File, the operation is executed, and the result is stored back in the Register File - in one clock cycle.
Six of the 32 registers can be used as three 16-bit indirect address register pointers for Data Space addressing - enabling efficient address calculations. One of the these address pointers can also be used
as an address pointer for look up tables in Flash Program memory. These added function registers are the 16 -bit X -, Y -, and Z -register, described later in this section.

The ALU supports arithmetic and logic operations between registers or between a constant and a register. Single register operations can also be executed in the ALU. After an arithmetic operation, the Status Register is updated to reflect information about the result of the operation.

The Program flow is provided by conditional and unconditional jump and call instructions, able to directly address the whole address space. Most AVR instructions have a single 16-bit word format. Every Program memory address contains a 16- or 32-bit instruction.

Program Flash memory space is divided in two sections, the Boot program section and the Application program section. Both sections have dedicated Lock Bits for write and read/write protection. The SPM instruction that writes into the Application Flash memory section must reside in the Boot program section.

During interrupts and subroutine calls, the return address Program Counter (PC) is stored on the Stack. The Stack is effectively allocated in the general data SRAM, and consequently the Stack size is only limited by the total SRAM size and the usage of the SRAM. All user programs must initialize the SP in the reset routine (before subroutines or interrupts are executed). The Stack Pointer SP is read/write accessible in the I/O space. The data SRAM can easily be accessed through the five different addressing modes supported in the AVR architecture.

The memory spaces in the AVR architecture are all linear and regular memory maps.
A flexible interrupt module has its control registers in the I/O space with an additional global interrupt enable bit in the Status Register. All interrupts have a separate Interrupt Vector in the Interrupt Vector table. The interrupts have priority in accordance with their Interrupt Vector position. The lower the Interrupt Vector address, the higher the priority.
The I/O memory space contains 64 addresses for CPU peripheral functions as Control Registers, SPI, and other I/O functions. The I/O Memory can be accessed directly, or as the Data Space locations following those of the Register File, $0 \times 20-0 \times 5$ F.

### 10.2. ALU - Arithmetic Logic Unit

The high-performance Atmel AVR ALU operates in direct connection with all the 32 general purpose working registers. Within a single clock cycle, arithmetic operations between general purpose registers or between a register and an immediate are executed. The ALU operations are divided into three main categories - arithmetic, logical, and bit-functions. Some implementations of the architecture also provide a powerful multiplier supporting both signed/unsigned multiplication and fractional format. See the "Instruction Set" section for a detailed description.

### 10.3. Status Register

The Status Register contains information about the result of the most recently executed arithmetic instruction. This information can be used for altering program flow in order to perform conditional operations. Note that the Status Register is updated after all ALU operations, as specified in the Instruction Set Reference. This will in many cases remove the need for using the dedicated compare instructions, resulting in faster and more compact code.

The Status Register is not automatically stored when entering an interrupt routine and restored when returning from an interrupt. This must be handled by software.

### 10.3.1. SREG - The AVR Status Register

When using the I/O specific commands IN and OUT, the I/O addresses $0 \times 00-0 \times 3 F$ must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: SREG
Offset: 0x3F
Reset: $0 \times 00$
Property: When addressing I/O Registers as data space the offset address is $0 \times 5 \mathrm{~F}$

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | T | H | S | V | N | Z | C |
| Access | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

## Bit 7 - I: Global Interrupt Enable

The Global Interrupt Enable bit must be set for the interrupts to be enabled. The individual interrupt enable control is then performed in separate control registers. If the Global Interrupt Enable Register is cleared, none of the interrupts are enabled independent of the individual interrupt enable settings. The Ibit is cleared by hardware after an interrupt has occurred, and is set by the RETI instruction to enable subsequent interrupts. The I-bit can also be set and cleared by the application with the SEI and CLI instructions, as described in the Instruction Set Reference.

## Bit 6 - T: Bit Copy Storage

The Bit Copy instructions BLD (Bit LoaD) and BST (Bit STore) use the T-bit as source or destination for the operated bit. A bit from a register in the Register File can be copied into T by the BST instruction, and a bit in T can be copied into a bit in a register in the Register File by the BLD instruction.

## Bit 5 - H: Half Carry Flag

The Half Carry Flag H indicates a Half Carry in some arithmetic operations. Half Carry is useful in BCD arithmetic. See the "Instruction Set Description" for detailed information.

## Bit 4 - S: Sign Bit, $\mathbf{S}=\mathbf{N} \oplus \mathbf{V}$

The S-bit is always an exclusive or between the Negative Flag N and the Two's Complement Overflow Flag V. See the "Instruction Set Description" for detailed information.

## Bit 3 - V: Two's Complement Overflow Flag

The Two's Complement Overflow Flag V supports two's complement arithmetics. See the "Instruction Set Description" for detailed information.

## Bit 2 - N: Negative Flag

The Negative Flag N indicates a negative result in an arithmetic or logic operation. See the "Instruction Set Description" for detailed information.

## Bit 1 - Z: Zero Flag

The Zero Flag Z indicates a zero result in an arithmetic or logic operation. See the "Instruction Set Description" for detailed information.

## Bit 0 - C: Carry Flag

The Carry Flag C indicates a Carry in an arithmetic or logic operation. See the "Instruction Set Description" for detailed information.

### 10.4. General Purpose Register File

The Register File is optimized for the Atmel AVR Enhanced RISC instruction set. In order to achieve the required performance and flexibility, the following input/output schemes are supported by the Register File:

- One 8-bit output operand and one 8-bit result input.
- Two 8-bit output operands and one 8-bit result input.
- Two 8-bit output operands and one 16-bit result input.
- One 16 -bit output operand and one 16 -bit result input.

The following figure shows the structure of the 32 general purpose working registers in the CPU.
Figure 10-2. AVR CPU General Purpose Working Registers

|  |  | Addr. |  |
| :---: | :---: | :---: | :---: |
|  | R0 | 0x00 |  |
|  | R1 | 0x01 |  |
|  | R2 | 0x02 |  |
|  | $\ldots$ |  |  |
|  | R13 | 0x0D |  |
| General | R14 | 0x0E |  |
| Purpose | R15 | 0x0F |  |
| Working | R16 | 0x10 |  |
| Registers | R17 | 0x11 |  |
|  | ... |  |  |
|  | R26 | $0 \times 1 \mathrm{~A}$ | X-register Low Byte |
|  | R27 | 0x1B | X-register High Byte |
|  | R28 | 0x1C | Y-register Low Byte |
|  | R29 | 0x1D | Y-register High Byte |
|  | R30 | 0x1E | Z-register Low Byte |
|  | R31 | 0x1F | Z-register High Byte |

Most of the instructions operating on the Register File have direct access to all registers, and most of them are single cycle instructions.

As shown in the figure above, each register is also assigned a Data memory address, mapping them directly into the first 32 locations of the user Data Space. Although not being physically implemented as SRAM locations, this memory organization provides great flexibility in access of the registers, as the X -, Y-, and Z-pointer Registers can be set to index any register in the file.

### 10.4.1. The X-register, Y-register and Z-register

The registers R26:R31 have some added functions to their general purpose usage. These registers are 16 -bit address pointers for indirect addressing of the Data Space. The three indirect address registers X , $Y$ and $Z$ are defined as described in the following figure.

Figure 10-3. The X -, Y - and Z -Registers

In the different addressing modes these address registers have functions as fixed displacement, automatic increment, and automatic decrement (see the Instruction Set Reference for details).

### 10.5. Stack Pointer

The Stack is mainly used for storing temporary data, for storing local variables and for storing return addresses after interrupts and subroutine calls. Note that the Stack is implemented as growing from higher to lower memory locations. The Stack Pointer Register always points to the top of the Stack. The Stack Pointer points to the data SRAM Stack area where the Subroutine and Interrupt Stacks are located. A Stack PUSH command will decrease the Stack Pointer.

The Stack in the data SRAM must be defined by the program before any subroutine calls are executed or interrupts are enabled. Initial Stack Pointer value equals the last address of the internal SRAM and the Stack Pointer must be set to point above start of the SRAM, refer to figure Data Memory Map in SRAM Data Memory.

The following table contains Stack Pointer details.
Table 10-1. Stack Pointer instructions

| Instruction | Stack pointer | Description |
| :--- | :--- | :--- |
| PUSH | Decremented by 1 | Data is pushed onto the stack |
| CALL <br> ICALL | Decremented by 2 | Return address is pushed onto the stack with a subroutine <br> call or interrupt |
| RCALL | Incremented by 1 | Data is popped from the stack |
| POP | Incremented by 2 | Return address is popped from the stack with return from <br> subroutine or return from interrupt |
| RET <br> RETI |  |  |

The AVR Stack Pointer is implemented as two 8-bit registers in the I/O space. The number of bits actually used is implementation dependent. Note that the data space in some implementations of the AVR architecture is so small that only SPL is needed. In this case, the SPH Register will not be present.

Figure 10-4. SPH and SPL - Stack Pointer High and Low Register

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | SPH |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0x3E | SP15 | SP14 | SP13 | SP12 | SP11 | SP10 | SP9 | SP8 |  |
| 0x3D | SP7 | SP6 | SP5 | SP4 | SP3 | SP2 | SP1 | SP0 | SPL |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |  |
| Read/Write | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |  |
|  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |  |
| Initial Value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |

### 10.6. Instruction Execution Timing

This section describes the general access timing concepts for instruction execution. The Atmel AVR CPU is driven by the CPU clock clk ${ }_{\text {CPU }}$, directly generated from the selected clock source for the chip. No internal clock division is used.

The following figure shows the parallel instruction fetches and instruction executions enabled by the Harvard architecture and the fast-access Register File concept. This is the basic pipelining concept to obtain up to 1 MIPS per MHz with the corresponding unique results for functions per cost, functions per clocks, and functions per power-unit.

Figure 10-5. The Parallel Instruction Fetches and Instruction Executions

The next figure shows the internal timing concept for the Register File. In a single clock cycle an ALU operation using two register operands is executed, and the result is stored back to the destination register.
Figure 10-6. Single Cycle ALU Operation

### 10.7. Reset and Interrupt Handling

The Atmel AVR provides several different interrupt sources. These interrupts and the separate Reset Vector each have a separate Program Vector in the Program memory space. All interrupts are assigned individual enable bits which must be written logic one together with the Global Interrupt Enable bit in the Status Register in order to enable the interrupt. Depending on the Program Counter value, interrupts may be automatically disabled when Boot Lock Bits BLB02 or BLB12 are programmed. This feature improves software security. See the section Memory Programming for details.

The lowest addresses in the Program memory space are by default defined as the Reset and Interrupt Vectors. The complete list of Vectors is shown in Interrupts. The list also determines the priority levels of the different interrupts. The lower the address the higher is the priority level. RESET has the highest priority, and next is INT0 - the External Interrupt Request 0 . The Interrupt Vectors can be moved to the start of the boot Flash section by setting the Interrupt Vector Select (IVSEL) bit in the General Interrupt Control Register (GICR). Refer to Interrupts for more information. The Reset Vector can also be moved to the start of the boot Flash section by programming the BOOTRST Fuse, see Boot Loader Support -Read-While-Write Self-Programming.

When an interrupt occurs, the Global Interrupt Enable I-bit is cleared and all interrupts are disabled. The user software can write logic one to the I-bit to enable nested interrupts. All enabled interrupts can then interrupt the current interrupt routine. The I-bit is automatically set when a Return from Interrupt instruction - RETI - is executed.

There are basically two types of interrupts. The first type is triggered by an event that sets the Interrupt Flag. For these interrupts, the Program Counter is vectored to the actual Interrupt Vector in order to execute the interrupt handling routine, and hardware clears the corresponding Interrupt Flag. Interrupt Flags can also be cleared by writing a logic one to the flag bit position(s) to be cleared. If an interrupt condition occurs while the corresponding interrupt enable bit is cleared, the Interrupt Flag will be set and remembered until the interrupt is enabled, or the flag is cleared by software. Similarly, if one or more interrupt conditions occur while the global interrupt enable bit is cleared, the corresponding Interrupt Flag(s) will be set and remembered until the global interrupt enable bit is set, and will then be executed by order of priority.

The second type of interrupts will trigger as long as the interrupt condition is present. These interrupts do not necessarily have Interrupt Flags. If the interrupt condition disappears before the interrupt is enabled, the interrupt will not be triggered.

When the AVR exits from an interrupt, it will always return to the main program and execute one more instruction before any pending interrupt is served.

Note that the Status Register is not automatically stored when entering an interrupt routine, nor restored when returning from an interrupt routine. This must be handled by software.

When using the CLI instruction to disable interrupts, the interrupts will be immediately disabled. No interrupt will be executed after the CLI instruction, even if it occurs simultaneously with the CLI instruction. The following example shows how this can be used to avoid interrupts during the timed EEPROM write sequence.

## Assembly Code Example

```
in r16, SREG ; store SREG value
cli ; disable interrupts during timed sequence
sbi EECR, EEMWE ; start EEPROM write
sbi EECR, EEWE
out SREG, r16 ; restore SREG value (I-bit)
```

## C Code Example

```
char cSREG;
cSREG = SREG; /* store SREG value */
/* disable interrupts during timed sequence */
CLI();
EECR |= (1<<EEMWE); /* start EEPROM write */
EECR |= (1<<EEWE);
SREG = cSREG; /* restore SREG value (I-bit) */
```

When using the SEI instruction to enable interrupts, the instruction following SEI will be executed before any pending interrupts, as shown in the following example.

## Assembly Code Example

```
sei ; set global interrupt enable
sleep ; enter sleep, waiting for interrupt
; note: will enter sleep before any pending
; interrupt(s)
```

## C Code Example

```
_enable_interrupt(); /* set global interrupt enable */
_SLEEP(); /* enter sleep, waiting for interrupt */
/* note: will enter sleep before any pending interrupt(s) */
```

### 10.7.1. Interrupt Response Time

The interrupt execution response for all the enabled Atmel AVR interrupts is four clock cycles minimum. After four clock cycles, the Program Vector address for the actual interrupt handling routine is executed. During this 4 -clock cycle period, the Program Counter is pushed onto the Stack. The Vector is normally a jump to the interrupt routine, and this jump takes three clock cycles. If an interrupt occurs during execution of a multi-cycle instruction, this instruction is completed before the interrupt is served. If an interrupt occurs when the MCU is in sleep mode, the interrupt execution response time is increased by four clock cycles. This increase comes in addition to the start-up time from the selected sleep mode.
A return from an interrupt handling routine takes four clock cycles. During these four clock cycles, the Program Counter (2 bytes) is popped back from the Stack, the Stack Pointer is incremented by 2, and the I-bit in SREG is set.

## 11. AVR Memories

### 11.1. Overview

This section describes the different memories in the Atmel AVR ATmega32A. The AVR architecture has two main memory spaces, the Data memory and the Program Memory space. In addition, the ATmega32A features an EEPROM Memory for data storage. All three memory spaces are linear and regular.

### 11.2. In-System Reprogrammable Flash Program Memory

The ATmega32A contains 32K bytes On-chip In-System Reprogrammable Flash memory for program storage. Since all AVR instructions are 16- or 32-bits wide, the Flash is organized as $16 \mathrm{~K} \times 16$ bits. For software security, the Flash Program memory space is divided into two sections, Boot Program section and Application Program section.

The Flash memory has an endurance of at least 10,000 write/erase cycles. The ATmega32A Program Counter (PC) is 14 bits wide, thus addressing the 16K Program memory locations. The operation of Boot Program section and associated Boot Lock Bits for software protection are described in detail in Boot Loader Support - Read-While-Write Self-Programming. Memory Programming contains a detailed description on Flash Programming in SPI, JTAG, or Parallel Programming mode.

Constant tables can be allocated within the entire Program memory address space (see the LPM - Load Program memory instruction description).

Timing diagrams for instruction fetch and execution are presented in Instruction Execution Timing.
Figure 11-1. Program Memory Map

### 11.3. SRAM Data Memory

The figure below shows how the Atmel AVR ATmega32A SRAM Memory is organized.
The lower 2144 Data memory locations address the Register File, the I/O Memory, and the internal data SRAM. The first 96 locations address the Register File and I/O Memory, and the next 2048 locations address the internal data SRAM.

The five different addressing modes for the Data memory cover: Direct, Indirect with Displacement, Indirect, Indirect with Pre-decrement, and Indirect with Post-increment. In the Register File, registers R26 to R31 feature the indirect addressing pointer registers.
The direct addressing reaches the entire data space.
The Indirect with Displacement mode reaches 63 address locations from the base address given by the Y- or Z-register.

When using register indirect addressing modes with automatic pre-decrement and post-increment, the address registers $\mathrm{X}, \mathrm{Y}$ and Z are decremented or incremented.

The 32 general purpose working registers, 64 I/O Registers, and the 2048 bytes of internal data SRAM in the ATmega32A are all accessible through all these addressing modes. The Register File is described in General Purpose Register File.

Figure 11-2. Data Memory Map

General Purpose Register File on page 24

### 11.3.1. Data Memory Access Times

This section describes the general access timing concepts for internal memory access. The internal data SRAM access is performed in two $\mathrm{clk}_{\text {CPU }}$ cycles as described in the figure below.

Figure 11-3. On-chip Data SRAM Access Cycles

### 11.4. EEPROM Data Memory

The Atmel AVR ATmega32A contains 1Kbyte of data EEPROM memory. It is organized as a separate data space, in which single bytes can be read and written. The EEPROM has an endurance of at least 100,000 write/erase cycles. The access between the EEPROM and the CPU is described below, specifying the EEPROM Address Registers, the EEPROM Data Register, and the EEPROM Control Register.

Memory Programming contains a detailed description on EEPROM Programming in SPI, JTAG, or Parallel Programming mode.

## Related Links

Memory Programming on page 327

### 11.4.1. EEPROM Read/Write Access

The EEPROM Access Registers are accessible in the I/O space.
The write access time for the EEPROM is given in the table "EEPROM Programming Time". A self-timing function, however, lets the user software detect when the next byte can be written. If the user code contains instructions that write the EEPROM, some precautions must be taken. In heavily filtered power supplies, $\mathrm{V}_{\mathrm{CC}}$ is likely to rise or fall slowly on Power-up/down. This causes the device for some period of time to run at a voltage lower than specified as minimum for the clock frequency used. See Preventing EEPROM Corruption for details on how to avoid problems in these situations.

In order to prevent unintentional EEPROM writes, a specific write procedure must be followed. Refer to the description of the EEPROM Control Register for details on this.

When the EEPROM is read, the CPU is halted for four clock cycles before the next instruction is executed. When the EEPROM is written, the CPU is halted for two clock cycles before the next instruction is executed.

## Related Links

EECR on page 36

### 11.4.2. EEPROM Write during Power-down Sleep Mode

When entering Power-down sleep mode while an EEPROM write operation is active, the EEPROM write operation will continue, and will complete before the Write Access time has passed. However, when the write operation is completed, the Oscillator continues running, and as a consequence, the device does not enter Power-down entirely. It is therefore recommended to verify that the EEPROM write operation is completed before entering Power-down.

### 11.4.3. Preventing EEPROM Corruption

During periods of low $\mathrm{V}_{\mathrm{CC}}$, the EEPROM data can be corrupted because the supply voltage is too low for the CPU and the EEPROM to operate properly. These issues are the same as for board level systems using EEPROM, and the same design solutions should be applied.

An EEPROM data corruption can be caused by two situations when the voltage is too low. First, a regular write sequence to the EEPROM requires a minimum voltage to operate correctly. Second, the CPU itself can execute instructions incorrectly, if the supply voltage is too low.

EEPROM data corruption can easily be avoided by following this design recommendation:
Keep the AVR RESET active (low) during periods of insufficient power supply voltage. This can be done by enabling the internal Brown-out Detector (BOD). If the detection level of the internal BOD does not match the needed detection level, an external low $\mathrm{V}_{\mathrm{CC}}$ Reset Protection circuit can be used. If a reset occurs while a write operation is in progress, the write operation will be completed provided that the power supply voltage is sufficient.

### 11.5. I/O Memory

The I/O space definition of the ATmega32A is shown in Register Summary.
All ATmega32A I/Os and peripherals are placed in the I/O space. The I/O locations are accessed by the IN and OUT instructions, transferring data between the 32 general purpose working registers and the I/O space. I/O Registers within the address range $0 \times 00-0 x 1 F$ are directly bit-accessible using the SBI and CBI instructions. In these registers, the value of single bits can be checked by using the SBIS and SBIC instructions. Refer to the instruction set section for more details. When using the I/O specific commands IN and OUT, the I/O addresses $0 \times 00-0 \times 3 F$ must be used. When addressing I/O Registers as data space using LD and ST instructions, $0 \times 20$ must be added to these addresses.

For compatibility with future devices, reserved bits should be written to zero if accessed. Reserved I/O memory addresses should never be written.

Some of the Status Flags are cleared by writing a logical one to them. Note that the CBI and SBI instructions will operate on all bits in the I/O Register, writing a one back into any flag read as set, thus clearing the flag. The CBI and SBI instructions work with registers $0 \times 00$ to $0 \times 1 \mathrm{~F}$ only.

The I/O and Peripherals Control Registers are explained in later sections.

Register Summary on page 399

### 11.6. Register Description

### 11.6.1. EEARL - The EEPROM Address Register Low

When using the I/O specific commands IN and OUT, the I/O addresses $0 \times 00-0 \times 3$ F must be used. When addressing I/O Registers as data space using LD and ST instructions, $0 \times 20$ must be added to these offset addresses.

Name: EEARL
Offset: $0 \times 1 \mathrm{E}$
Reset: $0 \times X X$
Property: When addressing I/O Registers as data space the offset address is $0 \times 3 \mathrm{E}$

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | EEAR7 | EEAR6 | EEAR5 | EEAR4 | EEAR3 | EEAR2 | EEAR1 | EEAR0 |
| Access | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | X | X | X | X | X | X | X | X |

Bits 7:0 - EEARn: EEPROM Address [n = 7:0]
The EEPROM Address Registers - EEARH and EEARL - specify the EEPROM address in the 1 Kbyte EEPROM space. The EEPROM data bytes are addressed linearly between 0 and 1024. The initial value of EEAR is undefined. A proper value must be written before the EEPROM may be accessed.

### 11.6.2. EEARH - The EEPROM Address Register High

When using the I/O specific commands IN and OUT, the I/O addresses $0 \times 00-0 \times 3$ F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: EEARH
Offset: 0x1F
Reset: 0xXX
Property: When addressing I/O Registers as data space the offset address is $0 \times 3 \mathrm{~F}$

Bit 1 - EEAR9: EEPROM Address
Bit 0 - EEAR8: EEPROM Address
Refer to EEARL.

### 11.6.3. EEDR - The EEPROM Data Register

When using the I/O specific commands IN and OUT, the I/O addresses $0 \times 00-0 \times 3 F$ must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: EEDR
Offset: 0x1D
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is $0 \times 3 \mathrm{D}$

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | EEDR7 | EEDR6 | EEDR5 | EEDR4 | EEDR3 | EEDR2 | EEDR1 | EEDR0 |
| Access | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Bits 7:0 - EEDRn: EEPROM Data [ $\mathrm{n}=\mathbf{7 : 0}$ ]
For the EEPROM write operation, the EEDR Register contains the data to be written to the EEPROM in the address given by the EEAR Register. For the EEPROM read operation, the EEDR contains the data read out from the EEPROM at the address given by EEAR.

- EEDR[7] is MSB
- EEDR[0] is LSB

### 11.6.4. EECR - The EEPROM Control Register

When using the I/O specific commands IN and OUT, the I/O addresses $0 \times 00-0 \times 3 F$ must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: EECR
Offset: 0x1C
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is $0 \times 3 \mathrm{C}$

## Bit 3 - EERIE: EEPROM Ready Interrupt Enable

Writing EERIE to one enables the EEPROM Ready Interrupt if the l-bit in SREG is set. Writing EERIE to zero disables the interrupt. The EEPROM Ready interrupt generates a constant interrupt when EEWE is cleared.

## Bit 2 - EEMWE: EEPROM Master Write Enable

The EEMWE bit determines whether setting EEWE to one causes the EEPROM to be written. When EEMWE is set, setting EEWE within four clock cycles will write data to the EEPROM at the selected address. If EEMWE is zero, setting EEWE will have no effect. When EEMWE has been written to one by software, hardware clears the bit to zero after four clock cycles. See the description of the EEWE bit for an EEPROM write procedure.

## Bit 1 - EEWE: EEPROM Write Enable

The EEPROM Write Enable Signal EEWE is the write strobe to the EEPROM. When address and data are correctly set up, the EEWE bit must be written to one to write the value into the EEPROM. The EEMWE bit must be written to one before a logical one is written to EEWE, otherwise no EEPROM write takes place. The following procedure should be followed when writing the EEPROM (the order of steps 3 and 4 is not essential):

1. Wait until EEWE becomes zero.
2. Wait until SPMEN in SPMCR becomes zero.
3. Write new EEPROM address to EEAR (optional).
4. Write new EEPROM data to EEDR (optional).
5. Write a logical one to the EEMWE bit while writing a zero to EEWE in EECR.
6. Within four clock cycles after setting EEMWE, write a logical one to EEWE.

The EEPROM can not be programmed during a CPU write to the Flash memory. The software must check that the Flash programming is completed before initiating a new EEPROM write. Step 2 is only relevant if the software contains a boot loader allowing the CPU to program the Flash. If the Flash is never being updated by the CPU, step 2 can be omitted. See Boot Loader Support - Read-While-Write Self-Programming for details about boot programming.
Caution: An interrupt between step 5 and step 6 will make the write cycle fail, since the EEPROM Master Write Enable will time-out. If an interrupt routine accessing the EEPROM is interrupting another EEPROM access, the EEAR or EEDR Register will be modified, causing the interrupted EEPROM access to fail. It is recommended to have the Global Interrupt Flag cleared during all the steps to avoid these problems.

When the write access time has elapsed, the EEWE bit is cleared by hardware. The user software can poll this bit and wait for a zero before writing the next byte. When EEWE has been set, the CPU is halted for two cycles before the next instruction is executed.

## Bit 0 - EERE: EEPROM Read Enable

The EEPROM Read Enable Signal EERE is the read strobe to the EEPROM. When the correct address is set up in the EEAR Register, the EERE bit must be written to a logic one to trigger the EEPROM read. The EEPROM read access takes one instruction, and the requested data is available immediately. When the EEPROM is read, the CPU is halted for four cycles before the next instruction is executed.

The user should poll the EEWE bit before starting the read operation. If a write operation is in progress, it is neither possible to read the EEPROM, nor to change the EEAR Register.

The calibrated Oscillator is used to time the EEPROM accesses. The following table lists the typical programming time for EEPROM access from the CPU.

Table 11-1. EEPROM Programming Time

| Symbol | Number of Calibrated RC Oscillator Cycles ${ }^{(1)}$ | Typ Programming Time |
| :--- | :--- | :--- |
| EEPROM Write (from CPU) | 8448 | 8.5 ms |

Note: 1. Uses 1 MHz clock, independent of CKSEL Fuse settings.
The following code examples show one assembly and one C function for writing to the EEPROM. The examples assume that interrupts are controlled (for example by disabling interrupts globally) so that no interrupts will occur during execution of these functions. The examples also assume that no Flash boot loader is present in the software. If such code is present, the EEPROM write function must also wait for any ongoing SPM command to finish.

```
Assembly Code Example
```

```
EEPROM_write:
```

EEPROM_write:
; Wäit for completion of previous write
sbic EECR,EEWE
rjmp EEPROM_write
; Set up ad\overline{dress (r18:r17) in address register}
out EEARH, r18
out EEARL, r17
; Write data (r16) to data register
out EEDR,r16
; Write logical one to EEMWE
sbi EECR,EEMWE
; Start eeprom write by setting EEWE
sbi EECR,EEWE
ret

```

\section*{C Code Example}
```

void EEPROM_write(unsigned int uiAddress, unsigned char ucData)
{
/* Wait for completion of previous write */
while(EECR \& (1<<EEWE))
;
/* Set up address and data registers */
EEAR = uiAddress;
EEDR = ucData;
/* Write logical one to EEMWE */
EECR |= (1<<EEMWE);
/* Start eeprom write by setting EEWE */
EECR |= (1<<EEWE);
}

```

The next code examples show assembly and C functions for reading the EEPROM. The examples assume that interrupts are controlled so that no interrupts will occur during execution of these functions.

\section*{Assembly Code Example}
```

EEPROM_read:
; Wäit for completion of previous write
sbic EECR,EEWE
rjmp EEPROM_read
; Set up ad\overline{dress (r18:r17) in address register}
out EEARH, r18
out EEARL, r17
; Start eeprom read by writing EERE
sbi EECR,EERE
; Read data from data register
in r16,EEDR
ret

```

\section*{C Code Example}
```

unsigned char EEPROM_read(unsigned int uiAddress)
{
/* Wait for completion of previous write */
while(EECR \& (1<<EEWE))
;
/* Set up address register */
EEAR = uiAddress;
/* Start eeprom read by writing EERE */
EECR |= (1<<EERE);
/* Return data from data register */
return EEDR;
}

```

\section*{12. System Clock and Clock Options}

\subsection*{12.1. Clock Systems and their Distribution}

The figure below presents the principal clock systems in the AVR and their distribution. All of the clocks need not be active at a given time. In order to reduce power consumption, the clocks to modules not being used can be halted by using different sleep modes, as described in Power Management and Sleep Modes. The clock systems are detailed in the following figure.

Figure 12-1. Clock Distribution

\subsection*{12.1.1. CPU Clock - clk \({ }_{\text {CPU }}\)}

The CPU clock is routed to parts of the system concerned with operation of the AVR core. Examples of such modules are the General Purpose Register File, the Status Register and the Data memory holding the Stack Pointer. Halting the CPU clock inhibits the core from performing general operations and calculations.

\subsection*{12.1.2. I/O Clock - clk \(_{/ / O}\)}

The I/O clock is used by the majority of the I/O modules, like Timer/Counters, SPI, and USART. The I/O clock is also used by the External Interrupt module, but note that some external interrupts are detected by asynchronous logic, allowing such interrupts to be detected even if the I/O clock is halted. Also note that address recognition in the TWI module is carried out asynchronously when \(\mathrm{cl}_{/ / \mathrm{O}}\) is halted, enabling TWI address reception in all sleep modes.

\subsection*{12.1.3. Flash Clock - clk FLASH}

The Flash clock controls operation of the Flash interface. The Flash clock is usually active simultaneously with the CPU clock.

\subsection*{12.1.4. Asynchronous Timer Clock - clk \(_{\text {ASY }}\)}

The Asynchronous Timer clock allows the Asynchronous Timer/Counter to be clocked directly from an external 32 kHz clock crystal. The dedicated clock domain allows using this Timer/Counter as a real-time counter even when the device is in sleep mode.

\subsection*{12.1.5. ADC Clock - clk \(_{\text {ADC }}\)}

The ADC is provided with a dedicated clock domain. This allows halting the CPU and I/O clocks in order to reduce noise generated by digital circuitry. This gives more accurate ADC conversion results.

\subsection*{12.2. Clock Sources}

The device has the following clock source options, selectable by Flash Fuse Bits as shown below. The clock from the selected source is input to the AVR clock generator, and routed to the appropriate modules.

Table 12-1. Device Clocking Options Select
\begin{tabular}{|l|l|}
\hline Device Clocking Option & CKSEL3:0 \({ }^{(1)}\) \\
\hline External Crystal/Ceramic Resonator & \(1111-1010\) \\
\hline External Low-frequency Crystal & 1001 \\
\hline External RC Oscillator & \(1000-0101\) \\
\hline Calibrated Internal RC Oscillator & \(0100-0001\) \\
\hline External Clock & 0000 \\
\hline
\end{tabular}

Note: 1. For all fuses " 1 " means unprogrammed while " 0 " means programmed.
The various choices for each clocking option is given in the following sections. When the CPU wakes up from Power-down or Power-save, the selected clock source is used to time the start-up, ensuring stable Oscillator operation before instruction execution starts. When the CPU starts from reset, there is as an additional delay allowing the power to reach a stable level before commencing normal operation. The Watchdog Oscillator is used for timing this real-time part of the start-up time. The number of WDT Oscillator cycles used for each time-out is shown in the table below. The frequency of the Watchdog Oscillator is voltage dependent as shown in Typical Characteristics.

Table 12-2. Number of Watchdog Oscillator Cycles
\begin{tabular}{|l|l|l|}
\hline Typical Time-out \(\left(\mathrm{V}_{\mathrm{cc}}=5.0 \mathrm{~V}\right)\) & Typical Time-out \(\left(\mathrm{V}_{\mathrm{cc}}=3.0 \mathrm{~V}\right)\) & Number of Cycles \\
\hline 4.1 ms & 4.3 ms & \(4 \mathrm{~K}(4,096)\) \\
\hline 65 ms & 69 ms & \(64 \mathrm{~K}(65,536)\) \\
\hline
\end{tabular}

\section*{Related Links}

Typical Characteristics on page 371

\subsection*{12.3. Default Clock Source}

The device is shipped with CKSEL = "0001" and SUT = " 10 ". The default clock source setting is therefore the Internal RC Oscillator with longest startup time. This default setting ensures that all users can make their desired clock source setting using an In-System or Parallel Programmer.

\subsection*{12.4. Crystal Oscillator}

XTAL1 and XTAL2 are input and output, respectively, of an inverting amplifier which can be configured for use as an On-chip Oscillator, as shown in the figure below. Either a quartz crystal or a ceramic resonator may be used. The CKOPT Fuse selects between two different Oscillator amplifier modes. When CKOPT is programmed, the Oscillator output will oscillate a full rail-to-rail swing on the output. This mode is suitable when operating in a very noisy environment or when the output from XTAL2 drives a second clock buffer. This mode has a wide frequency range. When CKOPT is unprogrammed, the Oscillator has a smaller output swing. This reduces power consumption considerably. This mode has a limited frequency range and it cannot be used to drive other clock buffers.

For resonators, the maximum frequency is 8 MHz with CKOPT unprogrammed and 16 MHz with CKOPT programmed. C1 and C2 should always be equal for both crystals and resonators. The optimal value of the capacitors depends on the crystal or resonator in use, the amount of stray capacitance, and the electromagnetic noise of the environment. Some initial guidelines for choosing capacitors for use with crystals are given in the next table. For ceramic resonators, the capacitor values given by the manufacturer should be used.

Figure 12-2. Crystal Oscillator Connections

The Oscillator can operate in three different modes, each optimized for a specific frequency range. The operating mode is selected by the fuses CKSEL3:1 as shown in the following table.

Table 12-3. Crystal Oscillator Operating Modes
\begin{tabular}{|l|l|l|l|}
\hline CKOPT \(^{(1)}\) & CKSEL3:1 & Frequency Range(MHz) & \begin{tabular}{l} 
Recommended Range for Capacitors C1 and C2 \\
for Use with Crystals (pF)
\end{tabular} \\
\hline 1 & \(101^{(2)}\) & \(0.4-0.9\) & - \\
\hline 1 & 110 & \(0.9-3.0\) & \(12-22\) \\
\hline 1 & 111 & \(3.0-8.0\) & \(12-22\) \\
\hline 0 & \(101,110,111\) & \(1.0-16.0\) & \(12-22\) \\
\hline
\end{tabular}

\section*{Note:}
1. When CKOPT is programmed (0), the oscillator output will be a full rail-to-rail swing on the output.
2. This option should not be used with crystals, only with ceramic resonators.

The CKSEL0 Fuse together with the SUT1:0 Fuses select the start-up times as shown in the next table.
Table 12-4. Start-up Times for the Crystal Oscillator Clock Selection
\begin{tabular}{|l|l|l|l|l|}
\hline CKSELO & SUT1:0 & \begin{tabular}{l} 
Start-up Time \\
from Power-down \\
and Power-save
\end{tabular} & \begin{tabular}{l} 
Additional Delay \\
from Reset \\
\(\left(\mathbf{V C C}_{\mathrm{CC}}=5.0 \mathrm{~V}\right)\)
\end{tabular} & Recommended Usage \\
\hline 0 & 00 & \(258 \mathrm{CK}^{(1)}\) & 4.1 ms & Ceramic resonator, fast rising power \\
\hline 0 & 01 & \(258 \mathrm{CK}^{(1)}\) & 65 ms & Ceramic resonator, slowly rising power \\
\hline 0 & 10 & \(1 \mathrm{~K} \mathrm{CK}^{(2)}\) & - & Ceramic resonator, BOD enabled \\
\hline 0 & 11 & \(1 \mathrm{~K} \mathrm{CK}^{(2)}\) & 4.1 ms & Ceramic resonator, fast rising power \\
\hline 1 & 00 & \(1 \mathrm{~K} \mathrm{CK}^{(2)}\) & 65 ms & Ceramic resonator, slowly rising power \\
\hline 1 & 01 & \(16 \mathrm{~K} \mathrm{CK}^{2}\) & - & Crystal Oscillator, BOD enabled \\
\hline 1 & 10 & 16 K CK & 4.1 ms & Crystal Oscillator, fast rising power \\
\hline 1 & 11 & 16 K CK & 65 ms & Crystal Oscillator, slowly rising power \\
\hline
\end{tabular}

\section*{Note:}
1. These options should only be used when not operating close to the maximum frequency of the device, and only if frequency stability at start-up is not important for the application. These options are not suitable for crystals.
2. These options are intended for use with ceramic resonators and will ensure frequency stability at start-up. They can also be used with crystals when not operating close to the maximum frequency of the device, and if frequency stability at start-up is not important for the application.

\subsection*{12.5. Low-frequency Crystal Oscillator}

To use a 32.768 kHz watch crystal as the clock source for the device, the Low-frequency Crystal Oscillator must be selected by setting the CKSEL Fuses to "1001". The crystal should be connected as shown in Figure 12-2. By programming the CKOPT Fuse, the user can enable internal capacitors on XTAL1 and XTAL2, thereby removing the need for external capacitors. The internal capacitors have a nominal value of 36 pF .

When this Oscillator is selected, start-up times are determined by the SUT Fuses as shown in the table below.

Table 12-5. Start-up Times for the Low-frequency Crystal Oscillator Clock Selection
\begin{tabular}{|l|l|l|l|}
\hline SUT1:0 & \begin{tabular}{l} 
Start-up Time from \\
Power-down and \\
Power-save
\end{tabular} & \begin{tabular}{l} 
Additional Delay \\
from Reset \\
\(\left(\mathbf{V C C}_{\text {C }}=5.0 \mathrm{~V}\right)\)
\end{tabular} & Recommended Usage \\
\hline 00 & \(1 \mathrm{~K} \mathrm{CK}^{(1)}\) & 4.1 ms & Fast rising power or BOD enabled \\
\hline 01 & \(1 \mathrm{~K} \mathrm{CK}^{(1)}\) & 65 ms & Slowly rising power \\
\hline 10 & \(32 \mathrm{~K} \mathrm{CK}^{2}\) & 65 ms & Stable frequency at start-up \\
\hline 11 & Reserved & & \\
\hline
\end{tabular}

Note: 1. These options should only be used if frequency stability at start-up is not important for the application.

\subsection*{12.6. External RC Oscillator}

For timing insensitive applications, the external RC configuration shown in the figure below can be used. The frequency is roughly estimated by the equation \(f=1 /(3 R C)\). C should be at least \(22 p F\). By programming the CKOPT Fuse, the user can enable an internal 36pF capacitor between XTAL1 and GND, thereby removing the need for an external capacitor.

Figure 12-3. External RC Configuration

The Oscillator can operate in four different modes, each optimized for a specific frequency range. The operating mode is selected by the fuses CKSEL3:0 as shown in the following table.

Table 12-6. External RC Oscillator Operating Modes
\begin{tabular}{|l|l|}
\hline CKSEL3:0 & Frequency Range (MHz) \\
\hline 0101 & \(0.1-0.9\) \\
\hline 0110 & \(0.9-3.0\) \\
\hline 0111 & \(3.0-8.0\) \\
\hline 1000 & \(8.0-12.0\) \\
\hline
\end{tabular}

When this Oscillator is selected, start-up times are determined by the SUT Fuses as shown in the table below.

Table 12-7. Start-up Times for the External RC Oscillator Clock Selection
\begin{tabular}{|l|l|l|l|}
\hline SUT1:0 & \begin{tabular}{l} 
Start-up Time from \\
Power-down and \\
Power-save
\end{tabular} & \begin{tabular}{l} 
Additional Delay \\
from Reset \\
\(\left(\mathbf{V}_{\mathrm{CC}}=5.0 \mathrm{~V}\right)\)
\end{tabular} & Recommended Usage \\
\hline 00 & 18 CK & - & BOD enabled \\
\hline 01 & 18 CK & 4.1 ms & Fast rising power \\
\hline 10 & 18 CK & 65 ms & Slowly rising power \\
\hline 11 & \(6 \mathrm{CK}^{(1)}\) & 4.1 ms & Fast rising power or BOD enabled \\
\hline
\end{tabular}

Note: 1. This option should not be used when operating close to the maximum frequency of the device.

\subsection*{12.7. Calibrated Internal RC Oscillator}

The calibrated internal RC Oscillator provides a fixed \(1.0,2.0,4.0\), or 8.0 MHz clock. All frequencies are nominal values at 5 V and \(25^{\circ} \mathrm{C}\). This clock may be selected as the system clock by programming the CKSEL Fuses as shown in the following table. If selected, it will operate with no external components.

The CKOPT Fuse should always be unprogrammed when using this clock option. During reset, hardware loads the 1 MHz calibration byte into the OSCCAL Register and thereby automatically calibrates the RC Oscillator. At \(5 \mathrm{~V}, 25^{\circ} \mathrm{C}\) and 1.0 MHz Oscillator frequency selected, this calibration gives a frequency within \(\pm 3 \%\) of the nominal frequency. Using calibration methods as described in application notes available at www.atmel.com/avr it is possible to achieve \(\pm 1 \%\) accuracy at any given \(V_{c c}\) and Temperature. When this Oscillator is used as the chip clock, the Watchdog Oscillator will still be used for the Watchdog Timer and for the Reset Time-out. For more information on the pre-programmed calibration value, see the section Calibration Byte.

Table 12-8. Internal Calibrated RC Oscillator Operating Modes
\begin{tabular}{|l|l|}
\hline CKSEL3:0 & Nominal Frequency (MHz) \\
\hline \(0001^{(1)}\) & 1.0 \\
\hline 0010 & 2.0 \\
\hline 0011 & 4.0 \\
\hline 0100 & 8.0 \\
\hline
\end{tabular}

Note: 1. The device is shipped with this option selected.
When this Oscillator is selected, start-up times are determined by the SUT Fuses as shown in the following table. XTAL1 and XTAL2 should be left unconnected (NC).
Table 12-9. Start-up Times for the Internal Calibrated RC Oscillator Clock Selection
\begin{tabular}{|l|l|l|l|}
\hline SUT1:0 & \begin{tabular}{l} 
Start-up Time from Power-down \\
and Power-save
\end{tabular} & \begin{tabular}{l} 
Additional Delay from Reset \\
\(\left(\mathbf{V}_{\text {cC }}=5.0 \mathrm{~V}\right)\)
\end{tabular} & Recommended Usage \\
\hline 00 & 6 CK & - & BOD enabled \\
\hline 01 & 6 CK & 4.1 ms & Fast rising power \\
\hline \(10^{(1)}\) & 6 CK & 65 ms & Slowly rising power \\
\hline 11 & Reserved & & \\
\hline
\end{tabular}

Note: 1. The device is shipped with this option selected.

\section*{Related Links}

Calibration Byte on page 330

\subsection*{12.8. External Clock}

To drive the device from an external clock source, XTAL1 should be driven as shown in the figure below. To run the device on an external clock, the CKSEL Fuses must be programmed to "0000". By programming the CKOPT Fuse, the user can enable an internal 36 pF capacitor between XTAL1 and GND.

Figure 12-4. External Clock Drive Configuration

When this clock source is selected, start-up times are determined by the SUT Fuses as shown in the following table.

Table 12-10. Start-up Times for the External Clock Selection
\begin{tabular}{|l|l|l|l|}
\hline SUT1:0 & \begin{tabular}{l} 
Start-up Time from \\
Power-down and \\
Power-save
\end{tabular} & \begin{tabular}{l} 
Additional Delay \\
from Reset \\
\((\mathbf{V c c}=5.0 \mathrm{~V})\)
\end{tabular} & Recommended Usage \\
\hline 00 & 6 CK & - & BOD enabled \\
\hline 01 & 6 CK & 4.1 ms & Fast rising power \\
\hline 10 & 6 CK & 65 ms & Slowly rising power \\
\hline 11 & Reserved & & \\
\hline
\end{tabular}

When applying an external clock, it is required to avoid sudden changes in the applied clock frequency to ensure stable operation of the MCU. A variation in frequency of more than \(2 \%\) from one clock cycle to the next can lead to unpredictable behavior. It is required to ensure that the MCU is kept in Reset during such changes in the clock frequency.

\subsection*{12.9. Timer/Counter Oscillator}

For AVR microcontrollers with Timer/Counter Oscillator pins (TOSC1 and TOSC2), the crystal is connected directly between the pins. No external capacitors are needed. The Oscillator is optimized for use with a 32.768 kHz watch crystal. Applying an external clock source to TOSC1 is not recommended.

Note: 1. The Timer/Counter Oscillator uses the same type of crystal oscillator as Low-Frequency Oscillator and the internal capacitors have the same nominal value of 36 pF .

\subsection*{12.10. Register Description}

\subsection*{12.10.1. OSCCAL - The Oscillator Calibration Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 x 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: OSCCAL
Offset: 0x31
Reset: 0x00
Property:
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & CAL7 & CAL6 & CAL5 & CAL4 & CAL3 & CAL2 & CAL1 & CALO \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & X & X & X & X & X & X & X & X \\
\hline
\end{tabular}

Bits 7:0 - CALn: Oscillator Calibration Value [ \(\mathrm{n}=7: 0\) ]
Writing the calibration byte to this address will trim the Internal Oscillator to remove process variations from the Oscillator frequency. During Reset, the 1 MHz calibration value which is located in the signature row High byte (address \(0 \times 00\) ) is automatically loaded into the OSCCAL Register. If the internal RC is used at other frequencies, the calibration values must be loaded manually. This can be done by first reading the signature row by a programmer, and then store the calibration values in the Flash or EEPROM. Then the value can be read by software and loaded into the OSCCAL Register. When OSCCAL is zero, the lowest available frequency is chosen. Writing non-zero values to this register will increase the frequency of the Internal Oscillator. Writing 0xFF to the register gives the highest available frequency. The calibrated Oscillator is used to time EEPROM and Flash access. If EEPROM or Flash is written, do not calibrate to more than \(10 \%\) above the nominal frequency. Otherwise, the EEPROM or Flash write may fail. Note that the Oscillator is intended for calibration to \(1.0,2.0,4.0\), or 8.0 MHz . Tuning to other values is not guaranteed, as indicated in the following table.

Table 12-11. Internal RC Oscillator Frequency Range
\begin{tabular}{|l|l|l|}
\hline OSCCAL Value & \begin{tabular}{l} 
Min Frequency in Percentage of \\
Nominal Frequency (\%)
\end{tabular} & \begin{tabular}{l}

\end{tabular} \\
\hline \(0 \times 00\) & 50 & 100 \\
\hline 0x7F & 75 & 150 \\
\hline 0xFF & 100 & 200 \\
\hline
\end{tabular}

\section*{13. Power Management and Sleep Modes}

\subsection*{13.1. Sleep Modes}

Sleep modes enable the application to shut down unused modules in the MCU, thereby saving power. The AVR provides various sleep modes allowing the user to tailor the power consumption to the application's requirements.
Figure Clock Distribution in section Clock Systems and their Distribution presents the different clock systems in the ATmega32A, and their distribution. The figure is helpful in selecting an appropriate sleep mode. The table below shows the different clock options and their wake-up sources.

Table 13-1. Active Clock Domains and Wake-up Sources in the Different Sleep Modes
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|c|}

\hline
\end{tabular}

\section*{Note:}
1. External Crystal or resonator selected as clock source.
2. If AS2 bit in ASSR is set.
3. Only INT2 or level interrupt INT1 and INTO.

To enter any of the six sleep modes, the SE bit in MCUCR must be written to logic one and a SLEEP instruction must be executed. The SM2, SM1, and SM0 bits in the MCUCR Register select which sleep mode (Idle, ADC Noise Reduction, Power-down, Power-save, Standby, or Extended Standby) will be activated by the SLEEP instruction. See Table 13-2 for a summary.

If an enabled interrupt occurs while the MCU is in a sleep mode, the MCU wakes up. The MCU is then halted for four cycles in addition to the start-up time, it executes the interrupt routine, and resumes execution from the instruction following SLEEP. The contents of the Register File and SRAM are unaltered when the device wakes up from sleep. If a reset occurs during sleep mode, the MCU wakes up and executes from the Reset Vector.

\section*{Related Links}

Clock Systems and their Distribution on page 39

\subsection*{13.2. Idle Mode}

When the SM2:0 bits are written to 000, the SLEEP instruction makes the MCU enter Idle mode, stopping the CPU but allowing SPI, USART, Analog Comparator, ADC, Two-wire Serial Interface, Timer/Counters, Watchdog, and the interrupt system to continue operating. This sleep mode basically halts \(\mathrm{clk}_{\mathrm{CPU}}\) and \(\mathrm{clk}_{\text {FLASH }}\), while allowing the other clocks to run.

Idle mode enables the MCU to wake up from external triggered interrupts as well as internal ones like the Timer Overflow and USART Transmit Complete interrupts. If wake-up from the Analog Comparator interrupt is not required, the Analog Comparator can be powered down by setting the ACD bit in the Analog Comparator Control and Status Register - ACSR. This will reduce power consumption in Idle mode. If the ADC is enabled, a conversion starts automatically when this mode is entered.

\subsection*{13.3. ADC Noise Reduction Mode}

When the SM2:0 bits are written to 001, the SLEEP instruction makes the MCU enter ADC Noise Reduction mode, stopping the CPU but allowing the ADC, the external interrupts, the Two-wire Serial Interface address watch, Timer/Counter2 and the Watchdog to continue operating (if enabled). This sleep mode basically halts \(\mathrm{clk}_{/ / \mathrm{O}}, \mathrm{clk}_{\mathrm{CPU}}\), and \(\mathrm{clk}_{\mathrm{FLASH}}\), while allowing the other clocks to run.
This improves the noise environment for the ADC, enabling higher resolution measurements. If the ADC is enabled, a conversion starts automatically when this mode is entered. Apart form the ADC Conversion Complete interrupt, only an External Reset, a Watchdog Reset, a Brown-out Reset, a Two-wire Serial Interface address match interrupt, a Timer/Counter2 interrupt, an SPM/EEPROM ready interrupt, an External level interrupt on INT0 or INT1, or an external interrupt on INT2 can wake up the MCU from ADC Noise Reduction mode.

\subsection*{13.4. Power-down Mode}

When the SM2:0 bits are written to 010, the SLEEP instruction makes the MCU enter Power-down mode. In this mode, the External Oscillator is stopped, while the External Interrupts, the Two-wire Serial Interface address watch, and the Watchdog continue operating (if enabled). Only an External Reset, a Watchdog Reset, a Brownout Reset, a Two-wire Serial Interface address match interrupt, an External Level Interrupt on INT0 or INT1, or an External Interrupt on INT2 can wake up the MCU. This sleep mode basically halts all generated clocks, allowing operation of asynchronous modules only.
Note that if a level triggered interrupt is used for wake-up from Power-down mode, the changed level must be held for some time to wake up the MCU. Refer to External Interrupts for details.
When waking up from Power-down mode, there is a delay from the wake-up condition occurs until the wake-up becomes effective. This allows the clock to restart and become stable after having been stopped. The wake-up period is defined by the same CKSEL Fuses that define the Reset Time-out period, as described in Clock Sources.

\section*{Related Links}

External Interrupts on page 69
Clock Sources on page 40

\subsection*{13.5. Power-save Mode}

When the SM2:0 bits are written to 011, the SLEEP instruction makes the MCU enter Power-save mode. This mode is identical to Power-down, with one exception:
- If Timer/Counter2 is clocked asynchronously, i.e. the AS2 bit in ASSR is set, Timer/Counter2 will run during sleep. The device can wake up from either Timer Overflow or Output Compare event from Timer/Counter2 if the corresponding Timer/Counter2 interrupt enable bits are set in TIMSK, and the global interrupt enable bit in SREG is set.
If the asynchronous timer is NOT clocked asynchronously, Power-down mode is recommended instead of Power-save mode because the contents of the registers in the asynchronous timer should be considered undefined after wake-up in Power-save mode if AS2 is 0 .

This sleep mode basically halts all clocks except clk \({ }_{\text {ASY }}\), allowing operation only of asynchronous modules, including Timer/Counter2 if clocked asynchronously.

\subsection*{13.6. Standby Mode}

When the SM2:0 bits are 110 and an external crystal/resonator clock option is selected, the SLEEP instruction makes the MCU enter Standby mode. This mode is identical to Power-down with the exception that the Oscillator is kept running. From Standby mode, the device wakes up in 6 clock cycles.

\subsection*{13.7. Extended Standby Mode}

When the SM2:0 bits are 111 and an external crystal/resonator clock option is selected, the SLEEP instruction makes the MCU enter Extended Standby mode. This mode is identical to Power-save mode with the exception that the Oscillator is kept running. From Extended Standby mode, the device wakes up in six clock cycles.

\subsection*{13.8. Minimizing Power Consumption}

There are several issues to consider when trying to minimize the power consumption in an AVR controlled system. In general, sleep modes should be used as much as possible, and the sleep mode should be selected so that as few as possible of the device's functions are operating. All functions not needed should be disabled. In particular, the following modules may need special consideration when trying to achieve the lowest possible power consumption.

\subsection*{13.8.1. Analog-to-Digital Converter (ADC)}

If enabled, the ADC will be enabled in all sleep modes. To save power, the ADC should be disabled before entering any sleep mode. When the ADC is turned off and on again, the next conversion will be an extended conversion. Refer to Analog-to-Digital Converter for details on ADC operation.

\section*{Related Links}

ADC - Analog to Digital Converter on page 258

\subsection*{13.8.2. Analog Comparator}

When entering Idle mode, the Analog Comparator should be disabled if not used. When entering ADC Noise Reduction mode, the Analog Comparator should be disabled. In the other sleep modes, the Analog Comparator is automatically disabled. However, if the Analog Comparator is set up to use the Internal Voltage Reference as input, the Analog Comparator should be disabled in all sleep modes. Otherwise, the Internal Voltage Reference will be enabled, independent of sleep mode. Refer to Analog Comparator for details on how to configure the Analog Comparator.

\section*{Related Links}

AC - Analog Comparator on page 253

\subsection*{13.8.3. Brown-out Detector}

If the Brown-out Detector is not needed in the application, this module should be turned off. If the Brownout Detector is enabled by the BODEN Fuse, it will be enabled in all sleep modes, and hence, always consume power. In the deeper sleep modes, this will contribute significantly to the total current consumption. Refer to Brown-out Detection for details on how to configure the Brown-out Detector.

\section*{Related Links}

Brown-out Detection on page 56

\subsection*{13.8.4. Internal Voltage Reference}

The Internal Voltage Reference will be enabled when needed by the Brown-out Detector, the Analog Comparator or the ADC. If these modules are disabled as described in the sections above, the internal voltage reference will be disabled and it will not be consuming power. When turned on again, the user must allow the reference to start up before the output is used. If the reference is kept on in sleep mode, the output can be used immediately. Refer to Internal Voltage Reference for details on the start-up time.

\section*{Related Links}

Internal Voltage Reference on page 57

\subsection*{13.8.5. Watchdog Timer}

If the Watchdog Timer is not needed in the application, this module should be turned off. If the Watchdog Timer is enabled, it will be enabled in all sleep modes, and hence, always consume power. In the deeper sleep modes, this will contribute significantly to the total current consumption. Refer to Watchdog Timer for details on how to configure the Watchdog Timer.

\section*{Related Links}

Watchdog Timer on page 57

\subsection*{13.8.6. Port Pins}

When entering a sleep mode, all port pins should be configured to use minimum power. The most important thing is then to ensure that no pins drive resistive loads. In sleep modes where the both the I/O clock ( \(\mathrm{Clk}_{\mathrm{I} / \mathrm{O}}\) ) and the ADC clock ( \(\mathrm{clk}_{\mathrm{ADC}}\) ) are stopped, the input buffers of the device will be disabled. This ensures that no power is consumed by the input logic when not needed. In some cases, the input logic is needed for detecting wake-up conditions, and it will then be enabled. Refer to the section Digital Input Enable and Sleep Modes for details on which pins are enabled. If the input buffer is enabled and the input signal is left floating or have an analog signal level close to \(\mathrm{V}_{\mathrm{Cc}} / 2\), the input buffer will use excessive power.

\section*{Related Links}

Digital Input Enable and Sleep Modes on page 78

\subsection*{13.8.7. JTAG Interface and On-chip Debug System}

If the On-chip debug system is enabled by the OCDEN Fuse and the chip enter Power down or Power save sleep mode, the main clock source remains enabled. In these sleep modes, this will contribute significantly to the total current consumption. There are three alternative ways to avoid this:
- Disable OCDEN Fuse.
- Disable JTAGEN Fuse.
- Write one to the JTD bit in MCUCSR.

The TDO pin is left floating when the JTAG interface is enabled while the JTAG TAP controller is not shifting data. If the hardware connected to the TDO pin does not pull up the logic level, power consumption will increase. Note that the TDI pin for the next device in the scan chain contains a pull-up
that avoids this problem. Writing the JTD bit in the MCUCSR register to one or leaving the JTAG fuse unprogrammed disables the JTAG interface.

\subsection*{13.9. Register Description}

\subsection*{13.9.1. MCUCR - MCU Control Register}

The MCU Control Register contains control bits for power management.
When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3\) F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: MCUCR
Offset: 0x35
Reset: \(0 \times 00\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 55\)
\begin{tabular}{rc|c|c|c|c|c|c|c|}
\multicolumn{1}{l}{ Bit } & 7 & 6 & 5 & 4 & 3 & 1 & \\
\cline { 2 - 8 } & SE & SM2 & SM1 & SM0 & & & \\
\hline Access & R/W & R/W & R/W & R/W & & \\
Reset & 0 & 0 & 0 & 0 & & & \\
\hline
\end{tabular}

\section*{Bit 7 - SE: Sleep Enable}

The SE bit must be written to logic one to make the MCU enter the sleep mode when the SLEEP instruction is executed. To avoid the MCU entering the sleep mode unless it is the programmer's purpose, it is recommended to set the Sleep Enable (SE) bit to one just before the execution of the SLEEP instruction and to clear it immediately after waking up.

Bits 6:4 - SMn: Sleep Mode \(n\) Select Bits [ \(\mathrm{n}=2: 0\) ]
These bits select between the six available sleep modes as shown in the table.
Table 13-2. Sleep Mode Select
\begin{tabular}{|l|l|l|l|}
\hline SM2 & SM1 & SM0 & Sleep Mode \\
\hline 0 & 0 & 0 & Idle \\
\hline 0 & 0 & 1 & ADC Noise Reduction \\
\hline 0 & 1 & 0 & Power-down \\
\hline 0 & 1 & 1 & Power-save \\
\hline 1 & 0 & 0 & Reserved \\
\hline 1 & 0 & 1 & Reserved \\
\hline 1 & 1 & 0 & Standby \({ }^{(1)}\) \\
\hline 1 & 1 & 1 & Extended Standby \({ }^{(1)}\) \\
\hline
\end{tabular}

Note: 1. Standby mode is only available with external crystals or resonators.

\section*{14. System Control and Reset}

\subsection*{14.1. Resetting the AVR}

During Reset, all I/O Registers are set to their initial values, and the program starts execution from the Reset Vector. The instruction placed at the Reset Vector must be a JMP - absolute jump - instruction to the reset handling routine. If the program never enables an interrupt source, the Interrupt Vectors are not used, and regular program code can be placed at these locations. This is also the case if the Reset Vector is in the Application section while the Interrupt Vectors are in the boot section or vice versa. The circuit diagram in the following section shows the Reset Logic. The Table in System and Reset Characteristics defines the electrical parameters of the reset circuitry.

The I/O ports of the AVR are immediately reset to their initial state when a reset source goes active. This does not require any clock source to be running.

After all reset sources have gone inactive, a delay counter is invoked, stretching the internal reset. This allows the power to reach a stable level before normal operation starts. The time-out period of the delay counter is defined by the user through the CKSEL Fuses. The different selections for the delay period are presented in Clock Sources.

\section*{Related Links}

System and Reset Characteristics on page 363
Clock Sources on page 40

\subsection*{14.2. Reset Sources}

The ATmega32A has five sources of Reset:
- Power-on Reset. The MCU is reset when the supply voltage is below the Power-on Reset threshold ( \(\mathrm{V}_{\mathrm{POT}}\) ).
- External Reset. The MCU is reset when a low level is present on the RESET pin for longer than the minimum pulse length.
- Watchdog Reset. The MCU is reset when the Watchdog Timer period expires and the Watchdog is enabled.
- Brown-out Reset. The MCU is reset when the supply voltage \(\mathrm{V}_{\mathrm{Cc}}\) is below the Brown-out Reset threshold \(\left(\mathrm{V}_{\mathrm{BOT}}\right)\) and the Brown-out Detector is enabled.
- JTAG AVR Reset. The MCU is reset as long as there is a logic one in the Reset Register, one of the scan chains of the JTAG system. Refer to the section IEEE 1149.1 (JTAG) Boundary-scan for details.

Figure 14-1. Reset Logic

\section*{Related Links}

IEEE 1149.1 (JTAG) Boundary-scan on page 287

\subsection*{14.2.1. Power-on Reset}

A Power-on Reset (POR) pulse is generated by an On-chip detection circuit. The detection level is defined in the table in System and Reset Characteristics. The POR is activated whenever \(\mathrm{V}_{\mathrm{CC}}\) is below the detection level. The POR circuit can be used to trigger the Start-up Reset, as well as to detect a failure in supply voltage.

A Power-on Reset (POR) circuit ensures that the device is reset from Power-on. Reaching the Power-on Reset threshold voltage invokes the delay counter, which determines how long the device is kept in RESET after \(\mathrm{V}_{\mathrm{CC}}\) rise. The RESET signal is activated again, without any delay, when \(\mathrm{V}_{\mathrm{CC}}\) decreases below the detection level.

Figure 14-2. MCU Start-up, RESET Tied to \(\mathbf{V}_{\text {CC }}\)

Figure 14-3. Figure: MCU Start-up, RESET Extended Externally

\section*{Related Links}

System and Reset Characteristics on page 363

\subsection*{14.2.2. External Reset}

An External Reset is generated by a low level on the RESET pin. Reset pulses longer than the minimum pulse width (see table in System and Reset Characteristics) will generate a reset, even if the clock is not running. Shorter pulses are not guaranteed to generate a reset. When the applied signal reaches the Reset Threshold Voltage \(-\mathrm{V}_{\mathrm{RST}}\) on its positive edge, the delay counter starts the MCU after the time-out period \(\mathrm{t}_{\text {TOUT }}\) has expired.

Figure 14-4. External Reset During Operation

Related Links
System and Reset Characteristics on page 363

\subsection*{14.2.3. Brown-out Detection}

ATmega32A has an On-chip Brown-out Detection (BOD) circuit for monitoring the \(\mathrm{V}_{\mathrm{CC}}\) level during operation by comparing it to a fixed trigger level. The trigger level for the BOD can be selected by the fuse BODLEVEL to be 2.7 V (BODLEVEL unprogrammed), or 4.0 V (BODLEVEL programmed). The trigger level has a hysteresis to ensure spike free Brown-out Detection. The hysteresis on the detection level should be interpreted as \(\mathrm{V}_{\mathrm{BOT}+}=\mathrm{V}_{\mathrm{BOT}}+\mathrm{V}_{\mathrm{HYST}} / 2\) and \(\mathrm{V}_{\mathrm{BOT}}=\mathrm{V}_{\mathrm{BOT}}-\mathrm{V}_{\mathrm{HYST}} / 2\).
The BOD circuit can be enabled/disabled by the fuse BODEN. When the BOD is enabled (BODEN programmed), and \(\mathrm{V}_{\mathrm{CC}}\) decreases to a value below the trigger level ( \(\mathrm{V}_{\text {BOT- }}\) in the figure below), the Brown-out Reset is immediately activated. When \(\mathrm{V}_{\mathrm{CC}}\) increases above the trigger level ( \(\mathrm{V}_{\mathrm{BOT}}\) + in the figure below), the delay counter starts the MCU after the time-out period \(\mathrm{t}_{\text {TOUT }}\) has expired.
The BOD circuit will only detect a drop in \(\mathrm{V}_{\mathrm{CC}}\) if the voltage stays below the trigger level for longer than \(t_{\text {BOD }}\) given in the table in System and Reset Characteristics.

Figure 14-5. Brown-out Reset During Operation

\section*{Related Links}

System and Reset Characteristics on page 363

\subsection*{14.2.4. Watchdog Reset}

When the Watchdog times out, it will generate a short reset pulse of 1 CK cycle duration. On the falling edge of this pulse, the delay timer starts counting the time-out period t tout. Refer to Watchdog Timer for details on operation of the Watchdog Timer.
Figure 14-6. Watchdog Reset During Operation

\subsection*{14.3. Internal Voltage Reference}

ATmega32A features an internal bandgap reference. This reference is used for Brown-out Detection, and it can be used as an input to the Analog Comparator or the ADC. The 2.56 V reference to the ADC is generated from the internal bandgap reference.

\subsection*{14.3.1. Voltage Reference Enable Signals and Start-up Time}

The voltage reference has a start-up time that may influence the way it should be used. The start-up time is given in the table in System and Reset Characteristics. To save power, the reference is not always turned on. The reference is on during the following situations:
1. When the BOD is enabled (by programming the BODEN Fuse).
2. When the bandgap reference is connected to the Analog Comparator (by setting the ACBG bit in ACSR).
3. When the ADC is enabled.

Thus, when the BOD is not enabled, after setting the ACBG bit or enabling the ADC, the user must always allow the reference to start up before the output from the Analog Comparator or ADC is used. To reduce power consumption in Power-down mode, the user can avoid the three conditions above to ensure that the reference is turned off before entering Power-down mode.

\section*{Related Links}

System and Reset Characteristics on page 363

\subsection*{14.4. Watchdog Timer}

The Watchdog Timer is clocked from a separate On-chip Oscillator which runs at 1 MHz . This is the typical value at \(\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}\). See characterization data for typical values at other \(\mathrm{V}_{\mathrm{Cc}}\) levels. By controlling the Watchdog Timer prescaler, the Watchdog Reset interval can be adjusted as shown in the figure below. The WDR - Watchdog Reset - instruction resets the Watchdog Timer. The Watchdog Timer is also reset when it is disabled and when a Chip Reset occurs. Eight different clock cycle periods can be selected to determine the reset period. If the reset period expires without another Watchdog Reset, the ATmega32A resets and executes from the Reset Vector. For timing details on the Watchdog Reset, refer to the Watchdog Reset.
To prevent unintentional disabling of the Watchdog, a special turn-off sequence must be followed when the Watchdog is disabled. Refer to the description of the Watchdog Timer Control Register for details.

Figure 14-7. Watchdog Timer

\section*{Related Links}

Watchdog Reset on page 56

\subsection*{14.5. Register Description}

\subsection*{14.5.1. MCUCSR - MCU Control and Status Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

The MCU Control and Status Register provides information on which reset source caused an MCU Reset.

Name: MCUCSR
Offset: 0x34
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 54\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & & & & JTRF & WDRF & BORF & EXTRF & PORF \\
\hline Access & & & & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & & & & - & - & - & - & - \\
\hline
\end{tabular}

\section*{Bit 4 - JTRF: JTAG Reset Flag}

This bit is set if a reset is being caused by a logic one in the JTAG Reset Register selected by the JTAG instruction AVR_RESET. This bit is reset by a Power-on Reset, or by writing a logic zero to the flag.

\section*{Bit 3 - WDRF: Watchdog Reset Flag}

This bit is set if a Watchdog Reset occurs. The bit is reset by a Power-on Reset, or by writing a logic zero to the flag.

\section*{Bit 2 - BORF: Brown-out Reset Flag}

This bit is set if a Brown-out Reset occurs. The bit is reset by a Power-on Reset, or by writing a logic zero to the flag.

\section*{Bit 1 - EXTRF: External Reset Flag}

This bit is set if an External Reset occurs. The bit is reset by a Power-on Reset, or by writing a logic zero to the flag.

\section*{Bit 0 - PORF: Power-on Reset Flag}

This bit is set if a Power-on Reset occurs. The bit is reset only by writing a logic zero to the flag. To make use of the Reset Flags to identify a reset condition, the user should read and then reset the MCUCSR as early as possible in the program. If the register is cleared before another reset occurs, the source of the reset can be found by examining the Reset Flags.

\subsection*{14.5.2. WDTCR - Watchdog Timer Control Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: WDTCR
Offset: 0x21
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 41\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & & & & WDTOE & WDE & WDP2 & WDP1 & WDP0 \\
\hline \multicolumn{4}{|l|}{Access} & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & & & & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bit 4 - WDTOE: Watchdog Turn-off Enable}

This bit must be set when the WDE bit is written to logic zero. Otherwise, the Watchdog will not be disabled. Once written to one, hardware will clear this bit after four clock cycles. Refer to the description of the WDE bit for a Watchdog disable procedure.

\section*{Bit 3 - WDE: Watchdog Enable}

When the WDE is written to logic one, the Watchdog Timer is enabled, and if the WDE is written to logic zero, the Watchdog Timer function is disabled. WDE can only be cleared if the WDTOE bit has logic level one. To disable an enabled Watchdog Timer, the following procedure must be followed:
1. In the same operation, write a logic one to WDTOE and WDE. A logic one must be written to WDE even though it is set to one before the disable operation starts.
2. Within the next four clock cycles, write a logic 0 to WDE. This disables the Watchdog.

Bits 2:0 - WDPn: Watchdog Timer Prescaler 2, 1, and 0 [ \(n=2: 0\) ]
The WDP2, WDP1, and WDP0 bits determine the Watchdog Timer prescaling when the Watchdog Timer is enabled. The different prescaling values and their corresponding Timeout Periods are shown in the table below.

Table 14-1. Watchdog Timer Prescale Select
\begin{tabular}{|l|l|l|l|l|l|}
\hline WDP2 & WDP1 & WDP0 & \begin{tabular}{l} 
Number of WDT Oscillator \\
Cycles
\end{tabular} & \begin{tabular}{l} 
Typical \\
Time-out at \\
\(\mathbf{V}_{\text {cc }}=3.0 \mathrm{~V}\)
\end{tabular} & \begin{tabular}{l} 
Typical \\
Time-out at \\
\(\mathbf{V}_{\mathrm{CC}}=5.0 \mathrm{~V}\)
\end{tabular} \\
\hline 0 & 0 & 0 & \(16 \mathrm{~K}(16,384)\) & 17.1 ms & 16.3 ms \\
\hline 0 & 0 & 1 & \(32 \mathrm{~K}(32,768)\) & 34.3 ms & 32.5 ms \\
\hline 0 & 1 & 0 & \(64 \mathrm{~K}(65,536)\) & 68.5 ms & 65 ms \\
\hline 0 & 1 & 1 & \(128 \mathrm{~K}(131,072)\) & 0.14 s & 0.13 s \\
\hline 1 & 0 & 0 & \(256 \mathrm{~K}(262,144)\) & 0.27 s & 0.26 s \\
\hline 1 & 0 & 1 & \(512 \mathrm{~K}(524,288)\) & 0.55 s & 0.52 s \\
\hline 1 & 1 & 0 & \(1,024 \mathrm{~K}(1,048,576)\) & 1.1 s & 1.0 s \\
\hline 1 & 1 & 1 & \(2,048 \mathrm{~K}(2,097,152)\) & 2.2 s & 2.1 s \\
\hline
\end{tabular}

The following code example shows one assembly and one C function for turning off the WDT. The example assumes that interrupts are controlled (for example by disabling interrupts globally) so that no interrupts will occur during execution of these functions.

\section*{Assembly Code Example}
```

WDT off:
; Reset WDT
wdr
; Write logical one to WDTOE and WDE
in r16, WDTCR
ldi r16, (1<<WDTOE)|(1<<WDE)
out WDTCR, r16
; Turn off WDT
ldi r16, (0<<WDE)
out WDTCR, r16
ret

```

\section*{C Code Example}
```

void WDT_off(void)
{
/* Reset WDT*/
_WDRC();
/* Write logical one to WDTOE and WDE */
WDTCR | = (1<<WDTOE) | ( }1<<\mathrm{ WDE );
/* Turn off WDT */
WDTCR = 0x00;
}

```

\section*{15. Interrupts}

This section describes the specifics of the interrupt handling performed by the ATmega32A. For a general explanation of the AVR interrupt handling, refer to Reset and Interrupt Handling.

\section*{Related Links}

Reset and Interrupt Handling on page 27

\subsection*{15.1. Interrupt Vectors in ATmega32A}

Table 15-1. Reset and Interrupt Vectors
\begin{tabular}{|c|c|c|c|}
\hline Vector No. & Program Address & Source & Interrupt Definition \\
\hline 1 & \(0 \times 000{ }^{(1)}\) & RESET & External Pin, Power-on Reset, Brown-out Reset, Watchdog Reset, and JTAG AVR Reset \\
\hline 2 & 0x002 & INTO & External Interrupt Request 0 \\
\hline 3 & 0x004 & INT1 & External Interrupt Request 1 \\
\hline 4 & 0x006 & INT2 & External Interrupt Request 2 \\

\hline 19 & 0x024 & ANA_COMP & Analog Comparator \\
\hline 20 & 0x026 & TWI & Two-wire Serial Interface \\
\hline 21 & 0x028 & SPM_RDY & Store Program Memory Ready \\
\hline
\end{tabular}

\section*{Note:}
1. When the BOOTRST fuse is programmed, the device will jump to the Boot Loader address at reset, see Boot Loader Support - Read-While-Write Self-Programming.
2. When the IVSEL bit in GICR is set, interrupt vectors will be moved to the start of the Boot Flash section. The address of each interrupt vector will then be address in this table added to the start address of the boot Flash section.

The next table shows Reset and interrupt vectors placement for the various combinations of BOOTRST and IVSEL settings. If the program never enables an interrupt source, the interrupt vectors are not used, and regular program code can be placed at these locations. This is also the case if the Reset Vector is in the Application section while the interrupt vectors are in the Boot section or vice versa.

Table 15-2. Reset and Interrupt Vectors Placement
\begin{tabular}{|l|l|l|l|}
\hline BOOTRST \(^{(1)}\) & IVSEL & Reset Address & Interrupt Vectors Start Address \\
\hline 1 & 0 & \(0 \times 0000\) & \(0 \times 0002\) \\
\hline 1 & 1 & \(0 \times 0000\) & Boot Reset Address + 0x0002 \\
\hline 0 & 0 & Boot Reset Address & \(0 \times 0002\) \\
\hline 0 & 1 & Boot Reset Address & Boot Reset Address + 0x0002 \\
\hline
\end{tabular}

Note: 1. The Boot Reset Address is shown in table Boot Size Configuration in the Boot Loader Parameters section. For the BOOTRST Fuse " 1 " means unprogrammed while " 0 " means programmed.

The most typical and general program setup for the Reset and Interrupt Vector Addresses in ATmega32A is:
\begin{tabular}{|c|c|c|c|}
\hline address & Labels Code & & Comments \\
\hline \$000 & jmp & RESET & ; Reset Handler \\

\subsection*{15.1.1. Moving Interrupts Between Application and Boot Space}

The General Interrupt Control Register controls the placement of the Interrupt Vector table.

\subsection*{15.2. Register Description}

\subsection*{15.2.1. GICR - General Interrupt Control Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: GICR
Offset: 0x3B
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 5 \mathrm{~B}\)

\section*{Bit 1 - IVSEL: Interrupt Vector Select}

When the IVSEL bit is cleared (zero), the Interrupt Vectors are placed at the start of the Flash memory. When this bit is set (one), the Interrupt Vectors are moved to the beginning of the Boot Loader section of the Flash. The actual address of the start of the boot Flash section is determined by the BOOTSZ Fuses. Refer to the section Boot Loader Support - Read-While-Write Self-Programming for details. To avoid unintentional changes of Interrupt Vector tables, a special write procedure must be followed to change the IVSEL bit:
1. Write the Interrupt Vector Change Enable (IVCE) bit to one.
2. Within four cycles, write the desired value to IVSEL while writing a zero to IVCE.

Interrupts will automatically be disabled while this sequence is executed. Interrupts are disabled in the cycle IVCE is set, and they remain disabled until after the instruction following the write to IVSEL. If IVSEL is not written, interrupts remain disabled for four cycles. The I-bit in the Status Register is unaffected by the automatic disabling.
Note: 1. If Interrupt Vectors are placed in the Boot Loader section and Boot Lock bit BLB02 is programmed, interrupts are disabled while executing from the Application section. If Interrupt Vectors are placed in the Application section and Boot Lock bit BLB12 is programed, interrupts are disabled while executing from the Boot Loader section. Refer to the section Boot Loader Support - Read-While-Write Self-Programming for details on Boot Lock Bits.

\section*{Bit 0 - IVCE: Interrupt Vector Change Enable}

The IVCE bit must be written to logic one to enable change of the IVSEL bit. IVCE is cleared by hardware four cycles after it is written or when IVSEL is written. Setting the IVCE bit will disable interrupts, as explained in the IVSEL description above. See Code Example below.
```

Assembly Code Example
Move interrupts:
; Enable change of Interrupt Vectors
ldi r16, (1<<IVCE)
out GICR, r16
; Move interrupts to boot Flash section
ldi r16, (1<<IVSEL)
out GICR, r16
ret

```

\section*{C Code Example}
```

void Move_interrupts(void)
{
/* Enable change of Interrupt Vectors */
GICR = (1<<IVCE);
/* Move interrupts to boot Flash section */
GICR = (1<<IVSEL);
}

```

\section*{16. External Interrupts}

The External Interrupts are triggered by the INT0, INT1, and INT2 pins. Observe that, if enabled, the interrupts will trigger even if the INT0:2 pins are configured as outputs. This feature provides a way of generating a software interrupt. The external interrupts can be triggered by a falling or rising edge or a low level (INT2 is only an edge triggered interrupt). This is set up as indicated in the specification for the MCU Control Register - MCUCR - and MCU Control and Status Register - MCUCSR. When the external interrupt is enabled and is configured as level triggered (only INTO/INT1), the interrupt will trigger as long as the pin is held low. Note that recognition of falling or rising edge interrupts on INT0 and INT1 requires the presence of an I/O clock, described in "Clock Systems and their Distribution" on page 25. Low level interrupts on INT0/INT1 and the edge interrupt on INT2 are detected asynchronously. This implies that these interrupts can be used for waking the part also from sleep modes other than Idle mode. The I/O clock is halted in all sleep modes except Idle mode.

Note that if a level triggered interrupt is used for wake-up from Power-down mode, the changed level must be held for some time to wake up the MCU. This makes the MCU less sensitive to noise. The changed level is sampled twice by the Watchdog Oscillator clock. The period of the Watchdog Oscillator is \(1 \mu \mathrm{~s}\) (nominal) at 5.0 V and \(25^{\circ} \mathrm{C}\). The frequency of the Watchdog Oscillator is voltage dependent as shown in "Electrical Characteristics" on page 296. The MCU will wake up if the input has the required level during this sampling or if it is held until the end of the start-up time. The start-up time is defined by the SUT fuses as described in "System Clock and Clock Options" on page 25. If the level is sampled twice by the Watchdog Oscillator clock but disappears before the end of the startup time, the MCU will still wake up, but no interrupt will be generated. The required level must be held long enough for the MCU to complete the wake up to trigger the level interrupt.

\subsection*{16.1. Register Description}

\subsection*{16.1.1. MCUCR - MCU Control Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: MCUCR
Offset: 0x35
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 55\)

Bits 3:2 - ISC1n: Interrupt Sense Control 1 Bit 1 and Bit 0 [ \(\mathrm{n}=1: 0\) ]
The External Interrupt 1 is activated by the external pin INT1 if the SREG I-bit and the corresponding interrupt mask in the GICR are set. The level and edges on the external INT1 pin that activate the interrupt are defined in the next table. The value on the INT1 pin is sampled before detecting edges. If edge or toggle interrupt is selected, pulses that last longer than one clock period will generate an interrupt. Shorter pulses are not guaranteed to generate an interrupt. If low level interrupt is selected, the low level must be held until the completion of the currently executing instruction to generate an interrupt.
Table 16-1. Interrupt 1 Sense Control
\begin{tabular}{|l|l|l|}
\hline ISC11 & ISC10 & Description \\
\hline 0 & 0 & The low level of INT1 generates an interrupt request. \\
\hline 0 & 1 & Any logical change on INT1 generates an interrupt request. \\
\hline 1 & 0 & The falling edge of INT1 generates an interrupt request. \\
\hline 1 & 1 & The rising edge of INT1 generates an interrupt request. \\
\hline
\end{tabular}

Bits 1:0 - ISCOn: Interrupt Sense Control 0 Bit 1 and Bit 0 [ \(n=1: 0]\)
The External Interrupt 0 is activated by the external pin INTO if the SREG I-flag and the corresponding interrupt mask are set. The level and edges on the external INTO pin that activate the interrupt are defined in the next table. The value on the INTO pin is sampled before detecting edges. If edge or toggle interrupt is selected, pulses that last longer than one clock period will generate an interrupt. Shorter pulses are not guaranteed to generate an interrupt. If low level interrupt is selected, the low level must be held until the completion of the currently executing instruction to generate an interrupt.
Table 16-2. Interrupt 0 Sense Control
\begin{tabular}{|l|l|l|}
\hline ISC01 & ISC00 & Description \\
\hline 0 & 0 & The low level of INTO generates an interrupt request. \\
\hline 0 & 1 & Any logical change on INTO generates an interrupt request. \\
\hline 1 & 0 & The falling edge of INTO generates an interrupt request. \\
\hline 1 & 1 & The rising edge of INTO generates an interrupt request. \\
\hline
\end{tabular}

\subsection*{16.1.2. MCUCSR - MCU Control and Status Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: MCUCSR
Offset: 0x34
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 54\)

Bit 6 - ISC2: ISC2: Interrupt Sense Control 2
The Asynchronous External Interrupt 2 is activated by the external pin INT2 if the SREG I-bit and the corresponding interrupt mask in GICR are set. If ISC2 is written to zero, a falling edge on INT2 activates the interrupt. If ISC2 is written to one, a rising edge on INT2 activates the interrupt. Edges on INT2 are registered asynchronously. Pulses on INT2 wider than the minimum pulse width given in the table below will generate an interrupt. Shorter pulses are not guaranteed to generate an interrupt. When changing the ISC2 bit, an interrupt can occur. Therefore, it is recommended to first disable INT2 by clearing its Interrupt Enable bit in the GICR Register. Then, the ISC2 bit can be changed. Finally, the INT2 Interrupt Flag should be cleared by writing a logical one to its Interrupt Flag bit (INTF2) in the GIFR Register before the interrupt is re-enabled.
Table 16-3. Asynchronous External Interrupt Characteristics
\begin{tabular}{|l|l|l|l|l|l|l|}

for \\
asynchronou \\
s external \\
interrupt
\end{tabular} & & 50 & ns \\
\hline
\end{tabular}

\subsection*{16.1.3. GICR - General Interrupt Control Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 x 00-0 x 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: GICR
Offset: 0x3B
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 5 \mathrm{~B}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & INT1 & INTO & INT2 & & & & & \\
\hline Access & R/W & R/W & R/W & & & & & \\
\hline Reset & 0 & 0 & 0 & & & & & \\
\hline
\end{tabular}

\section*{Bit 7 - INT1: External Interrupt Request 1 Enable}

When the INT1 bit is set (one) and the l-bit in the Status Register (SREG) is set (one), the external pin interrupt is enabled. The Interrupt Sense Control1 bits 1/0 (ISC11 and ISC10) in the MCU general Control Register (MCUCR) define whether the external interrupt is activated on rising and/or falling edge of the INT1 pin or level sensed. Activity on the pin will cause an interrupt request even if INT1 is configured as an output. The corresponding interrupt of External Interrupt Request 1 is executed from the INT1 Interrupt Vector.

\section*{Bit 6 - INTO: External Interrupt Request 0 Enable}

When the INTO bit is set (one) and the I-bit in the Status Register (SREG) is set (one), the external pin interrupt is enabled. The Interrupt Sense Control0 bits \(1 / 0\) (ISC01 and ISC00) in the MCU general Control Register (MCUCR) define whether the external interrupt is activated on rising and/or falling edge of the INT0 pin or level sensed. Activity on the pin will cause an interrupt request even if INTO is configured as an output. The corresponding interrupt of External Interrupt Request 0 is executed from the INTO Interrupt Vector.

\section*{Bit 5 - INT2: External Interrupt Request 2 Enable}

When the INT2 bit is set (one) and the I-bit in the Status Register (SREG) is set (one), the external pin interrupt is enabled. The Interrupt Sense Control2 bit (ISC2) in the MCU Control and Status Register (MCUCSR) defines whether the External Interrupt is activated on rising or falling edge of the INT2 pin. Activity on the pin will cause an interrupt request even if INT2 is configured as an output. The corresponding interrupt of External Interrupt Request 2 is executed from the INT2 Interrupt Vector.

\subsection*{16.1.4. GIFR - General Interrupt Flag Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 \mathrm{~F}\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: GIFR
Offset: 0x3A
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 5 \mathrm{~A}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 0 \\
\hline & INTF1 & INTF0 & INTF2 & & & & \\
\hline Access & R/W & R/W & R/W & & & & \\
\hline Reset & 0 & 0 & 0 & & & & \\
\hline
\end{tabular}

Bit 7 - INTF1: External Interrupt Flag 1
When an event on the INT1 pin triggers an interrupt request, INTF1 becomes set (one). If the I-bit in SREG and the INT1 bit in GICR are set (one), the MCU will jump to the corresponding Interrupt Vector. The flag is cleared when the interrupt routine is executed. Alternatively, the flag can be cleared by writing a logical one to it. This flag is always cleared when INT1 is configured as a level interrupt.

\section*{Bit 6 - INTFO: External Interrupt Flag 0}

When an event on the INTO pin triggers an interrupt request, INTFO becomes set (one). If the I-bit in SREG and the INTO bit in GICR are set (one), the MCU will jump to the corresponding Interrupt Vector. The flag is cleared when the interrupt routine is executed. Alternatively, the flag can be cleared by writing a logical one to it. This flag is always cleared when INTO is configured as a level interrupt.

\section*{Bit 5 - INTF2: External Interrupt Flag 2}

When an event on the INT2 pin triggers an interrupt request, INTF2 becomes set (one). If the I-bit in SREG and the INT2 bit in GICR are set (one), the MCU will jump to the corresponding Interrupt Vector. The flag is cleared when the interrupt routine is executed. Alternatively, the flag can be cleared by writing a logical one to it. Note that when entering some sleep modes with the INT2 interrupt disabled, the input buffer on this pin will be disabled. This may cause a logic change in internal signals which will set the INTF2 Flag. See Digital Input Enable and Sleep Modes for more information.

\section*{17. I/O Ports}

\subsection*{17.1. Overview}

All AVR ports have true Read-Modify-Write functionality when used as general digital I/O ports. This means that the direction of one port pin can be changed without unintentionally changing the direction of any other pin with the SBI and CBI instructions. The same applies when changing drive value (if configured as output) or enabling/disabling of pull-up resistors (if configured as input). Each output buffer has symmetrical drive characteristics with both high sink and source capability. The pin driver is strong enough to drive LED displays directly. All port pins have individually selectable pull-up resistors with a supply-voltage invariant resistance. All I/O pins have protection diodes to both \(\mathrm{V}_{\mathrm{CC}}\) and Ground as indicated in the following figure. Refer to Electrical Characteristics \(-T A=-40^{\circ} \mathrm{C}\) to \(85^{\circ} \mathrm{C}\) for a complete list of parameters.
Figure 17-1. I/O Pin Equivalent Schematic

All registers and bit references in this section are written in general form. A lower case "x" represents the numbering letter for the port, and a lower case " \(n\) " represents the bit number. However, when using the register or bit defines in a program, the precise form must be used (i.e., PORTB3 for bit 3 in Port B, here documented generally as PORTxn). The physical I/O Registers and bit locations are listed in Register Description.

Three I/O memory address locations are allocated for each port, one each for the Data Register PORTx, Data Direction Register - DDRx, and the Port Input Pins - PINx. The Port Input Pins I/O location is read only, while the Data Register and the Data Direction Register are read/write. In addition, the Pullup Disable - PUD bit in SFIOR disables the pull-up function for all pins in all ports when set.

Using the I/O port as General Digital I/O is described in Ports as General Digital I/O. Most port pins are multiplexed with alternate functions for the peripheral features on the device. How each alternate function interferes with the port pin is described in Alternate Port Functions. Refer to the individual module sections for a full description of the alternate functions.

Note that enabling the alternate function of some of the port pins does not affect the use of the other pins in the port as general digital I/O.

\section*{Related Links}

\subsection*{17.2. Ports as General Digital I/O}

The ports are bi-directional I/O ports with optional internal pull-ups. The following figure shows a functional description of one I/O-port pin, here generically called Pxn.

Figure 17-2. General Digital I/O \({ }^{(1)}\)

Note: 1. WPx, WDx, RRx, RPx, and RDx are common to all pins within the same port. clk \({ }_{/ / 0}\), SLEEP, and PUD are common to all ports

\subsection*{17.2.1. Configuring the Pin}

Each port pin consists of three register bits: DDxn, PORTxn, and PINxn. As shown in Register Description, the DDxn bits are accessed at the DDRx I/O address, the PORTxn bits at the PORTx I/O address, and the PINxn bits at the PINx I/O address.

The DDxn bit in the DDRx Register selects the direction of this pin. If DDxn is written logic one, Pxn is configured as an output pin. If DDxn is written logic zero, Pxn is configured as an input pin.
If PORTxn is written logic one when the pin is configured as an input pin, the pull-up resistor is activated. To switch the pull-up resistor off, PORTxn has to be written logic zero or the pin has to be configured as an output pin. The port pins are tri-stated when reset condition becomes active, even if no clocks are running.

If PORTxn is written logic one when the pin is configured as an output pin, the port pin is driven high (one). If PORTxn is written logic zero when the pin is configured as an output pin, the port pin is driven low (zero).
When switching between tri-state (\{DDxn, PORTxn\} = 0b00) and output high (\{DDxn, PORTxn\} = 0b11), an intermediate state with either pull-up enabled (\{DDxn, PORTxn\} = 0b01) or output low (\{DDxn,

PORTxn\} \(=0 b 10\) ) must occur. Normally, the pull-up enabled state is fully acceptable, as a high-impedant environment will not notice the difference between a strong high driver and a pull-up. If this is not the case, the PUD bit in the SFIOR Register can be set to disable all pull-ups in all ports.

Switching between input with pull-up and output low generates the same problem. The user must use either the tristate (\{DDxn, PORTxn\} = 0b00) or the output high state (\{DDxn, PORTxn\} =0b11) as an intermediate step.

The table below summarizes the control signals for the pin value.
Table 17-1. Port Pin Configurations
\begin{tabular}{|l|l|l|l|l|l|}
\hline DDxn & PORTxn & \begin{tabular}{l} 
PUD (in \\
SFIOR)
\end{tabular} & I/O & Pull-up & Comment \\
\hline 0 & 0 & x & Input & No & Tri-state (Hi-Z) \\
\hline 0 & 1 & 0 & Input & Yes & \begin{tabular}{l} 
Pxn will source current if \\
external pulled low.
\end{tabular} \\
\hline 0 & 1 & 1 & Input & No & Tri-state (Hi-Z) \\
\hline 1 & 0 & x & Output & No & Output Low (Sink) \\
\hline 1 & 1 & x & Output & No & Output High (Source) \\
\hline
\end{tabular}

\subsection*{17.2.2. Reading the Pin Value}

Independent of the setting of Data Direction bit DDxn, the port pin can be read through the PINxn Register Bit. As shown in Figure 17-2, the PINxn Register bit and the preceding latch constitute a synchronizer. This is needed to avoid metastability if the physical pin changes value near the edge of the internal clock, but it also introduces a delay. The next figure shows a timing diagram of the synchronization when reading an externally applied pin value. The maximum and minimum propagation delays are denoted \(t_{p d, \max }\) and \(t_{p d, \text { min }}\) respectively.
Figure 17-3. Synchronization when Reading an Externally Applied Pin value

Consider the clock period starting shortly after the first falling edge of the system clock. The latch is closed when the clock is low, and goes transparent when the clock is high, as indicated by the shaded region of the "SYNC LATCH" signal. The signal value is latched when the system clock goes low. It is clocked into the PINxn Register at the succeeding positive clock edge. As indicated by the two arrows
\(t_{p d, \text { max }}\) and \(t_{p d, \text { min }}\), a single signal transition on the pin will be delayed between \(1 / 2\) and \(1-1 / 2\) system clock period depending upon the time of assertion.

When reading back a software assigned pin value, a nop instruction must be inserted as indicated in the figure below. The out instruction sets the "SYNC LATCH" signal at the positive edge of the clock. In this case, the delay \(t_{\text {pd }}\) through the synchronizer is 1 system clock period.

Figure 17-4. Synchronization when Reading a Software Assigned Pin Value

The following code example shows how to set port B pins 0 and 1 high, 2 and 3 low, and define the port pins from 4 to 7 as input with pull-ups assigned to port pins 6 and 7 . The resulting pin values are read back again, but as previously discussed, a nop instruction is included to be able to read back the value recently assigned to some of the pins.
```

Assembly Code Example }\mp@subsup{}{}{(1)
; Define pull-ups and set outputs high
; Define directions for port pins
ldi r16,(1<<PB7)|(1<<PB6) | (1<<PB1) | (1<<PB0)
ldi r17,(1<<DDB3)|(1<<DDB2)|(1<<DDB1)|(1<<DDB0)
out PORTB,r16
out DDRB,r17
; Insert nop for synchronization
nop
; Read port pins
in r16,PINB
:.

```

\section*{C Code Example \({ }^{(1)}\)}
```

unsigned char i;
/* Define pull-ups and set outputs high */
/* Define directions for port pins */
PORTB = (1<<PB7) | (1<<PB6) | (1<<PB1)| (1<<PB0);
DDRB = (1<<DDB3)|(1<<DDB2) | (1<<DDB1) | (1<<DDB0);
/* Insert nop for synchronization*/
NOP();
T* Read port pins */
i = PINB;
:.

```

Note: 1. For the assembly program, two temporary registers are used to minimize the time from pull-ups are set on pins \(0,1,6\), and 7 , until the direction bits are correctly set, defining bit 2 and 3 as low and redefining bits 0 and 1 as strong high drivers.

\subsection*{17.2.3. Digital Input Enable and Sleep Modes}

As shown in figure Figure 17-2, the digital input signal can be clamped to ground at the input of the Schmitt Trigger. The signal denoted SLEEP in the figure, is set by the MCU Sleep Controller in Powerdown mode, Power-save mode, and Standby mode to avoid high power consumption if some input signals are left floating, or have an analog signal level close to \(\mathrm{V}_{\mathrm{CC}} / 2\).

SLEEP is overridden for port pins enabled as external interrupt pins. If the external interrupt request is not enabled, SLEEP is active also for these pins. SLEEP is also overridden by various other alternate functions as described in Alternate Port Functions.

If a logic high level ("one") is present on an Asynchronous External Interrupt pin configured as "Interrupt on Rising Edge, Falling Edge, or Any Logic Change on Pin" while the external interrupt is not enabled, the corresponding External Interrupt Flag will be set when resuming from the above mentioned sleep modes, as the clamping in these sleep modes produces the requested logic change.

\subsection*{17.2.4. Unconnected Pins}

If some pins are unused, it is recommended to ensure that these pins have a defined level. Even though most of the digital inputs are disabled in the deep sleep modes as described above, floating inputs should be avoided to reduce current consumption in all other modes where the digital inputs are enabled (Reset, Active mode and Idle mode).

The simplest method to ensure a defined level of an unused pin, is to enable the internal pull-up. In this case, the pull-up will be disabled during reset. If low power consumption during reset is important, it is recommended to use an external pull-up or pull-down. Connecting unused pins directly to \(\mathrm{V}_{\mathrm{Cc}}\) or GND is not recommended, since this may cause excessive currents if the pin is accidentally configured as an output.

\subsection*{17.3. Alternate Port Functions}

Most port pins have alternate functions in addition to being general digital I/Os. The following figure shows how the port pin control signals from the simplified Figure 17-2 can be overridden by alternate functions. The overriding signals may not be present in all port pins, but the figure serves as a generic description applicable to all port pins in the AVR microcontroller family.

Figure 17-5. Alternate Port Functions \({ }^{(1)}\)

Note: 1. WPx, WDx, RRx, RPx, and RDx are common to all pins within the same port. clk \({ }_{/ / 0}\), SLEEP, and PUD are common to all ports. All other signals are unique for each pin.

The following table summarizes the function of the overriding signals. The pin and port indexes from the figure above are not shown in the succeeding tables. The overriding signals are generated internally in the modules having the alternate function.

Table 17-2. Generic Description of Overriding Signals for Alternate Functions

\end{tabular} & \begin{tabular}{l} 
If this signal is set, the Output Driver Enable is controlled by the DDOV \\
signal. If this signal is cleared, the Output driver is enabled by the DDxn \\
Register bit.
\end{tabular} \\
\hline DDOV & \begin{tabular}{l} 
Data Direction \\
Override Value
\end{tabular} & \begin{tabular}{l} 
If DDOE is set, the Output Driver is enabled/disabled when DDOV is \\
set/cleared, regardless of the setting of the DDxn Register bit.
\end{tabular} \\
\hline PVOE & \begin{tabular}{l} 
Port Value Override \\
Enable
\end{tabular} & \begin{tabular}{l} 
If this signal is set and the Output Driver is enabled, the port value is \\
controlled by the PVOV signal. If PVOE is cleared, and the Output \\
Driver is enabled, the port Value is controlled by the PORTxn Register \\
bit.
\end{tabular} \\
\hline PVOV & \begin{tabular}{l} 
Port Value Override \\
Value
\end{tabular} & \begin{tabular}{l} 
If PVOE is set, the port value is set to PVOV, regardless of the setting of \\
the PORTxn Register bit.
\end{tabular} \\
\hline DIEOE & \begin{tabular}{l} 
Digital Input Enable \\
Override Enable
\end{tabular} & \begin{tabular}{l} 
If this bit is set, the Digital Input Enable is controlled by the DIEOV \\
signal. If this signal is cleared, the Digital Input Enable is determined by \\
MCU state (Normal mode, sleep mode).
\end{tabular} \\
\hline DIEOV & \begin{tabular}{l} 
Digital Input Enable \\
Override Value
\end{tabular} & \begin{tabular}{l} 
If DIEOE is set, the Digital Input is enabled/disabled when DIEOV is set// \\
cleared, regardless of the MCU state (Normal mode, sleep mode).
\end{tabular} \\
\hline DI & Digital Input & \begin{tabular}{l} 
This is the Digital Input to alternate functions. In the figure, the signal is \\
connected to the output of the Schmitt Trigger but before the \\
synchronizer. Unless the Digital Input is used as a clock source, the \\
module with the alternate function will use its own synchronizer.
\end{tabular} \\
\hline AIO & Analog Input/Output & \begin{tabular}{l} 
This is the Analog Input/output to/from alternate functions. The signal is \\
connected directly to the pad, and can be used bi-directionally.
\end{tabular} \\
\hline
\end{tabular}

The following subsections shortly describe the alternate functions for each port, and relate the overriding signals to the alternate function. Refer to the alternate function description for further details.

\subsection*{17.3.1. Alternate Functions of Port A}

Port \(A\) has an alternate function as analog input for the ADC as shown in the table below. If some Port A pins are configured as outputs, it is essential that these do not switch when a conversion is in progress. This might corrupt the result of the conversion.

Table 17-3. Port A Pins Alternate Functions
\begin{tabular}{|l|l|}
\hline Port Pin & Alternate Functions \\
\hline PA7 & ADC7 (ADC input channel 7) \\
\hline PA6 & ADC6 (ADC input channel 6) \\
\hline PA5 & ADC5 (ADC input channel 5) \\
\hline PA4 & ADC4 (ADC input channel 4) \\
\hline PA3 & ADC3 (ADC input channel 3) \\
\hline PA2 & ADC2 (ADC input channel 2) \\
\hline PA1 & ADC1 (ADC input channel 1) \\
\hline PA0 & ADC0 (ADC input channel 0) \\
\hline
\end{tabular}

The two tables below relates the alternate functions of Port A to the overriding signals shown in the figure in section Alternate Port Functions.
Table 17-4. Overriding Signals for Alternate Functions in PA7:PA4
\begin{tabular}{|l|l|l|l|l|}
\hline Signal Name & PA7/ADC7 & PA6/ADC6 & PA5/ADC5 & PA4/ADC4 \\
\hline PUOE & 0 & 0 & 0 & 0 \\
\hline PUOV & 0 & 0 & 0 & 0 \\
\hline DDOE & 0 & 0 & 0 & 0 \\
\hline DDOV & 0 & 0 & 0 & 0 \\
\hline PVOE & 0 & 0 & 0 & 0 \\
\hline PVOV & 0 & 0 & 0 & 0 \\
\hline DIEOE & 0 & 0 & 0 & 0 \\
\hline DIEOV & 0 & 0 & 0 & 0 \\
\hline DI & - & - & - & - \\
\hline AIO & ADC7 INPUT & ADC6 INPUT & ADC5 INPUT & ADC4 INPUT \\
\hline
\end{tabular}

Table 17-5. Overriding Signals for Alternate Functions in PA3:PA0
\begin{tabular}{|l|l|l|l|l|}
\hline Signal Name & PA3/ADC3 & PA2/ADC2 & PA1/ADC1 & PA0/ADC0 \\
\hline PUOE & 0 & 0 & 0 & 0 \\
\hline PUOV & 0 & 0 & 0 & 0 \\
\hline DDOE & 0 & 0 & 0 & 0 \\
\hline DDOV & 0 & 0 & 0 & 0 \\
\hline PVOE & 0 & 0 & 0 & 0 \\
\hline PVOV & 0 & 0 & 0 & 0 \\
\hline DIEOE & 0 & 0 & 0 & 0 \\
\hline DIEOV & 0 & 0 & 0 & 0 \\
\hline DI & - & - & - & - \\
\hline AIO & ADC3 INPUT & ADC2 INPUT & ADC1 INPUT & ADC0 INPUT \\
\hline
\end{tabular}

\subsection*{17.3.2. Alternate Functions of Port B}

The Port B pins with alternate functions are shown in the table below:
Table 17-6. Port B Pins Alternate Functions
\begin{tabular}{|l|l|}
\hline Port Pin & Alternate Functions \\
\hline PB7 & SCK (SPI Bus Serial Clock) \\
\hline PB6 & MISO (SPI Bus Master Input/Slave Output) \\
\hline PB5 & MOSI (SPI Bus Master Output/Slave Input) \\
\hline PB4 & \(\overline{\text { SS }}\) (SPI Slave Select Input) \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Port Pin & Alternate Functions \\
\hline PB3 & \begin{tabular}{l} 
AIN1 (Analog Comparator Negative Input) \\
OC0 (Timer/Counter0 Output Compare Match Output)
\end{tabular} \\
\hline PB2 & \begin{tabular}{l} 
AIN0 (Analog Comparator Positive Input) \\
INT2 (External Interrupt 2 Input)
\end{tabular} \\
\hline PB1 & T1 (Timer/Counter1 External Counter Input) \\
\hline PB0 & \begin{tabular}{l} 
T0 (Timer/Counter0 External Counter Input) \\
XCK (USART External Clock Input/Output)
\end{tabular} \\
\hline
\end{tabular}

The alternate pin configuration is as follows:

\section*{- SCK - Port B, Bit 7}

SCK: Master Clock output, Slave Clock input pin for SPI. When the SPI is enabled as a Slave, this pin is configured as an input regardless of the setting of DDB7. When the SPI is enabled as a Master, the data direction of this pin is controlled by DDB7. When the pin is forced by the SPI to be an input, the pull-up can still be controlled by the PORTB7 bit.

\section*{- MISO - Port B, Bit 6}

MISO: Master Data input, Slave Data output pin for SPI. When the SPI is enabled as a Master, this pin is configured as an input regardless of the setting of DDB6. When the SPI is enabled as a Slave, the data direction of this pin is controlled by DDB6. When the pin is forced by the SPI to be an input, the pull-up can still be controlled by the PORTB6 bit.
- MOSI - Port B, Bit 5

MOSI: SPI Master Data output, Slave Data input for SPI. When the SPI is enabled as a Slave, this pin is configured as an input regardless of the setting of DDB5. When the SPI is enabled as a Master, the data direction of this pin is controlled by DDB5. When the pin is forced by the SPI to be an input, the pull-up can still be controlled by the PORTB5 bit.

\section*{- \(\overline{\mathbf{S S}}\) - Port B, Bit 4}
\(\overline{\mathrm{SS}}\) : Slave Select input. When the SPI is enabled as a Slave, this pin is configured as an input regardless of the setting of DDB4. As a Slave, the SPI is activated when this pin is driven low. When the SPI is enabled as a Master, the data direction of this pin is controlled by DDB4. When the pin is forced by the SPI to be an input, the pull-up can still be controlled by the PORTB4 bit.

\section*{- AIN1/OC0 - Port B, Bit 3}

AIN1, Analog Comparator Negative Input. Configure the port pin as input with the internal pull-up switched off to avoid the digital port function from interfering with the function of the analog comparator.
OC0, Output Compare Match output: The PB3 pin can serve as an external output for the Timer/Counter0 Compare Match. The PB3 pin has to be configured as an output (DDB3 set (one)) to serve this function. The OCO pin is also the output pin for the PWM mode timer function.

\section*{- AINO/INT2 - Port B, Bit 2}

AINO, Analog Comparator Positive input. Configure the port pin as input with the internal pull-up switched off to avoid the digital port function from interfering with the function of the Analog Comparator.

INT2, External Interrupt Source 2: The PB2 pin can serve as an external interrupt source to the MCU.

\section*{- T1 - Port B, Bit 1}

T1, Timer/Counter1 Counter Source.
- T0/XCK - Port B, Bit 0

TO, Timer/Counter0 Counter Source.
XCK, USART External Clock. The Data Direction Register (DDBO) controls whether the clock is output (DDB0 set) or input (DDB0 cleared). The XCK pin is active only when the USART operates in Synchronous mode.

The tables below relate the alternate functions of Port B to the overriding signals shown in the figure in section Alternate Port Functions. SPI MSTR INPUT and SPI SLAVE OUTPUT constitute the MISO signal, while MOSI is divided into SPI MSTR OUTPUT and SPI SLAVE INPUT.

Table 17-7. Overriding Signals for Alternate Functions in PB7:PB4
\begin{tabular}{|l|l|l|l|l|}

\hline DIEOV & 0 & 1 & 0 & 0 \\
\hline DI & - & INT2 INPUT & T1 INPUT & XCK INPUT/TO INPUT \\
\hline AIO & AIN1 INPUT & AIN0 INPUT & - & - \\
\hline
\end{tabular}

\subsection*{17.3.3. Alternate Functions of Port C}

The Port \(C\) pins with alternate functions are shown in the table below. If the JTAG interface is enabled, the pull-up resistors on pins PC5(TDI), PC3(TMS) and PC2(TCK) will be activated even if a reset occurs.

Table 17-9. Port C Pins Alternate Functions
\begin{tabular}{|l|l|}
\hline Port Pin & Alternate Function \\
\hline PC7 & TOSC2 (Timer Oscillator Pin 2) \\
\hline PC6 & TOSC1 (Timer Oscillator Pin 1) \\
\hline PC5 & TDI (JTAG Test Data In) \\
\hline PC4 & TDO (JTAG Test Data Out) \\
\hline PC3 & TMS (JTAG Test Mode Select) \\
\hline PC2 & TCK (JTAG Test Clock) \\
\hline PC1 & SDA (Two-wire Serial Bus Data Input/Output Line) \\
\hline PC0 & SCL (Two-wire Serial Bus Clock Line) \\
\hline
\end{tabular}

The alternate pin configuration is as follows:

\section*{- TOSC2 - Port C, Bit 7}

TOSC2, Timer Oscillator pin 2: When the AS2 bit in ASSR is set (one) to enable asynchronous clocking of Timer/Counter2, pin PC7 is disconnected from the port, and becomes the inverting output of the Oscillator amplifier. In this mode, a Crystal Oscillator is connected to this pin, and the pin can not be used as an I/O pin.

\section*{- TOSC1 - Port C, Bit 6}

TOSC1, Timer Oscillator pin 1: When the AS2 bit in ASSR is set (one) to enable asynchronous clocking of Timer/Counter2, pin PC6 is disconnected from the port, and becomes the input of the inverting Oscillator amplifier. In this mode, a Crystal Oscillator is connected to this pin, and the pin can not be used as an I/O pin.

\section*{- TDI - Port C, Bit 5}

TDI, JTAG Test Data In: Serial input data to be shifted in to the Instruction Register or Data Register (scan chains). When the JTAG interface is enabled, this pin can not be used as an I/O pin.

\section*{- TDO - Port C, Bit 4}

TDO, JTAG Test Data Out: Serial output data from Instruction Register or Data Register. When the JTAG interface is enabled, this pin can not be used as an I/O pin.

The TDO pin is tri-stated unless TAP states that shifts out data are entered.

\section*{- TMS - Port C, Bit 3}

TMS, JTAG Test Mode Select: This pin is used for navigating through the TAP-controller state machine. When the JTAG interface is enabled, this pin can not be used as an I/O pin.

\section*{- TCK - Port C, Bit 2}

TCK, JTAG Test Clock: JTAG operation is synchronous to TCK. When the JTAG interface is enabled, this pin can not be used as an I/O pin.

\section*{- SDA - Port C, Bit 1}

SDA, Two-wire Serial Interface Data: When the TWEN bit in TWCR is set (one) to enable the Two-wire Serial Interface, pin PC1 is disconnected from the port and becomes the Serial Data I/O pin for the Twowire Serial Interface. In this mode, there is a spike filter on the pin to suppress spikes shorter than 50 ns on the input signal, and the pin is driven by an open drain driver with slew-rate limitation. When this pin is used by the Two-wire Serial Interface, the pull-up can still be controlled by the PORTC1 bit.
- SCL - Port C, Bit 0

SCL, Two-wire Serial Interface Clock: When the TWEN bit in TWCR is set (one) to enable the Two-wire Serial Interface, pin PCO is disconnected from the port and becomes the Serial Clock I/O pin for the Twowire Serial Interface. In this mode, there is a spike filter on the pin to suppress spikes shorter than 50 ns on the input signal, and the pin is driven by an open drain driver with slew-rate limitation. When this pin is used by the Two-wire Serial Interface, the pull-up can still be controlled by the PORTC0 bit.
The tables below relate the alternate functions of Port C to the overriding signals shown in Alternate Port Functions.

Table 17-10. Overriding Signals for Alternate Functions in PC7:PC4
\begin{tabular}{|l|l|l|l|l|}
\hline \begin{tabular}{l} 
Signal \\
Name
\end{tabular} & PC7/TOSC2 & PC6/TOSC1 & PC5/TDI & PC4/TDO \\
\hline PUOE & AS2 & AS2 & JTAGEN & JTAGEN \\
\hline PUOV & 0 & 0 & 1 & 0 \\
\hline DDOE & AS2 & AS2 & JTAGEN & JTAGEN \\
\hline DDOV & 0 & 0 & 0 & SHIFT_IR + \\
\hline PVOE & 0 & 0 & 0 & SHIFT_DR \\
\hline PVOV & 0 & 0 & 0 & JTAGEN \\
\hline DIEOE & AS2 & AS2 & TDO \\
\hline DIEOV & 0 & 0 & 0 & JTAGEN \\
\hline DI & - & - & - & 0 \\
\hline AIO & T/C2 OSC OUTPUT & T/C2 OSC INPUT & TDI & - \\
\hline
\end{tabular}

Table 17-11. Overriding Signals for Alternate Functions in PC3:PC0 \({ }^{(1)}\)
\begin{tabular}{|l|l|l|l|l|}
\hline \begin{tabular}{l} 
Signal \\
Name
\end{tabular} & PC3/TMS & PC2/TCK & PC1/SDA & PC0/SCL \\
\hline PUOE & JTAGEN & JTAGEN & TWEN & TWEN \\
\hline PUOV & 1 & 1 & PORTC1• \begin{tabular}{l} 
PUD
\end{tabular} & PORTC0• \(\overline{\text { PUD }}\) \\
\hline DDOE & JTAGEN & JTAGEN & TWEN & TWEN \\
\hline DDOV & 0 & 0 & SDA_OUT & SCL_OUT \\
\hline PVOE & 0 & 0 & TWEN & TWEN \\
\hline PVOV & 0 & 0 & 0 & 0 \\
\hline DIEOE & JTAGEN & JTAGEN & 0 & 0 \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|l|l|}
\hline \begin{tabular}{l} 
Signal \\
Name
\end{tabular} & PC3/TMS & PC2/TCK & PC1/SDA & PC0/SCL \\
\hline DIEOV & 0 & 0 & 0 & 0 \\
\hline DI & - & - & - & - \\
\hline AIO & TMS & TCK & SDA INPUT & SCL INPUT \\
\hline
\end{tabular}

Note: 1. When enabled, the Two-wire Serial Interface enables slew-rate controls on the output pins PC0 and PC1. This is not shown in the figure. In addition, spike filters are connected between the AIO outputs shown in the port figure and the digital logic of the TWI module.

\subsection*{17.3.4. Alternate Functions of Port D}

The Port D pins with alternate functions are shown in the table below:
Table 17-12. Port D Pins Alternate Functions
\begin{tabular}{|l|l|}
\hline Port Pin & Alternate Function \\
\hline PD7 & OC2 (Timer/Counter2 Output Compare Match Output) \\
\hline PD6 & ICP1 (Timer/Counter1 Input Capture Pin) \\
\hline PD5 & OC1A (Timer/Counter1 Output Compare A Match Output) \\
\hline PD4 & OC1B (Timer/Counter1 Output Compare B Match Output) \\
\hline PD3 & INT1 (External Interrupt 1 Input) \\
\hline PD2 & INT0 (External Interrupt 0 Input) \\
\hline PD1 & TXD (USART Output Pin) \\
\hline PD0 & RXD (USART Input Pin) \\
\hline
\end{tabular}

The alternate pin configuration is as follows:

\section*{- OC2 - Port D, Bit 7}

OC2, Timer/Counter2 Output Compare Match output: The PD7 pin can serve as an external output for the Timer/Counter2 Output Compare. The pin has to be configured as an output (DDD7 set (one)) to serve this function. The OC2 pin is also the output pin for the PWM mode timer function.
- ICP1 - Port D, Bit 6

ICP1 - Input Capture Pin: The PD6 pin can act as an Input Capture pin for Timer/Counter1.

\section*{- OC1A - Port D, Bit 5}

OC1A, Output Compare Match A output: The PD5 pin can serve as an external output for the Timer/ Counter1 Output Compare A. The pin has to be configured as an output (DDD5 set (one)) to serve this function. The OC1A pin is also the output pin for the PWM mode timer function.

\section*{- OC1B - Port D, Bit 4}

OC1B, Output Compare Match B output: The PD4 pin can serve as an external output for the Timer/ Counter1 Output Compare B. The pin has to be configured as an output (DDD4 set (one)) to serve this function. The OC1B pin is also the output pin for the PWM mode timer function.
```

- INT1 - Port D, Bit 3

```

INT1, External Interrupt Source 1: The PD3 pin can serve as an external interrupt source.

\section*{- INTO - Port D, Bit 2}

INTO, External Interrupt Source 0: The PD2 pin can serve as an external interrupt source.

\section*{-TXD - Port D, Bit 1}

TXD, Transmit Data (Data output pin for the USART). When the USART Transmitter is enabled, this pin is configured as an output regardless of the value of DDD1.

\section*{- RXD - Port D, Bit 0}

RXD, Receive Data (Data input pin for the USART). When the USART Receiver is enabled this pin is configured as an input regardless of the value of DDDO. When the USART forces this pin to be an input, the pull-up can still be controlled by the PORTDO bit.

The tables below relate the alternate functions of Port D to the overriding signals shown in the figure in section Alternate Port Functions.

Table 17-13. Overriding Signals for Alternate Functions PD7:PD4

\end{tabular}

\subsection*{17.4. Register Description}

\subsection*{17.4.1. SFIOR - Special Function IO Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: SFIOR
Offset: 0x30
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 50\)

Bit 2 - PUD: Pull-up Disable
When this bit is written to one, the pull-ups in the I/O ports are disabled even if the DDxn and PORTxn Registers are configured to enable the pull-ups (\{DDxn, PORTxn\} = 0b01). See Configuring the Pin for more details about this feature.

\subsection*{17.4.2. PORTA - Port A Data Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: PORTA
Offset: 0x1B
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 3 \mathrm{~B}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\

\section*{18. Timer/Counter0 and Timer/Counter1 Prescalers}

\subsection*{18.1. Overview}

Timer/Counte1 and Timer/Counter0 share the same prescaler module, but the Timer/Counters can have different prescaler settings. The description below applies to Timer/Counte1 and Timer/Counter0.

\subsection*{18.2. Internal Clock Source}

The Timer/Counter can be clocked directly by the system clock (by setting the CSn2:0 = 1). This provides the fastest operation, with a maximum Timer/Counter clock frequency equal to system clock frequency ( \(\mathrm{f}_{\mathrm{CLK}}\) _/ O) . Alternatively, one of four taps from the prescaler can be used as a clock source. The prescaled

\subsection*{18.3. Prescaler Reset}

The prescaler is free running (i.e., operates independently of the clock select logic of the Timer/Counter) and it is shared by Timer/Counte1 and Timer/Counter0. Since the prescaler is not affected by the Timer/ Counter's clock select, the state of the prescaler will have implications for situations where a prescaled clock is used. One example of prescaling artifacts occurs when the timer is enabled and clocked by the prescaler \((6>\operatorname{CSn} 2: 0>1)\). The number of system clock cycles from when the timer is enabled to the first count occurs can be from 1 to \(N+1\) system clock cycles, where \(N\) equals the prescaler divisor ( \(8,64,256\), or 1024).

It is possible to use the prescaler reset for synchronizing the Timer/Counter to program execution. However, care must be taken if the other Timer/Counter that shares the same prescaler also uses prescaling. A prescaler reset will affect the prescaler period for all Timer/Counters it is connected to.

\subsection*{18.4. External Clock Source}

An external clock source applied to the \(\mathrm{T} 1 / \mathrm{T} 0\) pin can be used as Timer/Counter clock ( \(\mathrm{clk}_{\mathrm{T}_{1}} / \mathrm{clk}_{\mathrm{T}_{0}}\) ). The T1/T0 pin is sampled once every system clock cycle by the pin synchronization logic. The synchronized (sampled) signal is then passed through the edge detector. The figure below shows a functional equivalent block diagram of the T1/T0 synchronization and edge detector logic. The registers are clocked at the positive edge of the internal system clock ( \(\mathrm{Clk}_{/ / \mathrm{O}}\) ). The latch is transparent in the high period of the internal system clock.
The edge detector generates one \(\mathrm{cl}_{\mathrm{T} 1} / \mathrm{clk}_{\mathrm{T}}\) pulse for each positive \((\mathrm{CSn2:0}=7)\) or negative \((\mathrm{CSn2:0}=\) 6) edge it detects.

Figure 18-1. T1/T0 Pin Sampling

The synchronization and edge detector logic introduces a delay of 2.5 to 3.5 system clock cycles from an edge has been applied to the \(\mathrm{T} 1 / \mathrm{T} 0\) pin to the counter is updated.

Enabling and disabling of the clock input must be done when T1/T0 has been stable for at least one system clock cycle, otherwise it is a risk that a false Timer/Counter clock pulse is generated.

Each half period of the external clock applied must be longer than one system clock cycle to ensure correct sampling. The external clock must be guaranteed to have less than half the system clock frequency ( \(\mathrm{f}_{\text {ExtCIk }}<\mathrm{f}_{\text {clk_I/ }} / 2\) ) given a \(50 / 50 \%\) duty cycle. Since the edge detector uses sampling, the maximum frequency of an external clock it can detect is half the sampling frequency (Nyquist sampling theorem). However, due to variation of the system clock frequency and duty cycle caused by Oscillator source (crystal, resonator, and capacitors) tolerances, it is recommended that maximum frequency of an external clock source is less than \(\mathrm{f}_{\mathrm{clk} \_/ / / 2} / 2.5\).
An external clock source can not be prescaled.
Figure 18-2. Prescaler for Timer/Counte1 and Timer/Counter0 \({ }^{(1)}\)

Note: 1. The synchronization logic on the input pins (T1/T0) is shown in figure T1/T0 Pin Sampling in this section.

\subsection*{18.5. Register Description}

\subsection*{18.5.1. SFIOR - Special Function IO Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: SFIOR
Offset: 0x30
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 50\)

Bit 0 - PSR10: Prescaler Reset Timer/Counter1 and Timer/Counter0
When this bit is written to one, the Timer/Counter1 and Timer/Counter0 prescaler will be reset. The bit will be cleared by hardware after the operation is performed. Writing a zero to this bit will have no effect. Note that Timer/Counter1 and Timer/Counter0 share the same prescaler and a reset of this prescaler will affect both timers. This bit will always be read as zero.

\section*{19. 16-bit Timer/Counter1}

\subsection*{19.1. Features}
- True 16-bit Design (i.e., allows 16-bit PWM)
- Two independent Output Compare Units
- Double Buffered Output Compare Registers
- One Input Capture Unit
- Input Capture Noise Canceler
- Clear Timer on Compare Match (Auto Reload)
- Glitch-free, Phase Correct Pulse Width Modulator (PWM)
- Variable PWM Period
- Frequency Generator
- External Event Counter
- Four independent interrupt Sources (TOV1, OCF1A, OCF1B, and ICF1)

\subsection*{19.2. Overview}

The 16-bit Timer/Counter unit allows accurate program execution timing (event management), wave generation, and signal timing measurement. Most register and bit references in this section are written in general form. A lower case " \(n\) " replaces the Timer/Counter number, and a lower case "x" replaces the Output Compare unit channel. However, when using the register or bit defines in a program, the precise form must be used i.e., TCNT1 for accessing Timer/Counter1 counter value and so on.

A simplified block diagram of the 16-bit Timer/Counter is shown in the following figure. For the actual placement of I/O pins, refer to Pin Configurations. CPU accessible I/O Registers, including I/O bits and I/O pins, are shown in bold. The device-specific I/O Register and bit locations are listed in the Register Description.

Figure 19-1. 16-bit Timer/Counter Block Diagram \({ }^{(1)}\)

Note: 1. Refer to Pin Configurations, table Port B Pins Alternate Functions in Alternate Functions of Port \(B\), and table Port D Pins Alternate Functions in Alternate Functions of Port D for Timer/Counter1 pin placement and description.

\section*{Related Links}

Pin Configurations on page 13
Alternate Functions of Port B on page 81
Alternate Functions of Port D on page 86

\subsection*{19.2.1. Registers}

The Timer/Counter (TCNTn), Output Compare Registers (OCRnA/B), and Input Capture Register (ICRn) are all 16 -bit registers. Special procedures must be followed when accessing the 16-bit registers. These procedures are described in the section Accessing 16-bit Registers. The Timer/Counter Control Registers (TCCRnA/B) are 8 -bit registers and have no CPU access restrictions. Interrupt requests (abbreviated to Int.Req. in the figure) signals are all visible in the Timer Interrupt Flag Register (TIFR). All interrupts are individually masked with the Timer Interrupt Mask Register (TIMSK). TIFR and TIMSK are not shown in the figure since these registers are shared by other timer units.

The Timer/Counter can be clocked internally, via the prescaler, or by an external clock source on the T1 pin. The Clock Select logic block controls which clock source and edge the Timer/Counter uses to increment (or decrement) its value. The Timer/Counter is inactive when no clock source is selected. The output from the clock select logic is referred to as the timer clock ( \(\mathrm{clk}_{\mathrm{Tn}_{n}}\) ).

The double buffered Output Compare Registers (OCRnA/B) are compared with the Timer/Counter value at all time. The result of the compare can be used by the waveform generator to generate a PWM or variable frequency output on the Output Compare Pin (OCnA/B). See Output Compare Units. The Compare Match event will also set the Compare Match Flag (OCFnA/B) which can be used to generate an Output Compare interrupt request.

The Input Capture Register can capture the Timer/Counter value at a given external (edge triggered) event on either the Input Capture Pin (ICPn) or on the Analog Comparator pins (see Analog Comparator). The Input Capture unit includes a digital filtering unit (Noise Canceler) for reducing the chance of capturing noise spikes.
The TOP value, or maximum Timer/Counter value, can in some modes of operation be defined by either the OCRnA Register, the ICRn Register, or by a set of fixed values. When using OCRnA as TOP value in a PWM mode, the OCRnA Register can not be used for generating a PWM output. However, the TOP value will in this case be double buffered allowing the TOP value to be changed in run time. If a fixed TOP value is required, the ICRn Register can be used as an alternative, freeing the OCRnA to be used as PWM output.

\section*{Related Links}

AC - Analog Comparator on page 253

\subsection*{19.2.2. Definitions}

The following definitions are used extensively throughout the document:
Table 19-1. Definitions
\begin{tabular}{|l|l|}
\hline BOTTOM & The counter reaches the BOTTOM when it becomes \(0 \times 0000\). \\
\hline MAX & The counter reaches its MAXimum when it becomes 0xFFFF (decimal 65535). \\
\hline TOP & \begin{tabular}{l} 
The counter reaches the TOP when it becomes equal to the highest value in the count \\
sequence. The TOP value can be assigned to be one of the fixed values: \(0 \times 00 \mathrm{FF}, 0 \times 01 \mathrm{FF}\), or \\
0x03FF, or to the value stored in the OCRnA or ICRn Register. The assignment is dependent \\
of the mode of operation.
\end{tabular} \\
\hline
\end{tabular}

\subsection*{19.2.3. Compatibility}

The 16-bit Timer/Counter has been updated and improved from previous versions of the 16 -bit AVR Timer/Counter. This 16-bit Timer/Counter is fully compatible with the earlier version regarding:
- All 16-bit Timer/Counter related I/O Register address locations, including Timer Interrupt Registers.
- Bit locations inside all 16-bit Timer/Counter Registers, including Timer Interrupt Registers.
- Interrupt Vectors.

The following control bits have changed name, but have same functionality and register location:
- PWM10 is changed to WGM10.
- PWM11 is changed to WGM11.
- CTC1 is changed to WGM12.

The following bits are added to the 16-bit Timer/Counter Control Registers:
- FOC1A and FOC1B are added to TCCR1A.
- WGM13 is added to TCCR1B.

The 16-bit Timer/Counter has improvements that will affect the compatibility in some special cases.

\subsection*{19.3. Accessing 16-bit Registers}

The TCNTn, OCRnA/B, and ICRn are 16 -bit registers that can be accessed by the AVR CPU via the 8 -bit data bus. A 16 -bit register must be byte accessed using two read or write operations. The 16 -bit timer has a single 8 -bit register for temporary storing of the High byte of the 16 -bit access. The same temporary register is shared between all 16 -bit registers within the 16 -bit timer. Accessing the Low byte triggers the

16-bit read or write operation. When the Low byte of a 16-bit register is written by the CPU, the High byte stored in the temporary register, and the Low byte written are both copied into the 16-bit register in the same clock cycle. When the Low byte of a 16-bit register is read by the CPU, the High byte of the 16-bit register is copied into the temporary register in the same clock cycle as the Low byte is read.

Not all 16-bit accesses uses the temporary register for the High byte. Reading the OCRnA/B 16-bit registers does not involve using the temporary register.

To do a 16-bit write, the High byte must be written before the Low byte. For a 16-bit read, the Low byte must be read before the High byte.

The following code examples show how to access the 16-bit Timer Registers assuming that no interrupts updates the temporary register. The same principle can be used directly for accessing the OCRnA/B and ICRn Registers. Note that when using " \(C\) ", the compiler handles the 16-bit access.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

    :.
    Set TCNTn to 0x01FF
    ldi r17,0x01
ldi r16,0xFF
out TCNTnH,r17
out TCNTnL,r16
; Read TCNTn into r17:r16
in r16,TCNTnL
in r17,TCNTnH
:.

```

\section*{C Code Example \({ }^{(1)}\)}
```

unsigned int i;
/* Set TCNTn to 0x01FF */
TCNTn = 0x1FF;
/* Read TCNTn into i */
i = TCNTn;
:.

```

Note: 1. See About Code Examples.
The assembly code example returns the TCNTn value in the r17:r16 Register pair.
It is important to notice that accessing 16-bit registers are atomic operations. If an interrupt occurs between the two instructions accessing the 16-bit register, and the interrupt code updates the temporary register by accessing the same or any other of the 16-bit Timer Registers, then the result of the access outside the interrupt will be corrupted. Therefore, when both the main code and the interrupt code update the temporary register, the main code must disable the interrupts during the 16-bit access.

The following code examples show how to do an atomic read of the TCNTn Register contents. Reading any of the OCRnA/B or ICRn Registers can be done by using the same principle.

\section*{Asesmbly Code Example \({ }^{(1)}\)}
```

TIM16 ReadTCNTn:
; S
in r18,SREG
; Disable interrupts
cli
Read TCNTn into r17:r16
n r16,TCNTnL
in r17,TCNTnH
; Restore global interrupt flag
out SREG,r18
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

unsigned int TIM16_ReadTCNTn( void )
{
unsigned char sreg;
unsigned int i;
/* Save global interrupt flag */
sreg = SREG;
/* Disable interrupts */
CLI();
/* Read TCNTn into i */
i = TCNTn;
/* Restore global interrupt flag */
SREG = sreg;
return i;
}

```

\section*{Note: 1. See About Code Examples.}

The assembly code example returns the TCNTn value in the r17:r16 Register pair.
The following code examples show how to do an atomic write of the TCNTn Register contents. Writing any of the OCRnA/B or ICRn Registers can be done by using the same principle.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

TIM16 WriteTCNTn:
; S
in r18,SREG
; Disable interrupts
cli
; Set TCNTn to r17:r16
out TCNTnH,r17
out TCNTnL,r16
; Restore global interrupt flag
out SREG,r18
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

void TIM16_WriteTCNTn( unsigned int i )
{
unsigned char sreg;
unsigned int i;
/* Save global interrupt flag */
sreg = SREG;
/* Disable interrupts */
CLI();
/* Set TCNTn to i */
TCNTn = i;
/* Restore global interrupt flag */
SREG = sreg;
}

```

Note: 1. See About Code Examples.
The assembly code example requires that the r17:r16 Register pair contains the value to be written to TCNTn.

\section*{Related Links}

About Code Examples on page 19

\subsection*{19.3.1. Reusing the Temporary High Byte Register}

If writing to more than one 16 -bit register where the High byte is the same for all registers written, then the High byte only needs to be written once. However, note that the same rule of atomic operation described previously also applies in this case.

\subsection*{19.4. Timer/Counter Clock Sources}

The Timer/Counter can be clocked by an internal or an external clock source. The clock source is selected by the clock select logic which is controlled by the clock select (CSn2:0) bits located in the Timer/Counter Control Register B (TCCRnB). For details on clock sources and prescaler, see Timer/ Counte1 and Timer/Counter0 Prescalers.

\section*{Related Links}

Timer/Counter0 and Timer/Counter1 Prescalers on page 102

\subsection*{19.5. Counter Unit}

The main part of the 16 -bit Timer/Counter is the programmable 16-bit bi-directional counter unit. The figure below shows a block diagram of the counter and its surroundings.
Figure 19-2. Counter Unit Block Diagram

Signal description (internal signals):
count Increment or decrement TCNTn by 1.
direction Select between increment and decrement.
clear Clear TCNTn (set all bits to zero).
\(\mathbf{c l}_{\mathbf{T n}} \quad\) Timer/Counter clock.
TOP Signalize that TCNTn has reached maximum value.
BOTTOM Signalize that TCNTn has reached minimum value (zero).
The 16-bit counter is mapped into two 8-bit I/O memory locations: counter high (TCNTnH) containing the upper eight bits of the counter, and Counter Low (TCNTnL) containing the lower eight bits. The TCNTnH Register can only be indirectly accessed by the CPU. When the CPU does an access to the TCNTnH I/O location, the CPU accesses the High byte temporary register (TEMP). The temporary register is updated with the TCNTnH value when the TCNTnL is read, and TCNTnH is updated with the temporary register value when TCNTnL is written. This allows the CPU to read or write the entire 16 -bit counter value within one clock cycle via the 8 -bit data bus. It is important to notice that there are special cases of writing to the TCNTn Register when the counter is counting that will give unpredictable results. The special cases are described in the sections where they are of importance.

Depending on the mode of operation used, the counter is cleared, incremented, or decremented at each timer clock \(\left(\mathrm{clk}_{\mathrm{Tn}_{n}}\right)\). The \(\mathrm{clk}_{\mathrm{Tn}_{n}}\) can be generated from an external or internal clock source, selected by the clock select bits (CSn2:0). When no clock source is selected \((C S n 2: 0=0)\) the timer is stopped. However,
the TCNTn value can be accessed by the CPU, independent of whether \(\mathrm{clk}_{\mathrm{T}_{n}}\) is present or not. A CPU write overrides (has priority over) all counter clear or count operations.

The counting sequence is determined by the setting of the Waveform Generation mode bits (WGMn3:0) located in the Timer/Counter Control Registers A and B (TCCRnA and TCCRnB). There are close connections between how the counter behaves (counts) and how waveforms are generated on the Output Compare Outputs OCnx. For more details about advanced counting sequences and waveform generation, see Modes of Operation.

The Timer/Counter Overflow (TOVn) flag is set according to the mode of operation selected by the WGMn3:0 bits. TOVn can be used for generating a CPU interrupt.

\subsection*{19.6. Input Capture Unit}

The Timer/Counter incorporates an Input Capture unit that can capture external events and give them a timestamp indicating time of occurrence. The external signal indicating an event, or multiple events, can be applied via the ICPn pin or alternatively, via the Analog Comparator unit. The time-stamps can then be used to calculate frequency, duty-cycle, and other features of the signal applied. Alternatively the timestamps can be used for creating a log of the events.

The Input Capture unit is illustrated by the block diagram below. The elements of the block diagram that are not directly a part of the Input Capture unit are gray shaded. The small " n " in register and bit names indicates the Timer/Counter number.

Figure 19-3. Input Capture Unit Block Diagram

When a change of the logic level (an event) occurs on the Input Capture Pin (ICPn), alternatively on the Analog Comparator Output (ACO), and this change confirms to the setting of the edge detector, a capture will be triggered. When a capture is triggered, the 16 -bit value of the counter (TCNTn) is written to the Input Capture Register (ICRn). The Input Capture Flag (ICFn) is set at the same system clock as the TCNTn value is copied into ICRn Register. If enabled (TICIEn = 1), the Input Capture Flag generates an

Input Capture interrupt. The ICFn Flag is automatically cleared when the interrupt is executed. Alternatively the ICFn Flag can be cleared by software by writing a logical one to its I/O bit location.

Reading the 16-bit value in the Input Capture Register (ICRn) is done by first reading the Low byte (ICRnL) and then the High byte (ICRnH). When the Low byte is read the High byte is copied into the High byte temporary register (TEMP). When the CPU reads the ICRnH I/O location it will access the TEMP Register.

The ICRn Register can only be written when using a Waveform Generation mode that utilizes the ICRn Register for defining the counter's TOP value. In these cases the Waveform Generation mode (WGMn3:0) bits must be set before the TOP value can be written to the ICRn Register. When writing the ICRn Register the High byte must be written to the ICRnH I/O location before the Low byte is written to ICRnL.

For more information on how to access the 16 -bit registers refer to Accessing 16-bit Registers.

\subsection*{19.6.1. Input Capture Pin Source}

The main trigger source for the Input Capture unit is the Input Capture Pin (ICPn). Timer/Counter 1 can alternatively use the Analog Comparator Output as trigger source for the Input Capture unit. The Analog Comparator is selected as trigger source by setting the Analog Comparator Input Capture (ACIC) bit in the Analog Comparator Control and Status Register (ACSR). Be aware that changing trigger source can trigger a capture. The Input Capture Flag must therefore be cleared after the change.
Both the Input Capture Pin (ICPn) and the Analog Comparator Output (ACO) inputs are sampled using the same technique as for the Tn pin (see figure Tn Pin Sampling in section External Clock Source). The edge detector is also identical. However, when the noise canceler is enabled, additional logic is inserted before the edge detector, which increases the delay by four system clock cycles. Note that the input of the noise canceler and edge detector is always enabled unless the Timer/Counter is set in a Waveform Generation mode that uses ICRn to define TOP.

An Input Capture can be triggered by software by controlling the port of the ICPn pin.

\section*{Related Links}

External Clock Source on page 102

\subsection*{19.6.2. Noise Canceler}

The noise canceler improves noise immunity by using a simple digital filtering scheme. The noise canceler input is monitored over four samples, and all four must be equal for changing the output that in turn is used by the edge detector.

The noise canceler is enabled by setting the Input Capture Noise Canceler (ICNCn) bit in Timer/Counter Control Register \(B\) (TCCRnB). When enabled the noise canceler introduces additional four system clock cycles of delay from a change applied to the input, to the update of the ICRn Register. The noise canceler uses the system clock and is therefore not affected by the prescaler.

\subsection*{19.6.3. Using the Input Capture Unit}

The main challenge when using the Input Capture unit is to assign enough processor capacity for handling the incoming events. The time between two events is critical. If the processor has not read the captured value in the ICRn Register before the next event occurs, the ICRn will be overwritten with a new value. In this case the result of the capture will be incorrect.
When using the Input Capture interrupt, the ICRn Register should be read as early in the interrupt handler routine as possible. Even though the Input Capture interrupt has relatively high priority, the maximum interrupt response time is dependent on the maximum number of clock cycles it takes to handle any of the other interrupt requests.

Using the Input Capture unit in any mode of operation when the TOP value (resolution) is actively changed during operation, is not recommended.

Measurement of an external signal's duty cycle requires that the trigger edge is changed after each capture. Changing the edge sensing must be done as early as possible after the ICRn Register has been read. After a change of the edge, the Input Capture Flag (ICFn) must be cleared by software (writing a logical one to the I/O bit location). For measuring frequency only, the clearing of the ICFn Flag is not required (if an interrupt handler is used).

\subsection*{19.7. Output Compare Units}

The 16-bit comparator continuously compares TCNTn with the Output Compare Register (OCRnx). If TCNT equals OCRnx the comparator signals a match. A match will set the Output Compare Flag (OCFnx) at the next timer clock cycle. If enabled (OCIEnx = 1), the Output Compare Flag generates an Output Compare interrupt. The OCFnx Flag is automatically cleared when the interrupt is executed. Alternatively the OCFnx Flag can be cleared by software by writing a logical one to its I/O bit location. The waveform generator uses the match signal to generate an output according to operating mode set by the Waveform Generation mode (WGMn3:0) bits and Compare Output mode (COMnx1:0) bits. The TOP and BOTTOM signals are used by the waveform generator for handling the special cases of the extreme values in some modes of operation (See Modes of Operation.)

A special feature of Output Compare unit A allows it to define the Timer/Counter TOP value (i.e. counter resolution). In addition to the counter resolution, the TOP value defines the period time for waveforms generated by the waveform generator.

The figure below shows a block diagram of the Output Compare unit. The small " n " in the register and bit names indicates the device number ( \(\mathrm{n}=\mathrm{n}\) for Timer/Counter n ), and the " x " indicates Output Compare unit (A/B). The elements of the block diagram that are not directly a part of the Output Compare unit are gray shaded.

Figure 19-4. Output Compare Unit, Block Diagram

The OCR1x Register is double buffered when using any of the twelve Pulse Width Modulation (PWM) modes. For the normal and Clear Timer on Compare (CTC) modes of operation, the double buffering is disabled. The double buffering synchronizes the update of the OCRnx Compare Register to either TOP or BOTTOM of the counting sequence. The synchronization prevents the occurrence of odd-length, nonsymmetrical PWM pulses, thereby making the output glitch-free.

The OCRnx Register access may seem complex, but this is not case. When the double buffering is enabled, the CPU has access to the OCRnx Buffer Register, and if double buffering is disabled the CPU will access the OCRnx directly. The content of the OCR1x (Buffer or Compare) Register is only changed by a write operation (the Timer/Counter does not update this register automatically as the TCNTn and ICRn Register). Therefore OCRnx is not read via the High byte temporary register (TEMP). However, it is a good practice to read the Low byte first as when accessing other 16-bit registers. Writing the OCRnx Registers must be done via the TEMP Register since the compare of all 16 -bit is done continuously. The High byte (OCRnxH) has to be written first. When the High byte I/O location is written by the CPU, the TEMP Register will be updated by the value written. Then when the Low byte (OCRnxL) is written to the lower eight bits, the High byte will be copied into the upper 8-bits of either the OCRnx buffer or OCRnx Compare Register in the same system clock cycle.

For more information of how to access the 16 -bit registers refer to Accessing 16-bit Registers.

\subsection*{19.7.1. Force Output Compare}

In non-PWM Waveform Generation modes, the match output of the comparator can be forced by writing a one to the Force Output Compare (FOCnx) bit. Forcing Compare Match will not set the OCFnx Flag or reload/clear the timer, but the OCnx pin will be updated as if a real Compare Match had occurred (the COMnx1:0 bits settings define whether the OCnx pin is set, cleared or toggled).

\subsection*{19.7.2. Compare Match Blocking by TCNTn Write}

All CPU writes to the TCNTn Register will block any Compare Match that occurs in the next timer clock cycle, even when the timer is stopped. This feature allows OCRnx to be initialized to the same value as TCNTn without triggering an interrupt when the Timer/Counter clock is enabled.

\subsection*{19.7.3. Using the Output Compare Unit}

Since writing TCNTn in any mode of operation will block all compare matches for one timer clock cycle, there are risks involved when changing TCNTn when using any of the Output Compare channels, independent of whether the Timer/Counter is running or not. If the value written to TCNTn equals the OCRnx value, the Compare Match will be missed, resulting in incorrect waveform generation. Do not write the TCNTn equal to TOP in PWM modes with variable TOP values. The Compare Match for the TOP will be ignored and the counter will continue to 0xFFFFF. Similarly, do not write the TCNTn value equal to BOTTOM when the counter is downcounting.

The setup of the OCnx should be performed before setting the Data Direction Register for the port pin to output. The easiest way of setting the OCnx value is to use the Force Output Compare (FOCnx) strobe bits in Normal mode. The OCnx Register keeps its value even when changing between Waveform Generation modes.

Be aware that the COMnx1:0 bits are not double buffered together with the compare value. Changing the COMnx1:0 bits will take effect immediately.

\subsection*{19.8. Compare Match Output Unit}

The Compare Output mode (COMnx1:0) bits have two functions. The waveform generator uses the COMnx1:0 bits for defining the Output Compare (OCnx) state at the next Compare Match. Secondly the COMnx1:0 bits control the OCnx pin output source. The figure below shows a simplified schematic of the logic affected by the COMnx1:0 bit setting. The I/O Registers, I/O bits, and I/O pins in the figure are shown in bold. Only the parts of the general I/O Port Control Registers (DDR and PORT) that are affected by the COMnx1:0 bits are shown. When referring to the OCnx state, the reference is for the internal OCnx Register, not the OCnx pin. If a System Reset occur, the OCnx Register is reset to " 0 ".

Figure 19-5. Compare Match Output Unit, Schematic

The general I/O port function is overridden by the Output Compare ( OCnx ) from the waveform generator if either of the COMnx1:0 bits are set. However, the OCnx pin direction (input or output) is still controlled by the Data Direction Register (DDR) for the port pin. The Data Direction Register bit for the OCnx pin (DDR_OCnx) must be set as output before the OCnx value is visible on the pin. The port override function is generally independent of the Waveform Generation mode, but there are some exceptions. Refer to Table 19-2, Table 19-3 and Table 19-4 for details.

The design of the Output Compare Pin logic allows initialization of the OCnx state before the output is enabled. Note that some COMnx1:0 bit settings are reserved for certain modes of operation. See Register Description.

The COMnx1:0 bits have no effect on the Input Capture unit.

\subsection*{19.8.1. Compare Output Mode and Waveform Generation}

The waveform generator uses the COMnx1:0 bits differently in normal, CTC, and PWM modes. For all modes, setting the COMnx1:0 = 0 tells the waveform generator that no action on the OCnx Register is to be performed on the next Compare Match. For compare output actions in the non-PWM modes refer to Table 19-2. For fast PWM mode refer to Table 19-3, and for phase correct and phase and frequency correct PWM refer to Table 19-4.

A change of the COMnx1:0 bits state will have effect at the first Compare Match after the bits are written. For nonPWM modes, the action can be forced to have immediate effect by using the FOCnx strobe bits.

\subsection*{19.9. Modes of Operation}

The mode of operation (i.e., the behavior of the Timer/Counter and the Output Compare pins) is defined by the combination of the Waveform Generation mode (WGMn3:0) and Compare Output mode (COMnx1:0) bits. The Compare Output mode bits do not affect the counting sequence, while the Waveform Generation mode bits do. The COMnx1:0 bits control whether the PWM output generated should be inverted or not (inverted or non-inverted PWM). For non-PWM modes the COMnx1:0 bits control whether the output should be set, cleared or toggle at a Compare Match. See Compare Match Output Unit.

For detailed timing information refer to Timer/Counter Timing Diagrams.

\subsection*{19.9.1. Normal Mode}

The simplest mode of operation is the Normal mode (WGMn3:0 \(=0\) ). In this mode the counting direction is always up (incrementing), and no counter clear is performed. The counter simply overruns when it passes its maximum 16-bit value (MAX = 0xFFFF) and then restarts from the BOTTOM ( \(0 \times 0000\) ). In normal operation the Timer/Counter Overflow Flag (TOVn) will be set in the same timer clock cycle as the TCNTn becomes zero. The TOVn Flag in this case behaves like a 17th bit, except that it is only set, not cleared. However, combined with the timer overflow interrupt that automatically clears the TOVn Flag, the timer resolution can be increased by software. There are no special cases to consider in the Normal mode, a new counter value can be written anytime.
The Input Capture unit is easy to use in Normal mode. However, observe that the maximum interval between the external events must not exceed the resolution of the counter. If the interval between events are too long, the timer overflow interrupt or the prescaler must be used to extend the resolution for the capture unit.
The Output Compare units can be used to generate interrupts at some given time. Using the Output Compare to generate waveforms in Normal mode is not recommended, since this will occupy too much of the CPU time.

\subsection*{19.9.2. Clear Timer on Compare Match (CTC) Mode}

In Clear Timer on Compare or CTC mode (WGMn3:0 = 4 or 12), the OCRnA or ICRn Register are used to manipulate the counter resolution. In CTC mode the counter is cleared to zero when the counter value (TCNTn) matches either the OCRnA (WGMn3:0 = 4) or the ICRn (WGMn3:0 = 12). The OCRnA or ICRn define the top value for the counter, hence also its resolution. This mode allows greater control of the Compare Match output frequency. It also simplifies the operation of counting external events.

The timing diagram for the CTC mode is shown below. The counter value (TCNTn) increases until a Compare Match occurs with either OCRnA or ICRn, and then counter (TCNTn) is cleared.

Figure 19-6. CTC Mode, Timing Diagram

An interrupt can be generated at each time the counter value reaches the TOP value by either using the OCFnA or ICFn Flag according to the register used to define the TOP value. If the interrupt is enabled, the interrupt handler routine can be used for updating the TOP value. However, changing the TOP to a value close to BOTTOM when the counter is running with none or a low prescaler value must be done with care since the CTC mode does not have the double buffering feature. If the new value written to OCRnA or ICRn is lower than the current value of TCNTn, the counter will miss the Compare Match. The counter will then have to count to its maximum value (0xFFFF) and wrap around starting at 0x0000 before the Compare Match can occur. In many cases this feature is not desirable. An alternative will then be to use the fast PWM mode using OCRnA for defining TOP (WGMn3:0 \(=15\) ) since the OCRnA then will be double buffered.

For generating a waveform output in CTC mode, the OCnA output can be set to toggle its logical level on each Compare Match by setting the Compare Output mode bits to toggle mode (COMnA1:0 = 1). The OCnA value will not be visible on the port pin unless the data direction for the pin is set to output (DDR_OCnA = 1). The waveform generated will have a maximum frequency of \(f_{\mathrm{OCnA}}=\mathrm{f}_{\mathrm{clk} \_/ 1 / 0} / 2\) when OCRnA is set to zero ( \(0 \times 0000\) ). The waveform frequency is defined by the following equation:
\(f_{\text {OCnA }}=\frac{f_{\text {clk } \_ \text {I } / \mathrm{O}}}{2 \cdot N \cdot(1+0 \mathrm{CRnA})}\)
\(N\) represents the prescaler factor ( \(1,8,64,256\), or 1024 ).
As for the Normal mode of operation, the Timer Counter TOVn Flag is set in the same timer clock cycle that the counter counts from MAX to \(0 \times 0000\).

\subsection*{19.9.3. Fast PWM Mode}

The fast Pulse Width Modulation or fast PWM mode (WGMn3:0 = 5, 6, 7, 14, or 15) provides a high frequency PWM waveform generation option. The fast PWM differs from the other PWM options by its single-slope operation. The counter counts from BOTTOM to TOP then restarts from BOTTOM. In noninverting Compare Output mode, the Output Compare (OCnx) is cleared on the Compare Match between TCNTn and OCRnx, and set at BOTTOM. In inverting Compare Output mode output is set on Compare Match and cleared at BOTTOM. Due to the singleslope operation, the operating frequency of the fast

PWM mode can be twice as high as the phase correct and phase and frequency correct PWM modes that use dual-slope operation. This high frequency makes the fast PWM mode well suited for power regulation, rectification, and DAC applications. High frequency allows physically small sized external components (coils, capacitors), hence reduces total system cost.
The PWM resolution for fast PWM can be fixed to 8-, 9-, or 10-bit, or defined by either ICRn or OCRnA. The minimum resolution allowed is 2 -bit (ICRn or OCRnA set to \(0 x 0003\) ), and the maximum resolution is 16-bit (ICRn or OCRnA set to MAX). The PWM resolution in bits can be calculated by using the following equation:
\(R_{\text {FPWM }}=\frac{\log (\mathrm{TOP}+1)}{\log (2)}\)
In fast PWM mode the counter is incremented until the counter value matches either one of the fixed values \(0 \times 00 F F\), \(0 \times 01 F F\), or \(0 \times 03 F F\) (WGMn3:0 = 5, 6, or 7), the value in ICRn (WGMn3:0 = 14), or the value in OCRnA (WGMn3:0 = 15). The counter is then cleared at the following timer clock cycle. The timing diagram for the fast PWM mode is shown in the figure below. The figure shows fast PWM mode when OCRnA or ICRn is used to define TOP. The TCNTn value is in the timing diagram shown as a histogram for illustrating the single-slope operation. The diagram includes non-inverted and inverted PWM outputs. The small horizontal line marks on the TCNTn slopes represent compare matches between OCRnx and TCNTn. The OCnx Interrupt Flag will be set when a Compare Match occurs.

Figure 19-7. Fast PWM Mode, Timing Diagram

The Timer/Counter Overflow Flag (TOVn) is set each time the counter reaches TOP. In addition the OCFnA or ICFn Flag is set at the same timer clock cycle as TOVn is set when either OCRnA or ICRn is used for defining the TOP value. If one of the interrupts are enabled, the interrupt handler routine can be used for updating the TOP and compare values.

When changing the TOP value the program must ensure that the new TOP value is higher or equal to the value of all of the Compare Registers. If the TOP value is lower than any of the Compare Registers, a Compare Match will never occur between the TCNTn and the OCRnx. Note that when using fixed TOP values the unused bits are masked to zero when any of the OCRnx Registers are written.

The procedure for updating ICRn differs from updating OCRnA when used for defining the TOP value. The ICRn Register is not double buffered. This means that if ICRn is changed to a low value when the counter is running with none or a low prescaler value, there is a risk that the new ICRn value written is lower than the current value of TCNTn. The result will then be that the counter will miss the Compare Match at the TOP value. The counter will then have to count to the MAX value ( \(0 x F F F F\) ) and wrap around starting at \(0 \times 0000\) before the Compare Match can occur. The OCRnA Register, however, is double buffered. This feature allows the OCRnA I/O location to be written anytime. When the OCRnA I/O location
is written the value written will be put into the OCRnA Buffer Register. The OCRnA Compare Register will then be updated with the value in the Buffer Register at the next timer clock cycle the TCNTn matches TOP. The update is done at the same timer clock cycle as the TCNTn is cleared and the TOVn Flag is set.

Using the ICRn Register for defining TOP works well when using fixed TOP values. By using ICRn, the OCRnA Register is free to be used for generating a PWM output on OCnA. However, if the base PWM frequency is actively changed (by changing the TOP value), using the OCRnA as TOP is clearly a better choice due to its double buffer feature.

In fast PWM mode, the compare units allow generation of PWM waveforms on the OCnx pins. Setting the COMnx1:0 bits to 2 will produce a non-inverted PWM and an inverted PWM output can be generated by setting the COMnx1:0 to 3 . Refer to table Table 19-3. The actual OCnx value will only be visible on the port pin if the data direction for the port pin is set as output (DDR_OCnx). The PWM waveform is generated by setting (or clearing) the OCnx Register at the Compare Match between OCRnx and TCNTn, and clearing (or setting) the OCnx Register at the timer clock cycle the counter is cleared (changes from TOP to BOTTOM).

The PWM frequency for the output can be calculated by the following equation:
\(f_{\text {OCnxPWM }}=\frac{f_{\text {clk } \_/ \mathrm{O}}}{N \cdot(1+\text { TOP })}\)
\(N\) represents the prescale divider (1, 8, 64, 256, or 1024).
The extreme values for the OCRnx Register represents special cases when generating a PWM waveform output in the fast PWM mode. If the OCRnx is set equal to BOTTOM ( \(0 \times 0000\) ) the output will be a narrow spike for each TOP +1 timer clock cycle. Setting the OCRnx equal to TOP will result in a constant high or low output (depending on the polarity of the output set by the COMnx1:0 bits.)
A frequency (with \(50 \%\) duty cycle) waveform output in fast PWM mode can be achieved by setting OCnA to toggle its logical level on each Compare Match (COMnA1:0 \(=1\) ). This applies only if OCRnA is used to define the TOP value ( \(\mathrm{WGMn} 3: 0=15\) ). The waveform generated will have a maximum frequency of \(f_{\mathrm{OCnA}}\) \(=f_{\text {clk_ }} / / / 2\) when OCRnA is set to zero ( \(0 \times 0000\) ). This feature is similar to the OCnA toggle in CTC mode, except the double buffer feature of the Output Compare unit is enabled in the fast PWM mode.

\subsection*{19.9.4. Phase Correct PWM Mode}

The phase correct Pulse Width Modulation or phase correct PWM mode (WGMn3:0 = 1, 2, 3, 10, or 11) provides a high resolution phase correct PWM waveform generation option. The phase correct PWM mode is, like the phase and frequency correct PWM mode, based on a dual-slope operation. The counter counts repeatedly from BOTTOM ( \(0 \times 0000\) ) to TOP and then from TOP to BOTTOM. In non-inverting Compare Output mode, the Output Compare (OCnx) is cleared on the Compare Match between TCNTn and OCRnx while upcounting, and set on the Compare Match while downcounting. In inverting Output Compare mode, the operation is inverted. The dual-slope operation has lower maximum operation frequency than single slope operation. However, due to the symmetric feature of the dual-slope PWM modes, these modes are preferred for motor control applications.
The PWM resolution for the phase correct PWM mode can be fixed to 8 -, 9 -, or 10 -bit, or defined by either ICRn or OCRnA. The minimum resolution allowed is 2-bit (ICRn or OCRnA set to 0x0003), and the maximum resolution is 16 -bit (ICRn or OCRnA set to MAX). The PWM resolution in bits can be calculated by using the following equation:
\(R_{\text {PCPWM }}=\frac{\log (\mathrm{TOP}+1)}{\log (2)}\)

In phase correct PWM mode the counter is incremented until the counter value matches either one of the fixed values \(0 \times 00 F F\), \(0 \times 01 \mathrm{FF}\), or \(0 \times 03 F F\) (WGMn3:0 \(=1,2\), or 3 ), the value in ICRn (WGMn3:0 \(=10\) ), or the value in OCRnA (WGMn3:0 = 11). The counter has then reached the TOP and changes the count direction. The TCNTn value will be equal to TOP for one timer clock cycle. The timing diagram for the phase correct PWM mode is shown in the figure below. The figure shows phase correct PWM mode when OCRnA or ICRn is used to define TOP. The TCNTn value is in the timing diagram shown as a histogram for illustrating the dual-slope operation. The diagram includes non-inverted and inverted PWM outputs. The small horizontal line marks on the TCNTn slopes represent compare matches between OCRnx and TCNTn. The OCnx Interrupt Flag will be set when a Compare Match occurs.

Figure 19-8. Phase Correct PWM Mode, Timing Diagram

The Timer/Counter Overflow Flag (TOVn) is set each time the counter reaches BOTTOM. When either OCRnA or ICRn is used for defining the TOP value, the OCnA or ICFn Flag is set accordingly at the same timer clock cycle as the OCRnx Registers are updated with the double buffer value (at TOP). The Interrupt Flags can be used to generate an interrupt each time the counter reaches the TOP or BOTTOM value.

When changing the TOP value the program must ensure that the new TOP value is higher or equal to the value of all of the Compare Registers. If the TOP value is lower than any of the Compare Registers, a Compare Match will never occur between the TCNTn and the OCRnx. Note that when using fixed TOP values, the unused bits are masked to zero when any of the OCRnx Registers are written. As the third period shown in the timing diagram above illustrates, changing the TOP actively while the Timer/Counter is running in the Phase Correct mode can result in an unsymmetrical output. The reason for this can be found in the time of update of the OCRnx Register. Since the OCRnx update occurs at TOP, the PWM period starts and ends at TOP. This implies that the length of the falling slope is determined by the previous TOP value, while the length of the rising slope is determined by the new TOP value. When these two values differ the two slopes of the period will differ in length. The difference in length gives the unsymmetrical result on the output.

It is recommended to use the Phase and Frequency Correct mode instead of the Phase Correct mode when changing the TOP value while the Timer/Counter is running. When using a static TOP value there are practically no differences between the two modes of operation.

In phase correct PWM mode, the compare units allow generation of PWM waveforms on the OCnx pins. Setting the COMnx1:0 bits to 2 will produce a non-inverted PWM and an inverted PWM output can be generated by setting the COMnx1:0 to 3 . Refer to Table 19-4. The actual OCnx value will only be visible
on the port pin if the data direction for the port pin is set as output (DDR_OCnx). The PWM waveform is generated by setting (or clearing) the OCnx Register at the Compare Match between OCRnx and TCNTn when the counter increments, and clearing (or setting) the OCnx Register at Compare Match between OCRnx and TCNTn when the counter decrements. The PWM frequency for the output when using phase correct PWM can be calculated by the following equation:
\(f_{\text {OCnxPCPWM }}=\frac{f_{\text {clk } \_ \text {I } / O}}{2 \cdot N \cdot T O P}\)
\(N\) variable represents the prescale divider (1, 8, 64, 256, or 1024).
The extreme values for the OCRnx Register represent special cases when generating a PWM waveform output in the phase correct PWM mode. If the OCRnx is set equal to BOTTOM the output will be continuously low and if set equal to TOP the output will be continuously high for non-inverted PWM mode. For inverted PWM the output will have the opposite logic values.
If OCRnA is used to define the TOP value (WGMn3:0 \(=11\) ) and COMnA1:0 \(=1\), the OCnA output will toggle with a \(50 \%\) duty cycle.

\subsection*{19.9.5. Phase and Frequency Correct PWM Mode}

The phase and frequency correct Pulse Width Modulation, or phase and frequency correct PWM mode (WGMn3:0 = 8 or 9 ) provides a high resolution phase and frequency correct PWM waveform generation option. The phase and frequency correct PWM mode is, like the phase correct PWM mode, based on a dual-slope operation. The counter counts repeatedly from BOTTOM ( \(0 \times 0000\) ) to TOP and then from TOP to BOTTOM. In non-inverting Compare Output mode, the Output Compare (OCnx) is cleared on the Compare Match between TCNTn and OCRnx while upcounting, and set on the Compare Match while downcounting. In inverting Compare Output mode, the operation is inverted. The dual-slope operation gives a lower maximum operation frequency compared to the single-slope operation. However, due to the symmetric feature of the dual-slope PWM modes, these modes are preferred for motor control applications.

The main difference between the phase correct, and the phase and frequency correct PWM mode is the time the OCRnx Register is updated by the OCRnx Buffer Register, (see Figure 19-8 and Figure 19-9).

The PWM resolution for the phase and frequency correct PWM mode can be defined by either ICRn or OCRnA. The minimum resolution allowed is 2-bit (ICRn or OCRnA set to \(0 \times 0003\) ), and the maximum resolution is 16 -bit (ICRn or OCRnA set to MAX). The PWM resolution in bits can be calculated using the following equation:
\(R_{\text {PFCPWM }}=\frac{\log (\mathrm{TOP}+1)}{\log (2)}\)
In phase and frequency correct PWM mode the counter is incremented until the counter value matches either the value in ICRn (WGMn3:0 = 8), or the value in OCRnA (WGMn3:0 = 9). The counter has then reached the TOP and changes the count direction. The TCNTn value will be equal to TOP for one timer clock cycle. The timing diagram for the phase correct and frequency correct PWM mode is shown on timing diagram below. The figure shows phase and frequency correct PWM mode when OCRnA or ICRn is used to define TOP. The TCNTn value is in the timing diagram shown as a histogram for illustrating the dual-slope operation. The diagram includes non-inverted and inverted PWM outputs. The small horizontal line marks on the TCNTn slopes represent compare matches between OCRnx and TCNTn. The OCnx Interrupt Flag will be set when a Compare Match occurs.

Figure 19-9. Phase and Frequency Correct PWM Mode, Timing Diagram

The Timer/Counter Overflow Flag (TOVn) is set at the same timer clock cycle as the OCRnx Registers are updated with the double buffer value (at BOTTOM). When either OCRnA or ICRn is used for defining the TOP value, the OCnA or ICFn Flag set when TCNTn has reached TOP. The Interrupt Flags can then be used to generate an interrupt each time the counter reaches the TOP or BOTTOM value.

When changing the TOP value the program must ensure that the new TOP value is higher or equal to the value of all of the Compare Registers. If the TOP value is lower than any of the Compare Registers, a Compare Match will never occur between the TCNTn and the OCRnx.

As the timing diagram above shows the output generated is, in contrast to the Phase Correct mode, symmetrical in all periods. Since the OCRnx Registers are updated at BOTTOM, the length of the rising and the falling slopes will always be equal. This gives symmetrical output pulses and is therefore frequency correct.

Using the ICRn Register for defining TOP works well when using fixed TOP values. By using ICRn, the OCRnA Register is free to be used for generating a PWM output on OCnA. However, if the base PWM frequency is actively changed by changing the TOP value, using the OCRnA as TOP is clearly a better choice due to its double buffer feature.

In phase and frequency correct PWM mode, the compare units allow generation of PWM waveforms on the OCnx pins. Setting the COMnx1:0 bits to 2 will produce a non-inverted PWM and an inverted PWM output can be generated by setting the COMnx1:0 to 3 . Refer to Table 19-4. The actual OCnx value will only be visible on the port pin if the data direction for the port pin is set as output (DDR_OCnx). The PWM waveform is generated by setting (or clearing) the OCnx Register at the Compare Match between OCRnx and TCNTn when the counter increments, and clearing (or setting) the OCnx Register at Compare Match between OCRnx and TCNTn when the counter decrements. The PWM frequency for the output when using phase and frequency correct PWM can be calculated by the following equation:
\(f_{\text {OCnxPFCPWM }}=\frac{f_{\text {clk } \_ \text {I } / O}}{2 \cdot N \cdot \text { TOP }}\)
The \(N\) variable represents the prescaler divider (1, 8, 64, 256, or 1024).
The extreme values for the OCRnx Register represents special cases when generating a PWM waveform output in the phase correct PWM mode. If the OCRnx is set equal to BOTTOM the output will be continuously low and if set equal to TOP the output will be set to high for non-inverted PWM mode. For inverted PWM the output will have the opposite logic values.

If OCRnA is used to define the TOP value (WGMn3:0 \(=9\) ) and COMnA1:0 \(=1\), the OCnA output will toggle with a \(50 \%\) duty cycle.

\subsection*{19.10. Timer/Counter Timing Diagrams}

The Timer/Counter is a synchronous design and the timer clock \(\left(\mathrm{clk}_{\mathrm{Tn}}\right)\) is therefore shown as a clock enable signal in the following figures. The figures include information on when Interrupt Flags are set, and when the OCRnx Register is updated with the OCRnx buffer value (only for modes utilizing double buffering). The next figure shows a timing diagram for the setting of OCFnx.

Figure 19-10. Timer/Counter Timing Diagram, Setting of OCFnx, no Prescaling

The next figure shows the same timing data, but with the prescaler enabled.
Figure 19-11. Timer/Counter Timing Diagram, Setting of OCFnx, with Prescaler (fclk_/o/8)

The next figure shows the count sequence close to TOP in various modes. When using phase and frequency correct PWM mode the OCRnx Register is updated at BOTTOM. The timing diagrams will be the same, but TOP should be replaced by BOTTOM, TOP-1 by BOTTOM+1 and so on. The same renaming applies for modes that set the TOVn Flag at BOTTOM.

Figure 19-12. Timer/Counter Timing Diagram, no Prescaling.

The next figure shows the same timing data, but with the prescaler enabled.
Figure 19-13. Timer/Counter Timing Diagram, with Prescaler ( \(\mathrm{f}_{\mathrm{clk}}{ }^{\prime} / \mathrm{O} / 8\) )

19.11. Register Description

\subsection*{19.11.1. TCCR1A - Timer/Counter1 Control Register A}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: TCCR1A
Offset: 0x2F
Reset: \(0 \times 00\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 4 \mathrm{~F}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & COM1A1 & COM1A0 & COM1B1 & COM1B0 & FOC1A & FOC1B & WGM11 & WGM10 \\
\hline Access & R/W & R/W & R/W & R/W & W & W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bits 7:6 - COM1An: Compare Output Mode for Channel A [n=1:0]}

Bits 5:4 - COM1Bn: Compare Output Mode for Channel B [n=1:0]
The COM1A1:0 and COM1B1:0 control the Output Compare pins (OC1A and OC1B respectively) behavior. If one or both of the COM1A1:0 bits are written to one, the OC1A output overrides the normal port functionality of the I/O pin it is connected to. If one or both of the COM1B1:0 bit are written to one, the OC1B output overrides the normal port functionality of the I/O pin it is connected to. However, note that the Data Direction Register (DDR) bit corresponding to the OC1A or OC1B pin must be set in order to enable the output driver.

When the OC1A or OC1B is connected to the pin, the function of the COM1n1:0 bits is dependent of the WGM13:0 bits setting. The table below shows the COM1n1:0 bit functionality when the WGM13:0 bits are set to a Normal or a CTC mode (non-PWM).

Table 19-2. Compare Output Mode, non-PWM
COM1A1/COM1B1 COM1A0/COM1B0 Description
\begin{tabular}{|l|l|l|}
\hline 0 & 0 & Normal port operation, OC1A/OC1B disconnected. \\
\hline 0 & 1 & Toggle OC1A/OC1B on Compare Match. \\
\hline 1 & 0 & \begin{tabular}{l} 
Clear OC1A/OC1B on Compare Match (Set output to low \\
level).
\end{tabular} \\
\hline 1 & 1 & \begin{tabular}{l} 
Set OC1A/OC1B on Compare Match (Set output to high \\
level).
\end{tabular} \\
\hline
\end{tabular}

The next table shows the COM1x1:0 bit functionality when the WGM13:0 bits are set to the fast PWM mode.

Table 19-3. Compare Output Mode, Fast PWM \({ }^{(1)}\)
\begin{tabular}{|c|c|l|}
\hline \begin{tabular}{l} 
COM1A1/ \\
COM1B1
\end{tabular} & \begin{tabular}{c}

\end{tabular} \\
\hline
\end{tabular}

Note: 1. A special case occurs when OCR1A/OCR1B equals TOP and COM1A1/COM1B1 is set. Refer to Phase Correct PWM Mode for details.

\section*{Bit 3 - FOC1A: Force Output Compare for channel A}

\section*{Bit 2 - FOC1B: Force Output Compare for channel B}

The FOC1A/FOC1B bits are only active when the WGM13:0 bits specifies a non-PWM mode. However, for ensuring compatibility with future devices, these bits must be set to zero when TCCR1A is written when operating in a PWM mode. When writing a logical one to the FOC1A/FOC1B bit, an immediate Compare Match is forced on the waveform generation unit. The OC1A/OC1B output is changed according to its COM1x1:0 bits setting. Note that the FOC1A/FOC1B bits are implemented as strobes. Therefore it is the value present in the COM1x1:0 bits that determine the effect of the forced compare.

A FOC1A/FOC1B strobe will not generate any interrupt nor will it clear the timer in Clear Timer on Compare Match (CTC) mode using OCR1A as TOP.

The FOC1A/FOC1B bits are always read as zero.

\section*{Bits 1:0 - WGM1n: Waveform Generation Mode [ \(\mathrm{n}=1: 0\) ]}

Combined with the WGM13:2 bits found in the TCCR1B Register, these bits control the counting sequence of the counter, the source for maximum (TOP) counter value, and what type of waveform generation to be used, refer to the table below. Modes of operation supported by the Timer/Counter unit are: Normal mode (counter), Clear Timer on Compare match (CTC) mode, and three types of Pulse Width Modulation (PWM) modes. (See Modes of Operation).

Table 19-5. Waveform Generation Mode Bit Description
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}

\hline 13 & 1 & 1 & 0 & 1 & Reserved & - & - & - \\
\hline 14 & 1 & 1 & 1 & 0 & Fast PWM & ICR1 & BOTTOM & TOP \\
\hline 15 & 1 & 1 & 1 & 1 & Fast PWM & OCR1A & BOTTOM & TOP \\
\hline
\end{tabular}

\section*{Note:}
1. The CTC1 and PWM11:0 bit definition names are obsolete. Use the WGM12:0 definitions. However, the functionality and location of these bits are compatible with previous versions of the timer.

\subsection*{19.11.2. TCCR1B - Timer/Counter1 Control Register B}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: TCCR1B
Offset: 0x2E
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 4 \mathrm{E}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & ICNC1 & ICES1 & & WGM13 & WGM12 & CS12 & CS11 & CS10 \\
\hline Access & R/W & \multicolumn{2}{|l|}{R/W} & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bit 7 - ICNC1: Input Capture Noise Canceler
Setting this bit (to one) activates the Input Capture Noise Canceler. When the noise canceler is activated, the input from the Input Capture pin (ICP1) is filtered. The filter function requires four successive equal valued samples of the ICP1 pin for changing its output. The Input Capture is therefore delayed by four Oscillator cycles when the noise canceler is enabled.

\section*{Bit 6 - ICES1: Input Capture Edge Select}

This bit selects which edge on the Input Capture pin (ICP1) that is used to trigger a capture event. When the ICES1 bit is written to zero, a falling (negative) edge is used as trigger, and when the ICES1 bit is written to one, a rising (positive) edge will trigger the capture.

When a capture is triggered according to the ICES1 setting, the counter value is copied into the Input Capture Register (ICR1). The event will also set the Input Capture Flag (ICF1), and this can be used to cause an Input Capture Interrupt, if this interrupt is enabled.

When the ICR1 is used as TOP value (see description of the WGM13:0 bits located in the TCCR1A and the TCCR1B Register), the ICP1 is disconnected and consequently the Input Capture function is disabled.

\section*{Bit 4 - WGM13: Waveform Generation Mode}

Refer to TCCR1A.

\section*{Bit 3 - WGM12: Waveform Generation Mode}

Refer to TCCR1A.
Bits 2:0-CS1n: Clock Select [ \(\mathrm{n}=0\) 0:2]
The three Clock Select bits select the clock source to be used by the Timer/Counter. Refer to figures Timer/Counter Timing Diagram, Setting of OCF1x, no Prescaling and Timer/Counter Timing Diagram, Setting of OCF1x, with Prescaler ( \(\mathrm{f}_{\text {clk_1/ }} / \mathrm{o} / 8\) ).

Table 19-6. Clock Select Bit Description
\begin{tabular}{|c|c|c|l|}
\hline CA12 & CA11 & CS10 & Description \\
\hline 0 & 0 & 0 & No clock source (Timer/Counter stopped). \\
\hline 0 & 0 & 1 & clk \(_{/ / 0} / 1\) (No prescaling) \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|l|}
\hline CA12 & CA11 & CS10 & Description \\
\hline 0 & 1 & 0 & clk \(_{/ / O} / 8\) (From prescaler) \\
\hline 0 & 1 & 1 & clk \(_{/ / O} / 64\) (From prescaler) \\
\hline 1 & 0 & 0 & clkI/O/256 (From prescaler) \(^{4}\) \\
\hline 1 & 0 & 1 & clk \(_{/ / 0} / 1024\) (From prescaler) \\
\hline 1 & 1 & 0 & External clock source on T1 pin. Clock on falling edge. \\
\hline 1 & 1 & 1 & External clock source on T1 pin. Clock on rising edge. \\
\hline
\end{tabular}

If external pin modes are used for the Timer/Counter1, transitions on the T1 pin will clock the counter even if the pin is configured as an output. This feature allows software control of the counting.

\subsection*{19.11.3. TCNT1L - Timer/Counter1 Low byte}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: TCNT1L
Offset: \(0 \times 2 C\)
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 4 \mathrm{C}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{TCNT1L[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - TCNT1L[7:0]: Timer/Counter 1 Low byte
The two Timer/Counter I/O locations (TCNT1H and TCNT1L, combined TCNT1) give direct access, both for read and for write operations, to the Timer/Counter unit 16-bit counter. To ensure that both the high and low bytes are read and written simultaneously when the CPU accesses these registers, the access is performed using an 8 -bit temporary High Byte Register (TEMP). This temporary register is shared by all the other 16-bit registers. Refer to Accessing 16-bit Registers for details.
Modifying the counter (TCNT1) while the counter is running introduces a risk of missing a compare match between TCNT1 and one of the OCR1x Registers.
Writing to the TCNT1 Register blocks (removes) the compare match on the following timer clock for all compare units.

\subsection*{19.11.4. TCNT1H - Timer/Counter1 High byte}

Name: TCNT1H
Offset: 0x2D
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 4 \mathrm{D}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{TCNT1H[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - TCNT1H[7:0]: Timer/Counter 1 High byte
Refer to TCNT1L.

\subsection*{19.11.5. OCR1AL - Output Compare Register 1 A Low byte}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 \mathrm{~F}\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: OCR1AL
Offset: 0x2A
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 4 \mathrm{~A}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{OCR1AL[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - OCR1AL[7:0]: Output Compare 1 A Low byte
The Output Compare Registers contain a 16 -bit value that is continuously compared with the counter value (TCNT1). A match can be used to generate an Output Compare interrupt, or to generate a waveform output on the OC1x pin.

The Output Compare Registers are 16 -bit in size. To ensure that both the high and low bytes are written simultaneously when the CPU writes to these registers, the access is performed using an 8 -bit temporary High Byte Register (TEMP). This temporary register is shared by all the other 16-bit registers. Refer to Accessing 16-bit Registers for details.

\subsection*{19.11.6. OCR1AH - Output Compare Register 1 A High byte}

Name: OCR1AH
Offset: 0x2B
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 4 \mathrm{~B}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{OCR1AH[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - OCR1AH[7:0]: Output Compare 1 A High byte
Refer to OCR1AL.

\subsection*{19.11.7. OCR1BL - Output Compare Register 1 B Low byte}

Name: OCR1BL
Offset: 0x28
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 48\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{OCR1BL[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - OCR1BL[7:0]: Output Compare 1 B Low byte
Refer to OCR1AL.

\subsection*{19.11.8. OCR1BH - Output Compare Register 1 B High byte}

Name: OCR1BH
Offset: 0x29
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 49\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{OCR1BH[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - OCR1BH[7:0]: Output Compare 1 B High byte
Refer to OCR1AL.

\subsection*{19.11.9. ICR1L - Input Capture Register 1 Low byte}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: ICR1L
Offset: 0x26
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 46\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{ICR1L[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - ICR1L[7:0]: Input Capture 1 Low byte
The Input Capture is updated with the counter (TCNT1) value each time an event occurs on the ICP1 pin (or optionally on the Analog Comparator output for Timer/Counter1). The Input Capture can be used for defining the counter TOP value.

The Input Capture Register is 16 -bit in size. To ensure that both the high and low bytes are read simultaneously when the CPU accesses these registers, the access is performed using an 8 -bit temporary High Byte Register (TEMP). This temporary register is shared by all the other 16-bit registers. Refer to Accessing 16.bit Registers for details.

\subsection*{19.11.10. ICR1H - Input Capture Register 1 High byte}

Name: ICR1H
Offset: 0x27
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 47\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{ICR1H[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - ICR1H[7:0]: Input Capture 1 High byte
Refer to ICR1L.

\subsection*{19.11.11. TIMSK - Timer/Counter Interrupt Mask Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Note: 1. This register contains interrupt control bits for several Timer/Counters, but only Timer1 bits are described in this section. The remaining bits are described in their respective timer sections.

Name: TIMSK
Offset: 0x39
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 59\)

\section*{Bit 5 - TICIE1: Timer/Counter1, Input Capture Interrupt Enable}

When this bit is written to one, and the I-flag in the Status Register is set (interrupts globally enabled), the Timer/Counter1 Input Capture interrupt is enabled. The corresponding Interrupt Vector (see Interrupts) is executed when the ICF1 Flag, located in TIFR, is set.

\section*{Bit 4 - OCIE1A: Timer/Counter1, Output Compare A Match Interrupt Enable}

When this bit is written to one, and the I-flag in the Status Register is set (interrupts globally enabled), the Timer/Counter1 Output Compare A match interrupt is enabled. The corresponding Interrupt Vector (see Interrupts) is executed when the OCF1A Flag, located in TIFR, is set.

\section*{Bit 3 - OCIE1B: Timer/Counter1, Output Compare B Match Interrupt Enable}

When this bit is written to one, and the I-flag in the Status Register is set (interrupts globally enabled), the Timer/Counter1 Output Compare B match interrupt is enabled. The corresponding Interrupt Vector (see Interrupts) is executed when the OCF1B Flag, located in TIFR, is set.

\section*{Bit 2 - TOIE1: Timer/Counter1, Overflow Interrupt Enable}

When this bit is written to one, and the I-flag in the Status Register is set (interrupts globally enabled), the Timer/Counter1 Overflow Interrupt is enabled. The corresponding Interrupt Vector (see Interrupts) is executed when the TOV1 Flag, located in TIFR, is set.

\subsection*{19.11.12. TIFR - Timer/Counter Interrupt Flag Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Note: 1. This register contains flag bits for several Timer/Counters, but only Timer1 bits are described in this section. The remaining bits are described in their respective timer sections.

Name: TIFR
Offset: 0x38
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 58\)

Bit 5 - ICF1: Timer/Counter1, Input Capture Flag
This flag is set when a capture event occurs on the ICP1 pin. When the Input Capture Register (ICR1) is set by the WGM13:0 to be used as the TOP value, the ICF1 Flag is set when the counter reaches the TOP value.

ICF1 is automatically cleared when the Input Capture Interrupt Vector is executed. Alternatively, ICF1 can be cleared by writing a logic one to its bit location.

\section*{Bit 4 - OCF1A: Timer/Counter1, Output Compare A Match Flag}

This flag is set in the timer clock cycle after the counter (TCNT1) value matches the Output Compare Register A (OCR1A).

Note that a Forced Output Compare (FOC1A) strobe will not set the OCF1A Flag.
OCF1A is automatically cleared when the Output Compare Match A Interrupt Vector is executed.
Alternatively, OCF1A can be cleared by writing a logic one to its bit location.

\section*{Bit 3 - OCF1B: Timer/Counter1, Output Compare B Match Flag}

This flag is set in the timer clock cycle after the counter (TCNT1) value matches the Output Compare Register B (OCR1B).

Note that a Forced Output Compare (FOC1B) strobe will not set the OCF1B Flag.
OCF1B is automatically cleared when the Output Compare Match B Interrupt Vector is executed.
Alternatively, OCF1B can be cleared by writing a logic one to its bit location.

\section*{Bit 2 - TOV1: Timer/Counter1, Overflow Flag}

The setting of this flag is dependent of the WGM13:0 bits setting. In Normal and CTC modes, the TOV1 Flag is set when the timer overflows. Refer to table Waveform Generation Mode Bit Description for the TOV1 Flag behavior when using another WGM13:0 bit setting.

TOV1 is automatically cleared when the Timer/Counter1 Overflow Interrupt Vector is executed.
Alternatively, TOV1 can be cleared by writing a logic one to its bit location.

\section*{20. 8-bit Timer/Counter2 with PWM and Asynchronous Operation}

\subsection*{20.1. Features}
- Single Channel Counter
- Clear Timer on Compare Match (Auto Reload)
- Glitch-free, phase Correct Pulse Width Modulator (PWM)
- Frequency Generator
-10-bit Clock Prescaler
- Overflow and Compare Match Interrupt Sources (TOV2 and OCF2)
- Allows Clocking from External 32kHz Watch Crystal Independent of the I/O Clock

\subsection*{20.2. Overview}

Timer/Counter2 is a general purpose, single channel, 8-bit Timer/Counter module. A simplified block diagram of the 8 -bit Timer/Counter is shown in the figure below. For the actual placement of \(I / O\) pins, refer to Pin Configurations. CPU accessible I/O Registers, including I/O bits and I/O pins, are shown in bold. The device-specific I/O Register and bit locations are listed in the Register Description.

Figure 20-1. 8-bit Timer/Counter Block Diagram

\section*{Related Links}

Pin Configurations on page 13

\subsection*{20.2.1. Registers}

The Timer/Counter (TCNT2) and Output Compare Register (OCR2) are 8-bit registers. Interrupt request (shorten as Int.Req.) signals are all visible in the Timer Interrupt Flag Register (TIFR). All interrupts are individually masked with the Timer Interrupt Mask Register (TIMSK). TIFR and TIMSK are not shown in the figure since these registers are shared by other timer units.

The Timer/Counter can be clocked internally, via the prescaler, or asynchronously clocked from the TOSC \(1 / 2\) pins, as detailed later in this section. The asynchronous operation is controlled by the Asynchronous Status Register (ASSR). The Clock Select logic block controls which clock source the Timer/Counter uses to increment (or decrement) its value. The Timer/Counter is inactive when no clock source is selected. The output from the clock select logic is referred to as the timer clock \(\left(\mathrm{clk}_{\mathrm{T}_{2}}\right)\).

The double buffered Output Compare Register (OCR2) is compared with the Timer/Counter value at all times. The result of the compare can be used by the waveform generator to generate a PWM or variable frequency output on the Output Compare Pin (OC2). For details, see Output Compare Unit. The Compare Match event will also set the Compare Flag (OCF2) which can be used to generate an Output Compare interrupt request.

\subsection*{20.2.2. Definitions}

Many register and bit references in this document are written in general form. A lower case " n " replaces the Timer/Counter number, in this case 2. However, when using the register or bit defines in a program, the precise form must be used (i.e., TCNT2 for accessing Timer/Counter2 counter value and so on).

The definitions in the following table are also used extensively throughout the document.
Table 20-1. Definitions
\begin{tabular}{|l|l|}
\hline BOTTOM & The counter reaches the BOTTOM when it becomes zero (0x00). \\
\hline MAX & The counter reaches its MAXimum when it becomes 0xFF (decimal 255). \\
\hline TOP & \begin{tabular}{l} 
The counter reaches the TOP when it becomes equal to the highest value in the \\
count sequence. The TOP value can be assigned to be the fixed value 0xFF (MAX) \\
or the value stored in the OCR2 Register. The assignment is dependent on the \\
mode of operation.
\end{tabular} \\
\hline
\end{tabular}

\subsection*{20.3. Timer/Counter Clock Sources}

The Timer/Counter can be clocked by an internal synchronous or an external asynchronous clock source. The clock source \(\mathrm{ck}_{\mathrm{T}_{2}}\) is by default equal to the MCU clock, \(\mathrm{clk}_{/ / \mathrm{O}}\). When the AS2 bit in the ASSR Register is written to logic one, the clock source is taken from the Timer/Counter Oscillator connected to TOSC1 and TOSC2. For details on asynchronous operation, refer to Asynchronous Operation of the Timer/Counter. For details on clock sources and prescaler, refer to Timer/Counter Prescaler.

\section*{Related Links}

Timer/Counter0 and Timer/Counter1 Prescalers on page 102

\subsection*{20.4. Counter Unit}

The main part of the 8 -bit Timer/Counter is the programmable bi-directional counter unit. The following figure shows a block diagram of the counter and its surrounding environment.

Figure 20-2. Counter Unit Block Diagram

Signal description (internal signals):
\begin{tabular}{ll} 
count & Increment or decrement TCNT2 by 1. \\
direction & Selects between increment and decrement. \\
clear & Clear TCNT2 (set all bits to zero). \\
\(\mathbf{c l k}_{\text {T2 }}\) & Timer/Counter clock. \\
TOP & Signalizes that TCNT2 has reached maximum value. \\
BOTTOM & Signalizes that TCNT2 has reached minimum value (zero).
\end{tabular}

Depending on the mode of operation used, the counter is cleared, incremented, or decremented at each timer clock ( \(\mathrm{clk}_{\mathrm{T} 2}\) ). \(\mathrm{clk}_{\mathrm{T} 2}\) can be generated from an external or internal clock source, selected by the clock select bits (CS22:0). When no clock source is selected (CS22:0 \(=0\) ) the timer is stopped. However, the TCNT2 value can be accessed by the CPU, regardless of whether \(\mathrm{clk}_{\mathrm{T} 2}\) is present or not. A CPU write overrides (has priority over) all counter clear or count operations.

The counting sequence is determined by the setting of the WGM21 and WGM20 bits located in the Timer/ Counter Control Register (TCCR2). There are close connections between how the counter behaves (counts) and how waveforms are generated on the Output Compare Output OC2. For more details about advanced counting sequences and waveform generation, refer to Modes of Operation .

The Timer/Counter Overflow (TOV2) Flag is set according to the mode of operation selected by the WGM21:0 bits. TOV2 can be used for generating a CPU interrupt.

\subsection*{20.5. Output Compare Unit}

The 8-bit comparator continuously compares TCNT2 with the Output Compare Register (OCR2). Whenever TCNT2 equals OCR2, the comparator signals a match. A match will set the Output Compare Flag (OCF2) at the next timer clock cycle. If enabled (OCIE2 \(=1\) ), the Output Compare Flag generates an Output Compare interrupt. The OCF2 Flag is automatically cleared when the interrupt is executed.
Alternatively, the OCF2 Flag can be cleared by software by writing a logical one to its I/O bit location. The waveform generator uses the match signal to generate an output according to operating mode set by the WGM21:0 bits and Compare Output mode (COM21:0) bits. The max and bottom signals are used by the waveform generator for handling the special cases of the extreme values in some modes of operation (refer to Modes of Operation).

The following figure shows a block diagram of the Output Compare unit.

Figure 20-3. Output Compare Unit, Block Diagram

The OCR2 Register is double buffered when using any of the Pulse Width Modulation (PWM) modes. For the normal and Clear Timer on Compare (CTC) modes of operation, the double buffering is disabled. The double buffering synchronizes the update of the OCR2 Compare Register to either top or bottom of the counting sequence. The synchronization prevents the occurrence of odd-length, non-symmetrical PWM pulses, thereby making the output glitch-free.

The OCR2 Register access may seem complex, but this is not case. When the double buffering is enabled, the CPU has access to the OCR2 Buffer Register, and if double buffering is disabled the CPU will access the OCR2 directly.

\subsection*{20.5.1. Force Output Compare}

In non-PWM Waveform Generation modes, the match output of the comparator can be forced by writing a one to the Force Output Compare (FOC2) bit. Forcing Compare Match will not set the OCF2 Flag or reload/clear the timer, but the OC2 pin will be updated as if a real Compare Match had occurred (the COM21:0 bits settings define whether the OC2 pin is set, cleared or toggled).

\subsection*{20.5.2. Compare Match Blocking by TCNT2 Write}

All CPU write operations to the TCNT2 Register will block any Compare Match that occurs in the next timer clock cycle, even when the timer is stopped. This feature allows OCR2 to be initialized to the same value as TCNT2 without triggering an interrupt when the Timer/Counter clock is enabled.

\subsection*{20.5.3. Using the Output Compare Unit}

Since writing TCNT2 in any mode of operation will block all compare matches for one timer clock cycle, there are risks involved when changing TCNT2 when using the Output Compare channel, independently of whether the Timer/Counter is running or not. If the value written to TCNT2 equals the OCR2 value, the

Compare Match will be missed, resulting in incorrect waveform generation. Similarly, do not write the TCNT2 value equal to BOTTOM when the counter is downcounting.

The setup of the OC2 should be performed before setting the Data Direction Register for the port pin to output. The easiest way of setting the OC2 value is to use the Force Output Compare (FOC2) strobe bit in Normal mode. The OC2 Register keeps its value even when changing between waveform generation modes.

Be aware that the COM21:0 bits are not double buffered together with the compare value. Changing the COM21:0 bits will take effect immediately.

\subsection*{20.6. Compare Match Output Unit}

The Compare Output mode (COM21:0) bits have two functions. The waveform generator uses the COM21:0 bits for defining the Output Compare (OC2) state at the next Compare Match. Also, the COM21:0 bits control the OC2 pin output source. The figure below shows a simplified schematic of the logic affected by the COM21:0 bit setting. The I/O Registers, I/O bits, and I/O pins in the figure are shown in bold. Only the parts of the general I/O Port Control Registers (DDR and PORT) that are affected by the COM21:0 bits are shown. When referring to the OC2 state, the reference is for the internal OC2 Register, not the OC2 pin.

Figure 20-4. Compare Match Output Unit, Schematic

The general I/O port function is overridden by the Output Compare (OC2) from the waveform generator if either of the COM21:0 bits are set. However, the OC2 pin direction (input or output) is still controlled by the Data Direction Register (DDR) for the port pin. The Data Direction Register bit for the OC2 pin (DDR_OC2) must be set as output before the OC2 value is visible on the pin. The port override function is independent of the Waveform Generation mode.

The design of the Output Compare Pin logic allows initialization of the OC2 state before the output is enabled. Note that some COM21:0 bit settings are reserved for certain modes of operation. See Register Description.

\subsection*{20.6.1. Compare Output Mode and Waveform Generation}

The Waveform Generator uses the COM21:0 bits differently in normal, CTC, and PWM modes. For all modes, setting the COM21:0 = 0 tells the waveform generator that no action on the OC2 Register is to be performed on the next Compare Match. For compare output actions in the non-PWM modes refer to table Compare Output Mode, Non-PWM Mode. For fast PWM mode, refer to table Compare Output Mode, Fast PWM Mode, and for phase correct PWM refer to table Compare Output Mode, Phase Correct PWM Mode.

A change of the COM21:0 bits state will have effect at the first Compare Match after the bits are written. For non-PWM modes, the action can be forced to have immediate effect by using the FOC2 strobe bits.

\subsection*{20.7. Modes of Operation}

The mode of operation (i.e., the behavior of the Timer/Counter and the Output Compare pins) is defined by the combination of the Waveform Generation mode (WGM21:0) and Compare Output mode (COM21:0) bits. The Compare Output mode bits do not affect the counting sequence, while the Waveform Generation mode bits do. The COM21:0 bits control whether the PWM output generated should be inverted or not (inverted or non-inverted PWM). For non-PWM modes the COM21:0 bits control whether the output should be set, cleared, or toggled at a Compare Match (refer to Compare Match Output Unit).

For detailed timing information refer to Timer/Counter Timing Diagrams.

\subsection*{20.7.1. Normal Mode}

The simplest mode of operation is the Normal mode (WGM21:0 \(=0\) ). In this mode the counting direction is always up (incrementing), and no counter clear is performed. The counter simply overruns when it passes its maximum 8 -bit value (TOP \(=0 \times F F\) ) and then restarts from the bottom ( \(0 \times 00\) ). In normal operation the Timer/Counter Overflow Flag (TOV2) will be set in the same timer clock cycle as the TCNT2 becomes zero. The TOV2 Flag in this case behaves like a ninth bit, except that it is only set, not cleared. However, combined with the timer overflow interrupt that automatically clears the TOV2 Flag, the timer resolution can be increased by software. There are no special cases to consider in the Normal mode, a new counter value can be written anytime.

The Output Compare unit can be used to generate interrupts at some given time. Using the Output Compare to generate waveforms in Normal mode is not recommended, since this will occupy too much of the CPU time.
20.7.2. Clear Timer on Compare Match (CTC) Mode

In Clear Timer on Compare or CTC mode (WGM21:0 = 2), the OCR2 Register is used to manipulate the counter resolution. In CTC mode the counter is cleared to zero when the counter value (TCNT2) matches the OCR2. The OCR2 defines the top value for the counter, hence also its resolution. This mode allows greater control of the Compare Match output frequency. It also simplifies the operation of counting external events.

The timing diagram for the CTC mode is shown in the figure below. The counter value (TCNT2) increases until a Compare Match occurs between TCNT2 and OCR2, and then counter (TCNT2) is cleared.

Figure 20-5. CTC Mode, Timing Diagram

An interrupt can be generated each time the counter value reaches the TOP value by using the OCF2 Flag. If the interrupt is enabled, the interrupt handler routine can be used for updating the TOP value. However, changing the TOP to a value close to BOTTOM when the counter is running with none or a low prescaler value must be done with care since the CTC mode does not have the double buffering feature. If the new value written to OCR2 is lower than the current value of TCNT2, the counter will miss the Compare Match. The counter will then have to count to its maximum value ( \(0 \times \mathrm{xFF}\) ) and wrap around starting at \(0 \times 00\) before the Compare Match can occur.

For generating a waveform output in CTC mode, the OC2 output can be set to toggle its logical level on each Compare Match by setting the Compare Output mode bits to toggle mode (COM21:0 = 1). The OC2 value will not be visible on the port pin unless the data direction for the pin is set to output. The waveform generated will have a maximum frequency of \(\mathrm{f}_{\mathrm{OC} 2}=\mathrm{f}_{\mathrm{clk} \_/ / / 2} / 2\) when OCR2 is set to zero ( \(0 \times 00\) ). The waveform frequency is defined by the following equation:
\(f_{\text {OCn }}=\frac{f_{\text {clk } \mathrm{I} / \mathrm{O}}}{2 \cdot N \cdot(1+0 \mathrm{OCn})}\)
The \(N\) variable represents the prescaler factor ( \(1,8,32,64,128,256\), or 1024).
As for the Normal mode of operation, the TOV2 Flag is set in the same timer clock cycle that the counter counts from MAX to \(0 \times 00\).

\subsection*{20.7.3. Fast PWM Mode}

The fast Pulse Width Modulation or fast PWM mode (WGM21:0 = 3) provides a high frequency PWM waveform generation option. The fast PWM differs from the other PWM option by its single-slope operation. The counter counts from BOTTOM to MAX then restarts from BOTTOM. In non-inverting Compare Output mode, the Output Compare (OC2) is cleared on the Compare Match between TCNT2 and OCR2, and set at BOTTOM. In inverting Compare Output mode, the output is set on Compare Match and cleared at BOTTOM. Due to the single-slope operation, the operating frequency of the fast PWM mode can be twice as high as the phase correct PWM mode that uses dual-slope operation. This high frequency makes the fast PWM mode well suited for power regulation, rectification, and DAC applications. High frequency allows physically small sized external components (coils, capacitors), and therefore reduces total system cost.

In fast PWM mode, the counter is incremented until the counter value matches the MAX value. The counter is then cleared at the following timer clock cycle. The timing diagram for the fast PWM mode is shown in the following figure. The TCNT2 value is in the timing diagram shown as a histogram for illustrating the single-slope operation. The diagram includes non-inverted and inverted PWM outputs. The
small horizontal line marks on the TCNT2 slopes represent compare matches between OCR2 and TCNT2.

Figure 20-6. Fast PWM Mode, Timing Diagram

The Timer/Counter Overflow Flag (TOV2) is set each time the counter reaches MAX. If the interrupt is enabled, the interrupt handler routine can be used for updating the compare value.

In fast PWM mode, the compare unit allows generation of PWM waveforms on the OC2 pin. Setting the COM21:0 bits to 2 will produce a non-inverted PWM and an inverted PWM output can be generated by setting the COM21:0 to 3 . The actual OC2 value will only be visible on the port pin if the data direction for the port pin is set as output. The PWM waveform is generated by setting (or clearing) the OC2 Register at the Compare Match between OCR2 and TCNT2, and clearing (or setting) the OC2 Register at the timer clock cycle the counter is cleared (changes from MAX to BOTTOM).

The PWM frequency for the output can be calculated by the following equation:
\(f_{\text {OCnPWM }}=\frac{f_{\text {clk } 1 / 0}}{N \cdot 256}\)
The N variable represents the prescaler factor ( \(1,8,32,64,128,256\), or 1024).
The extreme values for the OCR2 Register represent special cases when generating a PWM waveform output in the fast PWM mode. If the OCR2 is set equal to BOTTOM, the output will be a narrow spike for each MAX+1 timer clock cycle. Setting the OCR2 equal to MAX will result in a constantly high or low output (depending on the polarity of the output set by the COM21:0 bits.)
A frequency (with \(50 \%\) duty cycle) waveform output in fast PWM mode can be achieved by setting OC2 to toggle its logical level on each Compare Match (COM21:0 = 1). The waveform generated will have a maximum frequency of \(f_{\text {oc2 }}=f_{\text {clk_/Io }} / 2\) when OCR2 is set to zero. This feature is similar to the OC2 toggle in CTC mode, except the double buffer feature of the Output Compare unit is enabled in the fast PWM mode.

\subsection*{20.7.4. Phase Correct PWM Mode}

The phase correct PWM mode (WGM21:0 = 1) provides a high resolution phase correct PWM waveform generation option. The phase correct PWM mode is based on a dual-slope operation. The counter counts repeatedly from BOTTOM to MAX and then from MAX to BOTTOM. In non-inverting Compare Output
mode, the Output Compare (OC2) is cleared on the Compare Match between TCNT2 and OCR2 while upcounting, and set on the Compare Match while downcounting. In inverting Output Compare mode, the operation is inverted. The dual-slope operation has lower maximum operation frequency than single slope operation. However, due to the symmetric feature of the dual-slope PWM modes, these modes are preferred for motor control applications.
The PWM resolution for the phase correct PWM mode is fixed to eight bits. In phase correct PWM mode the counter is incremented until the counter value matches MAX. When the counter reaches MAX, it changes the count direction. The TCNT2 value will be equal to MAX for one timer clock cycle. The timing diagram for the phase correct PWM mode is shown on the following figure. The TCNT2 value is in the timing diagram shown as a histogram for illustrating the dual-slope operation. The diagram includes noninverted and inverted PWM outputs. The small horizontal line marks on the TCNT2 slopes represent compare matches between OCR2 and TCNT2.

Figure 20-7. Phase Correct PWM Mode, Timing Diagram

The Timer/Counter Overflow Flag (TOV2) is set each time the counter reaches BOTTOM. The Interrupt Flag can be used to generate an interrupt each time the counter reaches the BOTTOM value.

In phase correct PWM mode, the compare unit allows generation of PWM waveforms on the OC2 pin. Setting the COM21:0 bits to 2 will produce a non-inverted PWM. An inverted PWM output can be generated by setting the COM21:0 to 3 (refer to table Compare Output Mode, Phase Correct PWM Mode). The actual OC2 value will only be visible on the port pin if the data direction for the port pin is set as output. The PWM waveform is generated by clearing (or setting) the OC2 Register at the Compare Match between OCR2 and TCNT2 when the counter increments, and setting (or clearing) the OC2 Register at Compare Match between OCR2 and TCNT2 when the counter decrements. The PWM frequency for the output when using phase correct PWM can be calculated by the following equation:
\(f_{\text {OCnPCPWM }}=\frac{f_{\text {clk } \mathrm{I} / 0}}{N \cdot 510}\)
The \(N\) variable represents the prescaler factor ( \(1,8,32,64,128,256\), or 1024).
The extreme values for the OCR2 Register represent special cases when generating a PWM waveform output in the phase correct PWM mode. If the OCR2 is set equal to BOTTOM, the output will be
continuously low and if set equal to MAX the output will be continuously high for non-inverted PWM mode. For inverted PWM the output will have the opposite logic values.

At the very start of period 2 in the timing diagram above OCn has a transition from high to low even though there is no Compare Match. The point of this transition is to guarantee symmetry around BOTTOM. There are two cases that give a transition without Compare Match:
- OCR2A changes its value from MAX, like in the timing diagram above. When the OCR2A value is MAX the OCn pin value is the same as the result of a down-counting Compare Match. To ensure symmetry around BOTTOM the OCn value at MAX must correspond to the result of an up-counting Compare Match.
- The timer starts counting from a value higher than the one in OCR2A, and for that reason misses the Compare Match and hence the OCn change that would have happened on the way up.

\subsection*{20.8. Timer/Counter Timing Diagrams}

The following figures show the Timer/Counter in Synchronous mode, and the timer clock \(\left(\mathrm{clk}_{\mathrm{T} 2}\right)\) is therefore shown as a clock enable signal. In Asynchronous mode, clk \({ }_{l / O}\) should be replaced by the Timer/ Counter Oscillator clock. The figures include information on when Interrupt Flags are set. The following figure contains timing data for basic Timer/Counter operation. The figure shows the count sequence close to the MAX value in all modes other than phase correct PWM mode.

Figure 20-8. Timer/Counter Timing Diagram, no Prescaling

The next figure shows the same timing data, but with the prescaler enabled.
Figure 20-9. Timer/Counter Timing Diagram, with Prescaler ( \(\mathrm{c}_{\mathrm{clk}} \mathrm{I} / \mathrm{o}^{\prime} / 8\) )

The next figure shows the setting of OCF2 in all modes except CTC mode.

Figure 20-10. Timer/Counter Timing Diagram, Setting of OCF2, with Prescaler ( \(\mathrm{f}_{\mathrm{clk} \text { _// }} / 8\) )

The figure below shows the setting of OCF2 and the clearing of TCNT2 in CTC mode.
Figure 20-11. Timer/Counter Timing Diagram, Clear Timer on Compare Match Mode, with Prescaler ( \(\mathrm{f}_{\mathrm{clk}} \mathbf{1 / / 0} / 8\) )

\subsection*{20.9. Asynchronous Operation of the Timer/Counter}

\subsection*{20.9.1. Asynchronous Operation of Timer/Counter2}

When Timer/Counter2 operates asynchronously, some considerations must be taken.
- Warning: When switching between asynchronous and synchronous clocking of Timer/Counter2, the Timer Registers TCNT2, OCR2, and TCCR2 might be corrupted. A safe procedure for switching clock source is:
1. Disable the Timer/Counter2 interrupts by clearing OCIE2 and TOIE2.
2. Select clock source by setting AS2 as appropriate.
3. Write new values to TCNT2, OCR2, and TCCR2.
4. To switch to asynchronous operation: Wait for TCN2UB, OCR2UB, and TCR2UB.
5. Clear the Timer/Counter2 Interrupt Flags.
6. Enable interrupts, if needed.
- The Oscillator is optimized for use with a 32.768 kHz watch crystal. Applying an external clock to the TOSC1 pin may result in incorrect Timer/Counter2 operation. The CPU main clock frequency must be more than four times the Oscillator frequency.
- When writing to one of the registers TCNT2, OCR2, or TCCR2, the value is transferred to a temporary register, and latched after two positive edges on TOSC1. The user should not write a new value before the contents of the temporary register have been transferred to its destination. Each of the three mentioned registers have their individual temporary register, which means that e.g. writing to TCNT2 does not disturb an OCR2 write in progress. To detect that a transfer to the destination register has taken place, the Asynchronous Status Register - ASSR has been implemented.
- When entering Power-save mode after having written to TCNT2, OCR2, or TCCR2, the user must wait until the written register has been updated if Timer/Counter2 is used to wake up the device. Otherwise, the MCU will enter sleep mode before the changes are effective. This is particularly important if the Output Compare2 interrupt is used to wake up the device, since the Output Compare function is disabled during writing to OCR2 or TCNT2. If the write cycle is not finished, and the MCU enters sleep mode before the OCR2UB bit returns to zero, the device will never receive a Compare Match interrupt, and the MCU will not wake up.
- If Timer/Counter2 is used to wake the device up from Power-save or Extended Standby mode, precautions must be taken if the user wants to re-enter one of these modes: The interrupt logic needs one TOSC1 cycle to be reset. If the time between wake-up and re-entering sleep mode is less than one TOSC1 cycle, the interrupt will not occur, and the device will fail to wake up. If the user is in doubt whether the time before re-entering Power-save or Extended Standby mode is sufficient, the following algorithm can be used to ensure that one TOSC1 cycle has elapsed:
1. Write a value to TCCR2, TCNT2, or OCR2.
2. Wait until the corresponding Update Busy Flag in ASSR returns to zero.
3. Enter Power-save or Extended Standby mode.
- When the asynchronous operation is selected, the 32.768 kHz Oscillator for Timer/Counter2 is always running, except in Power-down and Standby modes. After a Power-up Reset or Wake-up from Power-down or Standby mode, the user should be aware of the fact that this Oscillator might take as long as one second to stabilize. The user is advised to wait for at least one second before using Timer/Counter2 after Power-up or Wake-up from Power-down or Standby mode. The contents of all Timer/Counter2 Registers must be considered lost after a wake-up from Power-down or Standby mode due to unstable clock signal upon start-up, no matter whether the Oscillator is in use or a clock signal is applied to the TOSC1 pin.
- Description of wake up from Power-save or Extended Standby mode when the timer is clocked asynchronously: When the interrupt condition is met, the wake up process is started on the following cycle of the timer clock, that is, the timer is always advanced by at least one before the processor can read the counter value. After wake-up, the MCU is halted for four cycles, it executes the interrupt routine, and resumes execution from the instruction following SLEEP.
- Reading of the TCNT2 Register shortly after wake-up from Power-save may give an incorrect result. Since TCNT2 is clocked on the asynchronous TOSC clock, reading TCNT2 must be done through a register synchronized to the internal I/O clock domain. Synchronization takes place for every rising TOSC1 edge. When waking up from Power-save mode, and the I/O clock (clk \({ }_{1 / 0}\) ) again becomes active, TCNT2 will read as the previous value (before entering sleep) until the next rising TOSC1 edge. The phase of the TOSC clock after waking up from Power-save mode is essentially unpredictable, as it depends on the wake-up time. The recommended procedure for reading TCNT2 is thus as follows:
1. Write any value to either of the registers OCR2 or TCCR2.
2. Wait for the corresponding Update Busy Flag to be cleared.
3. Read TCNT2.
- During asynchronous operation, the synchronization of the Interrupt Flags for the asynchronous timer takes three processor cycles plus one timer cycle. The timer is therefore advanced by at least one before the processor can read the timer value causing the setting of the Interrupt Flag. The Output Compare Pin is changed on the timer clock and is not synchronized to the processor clock.

\subsection*{20.10. Timer/Counter Prescaler}

Figure 20-12. Prescaler for Timer/Counter2

The clock source for Timer/Counter2 is named \(\mathrm{clk}_{\mathrm{T} 2 \mathrm{~S}}\). \(\mathrm{clk}_{\mathrm{T}_{22} \mathrm{~S}}\) is by default connected to the main system clock \(\mathrm{clk}_{/ / 0}\). By setting the AS2 bit in ASSR, Timer/Counter2 is asynchronously clocked from the TOSC1 pin. This enables use of Timer/Counter2 as a Real Time Counter (RTC). When AS2 is set, pins TOSC1 and TOSC2 are disconnected from Port C. A crystal can then be connected between the TOSC1 and TOSC2 pins to serve as an independent clock source for Timer/Counter2. The Oscillator is optimized for use with a 32.768 kHz crystal. Applying an external clock source to TOSC1 is not recommended.

For Timer/Counter2, the possible prescaled selections are: \(\mathrm{clk}_{\mathrm{T} 2 \mathrm{~S}} / 8, \mathrm{clk}_{\mathrm{T} 2 \mathrm{~S}} / 32\), \(\mathrm{ck}_{\mathrm{T} 2 \mathrm{~S}} / 64, \mathrm{clk}_{\mathrm{T} 2 \mathrm{~S}} / 128\), \(\mathrm{clk}_{\mathrm{T} 2 \mathrm{~S}} / 256\), and \(\mathrm{clk}_{\mathrm{T} 2 \mathrm{~S}} / 1024\). Additionally, \(\mathrm{clk}_{\mathrm{T} 2 \mathrm{~S}}\) as well as 0 (stop) may be selected. Setting the PSR2 bit in SFIOR resets the prescaler. This allows the user to operate with a predictable prescaler.

\subsection*{20.11. Register Description}

\subsection*{20.11.1. TCCR2 - Timer/Counter Control Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: TCCR2
Offset: 0x25
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 45\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & FOC2 & WGM20 & COM21 & COM20 & WGM21 & CS22 & CS21 & CS20 \\
\hline Access & W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - FOC2: Force Output Compare}

The FOC2 bit is only active when the WGM bits specify a non-PWM mode. However, for ensuring compatibility with future devices, this bit must be set to zero when TCCR2 is written when operating in PWM mode. When writing a logical one to the FOC2 bit, an immediate Compare Match is forced on the waveform generation unit. The OC2 output is changed according to its COM21:0 bits setting. Note that the FOC2 bit is implemented as a strobe. Therefore it is the value present in the COM21:0 bits that determines the effect of the forced compare.

A FOC2 strobe will not generate any interrupt, nor will it clear the timer in CTC mode using OCR2 as TOP.

The FOC2 bit is always read as zero.

\section*{Bit 6 - WGM20: Waveform Generation Mode [n=0:1]}

These bits control the counting sequence of the counter, the source for the maximum (TOP) counter value, and what type of waveform generation to be used. Modes of operation supported by the Timer/ Counter unit are: Normal mode, Clear Timer on Compare Match (CTC) mode, and two types of Pulse Width Modulation (PWM) modes. See table below and Modes of Operation.

Table 20-2. Waveform Generation Mode Bit Description
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline Mode & \begin{tabular}{l} 
WGM21 \\
(CTC2)
\end{tabular} & \begin{tabular}{l} 
WGM20 \\
(PWM2)
\end{tabular} & Timer/Counter Mode of Operation \({ }^{(1)}\) & TOP & \begin{tabular}{l} 
Update of \\
OCR2
\end{tabular} & \begin{tabular}{l} 
TOV2 Flag \\
Set
\end{tabular} \\
\hline 0 & 0 & 0 & Normal & 0xFF & Immediate & MAX \\
\hline 1 & 0 & 1 & PWM, Phase Correct & OxFF & TOP & BOTTOM \\
\hline 2 & 1 & 0 & CTC & OCR2 & Immediate & MAX \\
\hline 3 & 1 & 1 & Fast PWM & 0xFF & BOTTOM & MAX \\
\hline
\end{tabular}

Note: 1. The CTC2 and PWM2 bit definition names are now obsolete. Use the WGM21:0 definitions. However, the functionality and location of these bits are compatible with previous versions of the timer.

\section*{Bits 5:4 - COM2n: Compare Match Output Mode [n=1:0]}

These bits control the Output Compare Pin (OC2) behavior. If one or both of the COM21:0 bits are set, the OC2 output overrides the normal port functionality of the I/O pin it is connected to. However, note that
the Data Direction Register (DDR) bit corresponding to OC2 pin must be set in order to enable the output driver.

When OC2 is connected to the pin, the function of the COM21:0 bits depends on the WGM21:0 bit setting. The following table shows the COM21:0 bit functionality when the WGM21:0 bits are set to a normal or CTC mode (non-PWM).
Table 20-3. Compare Output Mode, Non-PWM Mode
\begin{tabular}{|l|l|l|}
\hline COM21 & COM20 & Description \\
\hline 0 & 0 & Normal port operation, OC2 disconnected. \\
\hline 0 & 1 & Toggle OC2 on Compare Match \\
\hline 1 & 0 & Clear OC2 on Compare Match \\
\hline 1 & 1 & Set OC2 on Compare Match \\
\hline
\end{tabular}

The next table shows the COM21:0 bit functionality when the WGM21:0 bits are set to fast PWM mode.
Table 20-4. Compare Output Mode, Fast PWM Mode \({ }^{(1)}\)
\begin{tabular}{|l|l|l|}
\hline COM21 & COM20 & Description \\
\hline 0 & 0 & Normal port operation, OC2 disconnected. \\
\hline 0 & 1 & Reserved \\
\hline 1 & 0 & \begin{tabular}{l} 
Clear OC2 on Compare Match, set OC2 at BOTTOM, \\
(non-inverting mode)
\end{tabular} \\
\hline 1 & 1 & \begin{tabular}{l} 
Set OC2 on Compare Match, clear OC2 at BOTTOM, \\
(inverting mode)
\end{tabular} \\
\hline
\end{tabular}

Note: 1. A special case occurs when OCR2 equals TOP and COM21 is set. In this case, the Compare Match is ignored, but the set or clear is done at BOTTOM. See Fast PWM Mode for more details.
The table below shows the COM21:0 bit functionality when the WGM21:0 bits are set to phase correct PWM mode.
Table 20-5. Compare Output Mode, Phase Correct PWM Mode \({ }^{(1)}\)
\begin{tabular}{|l|l|l|}
\hline COM21 & COM20 & Description \\
\hline 0 & 0 & Normal port operation, OC2 disconnected. \\
\hline 0 & 1 & Reserved \\
\hline 1 & 0 & \begin{tabular}{l} 
Clear OC2 on Compare Match when up-counting. Set OC2 on Compare Match when \\
downcounting.
\end{tabular} \\
\hline 1 & 1 & \begin{tabular}{l} 
Set OC2 on Compare Match when up-counting. Clear OC2 on Compare Match when \\
downcounting.
\end{tabular} \\
\hline
\end{tabular}

Note: 1. A special case occurs when OCR2 equals TOP and COM21 is set. In this case, the Compare Match is ignored, but the set or clear is done at TOP. See Phase Correct PWM Mode for more details.

Bit 3 - WGM21: Waveform Generation Mode [n=0:1]
Refer to WGM20.

Bits 2:0-CS2n: Clock Select [n=2:0]
The three Clock Select bits select the clock source to be used by the Timer/Counter.
Table 20-6. Clock Select Bit Description
\begin{tabular}{|c|c|c|l|}
\hline CS22 & CS21 & CS20 & Description \\
\hline 0 & 0 & 0 & No clock source (Timer/Counter stopped). \\
\hline 0 & 0 & 1 & clk \(_{/ / O} / 1\) (No prescaling) \\
\hline 0 & 1 & 0 & \(\mathrm{clk}_{/ / O} / 8\) (From prescaler) \\
\hline 0 & 1 & 1 & \(\mathrm{clk}_{/ / O} / 32\) (From prescaler) \\
\hline 1 & 0 & 0 & \(\mathrm{clkl}^{\prime} \mathrm{O} / 64\) (From prescaler) \\
\hline 1 & 0 & 1 & \(\mathrm{clk}_{/ / \mathrm{O}} / 128\) (From prescaler) \\
\hline 1 & 1 & 0 & \(\mathrm{clk}_{/ / \mathrm{O}} / 256\) (From prescaler) \\
\hline 1 & 1 & 1 & \(\mathrm{clk}_{/ / \mathrm{O}} / 1024\) (From prescaler) \\
\hline
\end{tabular}

\subsection*{20.11.2. TCNTO - Timer/Counter Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

The Timer/Counter Register gives direct access, both for read and write operations, to the Timer/Counter unit 8-bit counter. Writing to the TCNT0 Register blocks (removes) the Compare Match on the following timer clock. Modifying the counter (TCNTO) while the counter is running, introduces a risk of missing a Compare Match between TCNT0 and the OCRO Register.

Name: TCNTO
Offset: 0x24
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 44\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{TCNT0[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - TCNT0[7:0]

\subsection*{20.11.3. OCRO - Output Compare Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 \mathrm{~F}\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

The Output Compare Register contains an 8-bit value that is continuously compared with the counter value (TCNTO). A match can be used to generate an Output Compare interrupt, or to generate a waveform output on the OCO pin.

Name: OCRO
Offset: 0x23
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 43\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{OCR0[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - OCRO[7:0]

\subsection*{20.11.4. ASSR - Asynchronous Status Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: ASSR
Offset: 0x22
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 42\)

Bit 3 - AS2: Asynchronous Timer/Counter2
When AS2 is written to zero, Timer/Counter 2 is clocked from the I/O clock, clk \({ }_{/ / O}\). When AS2 is written to one, Timer/Counter 2 is clocked from a crystal Oscillator connected to the Timer Oscillator 1 (TOSC1) pin. When the value of AS2 is changed, the contents of TCNT2, OCR2, and TCCR2 might be corrupted.

\section*{Bit 2 - TCN2UB: Timer/Counter2 Update Busy}

When Timer/Counter2 operates asynchronously and TCNT2 is written, this bit becomes set. When TCNT2 has been updated from the temporary storage register, this bit is cleared by hardware. A logical zero in this bit indicates that TCNT2 is ready to be updated with a new value.

\section*{Bit 1 - OCR2UB: Output Compare Register2 Update Busy}

When Timer/Counter2 operates asynchronously and OCR2 is written, this bit becomes set. When OCR2 has been updated from the temporary storage register, this bit is cleared by hardware. A logical zero in this bit indicates that OCR2 is ready to be updated with a new value.

\section*{Bit 0 - TCR2UB: Timer/Counter Control Register2 Update Busy}

When Timer/Counter2 operates asynchronously and TCCR2 is written, this bit becomes set. When TCCR2 has been updated from the temporary storage register, this bit is cleared by hardware. A logical zero in this bit indicates that TCCR2 is ready to be updated with a new value.

If a write is performed to any of the three Timer/Counter2 Registers while its update busy flag is set, the updated value might get corrupted and cause an unintentional interrupt to occur.
The mechanisms for reading TCNT2, OCR2, and TCCR2 are different. When reading TCNT2, the actual timer value is read. When reading OCR2 or TCCR2, the value in the temporary storage register is read.

\subsection*{20.11.5. TIMSK - Timer/Counter Interrupt Mask Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: TIMSK
Offset: 0x39
Reset: \(0 \times 00\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 59\)

Bit 7 - OCIE2: Timer/Counter2 Output Compare Match Interrupt Enable
When the OCIE2 bit is written to one and the l-bit in the Status Register is set (one), the Timer/Counter2 Compare Match interrupt is enabled. The corresponding interrupt is executed if a Compare Match in Timer/Counter2 occurs (i.e., when the OCF2 bit is set in the Timer/Counter Interrupt Flag Register TIFR).

Bit 6 - TOIE2: Timer/Counter2 Overflow Interrupt Enable
When the TOIE2 bit is written to one and the l-bit in the Status Register is set (one), the Timer/Counter2 Overflow interrupt is enabled. The corresponding interrupt is executed if an overflow in Timer/Counter2 occurs (i.e., when the TOV2 bit is set in the Timer/Counter Interrupt Flag Register - TIFR).

\subsection*{20.11.6. TIFR - Timer/Counter Interrupt Flag Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: TIFR
Offset: 0x38
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 58\)

Bit 7 - OCF2: Output Compare Flag 2
The OCF2 bit is set (one) when a Compare Match occurs between the Timer/Counter2 and the data in OCR2 - Output Compare Register2. OCF2 is cleared by hardware when executing the corresponding interrupt Handling Vector. Alternatively, OCF2 is cleared by writing a logic one to the flag. When the I-bit in SREG, OCIE2 (Timer/Counter2 Compare Match Interrupt Enable), and OCF2 are set (one), the Timer/ Counter2 Compare Match Interrupt is executed.

Bit 6 - TOV2: Timer/Counter2 Overflow Flag
The TOV2 bit is set (one) when an overflow occurs in Timer/Counter2. TOV2 is cleared by hardware when executing the corresponding interrupt Handling Vector. Alternatively, TOV2 is cleared by writing a logic one to the flag. When the SREG I-bit, TOIE2 (Timer/Counter2 Overflow Interrupt Enable), and TOV2 are set (one), the Timer/Counter2 Overflow interrupt is executed. In PWM mode, this bit is set when Timer/Counter2 changes counting direction at 0x00.

\subsection*{20.11.7. SFIOR - Special Function IO Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: SFIOR
Offset: 0x30
Reset: 0
Property: When addressing I/O Registers as data space the offset address is \(0 \times 50\)

Bit 1 - PSR2: Prescaler Reset Timer/Counter2
When this bit is written to one, the Timer/Counter2 prescaler will be reset. The bit will be cleared by hardware after the operation is performed. Writing a zero to this bit will have no effect. This bit will always be read as zero if Timer/Counter2 is clocked by the internal CPU clock. If this bit is written when Timer/ Counter2 is operating in Asynchronous mode, the bit will remain one until the prescaler has been reset.

\section*{21. 8-bit Timer/Counter0 with PWM}

\subsection*{21.1. Features}
- Single Compare Unit Counter
- Clear Timer on Compare Match (Auto Reload)
- Glitch-free, phase Correct Pulse Width Modulator (PWM)
- Frequency Generator
- External Event Counter
- 10-bit Clock Prescaler
- Overflow and Compare Match Interrupt Sources (TOVO and OCFO)

\subsection*{21.2. Overview}

Timer/Counter0 is a general purpose, single compare unit, 8-bit Timer/Counter module. A simplified block diagram of the 8 -bit Timer/Counter is shown in the figure below. For the actual placement of \(I / O\) pins, refer to Pin Configurations. CPU accessible I/O Registers, including I/O bits and I/O pins, are shown in bold. The device-specific I/O Register and bit locations are listed in the Register Description.
Figure 21-1. 8-bit Timer/Counter Block Diagram

Related Links
Pin Configurations on page 13

\subsection*{21.2.1. Registers}

The Timer/Counter (TCNTO) and Output Compare Register (OCRO) are 8-bit registers. Interrupt request (abbreviated to Int.Req. in the figure) signals are all visible in the Timer Interrupt Flag Register (TIFR). All interrupts are individually masked with the Timer Interrupt Mask Register (TIMSK). TIFR and TIMSK are not shown in the figure since these registers are shared by other timer units.

The Timer/Counter can be clocked internally, via the prescaler, or by an external clock source on the TO pin. The Clock Select logic block controls which clock source and edge the Timer/Counter uses to increment (or decrement) its value. The Timer/Counter is inactive when no clock source is selected. The output from the clock select logic is referred to as the timer clock ( \(\mathrm{clk}_{\mathrm{T}_{0}}\) ).
The double buffered Output Compare Register (OCRO) is compared with the Timer/Counter value at all times. The result of the compare can be used by the waveform generator to generate a PWM or variable frequency output on the Output Compare Pin (OCO). For details, refer to Output Compare Unit. The Compare Match event will also set the Compare Flag (OCFO) which can be used to generate an Output Compare interrupt request.

\subsection*{21.2.2. Definitions}

Many register and bit references in this document are written in general form. A lower case " n " replaces the Timer/Counter number, in this case 0 . However, when using the register or bit defines in a program, the precise form must be used (i.e., TCNT0 for accessing Timer/Counter0 counter value and so on).

The definitions in the following table are also used extensively throughout the document.
Table 21-1. Definitions
\begin{tabular}{|l|l|}
\hline BOTTOM & The counter reaches the BOTTOM when it becomes zero (0x00). \\
\hline MAX & The counter reaches its MAXimum when it becomes 0xFF (decimal 255). \\
\hline TOP & \begin{tabular}{l} 
The counter reaches the TOP when it becomes equal to the highest value in the \\
count sequence. The TOP value can be assigned to be the fixed value 0xFF (MAX) \\
or the value stored in the OCR0 Register. The assignment is dependent on the \\
mode of operation.
\end{tabular} \\
\hline
\end{tabular}

\subsection*{21.3. Timer/Counter Clock Sources}

The Timer/Counter can be clocked by an internal or an external clock source. The clock source is selected by the clock select logic which is controlled by the clock select (CS02:0) bits located in the Timer/Counter Control Register (TCCRO). For details on clock sources and prescaler, see Timer/Counte1 and Timer/Counter0 Prescalers.

Related Links
Timer/Counter0 and Timer/Counter1 Prescalers on page 102

\subsection*{21.4. Counter Unit}

The main part of the 8-bit Timer/Counter is the programmable bi-directional counter unit. The following figure shows a block diagram of the counter and its surrounding environment.

Figure 21-2. Counter Unit Block Diagram

Signal description (internal signals):
\begin{tabular}{ll} 
count & Increment or decrement TCNTO by 1. \\
direction & Selects between increment and decrement. \\
clear & Clear TCNTO (set all bits to zero). \\
clk \(_{\text {T0 }}\) & Timer/Counter clock. \\
TOP & Signalizes that TCNT0 has reached maximum value. \\
BOTTOM & Signalizes that TCNT0 has reached minimum value (zero).
\end{tabular}

Depending on the mode of operation used, the counter is cleared, incremented, or decremented at each timer clock ( \(\mathrm{clk}_{\mathrm{T} 0}\) ). \(\mathrm{clk}_{\mathrm{T} 0}\) can be generated from an external or internal clock source, selected by the clock select bits (CS02:0). When no clock source is selected (CS02:0 \(=0\) ) the timer is stopped. However, the TCNT0 value can be accessed by the CPU, regardless of whether \(\mathrm{clk}_{\mathrm{T} 0}\) is present or not. A CPU write overrides (has priority over) all counter clear or count operations.

The counting sequence is determined by the setting of the WGM01 and WGM00 bits located in the Timer/ Counter Control Register (TCCRO). There are close connections between how the counter behaves (counts) and how waveforms are generated on the Output Compare Output OCO. For more details about advanced counting sequences and waveform generation, see Modes of Operation.

The Timer/Counter Overflow (TOV0) Flag is set according to the mode of operation selected by the WGM01:0 bits. TOV0 can be used for generating a CPU interrupt.

\subsection*{21.5. Output Compare Unit}

The 8-bit comparator continuously compares TCNT0 with the Output Compare Register (OCR0). Whenever TCNTO equals OCRO, the comparator signals a match. A match will set the Output Compare Flag (OCF0) at the next timer clock cycle. If enabled (OCIE0 \(=1\) and global interrupt flag in SREG is set), the Output Compare Flag generates an Output Compare interrupt. The OCF0 Flag is automatically cleared when the interrupt is executed. Alternatively, the OCF0 Flag can be cleared by software by writing a logical one to its I/O bit location. The waveform generator uses the match signal to generate an output according to operating mode set by the WGM01:0 bits and Compare Output mode (COM01:0) bits. The max and bottom signals are used by the waveform generator for handling the special cases of the extreme values in some modes of operation (see Modes of Operation).

The following figure shows a block diagram of the Output Compare unit.

Figure 21-3. Output Compare Unit, Block Diagram

The OCRO Register is double buffered when using any of the Pulse Width Modulation (PWM) modes. For the normal and Clear Timer on Compare (CTC) modes of operation, the double buffering is disabled. The double buffering synchronizes the update of the OCRO Compare Register to either top or bottom of the counting sequence. The synchronization prevents the occurrence of odd-length, non-symmetrical PWM pulses, thereby making the output glitch-free.

The OCR0 Register access may seem complex, but this is not case. When the double buffering is enabled, the CPU has access to the OCRO Buffer Register, and if double buffering is disabled the CPU will access the OCRO directly.

\subsection*{21.5.1. Force Output Compare}

In non-PWM Waveform Generation modes, the match output of the comparator can be forced by writing a one to the Force Output Compare (FOCO) bit. Forcing Compare Match will not set the OCFO Flag or reload/clear the timer, but the OCO pin will be updated as if a real Compare Match had occurred (the COM01:0 bits settings define whether the OC0 pin is set, cleared or toggled).

\subsection*{21.5.2. Compare Match Blocking by TCNTO Write}

All CPU write operations to the TCNT0 Register will block any Compare Match that occurs in the next timer clock cycle, even when the timer is stopped. This feature allows OCRO to be initialized to the same value as TCNTO without triggering an interrupt when the Timer/Counter clock is enabled.

\subsection*{21.5.3. Using the Output Compare Unit}

Since writing TCNTO in any mode of operation will block all compare matches for one timer clock cycle, there are risks involved when changing TCNTO when using the Output Compare channel, independently of whether the Timer/Counter is running or not. If the value written to TCNT0 equals the OCRO value, the Compare Match will be missed, resulting in incorrect waveform generation. Similarly, do not write the TCNTO value equal to BOTTOM when the counter is downcounting.

The setup of the OCO should be performed before setting the Data Direction Register for the port pin to output. The easiest way of setting the OC0 value is to use the Force Output Compare (FOC0) strobe bit in Normal mode. The OCO Register keeps its value even when changing between waveform generation modes.

Be aware that the COM01:0 bits are not double buffered together with the compare value. Changing the COM01:0 bits will take effect immediately.

\subsection*{21.6. Compare Match Output Unit}

The Compare Output mode (COM01:0) bits have two functions. The waveform generator uses the COM01:0 bits for defining the Output Compare (OCO) state at the next Compare Match. Also, the COM01:0 bits control the OC0 pin output source. The figure below shows a simplified schematic of the logic affected by the COM01:0 bit setting. The I/O Registers, I/O bits, and I/O pins in the figure are shown in bold. Only the parts of the general I/O Port Control Registers (DDR and PORT) that are affected by the COM01:0 bits are shown. When referring to the OC0 state, the reference is for the internal OCO Register, not the OCO pin. If a System Reset occur, the OCO Register is reset to " 0 ".

Figure 21-4. Compare Match Output Unit, Schematic

The general I/O port function is overridden by the Output Compare (OCO) from the waveform generator if either of the COM01:0 bits are set. However, the OC0 pin direction (input or output) is still controlled by the Data Direction Register (DDR) for the port pin. The Data Direction Register bit for the OC0 pin (DDR_OCO) must be set as output before the OCO value is visible on the pin. The port override function is independent of the Waveform Generation mode.

The design of the Output Compare Pin logic allows initialization of the OCO state before the output is enabled. Note that some COM01:0 bit settings are reserved for certain modes of operation. See Register Description.

\subsection*{21.6.1. Compare Output Mode and Waveform Generation}

The Waveform Generator uses the COM01:0 bits differently in normal, CTC, and PWM modes. For all modes, setting the COM01:0 \(=0\) tells the waveform generator that no action on the OC2 Register is to be performed on the next Compare Match. For compare output actions in the non-PWM modes refer to Table 21-3. For fast PWM mode, refer to Table 21-4, and for phase correct PWM refer to Table 21-5.

A change of the COM01:0 bits state will have effect at the first Compare Match after the bits are written. For non-PWM modes, the action can be forced to have immediate effect by using the FOCO strobe bits.

\subsection*{21.7. Modes of Operation}

The mode of operation (i.e., the behavior of the Timer/Counter and the Output Compare pins) is defined by the combination of the Waveform Generation mode (WGM01:0) and Compare Output mode (COM01:0) bits. The Compare Output mode bits do not affect the counting sequence, while the Waveform Generation mode bits do. The COM01:0 bits control whether the PWM output generated should be inverted or not (inverted or non-inverted PWM). For non-PWM modes the COM01:0 bits control whether the output should be set, cleared, or toggled at a Compare Match (see Compare Match Output Unit).
For detailed timing information refer to Timer/Counter Timing Diagrams.

\subsection*{21.7.1. Normal Mode}

The simplest mode of operation is the Normal mode (WGM01:0 = 0). In this mode the counting direction is always up (incrementing), and no counter clear is performed. The counter simply overruns when it passes its maximum 8 -bit value (TOP \(=0 x F F\) ) and then restarts from the bottom ( \(0 \times 00\) ). In normal operation the Timer/Counter Overflow Flag (TOVO) will be set in the same timer clock cycle as the TCNT0 becomes zero. The TOVO Flag in this case behaves like a ninth bit, except that it is only set, not cleared. However, combined with the timer overflow interrupt that automatically clears the TOVO Flag, the timer resolution can be increased by software. There are no special cases to consider in the Normal mode, a new counter value can be written anytime.
The Output Compare unit can be used to generate interrupts at some given time. Using the Output Compare to generate waveforms in Normal mode is not recommended, since this will occupy too much of the CPU time.

\subsection*{21.7.2. Clear Timer on Compare Match (CTC) Mode}

In Clear Timer on Compare or CTC mode (WGM01:0 = 2), the OCR0 Register is used to manipulate the counter resolution. In CTC mode the counter is cleared to zero when the counter value (TCNTO) matches the OCRO. The OCRO defines the top value for the counter, hence also its resolution. This mode allows greater control of the Compare Match output frequency. It also simplifies the operation of counting external events.

The timing diagram for the CTC mode is shown in the figure below. The counter value (TCNTO) increases until a Compare Match occurs between TCNTO and OCRO, and then counter (TCNTO) is cleared.

Figure 21-5. CTC Mode, Timing Diagram

An interrupt can be generated each time the counter value reaches the TOP value by using the OCFO Flag. If the interrupt is enabled, the interrupt handler routine can be used for updating the TOP value. However, changing the TOP to a value close to BOTTOM when the counter is running with none or a low prescaler value must be done with care since the CTC mode does not have the double buffering feature.

If the new value written to OCRO is lower than the current value of TCNTO, the counter will miss the Compare Match. The counter will then have to count to its maximum value ( \(0 \times \mathrm{XFF}\) ) and wrap around starting at \(0 \times 00\) before the Compare Match can occur.
For generating a waveform output in CTC mode, the OCO output can be set to toggle its logical level on each Compare Match by setting the Compare Output mode bits to toggle mode (COM01:0 = 1). The OC0 value will not be visible on the port pin unless the data direction for the pin is set to output. The waveform generated will have a maximum frequency of \(f_{\text {OC0 }}=f_{\text {clikı//0 }} / 2\) when OCR0 is set to zero ( \(0 \times 00\) ). The waveform frequency is defined by the following equation:
\(f_{\text {OCn }}=\frac{f_{\text {clk } \mathrm{l} / \mathrm{O}}}{2 \cdot N \cdot(1+0 \mathrm{CRn})}\)
The \(N\) variable represents the prescaler factor ( \(1,8,64,256\), or 1024).
As for the Normal mode of operation, the TOVO Flag is set in the same timer clock cycle that the counter counts from MAX to \(0 \times 00\).

\subsection*{21.7.3. Fast PWM Mode}

The fast Pulse Width Modulation or fast PWM mode (WGM01:0 = 3) provides a high frequency PWM waveform generation option. The fast PWM differs from the other PWM option by its single-slope operation. The counter counts from BOTTOM to MAX then restarts from BOTTOM. In non-inverting Compare Output mode, the Output Compare (OCO) is cleared on the Compare Match between TCNTO and OCRO, and set at BOTTOM. In inverting Compare Output mode, the output is set on Compare Match and cleared at BOTTOM. Due to the single-slope operation, the operating frequency of the fast PWM mode can be twice as high as the phase correct PWM mode that uses dual-slope operation. This high frequency makes the fast PWM mode well suited for power regulation, rectification, and DAC applications. High frequency allows physically small sized external components (coils, capacitors), and therefore reduces total system cost.

In fast PWM mode, the counter is incremented until the counter value matches the MAX value. The counter is then cleared at the following timer clock cycle. The timing diagram for the fast PWM mode is shown in the figure below. The TCNTO value is in the timing diagram shown as a histogram for illustrating the single-slope operation. The diagram includes non-inverted and inverted PWM outputs. The small horizontal line marks on the TCNTO slopes represent compare matches between OCRO and TCNTO.

Figure 21-6. Fast PWM Mode, Timing Diagram

The Timer/Counter Overflow Flag (TOVO) is set each time the counter reaches MAX. If the interrupt is enabled, the interrupt handler routine can be used for updating the compare value.

In fast PWM mode, the compare unit allows generation of PWM waveforms on the OCO pin. Setting the COM01:0 bits to 2 will produce a non-inverted PWM and an inverted PWM output can be generated by setting the COM01:0 to 3 (see Table 21-4). The actual OC0 value will only be visible on the port pin if the data direction for the port pin is set as output. The PWM waveform is generated by setting (or clearing) the OCO Register at the Compare Match between OCRO and TCNT0, and clearing (or setting) the OC0 Register at the timer clock cycle the counter is cleared (changes from MAX to BOTTOM).

The PWM frequency for the output can be calculated by the following equation:
\(f_{\text {OCnPWM }}=\frac{f_{\text {clk } \_ \text {I }}}{N \cdot 256}\)
The \(N\) variable represents the prescaler factor (1, 8, 32, 64, 128, 256 or 1024).
The extreme values for the OCRO Register represent special cases when generating a PWM waveform output in the fast PWM mode. If the OCRO is set equal to BOTTOM, the output will be a narrow spike for each MAX +1 timer clock cycle. Setting the OCRO equal to MAX will result in a constantly high or low output (depending on the polarity of the output set by the COM01:0 bits.)
A frequency (with \(50 \%\) duty cycle) waveform output in fast PWM mode can be achieved by setting OCO to toggle its logical level on each Compare Match (COM01:0 \(=1\) ). The waveform generated will have a maximum frequency of \(f_{\text {occ } 0}=f_{\text {clk_ }} / 0 / 2\) when OCRO is set to zero. This feature is similar to the OCO toggle in CTC mode, except the double buffer feature of the Output Compare unit is enabled in the fast PWM mode.

\subsection*{21.7.4. Phase Correct PWM Mode}

The phase correct PWM mode (WGM01:0 = 1) provides a high resolution phase correct PWM waveform generation option. The phase correct PWM mode is based on a dual-slope operation. The counter counts repeatedly from BOTTOM to MAX and then from MAX to BOTTOM. In non-inverting Compare Output mode, the Output Compare (OCO) is cleared on the Compare Match between TCNTO and OCRO while upcounting, and set on the Compare Match while downcounting. In inverting Output Compare mode, the
operation is inverted. The dual-slope operation has lower maximum operation frequency than single slope operation. However, due to the symmetric feature of the dual-slope PWM modes, these modes are preferred for motor control applications.

The PWM resolution for the phase correct PWM mode is fixed to eight bits. In phase correct PWM mode the counter is incremented until the counter value matches MAX. When the counter reaches MAX, it changes the count direction. The TCNTO value will be equal to MAX for one timer clock cycle. The timing diagram for the phase correct PWM mode is shown on the figure below. The TCNT0 value is in the timing diagram shown as a histogram for illustrating the dual-slope operation. The diagram includes noninverted and inverted PWM outputs. The small horizontal line marks on the TCNT0 slopes represent compare matches between OCRO and TCNTO.

Figure 21-7. Phase Correct PWM Mode, Timing Diagram

The Timer/Counter Overflow Flag (TOV0) is set each time the counter reaches BOTTOM. The Interrupt Flag can be used to generate an interrupt each time the counter reaches the BOTTOM value.

In phase correct PWM mode, the compare unit allows generation of PWM waveforms on the OC2 pin. Setting the COM21:0 bits to 2 will produce a non-inverted PWM. An inverted PWM output can be generated by setting the COM21:0 to 3 (refer to Table 21-5). The actual OC2 value will only be visible on the port pin if the data direction for the port pin is set as output. The PWM waveform is generated by clearing (or setting) the OCO Register at the Compare Match between OCRO and TCNTO when the counter increments, and setting (or clearing) the OCO Register at Compare Match between OCRO and TCNT0 when the counter decrements. The PWM frequency for the output when using phase correct PWM can be calculated by the following equation:
\(f_{\text {OCnPCPWM }}=\frac{f_{\text {clk } \mathrm{I} / 0}}{N \cdot 510}\)
The \(N\) variable represents the prescaler factor ( \(1,8,32,64,128,256\) or 1024).
The extreme values for the OCRO Register represent special cases when generating a PWM waveform output in the phase correct PWM mode. If the OCRO is set equal to BOTTOM, the output will be continuously low and if set equal to MAX the output will be continuously high for non-inverted PWM mode. For inverted PWM the output will have the opposite logic values.

At the very start of period 2 in the timing diagram OCn has a transition from high to low even though there is no Compare Match. The point of this transition is to guarantee symmetry around BOTTOM. There are two cases that give a transition without a Compare Match:
- OCRO changes its value from MAX, like in the timing diagram above. When the OCRO value is MAX the OCn pin value is the same as the result of a down-counting Compare Match. To ensure symmetry around BOTTOM the OCn value at MAX must correspond to the result of an up-counting Compare Match.
- The timer starts counting from a value higher than the one in OCRO, and for that reason misses the Compare Match and hence the OCn change that would have happened on the way up.

\subsection*{21.8. Timer/Counter Timing Diagrams}

The Timer/Counter is a synchronous design and the timer clock ( \(\mathrm{clk}_{\mathrm{T}}\) ) is therefore shown as a clock enable signal in the following figures. The figures include information on when interrupt flags are set. The first figure below contains timing data for basic Timer/Counter operation. It shows the count sequence close to the MAX value in all modes other than phase correct PWM mode.

Figure 21-8. Timer/Counter Timing Diagram, no Prescaling

The next figure shows the same timing data, but with the prescaler enabled.
Figure 21-9. Timer/Counter Timing Diagram, with Prescaler ( \(\mathrm{c}_{\mathrm{clk}} \mathrm{I} / \mathrm{o}^{\prime} / 8\) )

The next figure shows the setting of OCFO in all modes except CTC mode.

Figure 21-10. Timer/Counter Timing Diagram, Setting of OCFO, with Prescaler ( \(\mathrm{f}_{\mathrm{clk} \_/ / 0 / 8 \text { ) }}\)

The next figure shows the setting of OCFO and the clearing of TCNTO in CTC mode.
Figure 21-11. Timer/Counter Timing Diagram, Clear Timer on Compare Match Mode, with Prescaler (f \(\mathrm{c}_{\mathrm{clk}} \mathrm{l} / \mathrm{o}^{\prime} / 8\) )

\subsection*{21.9. Register Description}

\subsection*{21.9.1. TCCRO - Timer/Counter Control Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3\) F must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: TCCR0
Offset: 0x25
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 45\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & FOC0 & WGM00 & COM01 & COM00 & WGM01 & CS02 & CS01 & CSOO \\
\hline Access & W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - FOC0: Force Output Compare}

The FOCO bit is only active when the WGM00 bit specifies a non-PWM mode. However, for ensuring compatibility with future devices, this bit must be set to zero when TCCR0 is written when operating in PWM mode. When writing a logical one to the FOCO bit, an immediate Compare Match is forced on the waveform generation unit. The OC0 output is changed according to its COM21:0 bits setting. Note that the FOCO bit is implemented as a strobe. Therefore it is the value present in the COM01:0 bits that determines the effect of the forced compare.
A FOC0 strobe will not generate any interrupt, nor will it clear the timer in CTC mode using OCRO as TOP.

The FOCO bit is always read as zero.

\section*{Bit 6 - WGM00: Waveform Generation Mode}

These bits control the counting sequence of the counter, the source for the maximum (TOP) counter value, and what type of waveform generation to be used. Modes of operation supported by the Timer/ Counter unit are: Normal mode, Clear Timer on Compare Match (CTC) mode, and two types of Pulse Width Modulation (PWM) modes. See table below and Modes of Operation.

Table 21-2. Waveform Generation Mode Bit Description
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline Mode & \begin{tabular}{l} 
WGM01 \\
(CTC0)
\end{tabular} & \begin{tabular}{l} 
WGM00 \\
(PWM0)
\end{tabular} & Timer/Counter Mode of Operation(1) & TOP & \begin{tabular}{l} 
Update of \\
OCR0
\end{tabular} & \begin{tabular}{l} 
TOV0 Flag \\
Set
\end{tabular} \\
\hline 0 & 0 & 0 & Normal & 0xFF & Immediate & MAX \\
\hline 1 & 0 & 1 & PWM, Phase Correct & OxFF & TOP & BOTTOM \\
\hline 2 & 1 & 0 & CTC & OCR0 & Immediate & MAX \\
\hline 3 & 1 & 1 & Fast PWM & 0xFF & BOTTOM & MAX \\
\hline
\end{tabular}

Note: 1. The CTC0 and PWM0 bit definition names are now obsolete. Use the WGM01:0 definitions. However, the functionality and location of these bits are compatible with previous versions of the timer.

\section*{Bits 5:4-COMOn: Compare Match Output Mode [ \(\mathrm{n}=1: 0\) ]}

These bits control the Output Compare Pin (OCO) behavior. If one or both of the COM01:0 bits are set, the OC0 output overrides the normal port functionality of the I/O pin it is connected to. However, note that
the Data Direction Register (DDR) bit corresponding to the OC0 pin must be set in order to enable the output driver.

When OC0 is connected to the pin, the function of the COM01:0 bits depends on the WGM01:0 bit setting. The following table shows the COM01:0 bit functionality when the WGM01:0 bits are set to a normal or CTC mode (non-PWM).

Table 21-3. Compare Output Mode, Non-PWM Mode
\begin{tabular}{|l|l|l|}
\hline COM01 & COM00 & Description \\
\hline 0 & 0 & Normal port operation, OC0 disconnected. \\
\hline 0 & 1 & Toggle OCO on Compare Match \\
\hline 1 & 0 & Clear OCO on Compare Match \\
\hline 1 & 1 & Set OCO on Compare Match \\
\hline
\end{tabular}

The next table shows the COM01:0 bit functionality when the WGM01:0 bits are set to fast PWM mode.
Table 21-4. Compare Output Mode, Fast PWM Mode \({ }^{(1)}\)
\begin{tabular}{|l|l|l|}
\hline COM01 & COM00 & Description \\
\hline 0 & 0 & Normal port operation, OCO disconnected. \\
\hline 0 & 1 & Reserved \\
\hline 1 & 0 & \begin{tabular}{l} 
Clear OCO on Compare Match, set OCO at BOTTOM, \\
(non-inverting mode)
\end{tabular} \\
\hline 1 & 1 & \begin{tabular}{l} 
Set OCO on Compare Match, clear OCO at BOTTOM, \\
(inverting mode)
\end{tabular} \\
\hline
\end{tabular}

Note: 1. A special case occurs when OCR0 equals TOP and COM01 is set. In this case, the Compare Match is ignored, but the set or clear is done at BOTTOM. See Fast PWM Mode for more details.
The table below shows the COM01:0 bit functionality when the WGM01:0 bits are set to phase correct PWM mode.
Table 21-5. Compare Output Mode, Phase Correct PWM Mode \({ }^{(1)}\)
\begin{tabular}{|l|l|l|}
\hline COM01 & COM00 & Description \\
\hline 0 & 0 & Normal port operation, OC0 disconnected. \\
\hline 0 & 1 & Reserved \\
\hline 1 & 0 & \begin{tabular}{l} 
Clear OCO on Compare Match when up-counting. Set OCO on Compare Match when \\
downcounting.
\end{tabular} \\
\hline 1 & 1 & \begin{tabular}{l} 
Set OCO on Compare Match when up-counting. Clear OCO on Compare Match when \\
downcounting.
\end{tabular} \\
\hline
\end{tabular}

Note: 1. A special case occurs when OCR0 equals TOP and COM01 is set. In this case, the Compare Match is ignored, but the set or clear is done at TOP. See Phase Correct PWM Mode for more details.

Bit 3 - WGM01: Waveform Generation Mode [n=0:1]
Refer to WGMOO above.

\section*{Bits 2:0-CSOn: Clock Select [n=2:0]}

The three Clock Select bits select the clock source to be used by the Timer/Counter.
Table 21-6. Clock Select Bit Description
\begin{tabular}{|c|c|c|c|}
\hline CS02 & CS01 & CS00 & Description \\
\hline 0 & 0 & 0 & No clock source (Timer/Counter stopped). \\
\hline 0 & 0 & 1 & \(\mathrm{clk}_{1 / 0} / 1\) (No prescaling) \\
\hline 0 & 1 & 0 & \(\mathrm{clk}_{1 / 0} / 8\) (From prescaler) \\
\hline 0 & 1 & 1 & \(\mathrm{clk}_{1 / 0} / 64\) (From prescaler) \\
\hline 1 & 0 & 0 & clkl/O/256 (From prescaler) \\
\hline 1 & 0 & 1 & \(\mathrm{clk}_{1 / 0} / 1024\) (From prescaler) \\
\hline 1 & 1 & 0 & External clock source on T0 pin. Clock on falling edge. \\
\hline 1 & 1 & 1 & External clock source on T0 pin. Clock on falling edge. \\
\hline
\end{tabular}

If external pin modes are used for the Timer/Counter0, transitions on the T0 pin will clock the counter even if the pin is configured as an output. This feature allows software control of the counting.

\subsection*{21.9.2. TCNTO - Timer/Counter Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

The Timer/Counter Register gives direct access, both for read and write operations, to the Timer/Counter unit 8-bit counter. Writing to the TCNT0 Register blocks (removes) the Compare Match on the following timer clock. Modifying the counter (TCNTO) while the counter is running, introduces a risk of missing a Compare Match between TCNTO and the OCRO Register.

Name: TCNTO
Offset: 0x24
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 44\)
\begin{tabular}{rccccccccc}
\multicolumn{1}{c}{ Bit } & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\cline { 2 - 9 } & & \multicolumn{8}{c}{ TCNTO[7:0] } \\
Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{tabular}

Bits 7:0 - TCNT0[7:0]

\subsection*{21.9.3. OCRO - Output Compare Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

The Output Compare Register contains an 8-bit value that is continuously compared with the counter value (TCNTO). A match can be used to generate an Output Compare interrupt, or to generate a waveform output on the OCO pin.

Name: OCRO
Offset: 0x23
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 43\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{OCR0[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - OCRO[7:0]

\subsection*{21.9.4. TIMSK - Timer/Counter Interrupt Mask Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: TIMSK
Offset: 0x37
Reset: \(0 \times 00\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 57\)

Bit 1 - OCIEO: Timer/CounterTimer/Counter0 Output Compare Match Interrupt Enable When the OCIEO bit is written to one and the I-bit in the Status Register is set (one), the Timer/CounterO Compare Match interrupt is enabled. The corresponding interrupt is executed if a Compare Match in Timer/Counter0 occurs (i.e., when the OCFO bit is set in the Timer/Counter Interrupt Flag Register TIFR).

Bit 0 - TOIEO: Timer/CounterTimer/Counter0 Overflow Interrupt Enable
When the TOIEO bit is written to one and the I-bit in the Status Register is set (one), the Timer/Counter0 Overflow interrupt is enabled. The corresponding interrupt is executed if an overflow in Timer/Counter0 occurs (i.e., when the TOVO bit is set in the Timer/Counter Interrupt Flag Register - TIFR).

\subsection*{21.9.5. \(\quad\) TIFR - Timer/Counter Interrupt Flag Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: TIFR
Offset: 0x36
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 56\)

Bit 1 - OCFO: Output Compare Flag 0
The OCFO bit is set (one) when a Compare Match occurs between the Timer/Counter0 and the data in OCRO - Output Compare Register0. OCFO is cleared by hardware when executing the corresponding interrupt Handling Vector. Alternatively, OCFO is cleared by writing a logic one to the flag. When the I-bit in SREG, OCIEO (Timer/CounterO Compare Match Interrupt Enable), and OCFO are set (one), the Timer/ Counter0 Compare Match Interrupt is executed.

Bit 0 - TOVO: Timer/Counter0 Overflow Flag
The TOVO bit is set (one) when an overflow occurs in Timer/Counter0. TOVO is cleared by hardware when executing the corresponding interrupt Handling Vector. Alternatively, TOVO is cleared by writing a logic one to the flag. When the SREG I-bit, TOIEO (Timer/Counter0 Overflow Interrupt Enable), and TOV0 are set (one), the Timer/Counter0 Overflow interrupt is executed. In PWM mode, this bit is set when Timer/Counter0 changes counting direction at 0x00.

\section*{22. SPI - Serial Peripheral Interface}

\subsection*{22.1. Features}
- Full-duplex, Three-wire Synchronous Data Transfer
- Master or Slave Operation
- LSB First or MSB First Data Transfer
- Seven Programmable Bit Rates
- End of Transmission Interrupt Flag
- Write Collision Flag Protection
- Wake-up from Idle Mode
- Double Speed (CK/2) Master SPI Mode

\subsection*{22.2. Overview}

The Serial Peripheral Interface (SPI) allows high-speed synchronous data transfer between the ATmega32A and peripheral devices or between several AVR devices.

Figure 22-1. SPI Block Diagram \({ }^{(1)}\)

Note: 1. Refer to Pin Configurations, table Port B Pins Alternate Functions in Alternate Functions of Port \(B\) for SPI pin placement.

The interconnection between Master and Slave CPUs with SPI is shown in the figure below. The system consists of two shift registers, and a Master Clock generator. The SPI Master initiates the communication cycle when pulling low the Slave Select \(\overline{\mathrm{SS}}\) pin of the desired Slave. Master and Slave prepare the data to be sent in their respective Shift Registers, and the Master generates the required clock pulses on the SCK line to interchange data. Data is always shifted from Master to Slave on the Master Out - Slave In, MOSI, line, and from Slave to Master on the Master In - Slave Out, MISO, line. After each data packet, the Master will synchronize the Slave by pulling high the Slave Select, \(\overline{\mathrm{SS}}\), line.

When configured as a Master, the SPI interface has no automatic control of the \(\overline{\text { SS }}\) line. This must be handled by user software before communication can start. When this is done, writing a byte to the SPI Data Register starts the SPI clock generator, and the hardware shifts the eight bits into the Slave. After shifting one byte, the SPI clock generator stops, setting the end of Transmission Flag (SPIF). If the SPI interrupt enable bit (SPIE) in the SPCR Register is set, an interrupt is requested. The Master may continue to shift the next byte by writing it into SPDR, or signal the end of packet by pulling high the Slave Select, \(\overline{\mathrm{SS}}\) line. The last incoming byte will be kept in the Buffer Register for later use.

When configured as a Slave, the SPI interface will remain sleeping with MISO tri-stated as long as the \(\overline{\text { SS }}\) pin is driven high. In this state, software may update the contents of the SPI Data Register, SPDR, but the data will not be shifted out by incoming clock pulses on the SCK pin until the \(\overline{\mathrm{SS}}\) pin is driven low. As one byte has been completely shifted, the end of Transmission Flag, SPIF is set. If the SPI Interrupt Enable bit, SPIE, in the SPCR Register is set, an interrupt is requested. The Slave may continue to place new data to be sent into SPDR before reading the incoming data. The last incoming byte will be kept in the Buffer Register for later use.

Figure 22-2. SPI Master-slave Interconnection

The system is single buffered in the transmit direction and double buffered in the receive direction. This means that bytes to be transmitted cannot be written to the SPI Data Register before the entire shift cycle is completed. When receiving data, however, a received character must be read from the SPI Data Register before the next character has been completely shifted in. Otherwise, the first byte is lost.

In SPI Slave mode, the control logic will sample the incoming signal of the SCK pin. To ensure correct sampling of the clock signal, the minimum low and high periods should be:

Low period: longer than 2 CPU clock cycles.
High period: longer than 2 CPU clock cycles.
When the SPI is enabled, the data direction of the MOSI, MISO, SCK, and SS pins is overridden according to the table below. For more details on automatic port overrides, refer to Alternate Port Functions.

Table 22-1. SPI Pin Overrides \({ }^{(1)}\)
\begin{tabular}{|l|l|l|}
\hline Pin & Direction, Master SPI & Direction, Slave SPI \\
\hline MOSI & User Defined & Input \\
\hline MISO & Input & User Defined \\
\hline SCK & User Defined & Input \\
\hline\(\overline{\text { SS }}\) & User Defined & Input \\
\hline
\end{tabular}

Note: 1. Refer to table Port B Pins Alternate Functions in Alternate Functions of Port B for a detailed description of how to define the direction of the user defined SPI pins.

The following code examples show how to initialize the SPI as a Master and how to perform a simple transmission. DDR_SPI in the examples must be replaced by the actual Data Direction Register controlling the SPI pins. DD_MOSI, DD_MISO and DD_SCK must be replaced by the actual data direction bits for these pins. E.g. if MOSI is placed on pin PB5, replace DD_MOSI with DDB5 and DDR_SPI with DDRB.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

SPI_MasterInit:
; Set MOSI and SCK output, all others input
ldi r17,(1<<DD_MOSI)|(1<<DD_SCK)
out DDR_SPI,r1\overline{7}
; Enable S\overline{P}I, Master, set clock rate fck/16
ldi r17,(1<<SPE)|(1<<MSTR)|(1<<SPR0)
out SPCR,r17
ret
SPI_MasterTransmit:
; Start transmission of data (r16)
out SPDR,r16
Wait_Transmit:
; Wait for transmission complete
sbis SPSR,SPIF
rjmp Wait_Transmit
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

void SPI_MasterInit(void)
{
/* Set MOSI and SCK output, all others input */
DDR SPI = (1<<DD MOSI)|(1<<DD SCK);
/* Enable SPI, Māster, set clōck rate fck/16 */
SPCR = (1<<SPE)| (1<<MSTR) | (1<<SPR0);
}
void SPI_MasterTransmit(char cData)
{
/* Start transmission */
SPDR = cData;
/* Wait for transmission complete */
while(!(SPSR \& (1<<SPIF)))
;
}

```

Note: 1. See About Code Examples.

The following code examples show how to initialize the SPI as a Slave and how to perform a simple reception.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

SPI_SlaveInit:
; Set MISO output, all others input
ldi r17,(1<<DD MISO)
out DDR_SPI,r1\overline{7}
; Enable S\overline{PI}
ldi r17,(1<<SPE)
out SPCR,r17
ret
SPI SlaveReceive:
; Wait for reception complete
sbis SPSR,SPIF
rjmp SPI_SlaveReceive
; Read recēived data and return
in r16,SPDR
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

void SPI_SlaveInit(void)
{
/* Set MISO output, all others input */
DDR_SPI = (1<<DD_MISO);
/* Enable SPI */
SPCR = (1<<SPE);
}
char SPI_SlaveReceive(void)
{
/* Wait for reception complete */
while(!(SPSR \& (1<<SPIF)))
;
/* Return Data Register */
return SPDR;
}

```

Note: 1. See About Code Examples.

\section*{22.3. \(\overline{S S}\) Pin Functionality}

\subsection*{22.3.1. Slave Mode}

When the SPI is configured as a Slave, the Slave Select ( \(\overline{\mathrm{SS}}\) ) pin is always input. When \(\overline{\mathrm{SS}}\) is held low, the SPI is activated, and MISO becomes an output if configured so by the user. All other pins are inputs. When \(\overline{\mathrm{SS}}\) is driven high, all pins are inputs, and the SPI is passive, which means that it will not receive incoming data. The SPI logic will be reset once the \(\overline{\mathrm{SS}}\) pin is driven high.

The \(\overline{\mathrm{SS}}\) pin is useful for packet/byte synchronization to keep the slave bit counter synchronous with the master clock generator. When the \(\overline{\mathrm{SS}}\) pin is driven high, the SPI slave will immediately reset the send and receive logic, and drop any partially received data in the Shift Register.

\subsection*{22.3.2. Master Mode}

When the SPI is configured as a Master (MSTR in SPCR is set), the user can determine the direction of the \(\overline{\mathrm{SS}}\) pin.

If \(\overline{\mathrm{SS}}\) is configured as an output, the pin is a general output pin which does not affect the SPI system. Typically, the pin will be driving the \(\overline{\mathrm{SS}}\) pin of the SPI Slave.
If \(\overline{\mathrm{SS}}\) is configured as an input, it must be held high to ensure Master SPI operation. If the \(\overline{\mathrm{SS}}\) pin is driven low by peripheral circuitry when the SPI is configured as a Master with the \(\overline{S S}\) pin defined as an input, the SPI system interprets this as another master selecting the SPI as a slave and starting to send data to it. To avoid bus contention, the SPI system takes the following actions:
1. The MSTR bit in SPCR is cleared and the SPI system becomes a Slave. As a result of the SPI becoming a Slave, the MOSI and SCK pins become inputs.
2. The SPIF Flag in SPSR is set, and if the SPI interrupt is enabled, and the I-bit in SREG is set, the interrupt routine will be executed.

Thus, when interrupt-driven SPI transmission is used in Master mode, and there exists a possibility that \(\overline{\mathrm{SS}}\) is driven low, the interrupt should always check that the MSTR bit is still set. If the MSTR bit has been cleared by a slave select, it must be set by the user to re-enable SPI Master mode.

\subsection*{22.4. Data Modes}

There are four combinations of SCK phase and polarity with respect to serial data, which are determined by control bits CPHA and CPOL. The SPI data transfer formats are shown in the figures in this section. Data bits are shifted out and latched in on opposite edges of the SCK signal, ensuring sufficient time for data signals to stabilize. This is clearly seen by summarizing Table 22-3 and Table 22-4, as done below:

Table 22-2. CPOL and CPHA Functionality
\begin{tabular}{|l|l|l|l|}
\hline SPI Mode & Conditions & Leading Edge & Trailing Edge \\
\hline 0 & \(C P O L=0, C P H A=0\) & Sample (Rising) & Setup (Falling) \\
\hline 1 & \(C P O L=0, C P H A=1\) & Setup (Rising) & Sample (Falling) \\
\hline 2 & \(C P O L=1, C P H A=0\) & Sample (Falling) & Setup (Rising) \\
\hline 3 & \(C P O L=1, C P H A=1\) & Setup (Falling) & Sample (Rising) \\
\hline
\end{tabular}

Figure 22-3. SPI Transfer Format with \(\mathrm{CPHA}=0\)

Figure 22-4. SPI Transfer Format with CPHA = 1

\subsection*{22.5. Register Description}

\subsection*{22.5.1. SPCR - SPI Control Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: SPCR
Offset: 0x0D
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 2 \mathrm{D}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & SPIE & SPE & DORD & MSTR & CPOL & CPHA & SPR1 & SPR0 \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bit 7 - SPIE: SPI Interrupt Enable
This bit causes the SPI interrupt to be executed if SPIF bit in the SPSR Register is set and if the Global Interrupt Enable bit in SREG is set.

Bit 6 - SPE: SPI Enable
When the SPE bit is written to one, the SPI is enabled. This bit must be set to enable any SPI operations.

\section*{Bit 5 - DORD: Data Order}

When the DORD bit is written to one, the LSB of the data word is transmitted first.
When the DORD bit is written to zero, the MSB of the data word is transmitted first.

\section*{Bit 4 - MSTR: Master/Slave Select}

This bit selects Master SPI mode when written to one, and Slave SPI mode when written logic zero. If SS is configured as an input and is driven low while MSTR is set, MSTR will be cleared, and SPIF in SPSR will become set. The user will then have to set MSTR to re-enable SPI Master mode.

\section*{Bit 3 - CPOL: Clock Polarity}

When this bit is written to one, SCK is high when idle. When CPOL is written to zero, SCK is low when idle. Refer to the figures in Data Modes for an example. The CPOL functionality is summarized below:

Table 22-3. CPOL Functionality
\begin{tabular}{|c|c|c|}
\hline CPOL & Leading Edge & Trailing Edge \\
\hline 0 & Rising & Falling \\
\hline 1 & Falling & Rising \\
\hline
\end{tabular}

\section*{Bit 2 - CPHA: Clock Phase}

The settings of the Clock Phase bit (CPHA) determine if data is sampled on the leading (first) or trailing (last) edge of SCK. Refer to the figures in Data Modes for an example. The CPHA functionality is summarized below:

Table 22-4. CPHA Functionality
\begin{tabular}{|c|c|c|}
\hline CPHA & Leading Edge & Trailing Edge \\
\hline 0 & Sample & Setup \\
\hline 1 & Setup & Sample \\
\hline
\end{tabular}

Bits 1:0 - SPRn: SPI Clock Rate Select [ \(\mathrm{n}=1: 0\) ]
These two bits control the SCK rate of the device configured as a Master. SPR1 and SPR0 have no effect on the Slave. The relationship between SCK and the Oscillator Clock frequency \(f_{\text {osc }}\) is shown in the table below.

Table 22-5. Relationship between SCK and Oscillator Frequency
\begin{tabular}{|c|c|c|l|}
\hline SPI2X & SPR1 & SPR0 & SCK Frequency \\
\hline 0 & 0 & 0 & \(f_{\text {osd }} / 4\) \\
\hline 0 & 0 & 1 & \(\mathrm{f}_{\text {osd }} / 16\) \\
\hline 0 & 1 & 0 & \(\mathrm{f}_{\text {osd }} / 64\) \\
\hline 0 & 1 & 1 & \(\mathrm{f}_{\text {osd }} / 128\) \\
\hline 1 & 0 & 0 & \(\mathrm{f}_{\text {osd }} / 2\) \\
\hline 1 & 0 & 1 & \(\mathrm{f}_{\text {osd }} / 8\) \\
\hline 1 & 1 & 0 & \(\mathrm{f}_{\text {osd }} / 32\) \\
\hline 1 & 1 & 1 & \(\mathrm{f}_{\text {osd }} / 64\) \\
\hline
\end{tabular}

\subsection*{22.5.2. SPSR - SPI Status Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3\) F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: SPSR
Offset: 0x0E
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 2 \mathrm{E}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & SPIF & WCOL & & & & & & SPI2X \\
\hline Access & R & R & & & & & & R/W \\
\hline Reset & 0 & 0 & & & & & & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - SPIF: SPI Interrupt Flag}

When a serial transfer is complete, the SPIF Flag is set. An interrupt is generated if SPIE in SPCR is set and global interrupts are enabled. If \(\overline{\mathrm{SS}}\) is an input and is driven low when the SPI is in Master mode, this will also set the SPIF Flag. SPIF is cleared by hardware when executing the corresponding interrupt handling vector. Alternatively, the SPIF bit is cleared by first reading the SPI Status Register with SPIF set, then accessing the SPI Data Register (SPDR).

\section*{Bit 6 - WCOL: Write Collision Flag}

The WCOL bit is set if the SPI Data Register (SPDR) is written during a data transfer. The WCOL bit (and the SPIF bit) are cleared by first reading the SPI Status Register with WCOL set, and then accessing the SPI Data Register.

\section*{Bit 0 - SPI2X: Double SPI Speed Bit}

When this bit is written logic one the SPI speed (SCK Frequency) will be doubled when the SPI is in Master mode (refer to Table 22-5). This means that the minimum SCK period will be two CPU clock periods. When the SPI is configured as Slave, the SPI is only guaranteed to work at \(\mathrm{f}_{\text {osc }} / 4\) or lower.
The SPI interface on the ATmega32A is also used for program memory and EEPROM downloading or uploading. Refer to section Serial Downloading for serial programming and verification.

\subsection*{22.5.3. \(\quad\) SPDR - SPI Data Register is a read/write register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: SPDR
Offset: 0x0F
Reset: 0xXX
Property: When addressing I/O Registers as data space the offset address is \(0 \times 2 \mathrm{~F}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & SPID7 & SPID6 & SPID5 & SPID4 & SPID3 & SPID2 & SPID1 & SPID0 \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & X & x & X & x & X & X & X & X \\
\hline
\end{tabular}

Bits 7:0 - SPIDn: SPI Data
The SPI Data Register is a read/write register used for data transfer between the Register File and the SPI Shift Register. Writing to the register initiates data transmission. Reading the register causes the Shift Register Receive buffer to be read.
- SPID7 is MSB
- SPID0 is LSB

\section*{23. USART - Universal Synchronous and Asynchronous serial Receiver and Transmitter}

\subsection*{23.1. Features}
- Full Duplex Operation (Independent Serial Receive and Transmit Registers)
- Asynchronous or Synchronous Operation
- Master or Slave Clocked Synchronous Operation
- High Resolution Baud Rate Generator
- Supports Serial Frames with 5, 6, 7, 8, or 9 data bits and 1 or 2 stop bits
- Odd or Even Parity Generation and Parity Check Supported by Hardware
- Data OverRun Detection
- Framing Error Detection
- Noise Filtering Includes False Start Bit Detection and Digital Low Pass Filter
- Three Separate Interrupts on TX Complete, TX Data Register Empty and RX Complete
- Multi-processor Communication Mode
- Double Speed Asynchronous Communication Mode

\subsection*{23.2. Overview}

The Universal Synchronous and Asynchronous serial Receiver and Transmitter (USART) is a highlyflexible serial communication device. A simplified block diagram of the USART Transmitter is shown in the figure below. CPU accessible I/O Registers and I/O pins are shown in bold.

Figure 23-1. USART Block Diagram \({ }^{(1)}\)

Note: 1. Refer to Pin Configurations, table Overriding Signals for Alternate Functions PD7:PD4 and table Overriding Signals for Alternate Functions in PD3:PD0 in Alternate Functions of Port D for USART pin placement.

The dashed boxes in the block diagram separate the three main parts of the USART (listed from the top): Clock generator, Transmitter and Receiver. Control Registers are shared by all units. The clock generation logic consists of synchronization logic for external clock input used by synchronous slave operation, and the baud rate generator. The XCK (transfer clock) pin is only used by synchronous transfer mode. The Transmitter consists of a single write buffer, a serial Shift Register, Parity Generator and control logic for handling different serial frame formats. The write buffer allows a continuous transfer of data without any delay between frames. The Receiver is the most complex part of the USART module due to its clock and data recovery units. The recovery units are used for asynchronous data reception. In addition to the recovery units, the Receiver includes a parity checker, control logic, a Shift Register and a two level receive buffer (UDR). The Receiver supports the same frame formats as the Transmitter, and can detect Frame Error, Data OverRun and Parity Errors.

\section*{Related Links}

Pin Configurations on page 13
Alternate Functions of Port D on page 86

\subsection*{23.2.1. AVR USART vs. AVR UART - Compatibility}

The USART is fully compatible with the AVR UART regarding:
- Bit locations inside all USART Registers.
- Baud Rate Generation.
- Transmitter Operation.
- Transmit Buffer Functionality.
- Receiver Operation.

However, the receive buffering has two improvements that will affect the compatibility in some special cases:
- A second Buffer Register has been added. The two Buffer Registers operate as a circular FIFO buffer. Therefore the UDR must only be read once for each incoming data! More important is the fact that the Error Flags (FE and DOR) and the ninth data bit (RXB8) are buffered with the data in the receive buffer. Therefore the status bits must always be read before the UDR Register is read. Otherwise the error status will be lost since the buffer state is lost.
- The Receiver Shift Register can now act as a third buffer level. This is done by allowing the received data to remain in the serial Shift Register (see Block Diagram in previous section) if the Buffer Registers are full, until a new start bit is detected. The USART is therefore more resistant to Data OverRun (DOR) error conditions.

The following control bits have changed name, but have same functionality and register location:
- CHR9 is changed to UCSZ2.
- OR is changed to DOR.

\subsection*{23.3. Clock Generation}

The clock generation logic generates the base clock for the Transmitter and Receiver. The USART supports four modes of clock operation: normal asynchronous, double speed asynchronous, Master synchronous and Slave Synchronous mode. The UMSEL bit in USART Control and Status Register C (UCSRC) selects between asynchronous and synchronous operation. Double speed (Asynchronous mode only) is controlled by the U2X found in the UCSRA Register. When using Synchronous mode (UMSEL = 1), the Data Direction Register for the XCK pin (DDR_XCK) controls whether the clock source is internal (Master mode) or external (Slave mode). The XCK pin is only active when using Synchronous mode.

Below is a block diagram of the clock generation logic.

Figure 23-2. Clock Generation Logic, Block Diagram

Signal description:
txclk Transmitter clock (internal signal).
rxclk Receiver base clock (internal signal).
xcki Input from XCK pin (internal Signal). Used for synchronous slave operation.
xcko Clock output to XCK pin (internal signal). Used for synchronous master operation.
fosc XTAL pin frequency (System Clock).

\subsection*{23.3.1. Internal Clock Generation - The Baud Rate Generator}

Internal clock generation is used for the asynchronous and the synchronous master modes of operation. The description in this section refers to the block diagram above.
The USART Baud Rate Register (UBRR) and the down-counter connected to it function as a programmable prescaler or baud rate generator. The down-counter, running at system clock (fosc), is loaded with the UBRR value each time the counter has counted down to zero or when the UBRRL Register is written. A clock is generated each time the counter reaches zero. This clock is the baud rate generator clock output (= fosc/(UBRR+1)). The Transmitter divides the baud rate generator clock output by 2,8 , or 16 depending on mode. The baud rate generator output is used directly by the Receiver's clock and data recovery units. However, the recovery units use a state machine that uses 2,8 , or 16 states depending on mode set by the state of the UMSEL, U2X and DDR_XCK bits.
The table below contains equations for calculating the baud rate (in bits per second) and for calculating the UBRR value for each mode of operation using an internally generated clock source.

Table 23-1. Equations for Calculating Baud Rate Register Setting
\begin{tabular}{|l|l|l|}
\hline Operating Mode & \begin{tabular}{l} 
Equation for Calculating Baud \\
Rate
\end{tabular} & \begin{tabular}{l} 
Equation for Calculating UBRR \\
Value
\end{tabular} \\
\hline \begin{tabular}{l} 
Asynchronous Normal \\
mode \((\) U2X \(=0)\)
\end{tabular} & BAUD \(=\frac{f_{\text {OSC }}}{16(\text { UBRR }+1)}\) & UBRR \(=\frac{f_{\text {OSC }}}{16 \mathrm{BAUD}}-1\) \\
\hline \begin{tabular}{l} 
Asynchronous Double \\
Speed mode (U2X \(=1)\)
\end{tabular} & BAUD \(=\frac{f_{\text {OSC }}}{8(\mathbf{U B R R}+1)}\) & UBRR \(=\frac{f_{\text {OSC }}}{8 \mathrm{BAUD}}-1\) \\
\hline Synchronous Master mode & BAUD \(=\frac{f_{\text {OSC }}}{2(\mathbf{U B R R}+1)}\) & UBRR \(=\frac{f_{\text {OSC }}}{2 \mathrm{BAUD}}-1\) \\
\hline
\end{tabular}

Note: 1. The baud rate is defined to be the transfer rate in bit per second (bps).
BAUD Baud rate (in bits per second, bps).
fosc System oscillator clock frequency.
UBRR Contents of the UBRRH and UBRRL Registers, (0-4095).
Some examples of UBRR values for some system clock frequencies are found in Table 23-9.

\subsection*{23.3.2. Double Speed Operation (U2X)}

The transfer rate can be doubled by setting the U2X bit in UCSRA. Setting this bit only has effect for the asynchronous operation. Set this bit to zero when using synchronous operation.

Setting this bit will reduce the divisor of the baud rate divider from 16 to 8 , effectively doubling the transfer rate for asynchronous communication. Note however that the Receiver will in this case only use half the number of samples (reduced from 16 to 8 ) for data sampling and clock recovery, and therefore a more accurate baud rate setting and system clock are required when this mode is used.

For the Transmitter, there are no downsides.

\subsection*{23.3.3. External Clock}

External clocking is used by the synchronous slave modes of operation. The description in this section refers to Figure 23-2.
External clock input from the XCK pin is sampled by a synchronization register to minimize the chance of meta-stability. The output from the synchronization register must then pass through an edge detector before it can be used by the Transmitter and Receiver. This process introduces a two CPU clock period delay and therefore the maximum external XCK clock frequency is limited by the following equation:
\(f_{\text {XCK }}<\frac{f_{\text {OSC }}}{4}\)
The value of \(\mathrm{f}_{\text {osc }}\) depends on the stability of the system clock source. It is therefore recommended to add some margin to avoid possible loss of data due to frequency variations.

\subsection*{23.3.4. Synchronous Clock Operation}

When Synchronous mode is used (UMSEL = 1), the XCK pin will be used as either clock input (Slave) or clock output (Master). The dependency between the clock edges and data sampling or data change is the same. The basic principle is that data input (on RxD) is sampled at the opposite XCK clock edge of the edge the data output (TxD) is changed.

Figure 23-3. Synchronous Mode XCK Timing

The UCPOL bit UCRSC selects which XCK clock edge is used for data sampling and which is used for data change. As the figure above shows, when UCPOL is zero the data will be changed at rising XCK edge and sampled at falling XCK edge. If UCPOL is set, the data will be changed at falling XCK edge and sampled at rising XCK edge.

\subsection*{23.4. Frame Formats}

A serial frame is defined to be one character of data bits with synchronization bits (start and stop bits), and optionally a parity bit for error checking. The USART accepts all 30 combinations of the following as valid frame formats:
- 1 start bit
- \(5,6,7,8\), or 9 data bits
- no, even or odd parity bit
- 1 or 2 stop bits

A frame starts with the start bit followed by the least significant data bit. Then the next data bits, up to a total of nine, are succeeding, ending with the most significant bit. If enabled, the parity bit is inserted after the data bits, before the stop bits. When a complete frame is transmitted, it can be directly followed by a new frame, or the communication line can be set to an idle (high) state. The figure below illustrates the possible combinations of the frame formats. Bits inside brackets are optional.

Figure 23-4. Frame Formats

St Start bit, always low.
(n) Data bits (0 to 8).

P Parity bit. Can be odd or even.
Sp Stop bit, always high.
IDLE No transfers on the communication line (RxD or TxD). An IDLE line must be high.
The frame format used by the USART is set by the UCSZ2:0, UPM1:0 and USBS bits in UCSRB and UCSRC. The Receiver and Transmitter use the same setting. Note that changing the setting of any of these bits will corrupt all ongoing communication for both the Receiver and Transmitter.

The USART Character Size (UCSZ2:0) bits select the number of data bits in the frame. The USART Parity mode (UPM1:0) bits enable and set the type of parity bit. The selection between one or two stop bits is done by the USART Stop Bit Select (USBS) bit. The Receiver ignores the second stop bit. An FE (Frame Error) will therefore only be detected in the cases where the first stop bit is zero

\subsection*{23.4.1. Parity Bit Calculation}

The parity bit is calculated by doing an exclusive-or of all the data bits. If odd parity is used, the result of the exclusive or is inverted. The relation between the parity bit and data bits is as follows:
\[
\begin{aligned}
& P_{\text {even }}=d_{n-1} \oplus \ldots \oplus d_{3} \oplus d_{2} \oplus d_{1} \oplus d_{0} \oplus 1 \\
& P_{\text {odd }}=d_{n-1} \oplus \ldots \oplus d_{3} \oplus d_{2} \oplus d_{1} \oplus d_{0} \oplus 1 \\
& \mathbf{P}_{\text {even }} \\
& \begin{array}{l}
\text { Parity bit using even parity } \\
\mathbf{P}_{\text {odd }} \\
\mathbf{d}_{\mathbf{n}}
\end{array} \quad \text { Parity bit using odd parity }
\end{aligned}
\]

If used, the parity bit is located between the last data bit and first stop bit of a serial frame.

\subsection*{23.5. USART Initialization}

The USART has to be initialized before any communication can take place. The initialization process normally consists of setting the baud rate, setting frame format and enabling the Transmitter or the Receiver depending on the usage. For interrupt driven USART operation, the Global Interrupt Flag should be cleared (and interrupts globally disabled) when doing the initialization.

Before doing a re-initialization with changed baud rate or frame format, be sure that there are no ongoing transmissions during the period the registers are changed. The TXC Flag can be used to check that the Transmitter has completed all transfers, and the RXC Flag can be used to check that there are no unread data in the receive buffer. Note that the TXC Flag must be cleared before each transmission (before UDR is written) if it is used for this purpose.

The following simple USART initialization code examples show one assembly and one C function that are equal in functionality. The examples assume asynchronous operation using polling (no interrupts enabled) and a fixed frame format. The baud rate is given as a function parameter. For the assembly code, the baud rate parameter is assumed to be stored in the r17:r16 Registers. When the function writes to the UCSRC Register, the URSEL bit (MSB) must be set due to the sharing of I/O location by UBRRH and UCSRC.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

USART_Init:
; S
out UBRRH, r17
out UBRRL, r16
; Enable receiver and transmitter
ldi r16, (1<<RXEN)|(1<<TXEN)
out UCSRB,r16
; Set frame format: 8data, 2stop bit
ldi r16, (1<<URSEL)|(1<<USBS)|(3<<UCSZ0)
out UCSRC,r16
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

\#define FOSC 1843200 // Clock Speed

```
\#define BAUD 9600
```

\#define MYUBRR FOSC/16/BAUD-1
void main( void )
{
USART_Init(MYUBRR)
}
void USART_Init( unsigned int ubrr)
{
/*Set baud rate */
UBRROH = (unsigned char) (ubrr>>8);
UBRROL = (unsigned char)ubrr;
Enable receiver and transmitter */
UCSRB = (1<<RXEN)| (1<<TXEN);
/* Set frame format: 8data, 2stop bit */
UCSRC = (1<<URSEL) | (1<<USBS) | (3<<UCSZ0);
}

```

Note: 1. See About Code Examples.
More advanced initialization routines can be written to include frame format as parameters, disable interrupts, and so on. However, many applications use a fixed setting of the baud and control registers, and for these types of applications the initialization code can be placed directly in the main routine, or be combined with initialization code for other I/O modules.

\section*{Related Links}

About Code Examples on page 19

\subsection*{23.6. Data Transmission - The USART Transmitter}

The USART Transmitter is enabled by setting the Transmit Enable (TXEN) bit in the UCSRB Register. When the Transmitter is enabled, the normal port operation of the TxD pin is overridden by the USART and given the function as the Transmitter's serial output. The baud rate, mode of operation and frame format must be set up once before doing any transmissions. If synchronous operation is used, the clock on the XCK pin will be overridden and used as transmission clock.

\subsection*{23.6.1. Sending Frames with 5 to 8 Data Bits}

A data transmission is initiated by loading the transmit buffer with the data to be transmitted. The CPU can load the transmit buffer by writing to the UDR I/O location. The buffered data in the transmit buffer will be moved to the Shift Register when the Shift Register is ready to send a new frame. The Shift Register is loaded with new data if it is in idle state (no ongoing transmission) or immediately after the last stop bit of the previous frame is transmitted. When the Shift Register is loaded with new data, it will transfer one complete frame at the rate given by the Baud Register, U2X bit or by XCK depending on mode of operation.

The following code examples show a simple USART transmit function based on polling of the Data Register Empty (UDRE) Flag. When using frames with less than eight bits, the most significant bits written to the UDR are ignored. The USART has to be initialized before the function can be used. For the assembly code, the data to be sent is assumed to be stored in Register R16.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

USART Transmit:
; Wait for empty transmit buffer
sbis UCSRA,UDRE
rjmp USART Transmit
; Put data (r\overline{1}6) into buffer, sends the data
out UDR,r16
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

void USART_Transmit( unsigned char data )
{
/* Wait for empty transmit buffer */
while ( !( UCSRA \& (1<<UDRE)) )
;
/* Put data into buffer, sends the data */
UDR = data;
}

```

Note: 1. See About Code Examples.
The function simply waits for the transmit buffer to be empty by checking the UDRE Flag, before loading it with new data to be transmitted. If the Data Register Empty Interrupt is utilized, the interrupt routine writes the data into the buffer.

\section*{Related Links}

About Code Examples on page 19

\subsection*{23.6.2. Sending Frames with 9 Data Bits}

If 9-bit characters are used (UCSZ = 7), the ninth bit must be written to the TXB8 bit in UCSRB before the Low byte of the character is written to UDR. The following code examples show a transmit function that handles 9-bit characters. For the assembly code, the data to be sent is assumed to be stored in registers R17:R16.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

USART Transmit:
; \overline{Wait for empty transmit buffer}
sbis UCSRA,UDRE
rjmp USART Transmit
; Copy 9th bit from r17 to TXB8
cbi UCSRB,TXB8
sbrc r17,0
sbi UCSRB,TXB8
; Put LSB data (r16) into buffer, sends the data
out UDR,r16
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

void USART_Transmit( unsigned int data )
{
/* Wait for empty transmit buffer */
while ( !( UCSRA \& (1<<UDRE))) )
/* 'Copy 9th bit to TXB8 */
UCSRB \&= ~ (1<<TXB8);
if ( data \& 0x0100)
UCSRB |= (1<<TXB8);
/* Put data into buffer, sends the data */
UDR = data;
}

```

Note: 1. These transmit functions are written to be general functions. They can be optimized if the contents of the UCSRB is static. For example, only the TXB8 bit of the UCSRB Register is used after initialization.

The ninth bit can be used for indicating an address frame when using multi processor communication mode or for other protocol handling as for example synchronization.

\subsection*{23.6.3. Transmitter Flags and Interrupts}

The USART Transmitter has two flags that indicate its state: USART Data Register Empty (UDRE) and Transmit Complete (TXC). Both flags can be used for generating interrupts.

The Data Register Empty (UDRE) Flag indicates whether the transmit buffer is ready to receive new data. This bit is set when the transmit buffer is empty, and cleared when the transmit buffer contains data to be transmitted that has not yet been moved into the Shift Register. For compatibility with future devices, always write this bit to zero when writing the UCSRA Register.
When the Data Register empty Interrupt Enable (UDRIE) bit in UCSRB is written to one, the USART Data Register Empty Interrupt will be executed as long as UDRE is set (provided that global interrupts are enabled). UDRE is cleared by writing UDR. When interrupt-driven data transmission is used, the Data Register empty Interrupt routine must either write new data to UDR in order to clear UDRE or disable the Data Register empty Interrupt, otherwise a new interrupt will occur once the interrupt routine terminates.

The Transmit Complete (TXC) Flag bit is set one when the entire frame in the transmit Shift Register has been shifted out and there are no new data currently present in the transmit buffer. The TXC Flag bit is automatically cleared when a transmit complete interrupt is executed, or it can be cleared by writing a one to its bit location. The TXC Flag is useful in half-duplex communication interfaces (like the RS485 standard), where a transmitting application must enter Receive mode and free the communication bus immediately after completing the transmission.
When the Transmit Compete Interrupt Enable (TXCIE) bit in UCSRB is set, the USART Transmit Complete Interrupt will be executed when the TXC Flag becomes set (provided that global interrupts are enabled). When the transmit complete interrupt is used, the interrupt handling routine does not have to clear the TXC Flag, this is done automatically when the interrupt is executed.

\subsection*{23.6.4. Parity Generator}

The Parity Generator calculates the parity bit for the serial frame data. When parity bit is enabled (UPM1 \(=1\) ), the Transmitter control logic inserts the parity bit between the last data bit and the first stop bit of the frame that is sent.

\subsection*{23.6.5. Disabling the Transmitter}

The disabling of the Transmitter (setting the TXEN to zero) will not become effective until ongoing and pending transmissions are completed (i.e., when the Transmit Shift Register and Transmit Buffer Register do not contain data to be transmitted). When disabled, the Transmitter will no longer override the TxD pin.

\subsection*{23.7. Data Reception - The USART Receiver}

The USART Receiver is enabled by writing the Receive Enable (RXEN) bit in the UCSRB Register to one. When the Receiver is enabled, the normal pin operation of the RxD pin is overridden by the USART and given the function as the Receiver's serial input. The baud rate, mode of operation and frame format must be set up once before any serial reception can be done. If synchronous operation is used, the clock on the XCK pin will be used as transfer clock.

\subsection*{23.7.1. Receiving Frames with 5 to 8 Data Bits}

The Receiver starts data reception when it detects a valid start bit. Each bit that follows the start bit will be sampled at the baud rate or XCK clock, and shifted into the Receive Shift Register until the first stop bit of a frame is received. A second stop bit will be ignored by the Receiver. When the first stop bit is received (i.e., a complete serial frame is present in the Receive Shift Register), the contents of the Shift Register will be moved into the receive buffer. The receive buffer can then be read by reading the UDR I/O location.

The following code example shows a simple USART receive function based on polling of the Receive Complete (RXC) Flag. When using frames with less than eight bits the most significant bits of the data read from the UDR will be masked to zero. The USART has to be initialized before the function can be used.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

USART_Receive:
; W̄ait for data to be received
sbis UCSRA, RXC
rjmp USART_Receive
; Get and return received data from buffer
in r16, UDR
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

unsigned char USART_Receive( void )
{
/* Wait for data to be received */
while ( !(UCSRA \& (1<<RXC)) )
;
/* Get and return received data from buffer */
return UDR;
}

```

Note: 1. See About Code Examples.
The function simply waits for data to be present in the receive buffer by checking the RXC Flag, before reading the buffer and returning the value.

\section*{Related Links}

About Code Examples on page 19

\subsection*{23.7.2. Receiving Frames with 9 Data Bits}

If 9-bit characters are used (UCSZ=7) the ninth bit must be read from the RXB8 bit in UCSRB before reading the low bits from the UDR. This rule applies to the FE, DOR and PE Status Flags as well. Read status from UCSRA, then data from UDR. Reading the UDR I/O location will change the state of the receive buffer FIFO and consequently the TXB8, FE, DOR, and PE bits, which all are stored in the FIFO, will change.

The following code example shows a simple USART receive function that handles both 9-bit characters and the status bits.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

USART Receive:
; WWait for data to be received
sbis r16, RXC
rjmp USART Receive
; Get status and 9th bit, then data from buffer
in r18, UCSRA
in r17, UCSRB
in r16, UDR
; If error, return -1
andi r18,(1<<FE)|(1<<DOR)|(1<<PE)
breq USART_ReceiveNoError
ldi r17, HIGH(-1)
ldi r16, LOW(-1)
USART ReceiveNoError:
; Filter the 9th bit, then return
lsr r17
andi r17, 0x01
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

unsigned int USART_Receive( void )
{
unsigned char status, resh, resl;
/* Wait for data to be received */
while ( !(UCSRA \& (1<<RXC)) )
* ;
/* Get status and 9th bit, then data */
/* from buffer */
status = UCSRA;
resh = UCSRB;
resl = UDR;
/* If error, return -1 */
if ( status \& (1<<\textrm{FE})|(1<<\textrm{DOR})|(1<<\textrm{PE}) )
return -1;
/* Filter the 9th bit, then return */
resh = (resh >> 1) \& 0x01;
return ((resh << 8) | resl);
}

```

Note: 1. See About Code Examples.
The receive function example reads all the I/O Registers into the Register File before any computation is done. This gives an optimal receive buffer utilization since the buffer location read will be free to accept new data as early as possible.

\section*{Related Links}

About Code Examples on page 19

\subsection*{23.7.3. Receive Compete Flag and Interrupt}

The USART Receiver has one flag that indicates the Receiver state.
The Receive Complete (RXC) Flag indicates if there are unread data present in the receive buffer. This flag is one when unread data exist in the receive buffer, and zero when the receive buffer is empty (i.e., does not contain any unread data). If the Receiver is disabled ( \(\mathrm{RXEN}=0\) ), the receive buffer will be flushed and consequently the RXC bit will become zero.

When the Receive Complete Interrupt Enable (RXCIE) in UCSRB is set, the USART Receive Complete Interrupt will be executed as long as the RXC Flag is set (provided that global interrupts are enabled). When interrupt-driven data reception is used, the receive complete routine must read the received data from UDR in order to clear the RXC Flag, otherwise a new interrupt will occur once the interrupt routine terminates.

\subsection*{23.7.4. Receiver Error Flags}

The USART Receiver has three error flags: Frame Error (FE), Data OverRun (DOR) and Parity Error (PE). All can be accessed by reading UCSRA. Common for the error flags is that they are located in the receive buffer together with the frame for which they indicate the error status. Due to the buffering of the error flags, the UCSRA must be read before the receive buffer (UDR), since reading the UDR I/O location changes the buffer read location. Another equality for the error flags is that they can not be altered by software doing a write to the flag location. However, all flags must be set to zero when the UCSRA is written for upward compatibility of future USART implementations. None of the error flags can generate interrupts.

The Frame Error (FE) Flag indicates the state of the first stop bit of the next readable frame stored in the receive buffer. The FE Flag is zero when the stop bit was correctly read (as one), and the FE Flag will be one when the stop bit was incorrect (zero). This flag can be used for detecting out-of-sync conditions, detecting break conditions and protocol handling. The FE Flag is not affected by the setting of the USBS bit in UCSRC since the Receiver ignores all, except for the first, stop bits. For compatibility with future devices, always set this bit to zero when writing to UCSRA.

The Data OverRun (DOR) Flag indicates data loss due to a Receiver buffer full condition. A Data OverRun occurs when the receive buffer is full (two characters), it is a new character waiting in the Receive Shift Register, and a new start bit is detected. If the DOR Flag is set there was one or more serial frame lost between the frame last read from UDR, and the next frame read from UDR. For compatibility with future devices, always write this bit to zero when writing to UCSRA. The DOR Flag is cleared when the frame received was successfully moved from the Shift Register to the receive buffer.

The Parity Error (PE) Flag indicates that the next frame in the receive buffer had a parity error when received. If parity check is not enabled the PE bit will always be read zero. For compatibility with future devices, always set this bit to zero when writing to UCSRA. For more details see Parity Bit Calculation and Parity Checker.

\subsection*{23.7.5. Parity Checker}

The Parity Checker is active when the high USART Parity mode (UPM1) bit is set. Type of parity check to be performed (odd or even) is selected by the UPM0 bit. When enabled, the Parity Checker calculates the parity of the data bits in incoming frames and compares the result with the parity bit from the serial frame. The result of the check is stored in the receive buffer together with the received data and stop bits. The Parity Error (UPE) Flag can then be read by software to check if the frame had a parity error.
The UPE bit is set if the next character that can be read from the receive buffer had a parity error when received and the parity checking was enabled at that point (UPM1 = 1). This bit is valid until the receive buffer (UDR) is read.

\subsection*{23.7.6. Disabling the Receiver}

In contrast to the Transmitter, disabling of the Receiver will be immediate. Data from ongoing receptions will therefore be lost. When disabled (i.e., the RXEN is set to zero) the Receiver will no longer override the normal function of the RxD port pin. The Receiver buffer FIFO will be flushed when the Receiver is disabled. Remaining data in the buffer will be lost.

\subsection*{23.7.7. Flushing the Receive Buffer}

The Receiver buffer FIFO will be flushed when the Receiver is disabled (i.e., the buffer will be emptied of its contents). Unread data will be lost. If the buffer has to be flushed during normal operation, due to for instance an error condition, read the UDR I/O location until the RXC Flag is cleared. The following code example shows how to flush the receive buffer.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

USART_Flush:
sbis r16, RXC
ret
in r16, UDR
rjmp USART_Flush

```

\section*{C Code Example \({ }^{(1)}\)}
```

void USART_Flush( void )
{
unsigned char dummy;
while ( UCSRA \& (1<<RXC) ) dummy = UDR;
}

```

Note: 1. See About Code Examples.

About Code Examples on page 19

\subsection*{23.8. Asynchronous Data Reception}

The USART includes a clock recovery and a data recovery unit for handling asynchronous data reception. The clock recovery logic is used for synchronizing the internally generated baud rate clock to the incoming asynchronous serial frames at the RxD pin. The data recovery logic samples and low pass filters each incoming bit, thereby improving the noise immunity of the Receiver. The asynchronous reception operational range depends on the accuracy of the internal baud rate clock, the rate of the incoming frames, and the frame size in number of bits.

\subsection*{23.8.1. Asynchronous Clock Recovery}

The clock recovery logic synchronizes internal clock to the incoming serial frames. The figure below illustrates the sampling process of the start bit of an incoming frame. The sample rate is 16 times the baud rate for Normal mode, and eight times the baud rate for Double Speed mode. The horizontal arrows illustrate the synchronization variation due to the sampling process. Note the larger time variation when using the Double Speed mode ( \(\mathrm{U} 2 \mathrm{X}=1\) ) of operation. Samples denoted zero are samples done when the RxD line is idle (i.e., no communication activity).
Figure 23-5. Start Bit Sampling

When the clock recovery logic detects a high (idle) to low (start) transition on the RxD line, the start bit detection sequence is initiated. Let sample 1 denote the first zero-sample as shown in the figure. The clock recovery logic then uses samples 8,9 and 10 for Normal mode, and samples 4,5 and 6 for Double Speed mode (indicated with sample numbers inside boxes on the figure), to decide if a valid start bit is received. If two or more of these three samples have logical high levels (the majority wins), the start bit is rejected as a noise spike and the Receiver starts looking for the next high to low-transition. If however, a valid start bit is detected, the clock recovery logic is synchronized and the data recovery can begin. The synchronization process is repeated for each start bit.

\subsection*{23.8.2. Asynchronous Data Recovery}

When the Receiver clock is synchronized to the start bit, the data recovery can begin. The data recovery unit uses a state machine that has 16 states for each bit in Normal mode and eight states for each bit in Double Speed mode. The following figure shows the sampling of the data bits and the parity bit. Each of the samples is given a number that is equal to the state of the recovery unit.

Figure 23-6. Sampling of Data and Parity Bit

The decision of the logic level of the received bit is taken by doing a majority voting of the logic value to the three samples in the center of the received bit. The center samples are emphasized on the figure by
having the sample number inside boxes. The majority voting process is done as follows: If two or all three samples have high levels, the received bit is registered to be a logic 1. If two or all three samples have low levels, the received bit is registered to be a logic 0 . This majority voting process acts as a low pass filter for the incoming signal on the RxD pin. The recovery process is then repeated until a complete frame is received. Including the first stop bit. Note that the Receiver only uses the first stop bit of a frame.

The following figure shows the sampling of the stop bit and the earliest possible beginning of the start bit of the next frame.

Figure 23-7. Stop Bit Sampling and Next Start Bit Sampling

The same majority voting is done to the stop bit as done for the other bits in the frame. If the stop bit is registered to have a logic 0 value, the Frame Error (FE) Flag will be set.

A new high to low transition indicating the start bit of a new frame can come right after the last of the bits used for majority voting. For Normal Speed mode, the first low level sample can be at point marked (A) in the figure above. For Double Speed mode the first low level must be delayed to (B). (C) marks a stop bit of full length. The early start bit detection influences the operational range of the Receiver.

\subsection*{23.8.3. Asynchronous Operational Range}

The operational range of the Receiver is dependent on the mismatch between the received bit rate and the internally generated baud rate. If the Transmitter is sending frames at too fast or too slow bit rates, or the internally generated baud rate of the Receiver does not have a similar (refer to next table) base frequency, the Receiver will not be able to synchronize the frames to the start bit.

The following equations can be used to calculate the ratio of the incoming data rate and internal receiver baud rate.
\[
R_{\text {slow }}=\frac{(D+1) S}{S-1+D \cdot S+S_{F}} \quad R_{\text {fast }}=\frac{(D+2) S}{(D+1) S+S_{M}}
\]

D Sum of character size and parity size ( \(D=5\) - to 10-bit).
S Samples per bit. S = 16 for Normal Speed mode and \(S=8\) for Double Speed mode.
\(S_{F} \quad\) First sample number used for majority voting. \(S_{F}=8\) for Normal Speed and \(S_{F}=4\) for Double Speed mode.
\(S_{M} \quad\) Middle sample number used for majority voting. \(S_{M}=9\) for Normal Speed and \(S_{M}=5\) for Double Speed mode.
\(\mathbf{R}_{\text {slow }}\) is the ratio of the slowest incoming data rate that can be accepted in relation to the Receiver baud rate.
\(\mathbf{R}_{\text {fast }}\) is the ratio of the fastest incoming data rate that can be accepted in relation to the Receiver baud rate.

The following tables list the maximum receiver baud rate error that can be tolerated. Note that Normal Speed mode has higher toleration of baud rate variations.

Table 23-2. Recommended Maximum Receiver Baud Rate Error for Normal Speed Mode (U2X = 0)
\begin{tabular}{|l|l|l|l|l|}
\hline \begin{tabular}{l} 
D \\
\# (Data+Parity Bit)
\end{tabular} & \(\mathbf{R}_{\text {slow }}\) [\%] & \(R_{\text {fast }}[\%]\) & Max. Total Error [\%] & \begin{tabular}{l} 
Recommended Max Receiver Error \\
[\%]
\end{tabular} \\
\hline 5 & 93.20 & 106.67 & \(+6.67 /-6.8\) & \(\pm 3.0\) \\
\hline 6 & 94.12 & 105.79 & \(+5.79 /-5.88\) & \(\pm 2.5\) \\
\hline 7 & 94.81 & 105.11 & \(+5.11 /-5.19\) & \(\pm 2.0\) \\
\hline 8 & 95.36 & 104.58 & \(+4.58 /-4.54\) & \(\pm 2.0\) \\
\hline 9 & 95.81 & 104.14 & \(+4.14 /-4.19\) & \(\pm 1.5\) \\
\hline 10 & 96.17 & 103.78 & \(+3.78 /-3.83\) & \(\pm 1.5\) \\
\hline
\end{tabular}

Table 23-3. Recommended Maximum Receiver Baud Rate Error for Double Speed Mode (U2X = 1)
\begin{tabular}{|l|l|l|l|l|}
\hline \begin{tabular}{l} 
D \\
\# (Data+Parity Bit)
\end{tabular} & \(R_{\text {slow }}\) [\%] & \(R_{\text {fast }}\) [\%] & Max Total Error [\%] & \begin{tabular}{l} 
Recommended Max \\
Receiver Error [\%]
\end{tabular} \\
\hline 5 & 94.12 & 105.66 & \(+5.66 /-5.88\) & \(\pm 2.5\) \\
\hline 6 & 94.92 & 104.92 & \(+4.92 /-5.08\) & \(\pm 2.0\) \\
\hline 7 & 95.52 & 104.35 & \(+4.35 /-4.48\) & \(\pm 1.5\) \\
\hline 8 & 96.00 & 103.90 & \(+3.90 /-4.00\) & \(\pm 1.5\) \\
\hline 9 & 96.39 & 103.53 & \(+3.53 /-3.61\) & \(\pm 1.5\) \\
\hline 10 & 96.70 & 103.23 & \(+3.23 /-3.30\) & \(\pm 1.0\) \\
\hline
\end{tabular}

The recommendations of the maximum Receiver baud rate error was made under the assumption that the Receiver and Transmitter equally divides the maximum total error.

There are two possible sources for the Receivers Baud Rate error. The Receiver's system clock (XTAL) will always have some minor instability over the supply voltage range and the temperature range. When using a crystal to generate the system clock, this is rarely a problem, but for a resonator the system clock may differ more than \(2 \%\) depending of the resonators tolerance. The second source for the error is more controllable. The baud rate generator can not always do an exact division of the system frequency to get the baud rate wanted. In this case an UBRR value that gives an acceptable low error can be used if possible.

\subsection*{23.9. Multi-Processor Communication Mode}

Setting the Multi-processor Communication mode (MPCM) bit in UCSRA enables a filtering function of incoming frames received by the USART Receiver. Frames that do not contain address information will be ignored and not put into the receive buffer. This effectively reduces the number of incoming frames that has to be handled by the CPU, in a system with multiple MCUs that communicate via the same serial bus. The Transmitter is unaffected by the MPCM setting, but has to be used differently when it is a part of a system utilizing the Multi-processor Communication mode.

If the Receiver is set up to receive frames that contain 5 to 8 data bits, then the first stop bit indicates if the frame contains data or address information. If the Receiver is set up for frames with nine data bits, then the ninth bit (RXB8) is used for identifying address and data frames. When the frame type bit (the
first stop or the ninth bit) is one, the frame contains an address. When the frame type bit is zero the frame is a data frame.

The Multi-processor Communication mode enables several Slave MCUs to receive data from a Master MCU. This is done by first decoding an address frame to find out which MCU has been addressed. If a particular Slave MCU has been addressed, it will receive the following data frames as normal, while the other Slave MCUs will ignore the received frames until another address frame is received.

\subsection*{23.9.1. Using MPCM}

For an MCU to act as a Master MCU, it can use a 9-bit character frame format (UCSZ = 7). The ninth bit (TXB8) must be set when an address frame (TXB8 = 1) or cleared when a data frame (TXB \(=0\) ) is being transmitted. The Slave MCUs must in this case be set to use a 9-bit character frame format.
The following procedure should be used to exchange data in Multi-Processor Communication Mode:
1. All Slave MCUs are in Multi-processor Communication mode (MPCM in UCSRA is set).
2. The Master MCU sends an address frame, and all slaves receive and read this frame. In the Slave MCUs, the RXC Flag in UCSRA will be set as normal.
3. Each Slave MCU reads the UDR Register and determines if it has been selected. If so, it clears the MPCM bit in UCSRA, otherwise it waits for the next address byte and keeps the MPCM setting.
4. The addressed MCU will receive all data frames until a new address frame is received. The other Slave MCUs, which still have the MPCM bit set, will ignore the data frames.
5. When the last data frame is received by the addressed MCU, the addressed MCU sets the MPCM bit and waits for a new address frame from Master. The process then repeats from 2.
Using any of the 5 - to 8 -bit character frame formats is possible, but impractical since the Receiver must change between using n and \(\mathrm{n}+1\) character frame formats. This makes full-duplex operation difficult since the Transmitter and Receiver uses the same character size setting. If 5 - to 8 -bit character frames are used, the Transmitter must be set to use two stop bit (USBS = 1) since the first stop bit is used for indicating the frame type.

Do not use Read-Modify-Write instructions (SBI and CBI) to set or clear the MPCM bit. The MPCM bit shares the same I/O location as the TXC Flag and this might accidentally be cleared when using SBI or CBI instructions.

\subsection*{23.10. Accessing UBRRH/UCSRC Registers}

The UBRRH Register shares the same I/O location as the UCSRC Register. Therefore some special consideration must be taken when accessing this I/O location.

\subsection*{23.10.1. Write Access}

When doing a write access of this I/O location, the high bit of the value written, the USART Register Select (URSEL) bit, controls which one of the two registers that will be written. If URSEL is zero during a write operation, the UBRRH value will be updated. If URSEL is one, the UCSRC setting will be updated.

The following code examples show how to access the two registers.

\section*{Assembly Code Example \({ }^{(1)}\)}
; Set UBRRH to 2
    ldi r16,0x02
    out UBRRH,r16
    : .
    ; Set the USBS and the UCSZ1 bit to one, and
    the remaining bits to zero.
```

ldi r16,(1<<URSEL) | (1<<USBS) | (1<<UUCSZ1)
out UCSRC,r16
:.

```

\section*{C Code Example \({ }^{(1)}\)}
```

/* Set UBRRH to 2 */
UBRRH = 0x02;
:.

* Set the USBS and the UCSZ1 bit to one, and */
/* the remaining bits to zero. */
UCSRC = (1<<URSEL) | (1<<USBS) | (1<<UCSZ1);
:.

```

Note: 1. See About Code Examples.
As the code examples illustrate, write accesses of the two registers are relatively unaffected of the sharing of I/O location.

\section*{Related Links}

About Code Examples on page 19

\subsection*{23.10.2. Read Access}

Doing a read access to the UBRRH or the UCSRC Register is a more complex operation. However, in most applications, it is rarely necessary to read any of these registers.

The read access is controlled by a timed sequence. Reading the I/O location once returns the UBRRH Register contents. If the register location was read in previous system clock cycle, reading the register in the current clock cycle will return the UCSRC contents. Note that the timed sequence for reading the UCSRC is an atomic operation. Interrupts must therefore be controlled (e.g., by disabling interrupts globally) during the read operation.

The following code example shows how to read the UCSRC Register contents.

\section*{Assembly Code Example \({ }^{(1)}\)}
```

USART ReadUCSRC:
; Read UCSRC
in r16,UBRRH
in r16,UCSRC
ret

```

\section*{C Code Example \({ }^{(1)}\)}
```

unsigned char USART_ReadUCSRC( void )
{
unsigned char ucsrc;
/* Read UCSRC */
ucsrc = UBRRH;
ucsrc = UCSRC;
return ucsrc;
}

```

Note: 1. See About Code Examples.
The assembly code example returns the UCSRC value in r16.
Reading the UBRRH contents is not an atomic operation and therefore it can be read as an ordinary register, as long as the previous instruction did not access the register location.

\section*{Related Links}

About Code Examples on page 19

\subsection*{23.11. Register Description}

\subsection*{23.11.1. UDR - USART I/O Data Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: UDR
Offset: 0x0C
Reset: \(0 \times 00\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 2 \mathrm{C}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{TXB / RXB[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - TXB / RXB[7:0]: USART Transmit / Receive Data Buffer
The USART Transmit Data Buffer Register and USART Receive Data Buffer Registers share the same I/O address referred to as USART Data Register or UDR. The Transmit Data Buffer Register (TXB) will be the destination for data written to the UDR Register location. Reading the UDR Register location will return the contents of the Receive Data Buffer Register (RXB).
For 5-, 6-, or 7-bit characters the upper unused bits will be ignored by the Transmitter and set to zero by the Receiver.

The transmit buffer can only be written when the UDRE Flag in the UCSRA Register is set. Data written to UDR when the UDRE Flag is not set, will be ignored by the USART Transmitter. When data is written to the transmit buffer, and the Transmitter is enabled, the Transmitter will load the data into the Transmit Shift Register when the Shift Register is empty. Then the data will be serially transmitted on the TxD pin.

The receive buffer consists of a two level FIFO. The FIFO will change its state whenever the receive buffer is accessed. Due to this behavior of the receive buffer, do not use Read-Modify-Write instructions (SBI and CBI) on this location. Be careful when using bit test instructions (SBIC and SBIS), since these also will change the state of the FIFO.

\subsection*{23.11.2. UCSRA - USART Control and Status Register A}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: UCSRA
Offset: 0x0B
Reset: 0x20
Property: When addressing I/O Registers as data space the offset address is \(0 \times 2 B\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & RXC & TXC & UDRE & FE & DOR & PE & U2X & MPCM \\
\hline Access & R & R/W & R & R & R & R & R/W & R/W \\
\hline Reset & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - RXC: USART Receive Complete}

This flag bit is set when there are unread data in the receive buffer and cleared when the receive buffer is empty (i.e. does not contain any unread data). If the Receiver is disabled, the receive buffer will be flushed and consequently the RXC bit will become zero. The RXC Flag can be used to generate a Receive Complete interrupt (see description of the RXCIE bit).

\section*{Bit 6 - TXC: USART Transmit Complete}

This flag bit is set when the entire frame in the Transmit Shift Register has been shifted out and there are no new data currently present in the transmit buffer (UDR). The TXC Flag bit is automatically cleared when a transmit complete interrupt is executed, or it can be cleared by writing a one to its bit location. The TXC Flag can generate a Transmit Complete interrupt (see description of the TXCIE bit).

\section*{Bit 5 - UDRE: USART Data Register Empty}

The UDRE Flag indicates if the transmit buffer (UDR) is ready to receive new data. If UDRE is one, the buffer is empty, and therefore ready to be written. The UDRE Flag can generate a Data Register Empty interrupt (see description of the UDRIE bit).
UDRE is set after a reset to indicate that the Transmitter is ready.

\section*{Bit 4 - FE: Frame Error}

This bit is set if the next character in the receive buffer had a Frame Error when received (i.e., when the first stop bit of the next character in the receive buffer is zero). This bit is valid until the receive buffer (UDR) is read. The FE bit is zero when the stop bit of received data is one. Always set this bit to zero when writing to UCSRA.

\section*{Bit 3 - DOR: Data OverRun}

This bit is set if a Data OverRun condition is detected. A Data OverRun occurs when the receive buffer is full (two characters), it is a new character waiting in the Receive Shift Register, and a new start bit is detected. This bit is valid until the receive buffer (UDR) is read. Always set this bit to zero when writing to UCSRA.

\section*{Bit 2 - PE: Parity Error}

This bit is set if the next character in the receive buffer had a Parity Error when received and the parity checking was enabled at that point (UPM1 = 1). This bit is valid until the receive buffer (UDR) is read. Always set this bit to zero when writing to UCSRA.

\section*{Bit 1 - U2X: Double the USART Transmission Speed}

This bit only has effect for the asynchronous operation. Write this bit to zero when using synchronous operation.
Writing this bit to one will reduce the divisor of the baud rate divider from 16 to 8 effectively doubling the transfer rate for asynchronous communication.

\section*{Bit 0 - MPCM: Multi-processor Communication Mode}

This bit enables the Multi-processor Communication mode. When the MPCM bit is written to one, all the incoming frames received by the USART Receiver that do not contain address information will be ignored. The Transmitter is unaffected by the MPCM setting. For more detailed information see Multiprocessor Communication Mode.

\subsection*{23.11.3. UCSRB - USART Control and Status Register B}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3\) F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: UCSRB
Offset: 0x0A
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 2 \mathrm{~A}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & RXCIE & TXCIE & UDRIE & RXEN & TXEN & UCSZ2 & RXB8 & TXB8 \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - RXCIE: RX Complete Interrupt Enable}

Writing this bit to one enables interrupt on the RXC Flag. A USART Receive Complete interrupt will be generated only if the RXCIE bit is written to one, the Global Interrupt Flag in SREG is written to one and the RXC bit in UCSRA is set.

\section*{Bit 6 - TXCIE: TX Complete Interrupt Enable}

Writing this bit to one enables interrupt on the TXC Flag. A USART Transmit Complete interrupt will be generated only if the TXCIE bit is written to one, the Global Interrupt Flag in SREG is written to one and the TXC bit in UCSRA is set.

\section*{Bit 5 - UDRIE: USART Data Register Empty Interrupt Enable}

Writing this bit to one enables interrupt on the UDRE Flag. A Data Register Empty interrupt will be generated only if the UDRIE bit is written to one, the Global Interrupt Flag in SREG is written to one and the UDRE bit in UCSRA is set.

\section*{Bit 4 - RXEN: Receiver Enable}

Writing this bit to one enables the USART Receiver. The Receiver will override normal port operation for the RxD pin when enabled. Disabling the Receiver will flush the receive buffer invalidating the FE, DOR and PE Flags.

\section*{Bit 3 - TXEN: Transmitter Enable}

Writing this bit to one enables the USART Transmitter. The Transmitter will override normal port operation for the TxD pin when enabled. The disabling of the Transmitter (writing TXEN to zero) will not become effective until ongoing and pending transmissions are completed (i.e., when the Transmit Shift Register and Transmit Buffer Register do not contain data to be transmitted). When disabled, the Transmitter will no longer override the TxD port.

\section*{Bit 2 - UCSZ2: Character Size}

The UCSZ2 bits combined with the UCSZ1:0 bit in UCSRC sets the number of data bits (Character Size) in a frame the Receiver and Transmitter use.

\section*{Bit 1 - RXB8: Receive Data Bit 8}

RXB8 is the ninth data bit of the received character when operating with serial frames with nine data bits. Must be read before reading the low bits from UDR.

\section*{Bit 0 - TXB8: Transmit Data Bit 8}

TXB8 is the ninth data bit in the character to be transmitted when operating with serial frames with nine data bits. Must be written before writing the low bits to UDR.

\subsection*{23.11.4. UCSRC - USART Control and Status Register C}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

The UCSRC Register shares the same I/O location as the UBRRH Register. See the Accessing UBRRH/ UCSRC Registers section which describes how to access this register.

Name: UCSRC
Offset: 0x20
Reset: 0x06
Property: When addressing I/O Registers as data space the offset address is \(0 \times 40\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & URSEL & UMSEL & UPM1 & UPM0 & USBS & UCSZ1 & UCSZO & UCPOL \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - URSEL: Register Select}

This bit selects between accessing the UCSRC or the UBRRH Register. It is read as one when reading UCSRC. The URSEL must be one when writing the UCSRC.

\section*{Bit 6 - UMSEL: Mode Select}

This bit selects between Asynchronous and Synchronous mode of operation.
Table 23-4. UMSEL Bit Settings
\begin{tabular}{|c|l|}
\hline UMSEL Bit Settings & Mode \\
\hline 0 & Asynchronous Operation \\
\hline 1 & Synchronous Operation \\
\hline
\end{tabular}

\section*{Bits 5:4 - UPMn: Parity Mode [ \(\mathrm{n}=1: 0\) ]}

These bits enable and set type of Parity Generation and Check. If enabled, the Transmitter will automatically generate and send the parity of the transmitted data bits within each frame. The Receiver will generate a parity value for the incoming data and compare it to the UPMO setting. If a mismatch is detected, the PE Flag in UCSRA will be set.

Table 23-5. UPM Bits Settings
\begin{tabular}{|c|l|l|}
\hline UPM1 & UPM0 & ParityMode \\
\hline 0 & 0 & Disabled \\
\hline 0 & 1 & Reserved \\
\hline 1 & 0 & Enabled, Even Parity \\
\hline 1 & 1 & Enabled, Odd Parity \\
\hline
\end{tabular}

\section*{Bit 3 - USBS: Stop Bit Select}

This bit selects the number of stop bits to be inserted by the Transmitter. The Receiver ignores this setting.

Table 23-6. USBS Bit Settings
\begin{tabular}{|c|c|}
\hline USBS & Stop Bit(s) \\
\hline 0 & 1-bit \\
\hline 1 & 2-bit \\
\hline
\end{tabular}

Bits 2:1 - UCSZn: Character Size [ \(n=1: 0\) ]
The UCSZ1:0 bits combined with the UCSZ2 bit in UCSRB sets the number of data bits (Character Size) in a frame the Receiver and Transmitter use.
Table 23-7. UCSZ Bits Settings
\begin{tabular}{|l|l|l|l|}
\hline UCSZ2 & UCSZ1 & UCSZO & Character Size \\
\hline 0 & 0 & 0 & 5-bit \\
\hline 0 & 0 & 1 & 6-bit \\
\hline 0 & 1 & 0 & 7-bit \\
\hline 0 & 1 & 1 & 8-bit \\
\hline 1 & 0 & 0 & Reserved \\
\hline 1 & 0 & 1 & Reserved \\
\hline 1 & 1 & 0 & Reserved \\
\hline 1 & 1 & 1 & 9-bit \\
\hline
\end{tabular}

\section*{Bit 0 - UCPOL: Clock Polarity}

This bit is used for Synchronous mode only. Write this bit to zero when Asynchronous mode is used. The UCPOL bit sets the relationship between data output change and data input sample, and the synchronous clock (XCK).

Table 23-8. UCPOL Bit Settings
\begin{tabular}{|c|c|c|}
\hline UCPOL & \begin{tabular}{c} 
Transmitted Data Changed (Output of TxD \\
Pin)
\end{tabular} & \begin{tabular}{c} 
Received Data Sampled (Input on RxD \\
Pin)
\end{tabular} \\
\hline 0 & Rising XCK Edge & Falling XCK Edge \\
\hline 1 & Falling XCK Edge & Rising XCK Edge \\
\hline
\end{tabular}

\subsection*{23.11.5. UBRRL - USART Baud Rate Register Low}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3\) F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: UBRRL
Offset: 0x09
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 29\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & \multicolumn{8}{|c|}{UBBR[7:0]} \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - UBBR[7:0]: USART Baud Rate Register
This is a 12-bit register which contains the USART baud rate. The UBRRH contains the four most significant bits, and the UBRRL contains the eight least significant bits of the USART baud rate. Ongoing transmissions by the Transmitter and Receiver will be corrupted if the baud rate is changed. Writing UBRRL will trigger an immediate update of the baud rate prescaler.

\subsection*{23.11.6. UBBRH - USART Baud Rate Register High}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

The UBRRH Register shares the same I/O location as the UCSRC Register. See the Accessing UBRRH/ UCSRC Registers section which describes how to access this register.

Name: UBBRH
Offset: \(0 \times 20\)
Reset: \(0 \times 00\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 40\)
\begin{tabular}{rc|c|c|ccccc}
\multicolumn{1}{c}{ Bit } & 7 & \multicolumn{1}{c}{5} & 4 & 3 & 2 & 1 & 0 \\
\cline { 2 - 8 } & URSEL & & & & UBRR[3:0] & \\
\hline Access & R/W & & R/W & R/W & R/W \\
Reset & 0 & 0 & 0 & 0 & 0
\end{tabular}

\section*{Bit 7 - URSEL: Register Select}

This bit selects between accessing the UBRRH or the UCSRC Register. It is read as zero when reading UBRRH. The URSEL must be zero when writing the UBRRH.

Bits 3:0 - UBRR[3:0]: USART Baud Rate Register [ \(\mathrm{n}=11: 8\) ]
Refer to UBRRL.

\subsection*{23.12. Examples of Baud Rate Setting}

For standard crystal and resonator frequencies, the most commonly used baud rates for asynchronous operation can be generated by using the UBRR settings as listed in the table below.
UBRR values which yield an actual baud rate differing less than \(0.5 \%\) from the target baud rate, are bold in the table. Higher error ratings are acceptable, but the Receiver will have less noise resistance when the error ratings are high, especially for large serial frames (see Asynchronous Operational Range). The error values are calculated using the following equation:

Error \([\%]=\left(\frac{\text { BaudRate }_{\text {Closest Match }}}{\text { BaudRate }}-1\right) \times 100 \%\)
Table 23-9. Examples of UBRR Settings for Commonly Used Oscillator Frequencies
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|}

\section*{24. TWI - Two-wire Serial Interface}

\subsection*{24.1. Features}
- Simple, yet Powerful and Flexible Communication Interface, only two Bus Lines Needed
- Both Master and Slave Operation Supported
- Device can Operate as Transmitter or Receiver
- 7-bit Address Space Allows up to 128 Different Slave Addresses
- Multi-master Arbitration Support
- Up to \(400 k H z\) Data Transfer Speed
- Slew-rate Limited Output Drivers
- Noise Suppression Circuitry Rejects Spikes on Bus Lines
- Fully Programmable Slave Address with General Call Support
- Address Recognition Causes Wake-up When AVR is in Sleep Mode

\subsection*{24.2. Overview}

The TWI module is comprised of several submodules, as shown in the following figure. All registers drawn in a thick line are accessible through the AVR data bus.

Figure 24-1. Overview of the TWI Module

\subsection*{24.2.1. SCL and SDA Pins}

These pins interface the AVR TWI with the rest of the MCU system. The output drivers contain a slewrate limiter in order to conform to the TWI specification. The input stages contain a spike suppression unit removing spikes shorter than 50 ns . Note that the internal pull-ups in the AVR pads can be enabled by setting the PORT bits corresponding to the SCL and SDA pins, as explained in the I/O Port section. The internal pull-ups can in some systems eliminate the need for external ones.

\subsection*{24.2.2. Bit Rate Generator Unit}

This unit controls the period of SCL when operating in a Master mode. The SCL period is controlled by settings in the TWI Bit Rate Register (TWBR) and the Prescaler bits in the TWI Status Register (TWSR). Slave operation does not depend on Bit Rate or Prescaler settings, but the CPU clock frequency in the Slave must be at least 16 times higher than the SCL frequency. Note that slaves may prolong the SCL low period, thereby reducing the average TWI bus clock period.

The SCL frequency is generated according to the following equation:
SCL frequency \(=\frac{\text { CPU Clock frequency }}{16+2(\text { TWBR }) \cdot(\text { PrescalerValue })}\)
- TWBR = Value of the TWI Bit Rate Register
- PrescalerValue = Value of the prescaler, see description of the TWI Prescaler bit in the TWSR Status Register description (TWSR.TWPS)

Note: Pull-up resistor values should be selected according to the SCL frequency and the capacitive bus line load. See the Two-Wire Serial Interface Characteristics for a suitable value of the pull-up resistor.

\section*{Related Links}

Two-wire Serial Interface Characteristics on page 363

\subsection*{24.2.3. Bus Interface Unit}

This unit contains the Data and Address Shift Register (TWDR), a START/STOP Controller and Arbitration detection hardware. The TWDR contains the address or data bytes to be transmitted, or the address or data bytes received. In addition to the 8-bit TWDR, the Bus Interface Unit also contains a register containing the (N)ACK bit to be transmitted or received. This (N)ACK Register is not directly accessible by the application software. However, when receiving, it can be set or cleared by manipulating the TWI Control Register (TWCR). When in Transmitter mode, the value of the received (N)ACK bit can be determined by the value in the TWSR.

The START/STOP Controller is responsible for generation and detection of START, REPEATED START, and STOP conditions. The START/STOP controller is able to detect START and STOP conditions even when the AVR MCU is in one of the sleep modes, enabling the MCU to wake up if addressed by a Master.

If the TWI has initiated a transmission as Master, the Arbitration Detection hardware continuously monitors the transmission trying to determine if arbitration is in process. If the TWI has lost an arbitration, the Control Unit is informed. Correct action can then be taken and appropriate status codes generated.

\subsection*{24.2.4. Address Match Unit}

The Address Match unit checks if received address bytes match the seven-bit address in the TWI Address Register (TWAR). If the TWI General Call Recognition Enable (TWGCE) bit in the TWAR is written to one, all incoming address bits will also be compared against the General Call address. Upon an address match, the Control Unit is informed, allowing correct action to be taken. The TWI may or may not acknowledge its address, depending on settings in the TWCR. The Address Match unit is able to compare addresses even when the AVR MCU is in sleep mode, enabling the MCU to wake up if addressed by a Master. If another interrupt (e.g., INTO) occurs during TWI Power-down address match
and wakes up the CPU, the TWI aborts operation and return to it's idle state. If this cause any problems, ensure that TWI Address Match is the only enabled interrupt when entering Power-down.

\subsection*{24.2.5. Control Unit}

The Control unit monitors the TWI bus and generates responses corresponding to settings in the TWI Control Register (TWCR). When an event requiring the attention of the application occurs on the TWI bus, the TWI Interrupt Flag (TWINT) is asserted. In the next clock cycle, the TWI Status Register (TWSR) is updated with a status code identifying the event. The TWSR only contains relevant status information when the TWI Interrupt Flag is asserted. At all other times, the TWSR contains a special status code indicating that no relevant status information is available. As long as the TWINT Flag is set, the SCL line is held low. This allows the application software to complete its tasks before allowing the TWI transmission to continue.

The TWINT Flag is set in the following situations:
- After the TWI has transmitted a START/REPEATED START condition.
- After the TWI has transmitted SLA+R/W.
- After the TWI has transmitted an address byte.
- After the TWI has lost arbitration.
- After the TWI has been addressed by own slave address or general call.
- After the TWI has received a data byte.
- After a STOP or REPEATED START has been received while still addressed as a Slave.
- When a bus error has occurred due to an illegal START or STOP condition.

\subsection*{24.3. Two-Wire Serial Interface Bus Definition}

The Two-wire Serial Interface (TWI) is ideally suited for typical microcontroller applications. The TWI protocol allows the systems designer to interconnect up to 128 different devices using only two bidirectional bus lines, one for clock (SCL) and one for data (SDA). The only external hardware needed to implement the bus is a single pullup resistor for each of the TWI bus lines. All devices connected to the bus have individual addresses, and mechanisms for resolving bus contention are inherent in the TWI protocol.

Figure 24-2. TWI Bus Interconnection

\subsection*{24.3.1. TWI Terminology}

The following definitions are frequently encountered in this section.

Table 24-1. TWI Terminology
\begin{tabular}{|l|l|}
\hline Term & Description \\
\hline Master & The device that initiates and terminates a transmission. The Master also generates the SCL clock. \\
\hline Slave & The device addressed by a Master. \\
\hline Transmitter & The device placing data on the bus. \\
\hline Receiver & The device reading data from the bus. \\
\hline
\end{tabular}

\subsection*{24.3.2. Electrical Interconnection}

As depicted in Figure 24-2, both bus lines are connected to the positive supply voltage through pull-up resistors. The bus drivers of all TWI-compliant devices are open-drain or open-collector. This implements a wired-AND function which is essential to the operation of the interface. A low level on a TWI bus line is generated when one or more TWI devices output a zero. A high level is output when all TWI devices tristate their outputs, allowing the pull-up resistors to pull the line high. Note that all AVR devices connected to the TWI bus must be powered in order to allow any bus operation.
The number of devices that can be connected to the bus is only limited by the bus capacitance limit of 400 pF and the 7 -bit slave address space. A detailed specification of the electrical characteristics of the TWI is given in Two-wire Serial Interface Characteristics. Two different sets of specifications are presented there, one relevant for bus speeds below 100 kHz , and one valid for bus speeds up to 400 kHz .

\section*{Related Links}

Two-wire Serial Interface Characteristics on page 363

\subsection*{24.4. Data Transfer and Frame Format}

\subsection*{24.4.1. Transferring Bits}

Each data bit transferred on the TWI bus is accompanied by a pulse on the clock line. The level of the data line must be stable when the clock line is high. The only exception to this rule is for generating start and stop conditions.

Figure 24-3. Data Validity

Data Change

\subsection*{24.4.2. START and STOP Conditions}

The Master initiates and terminates a data transmission. The transmission is initiated when the Master issues a START condition on the bus, and it is terminated when the Master issues a STOP condition. Between a START and a STOP condition, the bus is considered busy, and no other master should try to seize control of the bus. A special case occurs when a new START condition is issued between a START
and STOP condition. This is referred to as a REPEATED START condition, and is used when the Master wishes to initiate a new transfer without relinquishing control of the bus. After a REPEATED START, the bus is considered busy until the next STOP. This is identical to the START behavior, and therefore START is used to describe both START and REPEATED START for the remainder of this datasheet, unless otherwise noted. As depicted below, START and STOP conditions are signalled by changing the level of the SDA line when the SCL line is high.

Figure 24-4. START, REPEATED START and STOP conditions

\subsection*{24.4.3. Address Packet Format}

All address packets transmitted on the TWI bus are 9 bits long, consisting of 7 address bits, one READ/ WRITE control bit and an acknowledge bit. If the READ/WRITE bit is set, a read operation is to be performed, otherwise a write operation should be performed. When a Slave recognizes that it is being addressed, it should acknowledge by pulling SDA low in the ninth SCL (ACK) cycle. If the addressed Slave is busy, or for some other reason can not service the Master's request, the SDA line should be left high in the ACK clock cycle. The Master can then transmit a STOP condition, or a REPEATED START condition to initiate a new transmission. An address packet consisting of a slave address and a READ or a WRITE bit is called SLA+R or SLA+W, respectively.
The MSB of the address byte is transmitted first. Slave addresses can freely be allocated by the designer, but the address 0000000 is reserved for a general call.

When a general call is issued, all slaves should respond by pulling the SDA line low in the ACK cycle. A general call is used when a Master wishes to transmit the same message to several slaves in the system. When the general call address followed by a Write bit is transmitted on the bus, all slaves set up to acknowledge the general call will pull the SDA line low in the ack cycle. The following data packets will then be received by all the slaves that acknowledged the general call. Note that transmitting the general call address followed by a Read bit is meaningless, as this would cause contention if several slaves started transmitting different data.
All addresses of the format 1111 xxx should be reserved for future purposes.
Figure 24-5. Address Packet Format

\subsection*{24.4.4. Data Packet Format}

All data packets transmitted on the TWI bus are nine bits long, consisting of one data byte and an acknowledge bit. During a data transfer, the Master generates the clock and the START and STOP conditions, while the Receiver is responsible for acknowledging the reception. An Acknowledge (ACK) is signalled by the Receiver pulling the SDA line low during the ninth SCL cycle. If the Receiver leaves the SDA line high, a NACK is signalled. When the Receiver has received the last byte, or for some reason cannot receive any more bytes, it should inform the Transmitter by sending a NACK after the final byte. The MSB of the data byte is transmitted first.

Figure 24-6. Data Packet Format

\subsection*{24.4.5. Combining Address and Data Packets Into a Transmission}

A transmission basically consists of a START condition, a SLA+R/W, one or more data packets and a STOP condition. An empty message, consisting of a START followed by a STOP condition, is illegal. Note that the Wired-ANDing of the SCL line can be used to implement handshaking between the Master and the Slave. The Slave can extend the SCL low period by pulling the SCL line low. This is useful if the clock speed set up by the Master is too fast for the Slave, or the Slave needs extra time for processing between the data transmissions. The Slave extending the SCL low period will not affect the SCL high period, which is determined by the Master. As a consequence, the Slave can reduce the TWI data transfer speed by prolonging the SCL duty cycle.

The following figure depicts a typical data transmission. Note that several data bytes can be transmitted between the SLA+R/W and the STOP condition, depending on the software protocol implemented by the application software.

Figure 24-7. Typical Data Transmission

\subsection*{24.5. Multi-master Bus Systems, Arbitration and Synchronization}

The TWI protocol allows bus systems with several masters. Special concerns have been taken in order to ensure that transmissions will proceed as normal, even if two or more masters initiate a transmission at the same time. Two problems arise in multi-master systems:
- An algorithm must be implemented allowing only one of the masters to complete the transmission. All other masters should cease transmission when they discover that they have lost the selection process. This selection process is called arbitration. When a contending master discovers that it has lost the arbitration process, it should immediately switch to Slave mode to check whether it is being addressed by the winning master. The fact that multiple masters have started transmission at the same time should not be detectable to the slaves, i.e. the data being transferred on the bus must not be corrupted.
- Different masters may use different SCL frequencies. A scheme must be devised to synchronize the serial clocks from all masters, in order to let the transmission proceed in a lockstep fashion. This will facilitate the arbitration process.

The wired-ANDing of the bus lines is used to solve both these problems. The serial clocks from all masters will be wired-ANDed, yielding a combined clock with a high period equal to the one from the Master with the shortest high period. The low period of the combined clock is equal to the low period of the Master with the longest low period. Note that all masters listen to the SCL line, effectively starting to count their SCL high and low time-out periods when the combined SCL line goes high or low, respectively.

Figure 24-8. SCL Synchronization Between Multiple Masters

Arbitration is carried out by all masters continuously monitoring the SDA line after outputting data. If the value read from the SDA line does not match the value the Master had output, it has lost the arbitration. Note that a Master can only lose arbitration when it outputs a high SDA value while another Master outputs a low value. The losing Master should immediately go to Slave mode, checking if it is being addressed by the winning Master. The SDA line should be left high, but losing masters are allowed to generate a clock signal until the end of the current data or address packet. Arbitration will continue until only one Master remains, and this may take many bits. If several masters are trying to address the same Slave, arbitration will continue into the data packet.

Figure 24-9. Arbitration Between Two Masters

Note that arbitration is not allowed between:
- A REPEATED START condition and a data bit.
- A STOP condition and a data bit.
- A REPEATED START and a STOP condition.

It is the user software's responsibility to ensure that these illegal arbitration conditions never occur. This implies that in multi-master systems, all data transfers must use the same composition of SLA+R/W and data packets. In other words: All transmissions must contain the same number of data packets, otherwise the result of the arbitration is undefined.

\subsection*{24.6. Using the TWI}

The AVR TWI is byte-oriented and interrupt based. Interrupts are issued after all bus events, like reception of a byte or transmission of a START condition. Because the TWI is interrupt-based, the application software is free to carry on other operations during a TWI byte transfer. Note that the TWI Interrupt Enable (TWIE) bit in TWCR together with the Global Interrupt Enable bit in SREG allow the application to decide whether or not assertion of the TWINT Flag should generate an interrupt request. If the TWIE bit is cleared, the application must poll the TWINT Flag in order to detect actions on the TWI bus.

When the TWINT Flag is asserted, the TWI has finished an operation and awaits application response. In this case, the TWI Status Register (TWSR) contains a value indicating the current state of the TWI bus. The application software can then decide how the TWI should behave in the next TWI bus cycle by manipulating the TWCR and TWDR Registers.

The following figure is a simple example of how the application can interface to the TWI hardware. In this example, a Master wishes to transmit a single data byte to a Slave. This description is quite abstract, a more detailed explanation follows later in this section. A simple code example implementing the desired behavior is also presented.

Figure 24-10. Interfacing the Application to the TWI in a Typical Transmission

1. The first step in a TWI transmission is to transmit a START condition. This is done by writing a specific value into TWCR, instructing the TWI hardware to transmit a START condition. Which value to write is described later on. However, it is important that the TWINT bit is set in the value written. Writing a one to TWINT clears the flag. The TWI will not start any operation as long as the TWINT bit in TWCR is set. Immediately after the application has cleared TWINT, the TWI will initiate transmission of the START condition.
2. When the START condition has been transmitted, the TWINT Flag in TWCR is set, and TWSR is updated with a status code indicating that the START condition has successfully been sent.
3. The application software should now examine the value of TWSR, to make sure that the START condition was successfully transmitted. If TWSR indicates otherwise, the application software might take some special action, like calling an error routine. Assuming that the status code is as expected, the application must load SLA+W into TWDR. Remember that TWDR is used both for address and data. After TWDR has been loaded with the desired SLA +W , a specific value must be written to TWCR, instructing the TWI hardware to transmit the SLA+W present in TWDR. Which value to write is described later on. However, it is important that the TWINT bit is set in the value written. Writing a one to TWINT clears the flag. The TWI will not start any operation as long as the TWINT bit in TWCR is set. Immediately after the application has cleared TWINT, the TWI will initiate transmission of the address packet.
4. When the address packet has been transmitted, the TWINT Flag in TWCR is set, and TWSR is updated with a status code indicating that the address packet has successfully been sent. The status code will also reflect whether a Slave acknowledged the packet or not.
5. The application software should now examine the value of TWSR, to make sure that the address packet was successfully transmitted, and that the value of the ACK bit was as expected. If TWSR indicates otherwise, the application software might take some special action, like calling an error routine. Assuming that the status code is as expected, the application must load a data packet into TWDR. Subsequently, a specific value must be written to TWCR, instructing the TWI hardware to transmit the data packet present in TWDR. Which value to write is described later on. However, it is important that the TWINT bit is set in the value written. Writing a one to TWINT clears the flag. The TWI will not start any operation as long as the TWINT bit in TWCR is set. Immediately after the application has cleared TWINT, the TWI will initiate transmission of the data packet.
6. When the data packet has been transmitted, the TWINT Flag in TWCR is set, and TWSR is updated with a status code indicating that the data packet has successfully been sent. The status code will also reflect whether a Slave acknowledged the packet or not.
7. The application software should now examine the value of TWSR, to make sure that the data packet was successfully transmitted, and that the value of the ACK bit was as expected. If TWSR indicates otherwise, the application software might take some special action, like calling an error routine. Assuming that the status code is as expected, the application must write a specific value to TWCR, instructing the TWI hardware to transmit a STOP condition. Which value to write is described later on. However, it is important that the TWINT bit is set in the value written. Writing a one to TWINT clears the flag. The TWI will not start any operation as long as the TWINT bit in TWCR is set. Immediately after the application has cleared TWINT, the TWI will initiate transmission of the STOP condition. Note that TWINT is NOT set after a STOP condition has been sent.

Even though this example is simple, it shows the principles involved in all TWI transmissions. These can be summarized as follows:
- When the TWI has finished an operation and expects application response, the TWINT Flag is set. The SCL line is pulled low until TWINT is cleared.
- When the TWINT Flag is set, the user must update all TWI Registers with the value relevant for the next TWI bus cycle. As an example, TWDR must be loaded with the value to be transmitted in the next bus cycle.
- After all TWI Register updates and other pending application software tasks have been completed, TWCR is written. When writing TWCR, the TWINT bit should be set. Writing a one to TWINT clears the flag. The TWI will then commence executing whatever operation was specified by the TWCR setting.

The following table lists assembly and C implementation examples. Note that the code below assumes that several definitions have been made, e.g. by using include-files.

Table 24-2. Assembly and C Code Example

\subsection*{24.6.1. Transmission Modes}

The TWI can operate in one of four major modes:
- Master Transmitter (MT)
- Master Receiver (MR)
- Slave Transmitter (ST)
- Slave Receiver (SR)

Several of these modes can be used in the same application. As an example, the TWI can use MT mode to write data into a TWI EEPROM, MR mode to read the data back from the EEPROM. If other masters are present in the system, some of these might transmit data to the TWI, and then SR mode would be used. It is the application software that decides which modes are legal.
The following sections describe each of these modes. Possible status codes are described along with figures detailing data transmission in each of the modes. These figures use the following abbreviations:
\begin{tabular}{|l|l|}
\hline S & START condition \\
\hline Rs & REPEATED START condition \\
\hline R & Read bit (high level at SDA) \\
\hline W & Write bit (low level at SDA) \\
\hline A & Acknowledge bit (low level at SDA) \\
\hline A & Not acknowledge bit (high level at SDA) \\
\hline Data & 8-bit data byte \\
\hline P & STOP condition \\
\hline SLA & Slave Address \\
\hline
\end{tabular}

Circles are used to indicate that the TWINT Flag is set. The numbers in the circles show the status code held in TWSR, with the prescaler bits masked to zero. At these points, actions must be taken by the application to continue or complete the TWI transfer. The TWI transfer is suspended until the TWINT Flag is cleared by software.

When the TWINT Flag is set, the status code in TWSR is used to determine the appropriate software action. For each status code, the required software action and details of the following serial transfer are given below in the Status Code table for each mode. Note that the prescaler bits are masked to zero in these tables.

\subsection*{24.6.2. Master Transmitter Mode}

In the Master Transmitter (MT) mode, a number of data bytes are transmitted to a Slave Receiver, see figure below. In order to enter a Master mode, a START condition must be transmitted. The format of the following address packet determines whether MT or Master Receiver (MR) mode is to be entered: If SLA \(+W\) is transmitted, MT mode is entered, if SLA+R is transmitted, MR mode is entered. All the status codes mentioned in this section assume that the prescaler bits are zero or are masked to zero.

Figure 24-11. Data Transfer in Master Transmitter Mode

A START condition is sent by writing a value to the TWI Control Register (TWCR) of the type TWCR=1x10x10x:
- The TWI Enable bit (TWCR.TWEN) must be written to '1' to enable the 2-wire Serial Interface
- The TWI Start Condition bit (TWCR.TWSTA) must be written to '1' to transmit a START condition
- The TWI Interrupt Flag (TWCR.TWINT) must be written to ' 1 ' to clear the flag.

The TWI will then test the 2-wire Serial Bus and generate a START condition as soon as the bus becomes free. After a START condition has been transmitted, the TWINT Flag is set by hardware, and the status code in TWSR will be \(0 \times 08\) (see Status Code table below). In order to enter MT mode, SLA+W must be transmitted. This is done by writing SLA+W to the TWI Data Register (TWDR). Thereafter, the TWCR.TWINT Flag should be cleared (by writing a ' 1 ' to it) to continue the transfer. This is accomplished by writing a value to TWRC of the type TWCR=1x00x10x.

When SLA+W have been transmitted and an acknowledgment bit has been received, TWINT is set again and a number of status codes in TWSR are possible. Possible status codes in Master mode are 0x18, \(0 \times 20\), or \(0 \times 38\). The appropriate action to be taken for each of these status codes is detailed in the Status Code table below.

When SLA+W has been successfully transmitted, a data packet should be transmitted. This is done by writing the data byte to TWDR. TWDR must only be written when TWINT is high. If not, the access will be discarded, and the Write Collision bit (TWWC) will be set in the TWCR Register. After updating TWDR, the TWINT bit should be cleared (by writing ' 1 ' to it) to continue the transfer. This is accomplished by writing again a value to TWCR of the type TWCR=1x00x10x.

This scheme is repeated until the last byte has been sent and the transfer is ended, either by generating a STOP condition or a by a repeated START condition. A repeated START condition is accomplished by writing a regular START value TWCR=1x10x10x. A STOP condition is generated by writing a value of the type TWCR=1x01x10x.

After a repeated START condition (status code 0x10), the 2-wire Serial Interface can access the same Slave again, or a new Slave without transmitting a STOP condition. Repeated START enables the Master
to switch between Slaves, Master Transmitter mode and Master Receiver mode without losing control of the bus.

This number (contained in TWSR) corresponds to a defined state of the 2-Wire Ser ial Bus The prescaler bits are z ero or mask ed to z ero

\subsection*{24.6.3. Master Receiver Mode}

In the Master Receiver (MR) mode, a number of data bytes are received from a Slave Transmitter (see next figure). In order to enter a Master mode, a START condition must be transmitted. The format of the following address packet determines whether Master Transmitter (MT) or MR mode is to be entered. If \(\mathrm{SLA}+\mathrm{W}\) is transmitted, MT mode is entered, if SLA+R is transmitted, MR mode is entered. All the status codes mentioned in this section assume that the prescaler bits are zero or are masked to zero.

Figure 24-13. Data Transfer in Master Receiver Mode

A START condition is sent by writing to the TWI Control register (TWCR) a value of the type TWCR=1x10x10x:
- TWCR.TWEN must be written to '1' to enable the 2-wire Serial Interface
- TWCR.TWSTA must be written to ' 1 ' to transmit a START condition
- TWCR.TWINT must be cleared by writing a ' 1 ' to it.

The TWI will then test the 2-wire Serial Bus and generate a START condition as soon as the bus becomes free. After a START condition has been transmitted, the TWINT Flag is set by hardware, and the status code in TWSR will be \(0 \times 08\) (see Status Code table below). In order to enter MR mode, SLA+R must be transmitted. This is done by writing SLA+R to TWDR. Thereafter, the TWINT flag should be cleared (by writing '1' to it) to continue the transfer. This is accomplished by writing the a value to TWCR of the type TWCE=1x00x10x.

When SLA+R have been transmitted and an acknowledgment bit has been received, TWINT is set again and a number of status codes in TWSR are possible. Possible status codes in Master mode are 0x38, \(0 \times 40\), or \(0 \times 48\). The appropriate action to be taken for each of these status codes is detailed in the table below. Received data can be read from the TWDR Register when the TWINT Flag is set high by hardware. This scheme is repeated until the last byte has been received. After the last byte has been received, the MR should inform the ST by sending a NACK after the last received data byte. The transfer is ended by generating a STOP condition or a repeated START condition. A repeated START condition is sent by writing to the TWI Control register (TWCR) a value of the type TWCR=1x10x10x again. A STOP condition is generated by writing TWCR=1xx01x10x:

After a repeated START condition (status code \(0 \times 10\) ) the 2-wire Serial Interface can access the same Slave again, or a new Slave without transmitting a STOP condition. Repeated START enables the Master to switch between Slaves, Master Transmitter mode and Master Receiver mode without losing control over the bus.

\subsection*{24.6.4. Slave Receiver Mode}

In the Slave Receiver (SR) mode, a number of data bytes are received from a Master Transmitter (see figure below). All the status codes mentioned in this section assume that the prescaler bits are zero or are masked to zero.

Figure 24-15. Data transfer in Slave Receiver mode

To initiate the SR mode, the TWI (Slave) Address Register (TWAR) and the TWI Control Register (TWCR) must be initialized as follows:

The upper seven bits of TWAR are the address to which the 2-wire Serial Interface will respond when addressed by a Master (TWAR.TWA[6:0]). If the LSB of TWAR is written to TWAR.TWGCI=1, the TWI will respond to the general call address ( \(0 \times 00\) ), otherwise it will ignore the general call address.

TWCR must hold a value of the type TWCR=0100010x - TWCR.TWEN must be written to ' 1 ' to enable the TWI. TWCR.TWEA bit must be written to '1' to enable the acknowledgement of the device's own slave address or the general call address. TWCR.TWSTA and TWSTO must be written to zero.

When TWAR and TWCR have been initialized, the TWI waits until it is addressed by its own slave address (or the general call address, if enabled) followed by the data direction bit. If the direction bit is ' 0 ' (write), the TWI will operate in SR mode, otherwise ST mode is entered. After its own slave address and the write bit have been received, the TWINT Flag is set and a valid status code can be read from TWSR. The status code is used to determine the appropriate software action, as detailed in the table below. The SR mode may also be entered if arbitration is lost while the TWI is in the Master mode (see states \(0 \times 68\) and \(0 \times 78\) ).

If the TWCR.TWEA bit is reset during a transfer, the TWI will return a "Not Acknowledge" ('1') to SDA after the next received data byte. This can be used to indicate that the Slave is not able to receive any more bytes. While TWEA is zero, the TWI does not acknowledge its own slave address. However, the 2wire Serial Bus is still monitored and address recognition may resume at any time by setting TWEA. This implies that the TWEA bit may be used to temporarily isolate the TWI from the 2-wire Serial Bus.

In all sleep modes other than Idle mode, the clock system to the TWI is turned off. If the TWEA bit is set, the interface can still acknowledge its own slave address or the general call address by using the 2 -wire Serial Bus clock as a clock source. The part will then wake up from sleep and the TWI will hold the SCL clock low during the wake up and until the TWINT Flag is cleared (by writing ' 1 ' to it). Further data reception will be carried out as normal, with the AVR clocks running as normal. Observe that if the AVR is set up with a long start-up time, the SCL line may be held low for a long time, blocking other data transmissions.

Note: The 2-wire Serial Interface Data Register (TWDR) does not reflect the last byte present on the bus when waking up from these Sleep modes.

\subsection*{24.6.5. Slave Transmitter Mode}

In the Slave Transmitter (ST) mode, a number of data bytes are transmitted to a Master Receiver, as in the figure below. All the status codes mentioned in this section assume that the prescaler bits are zero or are masked to zero.

Figure 24-17. Data Transfer in Slave Transmitter Mode

To initiate the SR mode, the TWI (Slave) Address Register (TWAR) and the TWI Control Register (TWCR) must be initialized as follows:

The upper seven bits of TWAR are the address to which the 2-wire Serial Interface will respond when addressed by a Master (TWAR.TWA[6:0]). If the LSB of TWAR is written to TWAR.TWGCI=1, the TWI will respond to the general call address \((0 \times 00)\), otherwise it will ignore the general call address.

TWCR must hold a value of the type TWCR=0100010x - TWEN must be written to one to enable the TWI. The TWEA bit must be written to one to enable the acknowledgement of the device's own slave address or the general call address. TWSTA and TWSTO must be written to zero.

When TWAR and TWCR have been initialized, the TWI waits until it is addressed by its own slave address (or the general call address if enabled) followed by the data direction bit. If the direction bit is " 1 " (read), the TWI will operate in ST mode, otherwise SR mode is entered. After its own slave address and the write bit have been received, the TWINT Flag is set and a valid status code can be read from TWSR. The status code is used to determine the appropriate software action. The appropriate action to be taken for each status code is detailed in the table below. The ST mode may also be entered if arbitration is lost while the TWI is in the Master mode (see state 0xBO).

If the TWCR.TWEA bit is written to zero during a transfer, the TWI will transmit the last byte of the transfer. State \(0 \times C 0\) or state \(0 \times C 8\) will be entered, depending on whether the Master Receiver transmits a NACK or ACK after the final byte. The TWI is switched to the not addressed Slave mode, and will ignore the Master if it continues the transfer. Thus the Master Receiver receives all '1' as serial data. State 0xC8 is entered if the Master demands additional data bytes (by transmitting ACK), even though the Slave has transmitted the last byte (TWEA zero and expecting NACK from the Master).

While TWCR.TWEA is zero, the TWI does not respond to its own slave address. However, the 2 -wire Serial Bus is still monitored and address recognition may resume at any time by setting TWEA. This implies that the TWEA bit may be used to temporarily isolate the TWI from the 2-wire Serial Bus.
In all sleep modes other than Idle mode, the clock system to the TWI is turned off. If the TWEA bit is set, the interface can still acknowledge its own slave address or the general call address by using the 2 -wire Serial Bus clock as a clock source. The part will then wake up from sleep and the TWI will hold the SCL clock will low during the wake up and until the TWINT Flag is cleared (by writing '1' to it). Further data transmission will be carried out as normal, with the AVR clocks running as normal. Observe that if the AVR is set up with a long start-up time, the SCL line may be held low for a long time, blocking other data transmissions.

Note: The 2-wire Serial Interface Data Register (TWDR) does not reflect the last byte present on the bus when waking up from these Sleep modes.

\(\square\) From slave to master

This number (contained in TWSR) corresponds to a defined state of the 2-Wire Ser ial Bus The prescaler bits are \(z\) ero or mask ed to \(z\) ero

\subsection*{24.6.6. Miscellaneous States}

There are two status codes that do not correspond to a defined TWI state, see the table below.
Status 0xF8 indicates that no relevant information is available because the TWINT Flag is not set. This occurs between other states, and when the TWI is not involved in a serial transfer.

Status 0x00 indicates that a bus error has occurred during a Two-wire Serial Bus transfer. A bus error occurs when a START or STOP condition occurs at an illegal position in the format frame. Examples of such illegal positions are during the serial transfer of an address byte, a data byte, or an acknowledge bit. When a bus error occurs, TWINT is set. To recover from a bus error, the TWSTO Flag must set and TWINT must be cleared by writing a logic one to it. This causes the TWI to enter the not addressed Slave mode and to clear the TWSTO Flag (no other bits in TWCR are affected). The SDA and SCL lines are released, and no STOP condition is transmitted.

Table 24-7. Miscellaneous States

\hline
\end{tabular}

\subsection*{24.6.7. Combining Several TWI Modes}

In some cases, several TWI modes must be combined in order to complete the desired action. Consider for example reading data from a serial EEPROM. Typically, such a transfer involves the following steps:
1. The transfer must be initiated.
2. The EEPROM must be instructed what location should be read.
3. The reading must be performed.
4. The transfer must be finished.

Note that data is transmitted both from Master to Slave and vice versa. The Master must instruct the Slave what location it wants to read, requiring the use of the MT mode. Subsequently, data must be read from the Slave, implying the use of the MR mode. Thus, the transfer direction must be changed. The Master must keep control of the bus during all these steps, and the steps should be carried out as an atomical operation. If this principle is violated in a multimaster system, another Master can alter the data pointer in the EEPROM between steps 2 and 3 , and the Master will read the wrong data location. Such a change in transfer direction is accomplished by transmitting a REPEATED START between the transmission of the address byte and reception of the data. After a REPEATED START, the Master keeps ownership of the bus. The following figure shows the flow in this transfer.

Figure 24-19. Combining Several TWI Modes to Access a Serial EEPROM

\subsection*{24.7. Multi-master Systems and Arbitration}

If multiple masters are connected to the same bus, transmissions may be initiated simultaneously by one or more of them. The TWI standard ensures that such situations are handled in such a way that one of the masters will be allowed to proceed with the transfer, and that no data will be lost in the process. An example of an arbitration situation is depicted below, where two masters are trying to transmit data to a Slave Receiver.

Figure 24-20. An Arbitration Example

Several different scenarios may arise during arbitration, as described below:
- Two or more masters are performing identical communication with the same Slave. In this case, neither the Slave nor any of the masters will know about the bus contention.
- Two or more masters are accessing the same Slave with different data or direction bit. In this case, arbitration will occur, either in the READ/WRITE bit or in the data bits. The masters trying to output a ' 1 ' on SDA while another Master outputs a zero will lose the arbitration. Losing masters will switch to not addressed Slave mode or wait until the bus is free and transmit a new START condition, depending on application software action.
- Two or more masters are accessing different slaves. In this case, arbitration will occur in the SLA bits. Masters trying to output a '1' on SDA while another Master outputs a zero will lose the arbitration. Masters losing arbitration in SLA will switch to Slave mode to check if they are being addressed by the winning Master. If addressed, they will switch to SR or ST mode, depending on the value of the READ/WRITE bit. If they are not being addressed, they will switch to not addressed Slave mode or wait until the bus is free and transmit a new START condition, depending on application software action.

This is summarized in the next figure. Possible status values are given in circles.
Figure 24-21. Possible Status Codes Caused by Arbitration

\subsection*{24.8. Register Description}

\subsection*{24.8.1. TWBR - TWI Bit Rate Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 \mathrm{~F}\) must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: TWBR
Offset: 0x00
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 20\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & TWBR7 & TWBR6 & TWBR5 & TWBR4 & TWBR3 & TWBR2 & TWBR1 & TWBRO \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - TWBRn: TWI Bit Rate Register [ \(\mathrm{n}=7\) 7:0]
TWBR selects the division factor for the bit rate generator. The bit rate generator is a frequency divider which generates the SCL clock frequency in the Master modes. See Bit Rate Generator Unit for calculating bit rates.

\subsection*{24.8.2. TWCR - TWI Control Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

The TWCR is used to control the operation of the TWI. It is used to enable the TWI, to initiate a Master access by applying a START condition to the bus, to generate a Receiver acknowledge, to generate a stop condition, and to control halting of the bus while the data to be written to the bus are written to the TWDR. It also indicates a write collision if data is attempted written to TWDR while the register is inaccessible.

Name: TWCR
Offset: 0x36
Reset: \(0 \times 00\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 56\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & TWINT & TWEA & TWSTA & TWSTO & TWWC & TWEN & & TWIE \\
\hline Access & R/W & R/W & R/W & R/W & R & R/W & & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - TWINT: TWI Interrupt Flag}

This bit is set by hardware when the TWI has finished its current job and expects application software response. If the I-bit in SREG and TWIE in TWCR are set, the MCU will jump to the TWI Interrupt Vector. While the TWINT Flag is set, the SCL low period is stretched. The TWINT Flag must be cleared by software by writing a logic one to it.

Note that this flag is not automatically cleared by hardware when executing the interrupt routine. Also note that clearing this flag starts the operation of the TWI, so all accesses to the TWI Address Register (TWAR), TWI Status Register (TWSR), and TWI Data Register (TWDR) must be complete before clearing this flag.

\section*{Bit 6 - TWEA: TWI Enable Acknowledge}

The TWEA bit controls the generation of the acknowledge pulse. If the TWEA bit is written to one, the ACK pulse is generated on the TWI bus if the following conditions are met:
1. The device's own slave address has been received.
2. A general call has been received, while the TWGCE bit in the TWAR is set.
3. A data byte has been received in Master Receiver or Slave Receiver mode.

By writing the TWEA bit to zero, the device can be virtually disconnected from the 2-wire Serial Bus temporarily. Address recognition can then be resumed by writing the TWEA bit to one again.

\section*{Bit 5 - TWSTA: TWI START Condition}

The application writes the TWSTA bit to one when it desires to become a Master on the 2-wire Serial Bus. The TWI hardware checks if the bus is available, and generates a START condition on the bus if it is free. However, if the bus is not free, the TWI waits until a STOP condition is detected, and then generates a new START condition to claim the bus Master status. TWSTA must be cleared by software when the START condition has been transmitted.

\section*{Bit 4 - TWSTO: TWI STOP Condition}

Writing the TWSTO bit to one in Master mode will generate a STOP condition on the 2 -wire Serial Bus. When the STOP condition is executed on the bus, the TWSTO bit is cleared automatically. In Slave mode, setting the TWSTO bit can be used to recover from an error condition. This will not generate a STOP condition, but the TWI returns to a well-defined unaddressed Slave mode and releases the SCL and SDA lines to a high impedance state.

\section*{Bit 3 - TWWC: TWI Write Collision Flag}

The TWWC bit is set when attempting to write to the TWI Data Register - TWDR when TWINT is low. This flag is cleared by writing the TWDR Register when TWINT is high.

\section*{Bit 2 - TWEN: TWI Enable}

The TWEN bit enables TWI operation and activates the TWI interface. When TWEN is written to one, the TWI takes control over the I/O pins connected to the SCL and SDA pins, enabling the slew-rate limiters and spike filters. If this bit is written to zero, the TWI is switched off and all TWI transmissions are terminated, regardless of any ongoing operation.

Bit 0 - TWIE: TWI Interrupt Enable
When this bit is written to one, and the l-bit in SREG is set, the TWI interrupt request will be activated for as long as the TWINT Flag is high.

\subsection*{24.8.3. TWSR - TWI Status Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3\) F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: TWSR
Offset: 0x01
Reset: 0xF8
Property: When addressing I/O Registers as data space the offset address is \(0 \times 21\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & TWS4 & TWS3 & TWS2 & TWS1 & TWS0 & & TWPS1 & TWPS0 \\
\hline Access & R & R & R & R & R & & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 1 & & 0 & 0 \\
\hline
\end{tabular}

Bits 7:3 - TWSn: TWI Status Bit 7 [ \(\mathrm{n}=7: 3\) ]
The TWS[7:3] reflect the status of the TWI logic and the 2 -wire Serial Bus. The different status codes are described later in this section. Note that the value read from TWSR contains both the 5 -bit status value and the 2-bit prescaler value. The application designer should mask the prescaler bits to zero when checking the Status bits. This makes status checking independent of prescaler setting. This approach is used in this datasheet, unless otherwise noted.

Bits 1:0 - TWPSn: TWI Prescaler [ \(n=1: 0\) ]
These bits can be read and written, and control the bit rate prescaler.
Table 24-8. TWI Bit Rate Prescaler
\begin{tabular}{|l|c|l|}
\hline TWPS1 & TWPS0 & Prescaler Value \\
\hline 0 & 0 & 1 \\
\hline 0 & 1 & 4 \\
\hline 1 & 0 & 16 \\
\hline 1 & 1 & 64 \\
\hline
\end{tabular}

To calculate bit rates, refer to Bit Rate Generator Unit. The value of TWPS1:0 is used in the equation.

\subsection*{24.8.4. TWDR - TWI Data Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3\) F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

In Transmit mode, TWDR contains the next byte to be transmitted. In Receive mode, the TWDR contains the last byte received. It is writable while the TWI is not in the process of shifting a byte. This occurs when the TWI Interrupt Flag (TWINT) is set by hardware. Note that the Data Register cannot be initialized by the user before the first interrupt occurs. The data in TWDR remains stable as long as TWINT is set. While data is shifted out, data on the bus is simultaneously shifted in. TWDR always contains the last byte present on the bus, except after a wake up from a sleep mode by the TWI interrupt. In this case, the contents of TWDR is undefined. In the case of a lost bus arbitration, no data is lost in the transition from Master to Slave. Handling of the ACK bit is controlled automatically by the TWI logic, the CPU cannot access the ACK bit directly.

Name: TWDR
Offset: 0x03
Reset: 0xFF
Property: When addressing I/O Registers as data space the offset address is \(0 \times 23\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & TWD7 & TWD6 & TWD5 & TWD4 & TWD3 & TWD2 & TWD1 & TWD0 \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\hline
\end{tabular}

Bits 7:0 - TWDn: TWI Data [n=7:0]
These eight bits constitute the next data byte to be transmitted, or the latest data byte received on the 2wire Serial Bus.

\subsection*{24.8.5. TWAR - TWI (Slave) Address Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

The TWAR should be loaded with the 7-bit Slave address (in the seven most significant bits of TWAR) to which the TWI will respond when programmed as a Slave Transmitter or Receiver, and not needed in the Master modes. In multimaster systems, TWAR must be set in masters which can be addressed as Slaves by other Masters.

The LSB of TWAR is used to enable recognition of the general call address ( \(0 \times 00\) ). There is an associated address comparator that looks for the slave address (or general call address if enabled) in the received serial address. If a match is found, an interrupt request is generated.

Name: TWAR
Offset: 0x02
Reset: 0x7F
Property: When addressing I/O Registers as data space the offset address is \(0 \times 22\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & TWA6 & TWA5 & TWA4 & TWA3 & TWA2 & TWA1 & TWA0 & TWGCE \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
\hline
\end{tabular}

Bits 7:1 - TWAn: TWI (Slave) Address [ \(\mathrm{n}=6: 0\) ]
These seven bits constitute the slave address of the TWI unit.
Bit 0 - TWGCE: TWI General Call Recognition Enable Bit
If set, this bit enables the recognition of a General Call given over the Two-wire Serial Bus.

\section*{25. AC - Analog Comparator}

\subsection*{25.1. Overview}

The Analog Comparator compares the input values on the positive pin AIN0 and negative pin AIN1. When the voltage on the positive pin AINO is higher than the voltage on the negative pin AIN1, the Analog Comparator Output, ACO, is set. The comparator's output can be set to trigger the Timer/Counter1 Input Capture function. In addition, the comparator can trigger a separate interrupt, exclusive to the Analog Comparator. The user can select Interrupt triggering on comparator output rise, fall or toggle. A block diagram of the comparator and its surrounding logic is shown in the figure below.

Figure 25-1. Analog Comparator Block Diagram \({ }^{(2)}\)

\section*{Note:}
1. See Table Analog Comparator Multiplexed Input in next section.
2. Refer to the Pin Configuration and the Port D Pins Alternate Functions Table.

\section*{Related Links}

Pin Configurations on page 13
Alternate Functions of Port D on page 86

\subsection*{25.2. Analog Comparator Multiplexed Input}

It is possible to select any of the ADC7:0 pins to replace the negative input to the Analog Comparator. The ADC multiplexer is used to select this input, and consequently the ADC must be switched off to utilize this feature. If the Analog Comparator Multiplexer Enable bit (ACME in SFIOR) is set and the ADC is switched off (ADEN in ADCSRA is zero), MUX2:0 in ADMUX select the input pin to replace the negative input to the Analog Comparator, as shown in the table below. If ACME is cleared or ADEN is set, AIN1 is applied to the negative input to the Analog Comparator.
Table 25-1. Analog Comparator Multiplexed Input
\begin{tabular}{|l|l|l|l|}
\hline ACME & ADEN & MUX[2:0] & Analog Comparator Negative Input \\
\hline 0 & x & xxx & AIN1 \\
\hline 1 & 1 & xxx & AIN1 \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|l|}
\hline ACME & ADEN & MUX[2:0] & Analog Comparator Negative Input \\
\hline 1 & 0 & 000 & ADC0 \\
\hline 1 & 0 & 001 & ADC1 \\
\hline 1 & 0 & 010 & ADC2 \\
\hline 1 & 0 & 011 & ADC3 \\
\hline 1 & 0 & 100 & ADC4 \\
\hline 1 & 0 & 101 & ADC5 \\
\hline 1 & 0 & 110 & ADC6 \\
\hline 1 & 0 & 111 & ADC7 \\
\hline
\end{tabular}

\subsection*{25.3. Register Description}

\subsection*{25.3.1. SFIOR - Analog Comparator Control and Status Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: SFIOR
Offset: 0x30
Reset: N/A
Property: When addressing I/O Registers as data space the offset address is \(0 \times 50\)

Bit 3 - ACME: Analog Comparator Multiplexer Enable
When this bit is written logic one and the ADC is switched off (ADEN in ADCSRA is zero), the ADC multiplexer selects the negative input to the Analog Comparator. When this bit is written logic zero, AIN1 is applied to the negative input of the Analog Comparator. For a detailed description of this bit, see Analog Comparator Multiplexed Input table.

\subsection*{25.3.2. ACSR - Analog Comparator Control and Status Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 \mathrm{~F}\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: ACSR
Offset: 0x08
Reset: N/A
Property: When addressing I/O Registers as data space the offset address is \(0 \times 28\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & ACD & ACBG & ACO & ACl & ACIE & ACIC & ACIS1 & ACIS0 \\
\hline Access & R/W & R/W & R & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & a & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - ACD: Analog Comparator Disable}

When this bit is written logic one, the power to the Analog Comparator is switched off. This bit can be set at any time to turn off the Analog Comparator. This will reduce power consumption in Active and Idle mode. When changing the ACD bit, the Analog Comparator Interrupt must be disabled by clearing the ACIE bit in ACSR. Otherwise an interrupt can occur when the bit is changed.

\section*{Bit 6 - ACBG: Analog Comparator Bandgap Select}

When this bit is set, a fixed bandgap reference voltage replaces the positive input to the Analog Comparator. When this bit is cleared, AINO is applied to the positive input of the Analog Comparator.

\section*{Bit 5 - ACO: Analog Comparator Output}

The output of the Analog Comparator is synchronized and then directly connected to ACO. The synchronization introduces a delay of 1-2 clock cycles.

\section*{Bit 4 - ACI: Analog Comparator Interrupt Flag}

This bit is set by hardware when a comparator output event triggers the interrupt mode defined by ACIS1 and ACISO. The Analog Comparator interrupt routine is executed if the ACIE bit is set and the I-bit in SREG is set. ACI is cleared by hardware when executing the corresponding interrupt handling vector. Alternatively, ACl is cleared by writing a logic one to the flag.

\section*{Bit 3-ACIE: Analog Comparator Interrupt Enable}

When the ACIE bit is written logic one and the I-bit in the Status Register is set, the Analog Comparator interrupt is activated. When written logic zero, the interrupt is disabled.

\section*{Bit 2 - ACIC: Analog Comparator Input Capture Enable}

When written logic one, this bit enables the input capture function in Timer/Counter1 to be triggered by the Analog Comparator. The comparator output is in this case directly connected to the input capture front-end logic, making the comparator utilize the noise canceler and edge select features of the Timer/ Counter1 Input Capture interrupt. When written logic zero, no connection between the Analog Comparator and the input capture function exists. To make the comparator trigger the Timer/Counter1 Input Capture interrupt, the ICIE1 bit in the Timer Interrupt Mask Register (TIMSK1) must be set.

Bits 1:0 - ACISn: Analog Comparator Interrupt Mode Select [ \(\mathrm{n}=1: 0\) ]
These bits determine which comparator events that trigger the Analog Comparator interrupt.

Table 25-2. ACIS[1:0] Settings
\begin{tabular}{|c|c|l|}
\hline ACIS1 & ACIS0 & Interrupt Mode \\
\hline 0 & 0 & Comparator Interrupt on Output Toggle. \\
\hline 0 & 1 & Reserved \\
\hline 1 & 0 & Comparator Interrupt on Falling Output Edge. \\
\hline 1 & 1 & Comparator Interrupt on Rising Output Edge. \\
\hline
\end{tabular}

When changing the ACIS1/ACIS0 bits, the Analog Comparator Interrupt must be disabled by clearing its Interrupt Enable bit in the ACSR Register. Otherwise an interrupt can occur when the bits are changed.

\section*{26. ADC - Analog to Digital Converter}

\subsection*{26.1. Features}
- 10-bit Resolution
- 0.5 LSB Integral Non-Linearity
- \(\pm 2\) LSB Absolute Accuracy
- 13-260 s Conversion Time
- Up to 15 ksps at Maximum Resolution
- 8 Multiplexed Single Ended Input Channels
- 7 Differential Input Channels
- 2 Differential Input Channels with Optional Gain of 10x and 200x
- Optional Left Adjustment for ADC Result Readout
- 0 - \(\mathrm{V}_{\mathrm{CC}}\) ADC Input Voltage Range
- 2.7 - \(\mathrm{V}_{\mathrm{CC}}\) Differential ADC Voltage Range
- Selectable 2.56V ADC Reference Voltage
- Free Running or Single Conversion Mode
- ADC Start Conversion by Auto Triggering on Interrupt Sources
- Interrupt on ADC Conversion Complete
- Sleep Mode Noise Canceler

\subsection*{26.2. Overview}

The ATmega32A features a 10 -bit successive approximation ADC. The ADC is connected to an 8 channel Analog Multiplexer which allows 8 single-ended voltage inputs constructed from the pins of Port A. The single-ended voltage inputs refer to 0 V (GND).

The device also supports 16 differential voltage input combinations. Two of the differential inputs (ADC1, ADC0 and ADC3, ADC2) are equipped with a programmable gain stage, providing amplification steps of \(0 \mathrm{~dB}(1 \mathrm{x}), 20 \mathrm{~dB}(10 \mathrm{x})\), or \(46 \mathrm{~dB}(200 \mathrm{x})\) on the differential input voltage before the \(\mathrm{A} / D\) conversion. Seven differential analog input channels share a common negative terminal (ADC1), while any other ADC input can be selected as the positive input terminal. If 1 x or 10 x gain is used, 8 -bit resolution can be expected. If \(200 x\) gain is used, 7 -bit resolution can be expected.

The ADC contains a Sample and Hold circuit which ensures that the input voltage to the ADC is held at a constant level during conversion. A block diagram of the ADC is shown below.
The \(A D C\) has a separate analog supply voltage pin, \(A V_{C C}\). \(A V_{C C}\) must not differ more than \(\pm 0.3 \mathrm{~V}\) from \(V_{C C}\). See section ADC Noise Canceler on how to connect this pin.

Internal reference voltages of nominally 2.56 V or \(\mathrm{AV}_{\mathrm{CC}}\) are provided On-chip. The voltage reference may be externally decoupled at the AREF pin by a capacitor for better noise performance.

Figure 26-1. Analog to Digital Converter Block Schematic Operation

The ADC converts an analog input voltage to a 10-bit digital value through successive approximation. The minimum value represents GND and the maximum value represents the voltage on the AREF pin minus 1 LSB. Optionally, AVCC or an internal 2.56 V reference voltage may be connected to the AREF pin by writing to the REFSn bits in the ADMUX Register. The internal voltage reference may thus be decoupled by an external capacitor at the AREF pin to improve noise immunity.

The analog input channel and differential gain are selected by writing to the MUX bits in ADMUX. Any of the ADC input pins, as well as GND and a fixed bandgap voltage reference, can be selected as single ended inputs to the ADC. A selection of ADC input pins can be selected as positive and negative inputs to the differential gain amplifier.
If differential channels are selected, the differential gain stage amplifies the voltage difference between the selected input channel pair by the selected gain factor. This amplified value then becomes the analog input to the ADC. If single ended channels are used, the gain amplifier is bypassed altogether.

The ADC is enabled by setting the ADC Enable bit, ADEN in ADCSRA. Voltage reference and input channel selections will not go into effect until ADEN is set. The ADC does not consume power when ADEN is cleared, so it is recommended to switch off the ADC before entering power saving sleep modes.

The ADC generates a 10-bit result which is presented in the ADC Data Registers, ADCH and ADCL. By default, the result is presented right adjusted, but can optionally be presented left adjusted by setting the ADLAR bit in ADMUX.

If the result is left adjusted and no more than 8 -bit precision is required, it is sufficient to read ADCH. Otherwise, ADCL must be read first, then \(A D C H\), to ensure that the content of the data registers belongs to the same conversion. Once ADCL is read, ADC access to data registers is blocked. This means that if ADCL has been read, and a conversion completes before ADCH is read, neither register is updated and the result from the conversion is lost. When ADCH is read, ADC access to the ADCH and ADCL Registers is re-enabled.

The ADC has its own interrupt which can be triggered when a conversion completes. When ADC access to the data registers is prohibited between reading of ADCH and ADCL, the interrupt will trigger even if the result is lost.

\subsection*{26.3. Starting a Conversion}

A single conversion is started by writing a logical one to the ADC Start Conversion bit, ADSC. This bit stays high as long as the conversion is in progress and will be cleared by hardware when the conversion is completed. If a different data channel is selected while a conversion is in progress, the ADC will finish the current conversion before performing the channel change.
Alternatively, a conversion can be triggered automatically by various sources. Auto Triggering is enabled by setting the ADC Auto Trigger Enable bit, ADATE in ADCSRA. The trigger source is selected by setting the ADC Trigger Select bits, ADTS in ADCSRB (see description of the ADTS bits for a list of the trigger sources). When a positive edge occurs on the selected trigger signal, the ADC prescaler is reset and a conversion is started. This provides a method of starting conversions at fixed intervals. If the trigger signal still is set when the conversion completes, a new conversion will not be started. If another positive edge occurs on the trigger signal during conversion, the edge will be ignored. Note that an interrupt flag will be set even if the specific interrupt is disabled or the Global Interrupt Enable bit in SREG is cleared. A conversion can thus be triggered without causing an interrupt. However, the interrupt flag must be cleared in order to trigger a new conversion at the next interrupt event.

Figure 26-2. ADC Auto Trigger Logic

Using the ADC Interrupt Flag as a trigger source makes the ADC start a new conversion as soon as the ongoing conversion has finished. The ADC then operates in Free Running mode, constantly sampling and updating the ADC Data Register. The first conversion must be started by writing a logical one to the ADSC bit in ADCSRA. In this mode the ADC will perform successive conversions independently of whether the ADC Interrupt Flag, ADIF is cleared or not.

If Auto Triggering is enabled, single conversions can be started by writing ADSC in ADCSRA to one. ADSC can also be used to determine if a conversion is in progress. The ADSC bit will be read as one during a conversion, independently of how the conversion was started.

\subsection*{26.4. Prescaling and Conversion Timing}

Figure 26-3. ADC Prescaler

By default, the successive approximation circuitry requires an input clock frequency between 50 kHz and 200 kHz to get maximum resolution. If a lower resolution than 10 bits is needed, the input clock frequency to the ADC can be higher than 200 kHz to get a higher sample rate.

The ADC module contains a prescaler, which generates an acceptable ADC clock frequency from any CPU frequency above 100 kHz . The prescaling is set by the ADPS bits in ADCSRA. The prescaler starts counting from the moment the ADC is switched on by setting the ADEN bit in ADCSRA. The prescaler keeps running for as long as the ADEN bit is set, and is continuously reset when ADEN is low.
When initiating a single ended conversion by setting the ADSC bit in ADCSRA, the conversion starts at the following rising edge of the ADC clock cycle. See Differential Gain Channels for details on differential conversion timing.

A normal conversion takes 13 ADC clock cycles. The first conversion after the ADC is switched on (ADEN in ADCSRA is set) takes 25 ADC clock cycles in order to initialize the analog circuitry.

The actual sample-and-hold takes place 1.5 ADC clock cycles after the start of a normal conversion and 13.5 ADC clock cycles after the start of a first conversion. When a conversion is complete, the result is written to the ADC Data Registers, and ADIF is set. In single conversion mode, ADSC is cleared simultaneously. The software may then set ADSC again, and a new conversion will be initiated on the first rising ADC clock edge.

When Auto Triggering is used, the prescaler is reset when the trigger event occurs. This assures a fixed delay from the trigger event to the start of conversion. In this mode, the sample-and-hold takes place two ADC clock cycles after the rising edge on the trigger source signal. Three additional CPU clock cycles are used for synchronization logic.

When using Differential mode, along with auto trigging from a source other that the ADC Conversion Complete, each conversion will require 25 ADC clocks. This is because the ADC must be disabled and re-enabled after every conversion.

In Free Running mode, a new conversion will be started immediately after the conversion completes, while ADSC remains high. For a summary of conversion times, see table ADC Conversion Time at the end of this section.

Figure 26-4. ADC Timing Diagram, First Conversion (Single Conversion Mode)

Figure 26-5. ADC Timing Diagram, Single Conversion

Figure 26-6. ADC Timing Diagram, Auto Triggered Conversion

Figure 26-7. ADC Timing Diagram, Free Running Conversion

Table 26-1. ADC Conversion Time
\begin{tabular}{|l|l|l|}
\hline Condition & \begin{tabular}{l} 
Sample \& Hold \\
(Cycles from Start of Conversion)
\end{tabular} & \begin{tabular}{l} 
Conversion Time \\
(Cycles)
\end{tabular} \\
\hline First conversion & 13.5 & 25 \\
\hline Normal conversions, single ended & 1.5 & 13 \\
\hline Auto Triggered conversions & 2 & 13.5 \\
\hline Normal conversions, differential & \(1.5 / 2.5\) & \(13 / 14\) \\
\hline
\end{tabular}

\subsection*{26.4.1. Differential Gain Channels}

When using differential gain channels, certain aspects of the conversion need to be taken into consideration.

Differential conversions are synchronized to the internal clock \(\mathrm{CK}_{\mathrm{ADC} 2}\) equal to half the ADC clock. This synchronization is done automatically by the ADC interface in such a way that the sample-and-hold occurs at a specific edge of \(\mathrm{CK}_{\mathrm{ADC} 2}\). A conversion initiated by the user (that is, all single conversions, and the first free running conversion) when \(\mathrm{CK}_{\mathrm{ADC2}}\) is low will take the same amount of time as a single ended conversion ( 13 ADC clock cycles from the next prescaled clock cycle). A conversion initiated by the user when \(\mathrm{CK}_{\mathrm{ADC} 2}\) is high will take 14 ADC clock cycles due to the synchronization mechanism. In free running mode, a new conversion is initiated immediately after the previous conversion completes, and since \(\mathrm{CK}_{\text {ADC2 }}\) is high at this time, all automatically started (that is, all but the first) free running conversions will take 14 ADC clock cycles.

The gain stage is optimized for a bandwidth of 4 kHz at all gain settings. Higher frequencies may be subjected to non-linear amplification. An external low-pass filter should be used if the input signal contains higher frequency components than the gain stage bandwidth. Note that the ADC clock frequency is independent of the gain stage bandwidth limitation. For example the ADC clock period may be \(6 \mu \mathrm{~s}\), allowing a channel to be sampled at 12 kSPS , regardless of the bandwidth of this channel.

If differential gain channels are used and conversions are started by Auto Triggering, the ADC must be switched off between conversions. When Auto Triggering is used, the ADC prescaler is reset before the conversion is started. Since the gain stage is dependent of a stable ADC clock prior to the conversion, this conversion will not be valid. By disabling and then re-enabling the ADC between each conversion
(writing ADEN in ADCSRA to " 0 " then to " 1 "), only extended conversions are performed. The result from the extended conversions will be valid. Refer to Prescaling and Conversion Timing for timing details.

\subsection*{26.5. Changing Channel or Reference Selection}

The MUXn and REFS1:0 bits in the ADMUX Register are single buffered through a temporary register to which the CPU has random access. This ensures that the channels and reference selection only takes place at a safe point during the conversion. The channel and reference selection is continuously updated until a conversion is started. Once the conversion starts, the channel and reference selection is locked to ensure a sufficient sampling time for the ADC. Continuous updating resumes in the last ADC clock cycle before the conversion completes (ADIF in ADCSRA is set). Note that the conversion starts on the following rising ADC clock edge after ADSC is written. The user is thus advised not to write new channel or reference selection values to ADMUX until one ADC clock cycle after ADSC is written.

If Auto Triggering is used, the exact time of the triggering event can be indeterministic. Special care must be taken when updating the ADMUX Register, in order to control which conversion will be affected by the new settings.

If both ADATE and ADEN is written to one, an interrupt event can occur at any time. If the ADMUX Register is changed in this period, the user cannot tell if the next conversion is based on the old or the new settings. ADMUX can be safely updated in the following ways:
1. When ADATE or ADEN is cleared.
2. During conversion, minimum one ADC clock cycle after the trigger event.
3. After a conversion, before the interrupt flag used as trigger source is cleared.

When updating ADMUX in one of these conditions, the new settings will affect the next ADC conversion.
Special care should be taken when changing differential channels. Once a differential channel has been selected, the gain stage may take as much as \(125 \mu \mathrm{~s}\) to stabilize to the new value. Thus conversions should not be started within the first \(125 \mu \mathrm{~s}\) after selecting a new differential channel. Alternatively, conversion results obtained within this period should be discarded.

The same settling time should be observed for the first differential conversion after changing ADC reference (by changing the REFS1:0 bits in ADMUX).

\subsection*{26.5.1. ADC Input Channels}

When changing channel selections, the user should observe the following guidelines to ensure that the correct channel is selected:
- In Single Conversion mode, always select the channel before starting the conversion. The channel selection may be changed one ADC clock cycle after writing one to ADSC. However, the simplest method is to wait for the conversion to complete before changing the channel selection.
- In Free Running mode, always select the channel before starting the first conversion. The channel selection may be changed one ADC clock cycle after writing one to ADSC. However, the simplest method is to wait for the first conversion to complete, and then change the channel selection. Since the next conversion has already started automatically, the next result will reflect the previous channel selection. Subsequent conversions will reflect the new channel selection.

When switching to a differential gain channel, the first conversion result may have a poor accuracy due to the required settling time for the automatic offset cancellation circuitry. The user should preferably disregard the first conversion result.

\subsection*{26.5.2. ADC Voltage Reference}

The reference voltage for the ADC ( \(V_{\text {REF }}\) ) indicates the conversion range for the ADC. Single ended channels that exceed \(\mathrm{V}_{\text {REF }}\) will result in codes close to \(0 \times 3 F F\). \(\mathrm{V}_{\text {REF }}\) can be selected as either \(\mathrm{AV}_{\mathrm{CC}}\), internal 2.56 V reference, or external AREF pin.
\(\mathrm{AV}_{\mathrm{CC}}\) is connected to the ADC through a passive switch. The internal 2.56 V reference is generated from the internal bandgap reference \(\left(\mathrm{V}_{\mathrm{BG}}\right)\) through an internal amplifier. In either case, the external AREF pin is directly connected to the ADC, and the reference voltage can be made more immune to noise by connecting a capacitor between the AREF pin and ground. \(V_{\text {REF }}\) can also be measured at the AREF pin with a high impedance voltmeter. Note that \(\mathrm{V}_{\text {REF }}\) is a high impedance source, and only a capacitive load should be connected in a system.
If the user has a fixed voltage source connected to the AREF pin, the user may not use the other reference voltage options in the application, as they will be shorted to the external voltage. If no external voltage is applied to the AREF pin, the user may switch between \(A V_{C C}\) and 2.56 V as reference selection. The first ADC conversion result after switching reference voltage source may be inaccurate, and the user is advised to discard this result.

If differential channels are used, the selected reference should not be closer to \(\mathrm{AV}_{\mathrm{CC}}\) than indicated in table ADC Characteristics, Differential Channels in ADC Characteristics

\section*{Related Links}

ADC Characteristics on page 367

\subsection*{26.6. ADC Noise Canceler}

The ADC features a noise canceler that enables conversion during sleep mode to reduce noise induced from the CPU core and other I/O peripherals. The noise canceler can be used with ADC Noise Reduction and Idle mode. To make use of this feature, the following procedure should be used:
1. Make sure that the ADC is enabled and is not busy converting. Single Conversion mode must be selected and the ADC conversion complete interrupt must be enabled.
2. Enter ADC Noise Reduction mode (or Idle mode). The ADC will start a conversion once the CPU has been halted.
3. If no other interrupts occur before the ADC conversion completes, the ADC interrupt will wake up the CPU and execute the ADC Conversion Complete interrupt routine. If another interrupt wakes up the CPU before the ADC conversion is complete, that interrupt will be executed, and an ADC Conversion Complete interrupt request will be generated when the ADC conversion completes. The CPU will remain in active mode until a new sleep command is executed.
Note: The ADC will not be automatically turned off when entering other sleep modes than Idle mode and ADC Noise Reduction mode. The user is advised to write zero to ADCRSA.ADEN before entering such sleep modes to avoid excessive power consumption. If the ADC is enabled in such sleep modes and the user wants to perform differential conversions, the user is advised to switch the ADC off and on after waking up from sleep to prompt an extended conversion to get a valid result.

\subsection*{26.6.1. Analog Input Circuitry}

The analog input circuitry for single ended channels is illustrated below. An analog source applied to ADCn is subjected to the pin capacitance and input leakage of that pin, regardless of whether that channel is selected as input for the ADC. When the channel is selected, the source must drive the S/H capacitor through the series resistance (combined resistance in the input path).
The ADC is optimized for analog signals with an output impedance of approximately \(10 \mathrm{k} \Omega\) or less. If such a source is used, the sampling time will be negligible. If a source with higher impedance is used, the
sampling time will depend on how long time the source needs to charge the S/H capacitor, with can vary widely. The user is recommended to only use low impedance sources with slowly varying signals, since this minimizes the required charge transfer to the \(\mathrm{S} / \mathrm{H}\) capacitor.

If differential gain channels are used, the input circuitry looks somewhat different, although source impedances of a few hundred \(k \Omega\) or less is recommended.

Signal components higher than the Nyquist frequency ( \(\mathrm{f}_{\mathrm{ADC}} / 2\) ) should not be present for either kind of channels, to avoid distortion from unpredictable signal convolution. The user is advised to remove high frequency components with a low-pass filter before applying the signals as inputs to the ADC.

Figure 26-8. Analog Input Circuitry

\subsection*{26.6.2. Analog Noise Canceling Techniques}

Digital circuitry inside and outside the device generates EMI which might affect the accuracy of analog measurements. If conversion accuracy is critical, the noise level can be reduced by applying the following techniques:
1. Keep analog signal paths as short as possible. Make sure analog tracks run over the ground plane, and keep them well away from high-speed switching digital tracks.
2. The \(A V_{C C}\) pin on the device should be connected to the digital \(V_{C C}\) supply voltage via an LC network as shown in the figure below.
3. Use the ADC noise canceler function to reduce induced noise from the CPU.
4. If any ADC port pins are used as digital outputs, it is essential that these do not switch while a conversion is in progress.

Figure 26-9. ADC Power Connections

\subsection*{26.6.3. Offset Compensation Schemes}

The gain stage has a built-in offset cancellation circuitry that nulls the offset of differential measurements as much as possible. The remaining offset in the analog path can be measured directly by selecting the same channel for both differential inputs. This offset residue can be then subtracted in software from the measurement results. Using this kind of software based offset correction, offset on any channel can be reduced below one LSB.

\subsection*{26.6.4. ADC Accuracy Definitions}

An n-bit single-ended ADC converts a voltage linearly between GND and \(\mathrm{V}_{\text {REF }}\) in \(2^{\mathrm{n}}\) steps (LSBs). The lowest code is read as 0 , and the highest code is read as \(2^{n}-1\).

Several parameters describe the deviation from the ideal behavior:
- Offset: The deviation of the first transition (0x000 to 0x001) compared to the ideal transition (at 0.5 LSB). Ideal value: 0 LSB.

Figure 26-10. Offset Error

- Gain error: After adjusting for offset, the gain error is found as the deviation of the last transition ( \(0 \times 3\) FE to \(0 \times 3 F F\) ) compared to the ideal transition (at 1.5 LSB below maximum). Ideal value: 0 LSB.

Figure 26-11. Gain Error

- Integral Non-linearity (INL): After adjusting for offset and gain error, the INL is the maximum deviation of an actual transition compared to an ideal transition for any code. Ideal value: 0 LSB.

Figure 26-12. Integral Non-linearity (INL)

- Differential Non-linearity (DNL): The maximum deviation of the actual code width (the interval between two adjacent transitions) from the ideal code width ( 1 LSB ). Ideal value: 0 LSB.

Figure 26-13. Differential Non-linearity (DNL)

- Quantization Error: Due to the quantization of the input voltage into a finite number of codes, a range of input voltages ( 1 LSB wide) will code to the same value. Always \(\pm 0.5\) LSB.
- Absolute accuracy: The maximum deviation of an actual (unadjusted) transition compared to an ideal transition for any code. This is the compound effect of offset, gain error, differential error, nonlinearity, and quantization error. Ideal value: \(\pm 0.5\) LSB.

\subsection*{26.7. ADC Conversion Result}

After the conversion is complete (ADCSRA.ADIF is high), the conversion result can be found in the ADC Result Registers (ADCL, ADCH).

For single ended conversion, the result is
\(\mathrm{ADC}=\frac{V_{\text {IN }} \cdot 1024}{V_{\text {REF }}}\)
where \(\mathrm{V}_{\mathrm{IN}}\) is the voltage on the selected input pin, and \(\mathrm{V}_{\text {REF }}\) the selected voltage reference (see Table \(26-3\) and Table 26-4). \(0 \times 000\) represents analog ground, and \(0 \times 3 F F\) represents the selected reference voltage minus one LSB.

If differential channels are used, the result is
\(\mathrm{ADC}=\frac{\left(\mathrm{V}_{\mathrm{POS}}-\mathrm{V}_{\mathrm{NEG}}\right) \cdot \mathrm{GAIN} \cdot 512}{V_{\mathrm{REF}}}\)
where \(\mathrm{V}_{\mathrm{POS}}\) is the voltage on the positive input pin, \(\mathrm{V}_{\text {NEG }}\) the voltage on the negative input pin, GAIN the selected gain factor, and VREF the selected voltage reference. The result is presented in two's complement form, from \(0 \times 200(-512 d)\) through \(0 \times 1\) FF ( +511 d ). Note that if the user wants to perform a quick polarity check of the results, it is sufficient to read the MSB of the result (ADC9 in ADCH). If this bit is one, the result is negative, and if this bit is zero, the result is positive. The next figure shows the decoding of the differential input range.

The table below shows the resulting output codes if the differential input channel pair (ADCn - ADCm) is selected with a gain of GAIN and a reference voltage of \(\mathrm{V}_{\text {REF }}\).

Figure 26-14. Differential Measurement Range

Table 26-2. Correlation Between Input Voltage and Output Codes
\begin{tabular}{|c|c|c|}
\hline \(\mathrm{V}_{\text {ADCn }}\) & Read Code & Corresponding decimal value \\
\hline \(\mathrm{V}_{\text {ADCm }}+\mathrm{V}_{\text {REF }} / \mathrm{GAIN}\) & 0x1FF & 511 \\
\hline \(\mathrm{V}_{\text {ADCm }}+511 / 512 \mathrm{~V}_{\text {REF }} / \mathrm{GAIN}\) & 0x1FF & 511 \\
\hline \(\mathrm{V}_{\text {ADCm }}+510 / 512 \mathrm{~V}_{\text {REF }} / \mathrm{GAIN}\) & 0x1FE & 510 \\
\hline \(\therefore\) & : & :. \\
\hline \(\mathrm{V}_{\text {ADCm }}+1 / 512 \mathrm{~V}_{\text {REF }} / \mathrm{GAIN}\) & 0x001 & 1 \\
\hline \(\mathrm{V}_{\text {ADCm }}\) & 0x000 & 0 \\
\hline \(\mathrm{V}_{\text {ADCm }}-1 / 512 \mathrm{~V}_{\text {REF }} / \mathrm{GAIN}\) & 0x3FF & -1 \\
\hline :. & : & :. \\
\hline \(\mathrm{V}_{\text {ADCm }}-511 / 512 \mathrm{~V}_{\text {REF }} / \mathrm{GAIN}\) & 0x201 & -511 \\
\hline \(\mathrm{V}_{\text {ADCm }}-\mathrm{V}_{\text {REF }} / \mathrm{GAIN}\) & 0x200 & -512 \\
\hline
\end{tabular}

\section*{Example:}

ADMUX \(=0 x E D(A D C 3-A D C 2,10 x\) gain, 2.56 V reference, left adjusted result)

Voltage on ADC3 is 300 mV , voltage on \(\mathrm{ADC2}\) is 500 mV .
\[
\text { ADCR }=512 \times 10 \times(300-500) / 2560=-400=0 \times 270
\]

ADCL will thus read \(0 \times 00\), and ADCH will read \(0 \times 9 \mathrm{C}\). Writing zero to ADLAR right adjusts the result: \(A D C L=0 \times 70, A D C H=0 \times 02\).

\subsection*{26.8. Register Description}

\subsection*{26.8.1. ADMUX - ADC Multiplexer Selection Register}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: ADMUX
Offset: 0x07
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 27\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & REFS1 & REFS0 & ADLAR & MUX4 & MUX3 & MUX2 & MUX1 & MUXO \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:6-REFSn: Reference Selection [ \(\mathrm{n}=1: 0\) ]
These bits select the voltage reference for the ADC. If these bits are changed during a conversion, the change will not go in effect until this conversion is complete (ADIF in ADCSRA is set). The internal voltage reference options may not be used if an external reference voltage is being applied to the AREF pin.

Table 26-3. ADC Voltage Reference Selection

\section*{REFS[1:0] Voltage Reference Selection}
\begin{tabular}{|l|l|}
\hline 00 & AREF, Internal \(\mathrm{V}_{\text {ref }}\) turned off \\
\hline 01 & AV CC with external capacitor at AREF pin \\
\hline 10 & Reserved \\
\hline 11 & Internal 2.56 V Voltage Reference with external capacitor at AREF pin \\
\hline
\end{tabular}

\section*{Bit 5 - ADLAR: ADC Left Adjust Result}

The ADLAR bit affects the presentation of the ADC conversion result in the ADC Data Register. Write one to ADLAR to left adjust the result. Otherwise, the result is right adjusted. Changing the ADLAR bit will affect the ADC Data Register immediately, regardless of any ongoing conversions. For a complete description of this bit, see ADCL and ADCH.

\section*{Bits 4:0 - MUXn: Analog Channel Selection [ \(n=4: 0\) ]}

The value of these bits selects which combination of analog inputs are connected to the ADC. These bits also select the gain for the differential channels. Refer to table below for details. If these bits are changed during a conversion, the change will not go in effect until this conversion is complete (ADIF in ADCSRA is set).

Table 26-4. Input Channel and Gain Selections

\begin{tabular}{|c|l|l|l|}
\hline MUX[4:0] & Single Ended Input & \begin{tabular}{l} 
Positive Differential \\
Input
\end{tabular} & \begin{tabular}{l} 
Negative Differential \\
Input
\end{tabular} \\
\hline 11110 & \(1.22 \mathrm{~V}\left(\mathrm{~V}_{\mathrm{BG}}\right)\) & Gain \\
\hline 11111 & \(\mathrm{OV}(\mathrm{GND})\) & A & \\
\hline
\end{tabular}

Note: 1. Can be used for offset calibration.

\subsection*{26.8.2. ADCSRA - ADC Control and Status Register A}

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: ADCSRA
Offset: 0x06
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 26\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & ADEN & ADSC & ADATE & ADIF & ADIE & ADPS2 & ADPS1 & ADPS0 \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - ADEN: ADC Enable}

Writing this bit to one enables the ADC. By writing it to zero, the ADC is turned off. Turning the ADC off while a conversion is in progress, will terminate this conversion.

\section*{Bit 6 - ADSC: ADC Start Conversion}

In Single Conversion mode, write this bit to one to start each conversion. In Free Running mode, write this bit to one to start the first conversion. The first conversion after ADSC has been written after the ADC has been enabled, or if ADSC is written at the same time as the ADC is enabled, will take 25 ADC clock cycles instead of the normal 13. This first conversion performs initialization of the ADC.

ADSC will read as one as long as a conversion is in progress. When the conversion is complete, it returns to zero. Writing zero to this bit has no effect.

\section*{Bit 5 - ADATE: ADC Auto Trigger Enable}

When this bit is written to one, Auto Triggering of the ADC is enabled. The ADC will start a conversion on a positive edge of the selected trigger signal. The trigger source is selected by setting the ADC Trigger Select bits, ADTS in SFIOR.

\section*{Bit 4 - ADIF: ADC Interrupt Flag}

This bit is set when an ADC conversion completes and the Data Registers are updated. The ADC Conversion Complete Interrupt is executed if the ADIE bit and the I-bit in SREG are set. ADIF is cleared by hardware when executing the corresponding interrupt Handling Vector. Alternatively, ADIF is cleared by writing a logical one to the flag. Beware that if doing a Read-Modify-Write on ADCSRA, a pending interrupt can be disabled. This also applies if the SBI and CBI instructions are used.

\section*{Bit 3 - ADIE: ADC Interrupt Enable}

When this bit is written to one and the I-bit in SREG is set, the ADC Conversion Complete Interrupt is activated.

Bits 2:0 - ADPSn: ADC Prescaler Select [n=2:0]
These bits determine the division factor between the XTAL frequency and the input clock to the ADC.

Table 26-5. ADC Prescaler Selections
\begin{tabular}{|l|l|}
\hline ADPS[2:0] & Division Factor \\
\hline 000 & 2 \\
\hline 001 & 2 \\
\hline 010 & 4 \\
\hline 011 & 8 \\
\hline 100 & 16 \\
\hline 101 & 32 \\
\hline 110 & 64 \\
\hline 111 & 128 \\
\hline
\end{tabular}

\subsection*{26.8.3. ADCL - ADC Data Register Low (ADLAR=0)}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

When an ADC conversion is complete, the result is found in these two registers. If differential channels are used, the result is presented in two's complement form.

When ADCL is read, the ADC Data Register is not updated until ADCH is read. Consequently, if the result is left adjusted and no more than 8 -bit precision is required, it is sufficient to read ADCH. Otherwise, ADCL must be read first, then ADCH.

The ADLAR bit and the MUXn bits in ADMUX affect the way the result is read from the registers. If ADLAR is set, the result is left adjusted. If ADLAR is cleared (default), the result is right adjusted.

Name: ADCL
Offset: 0x04
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 24\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & ADC7 & ADC6 & ADC5 & ADC4 & ADC3 & ADC2 & ADC1 & ADC0 \\
\hline Access & R & R & R & R & R & R & R & R \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bits 7:0 - ADCn: ADC Conversion Result [ \(\mathrm{n}=7\) 7:0]
These bits represent the result from the conversion. Refer to ADC Conversion Result for details.

\subsection*{26.8.4. ADCH - ADC Data Register High (ADLAR=0)}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: ADCH
Offset: 0x05
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 25\)

Bit 1 - ADC9: ADC Conversion Result Refer to ADCL

Bit 0 - ADC8: ADC Conversion Result

\subsection*{26.8.5. ADCL - ADC Data Register Low (ADLAR=1)}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, \(0 \times 20\) must be added to these offset addresses.

Name: ADCL
Offset: 0x04
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 24\)

Bit 7 - ADC1: ADC Conversion Result Refer to ADCL

Bit 6 - ADC0: ADC Conversion Result

\subsection*{26.8.6. \(A D C H\) - ADC Data Register High (ADLAR=1)}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: ADCH
Offset: 0x05
Reset: \(0 \times 00\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 25\)
\begin{tabular}{cc|c|c|c|c|c|c|c}
\multicolumn{1}{c}{ Bit } & 7 & \multicolumn{1}{c}{6} & \multicolumn{1}{c}{5} & \multicolumn{2}{c}{3} & \multicolumn{2}{c}{2} & 1 \\
\cline { 2 - 9 } & ADC9 & ADC8 & ADC7 & ADC6 & ADC5 & ADC4 & ADC3 & ADC2 \\
\hline Access & R & R & R & R & R & R & R & R \\
Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{tabular}

Bit 7 - ADC9: ADC Conversion Result
Bit 6 - ADC8: ADC Conversion Result
Bit 5 - ADC7: ADC Conversion Result
Bit 4 - ADC6: ADC Conversion Result
Bit 3 - ADC5: ADC Conversion Result
Bit 2 - ADC4: ADC Conversion Result
Bit 1 - ADC3: ADC Conversion Result
Bit 0 - ADC2: ADC Conversion Result
Refer to ADCL

\subsection*{26.8.7. SFIOR - Special Function IO Register}

Name: SFIOR
Offset: 0x30
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 50\)

Bits 7:5 - ADTSn: ADC Auto Trigger Source [ \(\mathrm{n}=2: 0\) ]
If ADATE in ADCSRA is written to one, the value of these bits selects which source will trigger an ADC conversion. If ADATE is cleared, the ADTS2:0 settings will have no effect. A conversion will be triggered by the rising edge of the selected Interrupt Flag. Note that switching from a trigger source that is cleared to a trigger source that is set, will generate a positive edge on the trigger signal. If ADEN in ADCSRA is set, this will start a conversion. Switching to Free Running mode (ADTS[2:0]=0) will not cause a trigger event, even if the ADC Interrupt Flag is set.

Table 26-6. ADC Auto Trigger Source Selections
\begin{tabular}{|l|l|}
\hline ADTS[2:0] & Trigger Source \\
\hline 000 & Free Running mode \\
\hline 001 & Analog Comparator \\
\hline 010 & External Interrupt Request 0 \\
\hline 011 & Timer/Counter0 Compare Match \\
\hline 100 & Timer/Counter0 Overflow \\
\hline 101 & Timer/Counter1 Compare Match B \\
\hline 110 & Timer/Counter1 Overflow \\
\hline 111 & Timer/Counter1 Capture Event \\
\hline
\end{tabular}

\section*{27. JTAG Interface and On-chip Debug System}

\subsection*{27.1. Features}
- JTAG (IEEE std. 1149.1 Compliant) Interface
- Boundary-scan Capabilities According to the IEEE std. 1149.1 (JTAG) Standard
- Debugger Access to:
- All Internal Peripheral Units
- Internal and External RAM
- The Internal Register File
- Program Counter
- EEPROM and Flash Memories
- Extensive On-chip Debug Support for Break Conditions, Including:
- AVR Break Instruction
- Break on Change of Program Memory Flow
- Single Step Break
- Program Memory Breakpoints on Single Address or Address Range
- Data Memory Breakpoints on Single Address or Address Range
- Programming of Flash, EEPROM, Fuses, and Lock Bits through the JTAG Interface
- On-chip Debugging Supported by Atmel Studio

\subsection*{27.2. Overview}

The AVR IEEE std. 1149.1 compliant JTAG interface can be used for:
- Testing PCBs by using the JTAG Boundary-scan capability
- Programming the non-volatile memories, Fuses and Lock bits
- On-chip debugging

A brief description is given in the following sections. Detailed descriptions for Programming via the JTAG interface, and using the Boundary-scan Chain can be found in the sections Programming Via the JTAG Interface and IEEE 1149.1 (JTAG) Boundary-scan, respectively. The On-chip Debug support is considered being private JTAG instructions, and distributed within ATMEL and to selected third party vendors only.

Figure 27-1 shows the JTAG interface and the On-chip Debug system. The TAP Controller is a state machine controlled by the TCK and TMS signals. The TAP Controller selects either the JTAG Instruction Register or one of several Data Registers as the scan chain (Shift Register) between the TDI - input and TDO - output. The Instruction Register holds JTAG instructions controlling the behavior of a Data Register.

The ID-Register, Bypass Register, and the Boundary-scan Chain are the data registers used for boardlevel testing. The JTAG Programming Interface (actually consisting of several physical and virtual Data Registers) is used for serial programming via the JTAG interface. The Internal Scan Chain and Break Point Scan Chain are used for On-chip debugging only.

\section*{Related Links}

Programming Via the JTAG Interface on page 345

\subsection*{27.3. TAP - Test Access Port}

The JTAG interface is accessed through four of the AVR's pins. In JTAG terminology, these pins constitute the Test Access Port - TAP. These pins are:
- TMS: Test mode select. This pin is used for navigating through the TAP-controller state machine.
- TCK: Test clock. JTAG operation is synchronous to TCK.
- TDI: Test Data In. Serial input data to be shifted in to the Instruction Register or Data Register (Scan Chains).

\section*{- TDO: Test Data Out. Serial output data from Instruction Register or Data Register.}

The IEEE std. 1149.1 also specifies an optional TAP signal; TRST - Test ReSeT - which is not provided.
When the JTAGEN fuse is unprogrammed, these four TAP pins are normal port pins and the TAP controller is in reset. When programmed and the JTD bit in MCUCSR is cleared, the TAP input signals are internally pulled high and the JTAG is enabled for Boundary-scan and programming. In this case, the TAP output pin (TDO) is left floating in states where the JTAG TAP controller is not shifting data, and must therefore be connected to a pull-up resistor or other hardware having pull-ups (for instance the TDI-input of the next device in the scan chain). The device is shipped with this fuse programmed.
For the On-chip Debug system, in addition to the JTAG interface pins, the RESET pin is monitored by the debugger to be able to detect External Reset sources. The debugger can also pull the RESET pin low to reset the whole system, assuming only open collectors on the Reset line are used in the application.

Figure 27-1. Block Diagram

Figure 27-2. TAP Controller State Diagram

\subsection*{27.4. TAP Controller}

The TAP controller is a 16 -state finite state machine that controls the operation of the Boundary-scan circuitry, JTAG programming circuitry, or On-chip Debug system. The state transitions depicted in Figure 27-2 depend on the signal present on TMS (shown adjacent to each state transition) at the time of the rising edge at TCK. The initial state after a Power-on Reset is Test-Logic-Reset.

As a definition in this document, the LSB is shifted in and out first for all Shift Registers.
Assuming Run-Test//dle is the present state, a typical scenario for using the JTAG interface is:
- At the TMS input, apply the sequence \(1,1,0,0\) at the rising edges of TCK to enter the Shift Instruction Register - Shift-IR state. While in this state, shift the 4 bits of the JTAG instructions into the JTAG instruction register from the TDI input at the rising edge of TCK. The TMS input must be
held low during input of the 3 LSBs in order to remain in the Shift-IR state. The MSB of the instruction is shifted in when this state is left by setting TMS high. While the instruction is shifted in from the TDI pin, the captured IR-state \(0 \times 01\) is shifted out on the TDO pin. The JTAG Instruction selects a particular Data Register as path between TDI and TDO and controls the circuitry surrounding the selected Data Register.
- Apply the TMS sequence \(1,1,0\) to re-enter the Run-Test/Idle state. The instruction is latched onto the parallel output from the Shift Register path in the Update-IR state. The Exit-IR, Pause-IR, and Exit2-IR states are only used for navigating the state machine.
- At the TMS input, apply the sequence \(1,0,0\) at the rising edges of TCK to enter the Shift Data Register - Shift-DR state. While in this state, upload the selected Data Register (selected by the present JTAG instruction in the JTAG Instruction Register) from the TDI input at the rising edge of TCK. In order to remain in the Shift-DR state, the TMS input must be held low during input of all bits except the MSB. The MSB of the data is shifted in when this state is left by setting TMS high. While the Data Register is shifted in from the TDI pin, the parallel inputs to the Data Register captured in the Capture-DR state is shifted out on the TDO pin.
- Apply the TMS sequence 1, 1, 0 to re-enter the Run-Test//dle state. If the selected Data Register has a latched parallel-output, the latching takes place in the Update-DR state. The Exit-DR, PauseDR, and Exit2-DR states are only used for navigating the state machine.

As shown in the state diagram, the Run-Test/Idle state need not be entered between selecting JTAG instruction and using Data Registers, and some JTAG instructions may select certain functions to be performed in the Run- Test//dle, making it unsuitable as an Idle state.
Note: 1. Independent of the initial state of the TAP Controller, the Test-Logic-Reset state can always be entered by holding TMS high for 5 TCK clock periods.
For detailed information on the JTAG specification, refer to the literature listed in Bibliography.

\subsection*{27.5. Using the Boundary-scan Chain}

A complete description of the Boundary-scan capabilities are given in the section IEEE 1149.1 (JTAG) Boundary-scan.

\subsection*{27.6. Using the On-chip Debug System}

As shown in Figure 27-1, the hardware support for On-chip Debugging consists mainly of:
- A scan chain on the interface between the internal AVR CPU and the internal peripheral units
- Break point unit
- Communication interface between the CPU and JTAG system

All read or modify/write operations needed for implementing the Debugger are done by applying AVR instructions via the internal AVR CPU Scan Chain. The CPU sends the result to an I/O memory mapped location which is part of the communication interface between the CPU and the JTAG system.

The Break point Unit implements Break on Change of Program Flow, Single Step Break, two Program Memory Break points, and two combined break points. Together, the four break points can be configured as either:
- 4 Single Program Memory break points
- 3 Single Program Memory break points +1 single Data Memory break point
- 2 Single Program Memory break points +2 single Data Memory break points
- 2 Single Program Memory break points +1 Program Memory break point with mask ("range break point")
- 2 Single Program Memory break points + 1 Data Memory break point with mask ("range break point")

A debugger, like the Atmel Studio \({ }^{\circledR}\), may however use one or more of these resources for its internal purpose, leaving less flexibility to the end-user.

A list of the On-chip Debug specific JTAG instructions is given in On-chip Debug Specific JTAG Instructions.

The JTAGEN fuse must be programmed to enable the JTAG Test Access Port. In addition, the OCDEN fuse must be programmed and no Lock bits must be set for the On-chip Debug system to work. As a security feature, the On-chip Debug system is disabled when any Lock bits are set. Otherwise, the Onchip Debug system would have provided a back-door into a secured device.
The Atmel Studio enables the user to fully control execution of programs on an AVR device with On-chip Debug capability, AVR In-Circuit Emulator, or the built-in AVR Instruction Set Simulator. Atmel Studio supports source level execution of Assembly programs assembled with Atmel Corporation's AVR Assembler and C programs compiled with third party vendors' compilers.

For a full description of the Atmel Studio, please refer to the Atmel Studio User Guide found in the Online Help in Atmel Studio. Only highlights are presented in this document.

All necessary execution commands are available in Atmel Studio, both on source level and on disassembly level. The user can execute the program, single step through the code either by tracing into or stepping over functions, step out of functions, place the cursor on a statement and execute until the statement is reached, stop the execution, and reset the execution target. In addition, the user can have an unlimited number of code break points (using the BREAK instruction) and up to two data memory break points, alternatively combined as a mask (range) break point.

\subsection*{27.7. On-chip Debug Specific JTAG Instructions}

The On-chip debug support is considered being private JTAG instructions, and distributed within ATMEL and to selected third-party vendors only. Instruction opcodes are listed for reference.

PRIVATE0; 0x8
Private JTAG instruction for accessing On-chip Debug system.

\section*{PRIVATE1; 0x9}

Private JTAG instruction for accessing On-chip Debug system.

\section*{PRIVATE2; 0xA}

Private JTAG instruction for accessing On-chip Debug system.

\section*{PRIVATE3; 0xB}

Private JTAG instruction for accessing On-chip Debug system.

\subsection*{27.8. Using the JTAG Programming Capabilities}

Programming of AVR parts via JTAG is performed via the four-pin JTAG port, TCK, TMS, TDI, and TDO. These are the only pins that need to be controlled/observed to perform JTAG programming (in addition to power pins). It is not required to apply 12 V externally. The JTAGEN fuse must be programmed and the JTD bit in the MCUCSR Register must be cleared to enable the JTAG Test Access Port.

The JTAG programming capability supports:
- Flash programming and verifying
- EEPROM programming and verifying
- Fuse programming and verifying
- Lock bit programming and verifying

The Lock bit security is exactly as in Parallel Programming mode. If the Lock bits LB1 or LB2 are programmed, the OCDEN Fuse cannot be programmed unless first doing a chip erase. This is a security feature that ensures no back-door exists for reading out the content of a secured device.

The details on programming through the JTAG interface and programming specific JTAG instructions are given in the section Programming Via the JTAG Interface.

\subsection*{27.9. Bibliography}

For more information about general Boundary-scan, the following literature can be consulted:
- IEEE: IEEE Std 1149.1-1990. IEEE Standard Test Access Port and Boundary-scan Architecture, IEEE, 1993
- Colin Maunder: The Board Designers Guide to Testable Logic Circuits, Addison-Wesley, 1992

\subsection*{27.10. IEEE 1149.1 (JTAG) Boundary-scan}

\subsection*{27.10.1. Features}
- JTAG (IEEE std. 1149.1 Compliant) Interface
- Boundary-scan Capabilities According to the JTAG Standard
- Full Scan of all Port Functions as well as Analog Circuitry having Off-chip Connections
- Supports the Optional IDCODE Instruction
- Additional Public AVR_RESET Instruction to Reset the AVR

\subsection*{27.10.2. System Overview}

The Boundary-scan Chain has the capability of driving and observing the logic levels on the digital I/O pins, as well as the boundary between digital and analog logic for analog circuitry having off-chip connections. At system level, all ICs having JTAG capabilities are connected serially by the TDI/TDO signals to form a long Shift Register. An external controller sets up the devices to drive values at their output pins, and observe the input values received from other devices. The controller compares the received data with the expected result. In this way, Boundary-scan provides a mechanism for testing interconnections and integrity of components on Printed Circuits Boards by using the four TAP signals only.

The four IEEE 1149.1 defined mandatory JTAG instructions IDCODE, BYPASS, SAMPLE/PRELOAD, and EXTEST, as well as the AVR specific public JTAG instruction AVR_RESET can be used for testing the Printed Circuit Board. Initial scanning of the data register path will show the ID-code of the device, since IDCODE is the default JTAG instruction. It may be desirable to have the AVR device in reset during test mode. If not reset, inputs to the device may be determined by the scan operations, and the internal software may be in an undetermined state when exiting the test mode. Entering Reset, the outputs of any Port Pin will instantly enter the high impedance state, making the HIGHZ instruction redundant. If needed,
the BYPASS instruction can be issued to make the shortest possible scan chain through the device. The device can be set in the Reset state either by pulling the external RESET pin low, or issuing the AVR_RESET instruction with appropriate setting of the Reset Data Register.
The EXTEST instruction is used for sampling external pins and loading output pins with data. The data from the output latch will be driven out on the pins as soon as the EXTEST instruction is loaded into the JTAG IR-register. Therefore, the SAMPLE/PRELOAD should also be used for setting initial values to the scan ring, to avoid damaging the board when issuing the EXTEST instruction for the first time. SAMPLE/ PRELOAD can also be used for taking a snapshot of the external pins during normal operation of the part.
The JTAGEN fuse must be programmed and the JTD bit in the I/O register MCUCSR must be cleared to enable the JTAG Test Access Port.

When using the JTAG interface for Boundary-scan, using a JTAG TCK clock frequency higher than the internal chip frequency is possible. The chip clock is not required to run.

\subsection*{27.11. Data Registers}

The data registers relevant for Boundary-scan operations are:
- Bypass Register
- Device Identification Register
- Reset Register
- Boundary-scan Chain

\subsection*{27.11.1. Bypass Register}

The Bypass Register consists of a single Shift Register stage. When the Bypass Register is selected as path between TDI and TDO, the register is reset to 0 when leaving the Capture-DR controller state. The Bypass Register can be used to shorten the scan chain on a system when the other devices are to be tested.

\subsection*{27.11.2. Device Identification Register}

The figure below shows the structure of the Device Identification Register.
Figure 27-3. The format of the Device Identification Register
\begin{tabular}{|c|c|c|c|c|c|}
\hline & \multicolumn{2}{|l|}{MSB} & & \multicolumn{2}{|r|}{LSB} \\
\hline Bit & 31 & \multicolumn{2}{|c|}{\(12 \quad 11\)} & 1 & 0 \\
\hline Device ID & Version & Part Number & Manufacturer ID & & 1 \\
\hline & 4 bits & 16 bits & 11 bits & & -bit \\
\hline
\end{tabular}

\subsection*{27.11.2.1. Version}

Version is a 4-bit number identifying the revision of the component. The JTAG version number follows the revision of the device, and wraps around at revision \(P(0 \times F)\). Revision \(A\) and \(Q\) is \(0 \times 0\), revision \(B\) and \(R\) is \(0 \times 1\) and so on.

\subsection*{27.11.2.2. Part Number}

The part number is a 16 -bit code identifying the component. The JTAG Part Number for ATmega32A is listed in the table below.

Table 27-1. AVR JTAG Part Number
\begin{tabular}{|l|l|}
\hline Part Number & JTAG Part Number (Hex) \\
\hline ATmega32A & \(0 \times 9502\) \\
\hline
\end{tabular}

\subsection*{27.11.2.3. Manufacturer ID}

The Manufacturer ID is a 11-bit code identifying the manufacturer. The JTAG manufacturer ID for ATMEL is listed in the table below.

Table 27-2. Manufacturer ID
\begin{tabular}{|l|l|}
\hline Manufacturer & JTAG Manufacturer ID (Hex) \\
\hline ATMEL & \(0 \times 01 F\) \\
\hline
\end{tabular}

\subsection*{27.11.3. Reset Register}

The Reset Register is a Test Data Register used to reset the part. Since the AVR tri-states Port Pins when reset, the Reset Register can also replace the function of the unimplemented optional JTAG instruction HIGHZ.

A high value in the Reset Register corresponds to pulling the External Reset low. The part is reset as long as there is a high value present in the Reset Register. Depending on the Fuse settings for the clock options, the part will remain reset for a Reset Time-Out Period (refer to Clock Sources) after releasing the Reset Register. The output from this Data Register is not latched, so the Reset will take place immediately, as shown in the figure below.

Figure 27-4. Reset Register

\section*{Related Links}

Clock Sources on page 40

\subsection*{27.11.4. Boundary-scan Chain}

The Boundary-scan Chain has the capability of driving and observing the logic levels on the digital I/O pins, as well as the boundary between digital and analog logic for analog circuitry having off-chip connections. Refer to Boundary-scan Chain for a complete description.

\subsection*{27.12. Boundry-scan Specific JTAG Instructions}

The Instruction Register is 4-bit wide, supporting up to 16 instructions. Listed below are the JTAG instructions useful for Boundary-scan operation. Note that the optional HIGHZ instruction is not implemented, but all outputs with tri-state capability can be set in high-impedant state by using the AVR_RESET instruction, since the initial state for all port pins is tri-state.

As a definition in this data sheet, the LSB is shifted in and out first for all Shift Registers.
The OPCODE for each instruction is shown behind the instruction name in hex format. The text describes which data register is selected as path between TDI and TDO for each instruction.

\subsection*{27.12.1. EXTEST; 0x0}

Mandatory JTAG instruction for selecting the Boundary-scan Chain as Data Register for testing circuitry external to the AVR package. For port-pins, Pull-up Disable, Output Control, Output Data, and Input Data are all accessible in the scan chain. For Analog circuits having off-chip connections, the interface between the analog and the digital logic is in the scan chain. The contents of the latched outputs of the Boundary-scan chain is driven out as soon as the JTAG IR-register is loaded with the EXTEST instruction.

The active states are:
- Capture-DR: Data on the external pins are sampled into the Boundary-scan Chain.
- Shift-DR: The Internal Scan Chain is shifted by the TCK input.
- Update-DR: Data from the scan chain is applied to output pins.

\subsection*{27.12.2. IDCODE; 0x1}

Optional JTAG instruction selecting the 32-bit ID Register as Data Register. The ID Register consists of a version number, a device number and the manufacturer code chosen by JEDEC. This is the default instruction after power-up.

The active states are:
- Capture-DR: Data in the IDCODE Register is sampled into the Boundary-scan Chain.
- Shift-DR: The IDCODE scan chain is shifted by the TCK input.

\subsection*{27.12.3. SAMPLE_PRELOAD; 0x2}

Mandatory JTAG instruction for pre-loading the output latches and taking a snap-shot of the input/output pins without affecting the system operation. However, the output latches are not connected to the pins. The Boundary-scan Chain is selected as Data Register.

The active states are:
- Capture-DR: Data on the external pins are sampled into the Boundary-scan Chain.
- Shift-DR: The Boundary-scan Chain is shifted by the TCK input.
- Update-DR: Data from the Boundary-scan Chain is applied to the output latches. However, the output latches are not connected to the pins.

\subsection*{27.12.4. AVR_RESET; 0xC}

The AVR specific public JTAG instruction for forcing the AVR device into the Reset mode or releasing the JTAG Reset source. The TAP controller is not reset by this instruction. The one bit Reset Register is selected as Data Register. Note that the Reset will be active as long as there is a logic 'one' in the Reset Chain. The output from this chain is not latched.

The active states are:
- Shift-DR: The Reset Register is shifted by the TCK input.

\subsection*{27.12.5. BYPASS; 0xF}

Mandatory JTAG instruction selecting the Bypass Register for Data Register.
The active states are:
- Capture-DR: Loads a logic "0" into the Bypass Register.
- Shift-DR: The Bypass Register cell between TDI and TDO is shifted.

\subsection*{27.13. Boundary-scan Chain}

The Boundary-scan chain has the capability of driving and observing the logic levels on the digital I/O pins, as well as the boundary between digital and analog logic for analog circuitry having off-chip connections.

\subsection*{27.13.1. Scanning the Digital Port Pins}

The first figure below shows the Boundary-scan Cell for a bi-directional port pin with pull-up function. The cell consists of a standard Boundary-scan cell for the Pull-up Enable - PUExn - function, and a bidirectional pin cell that combines the three signals, Output Control - OCxn, Output Data - ODxn, and Input Data - IDxn, into only a two-stage Shift Register. The port and pin indexes are not used in the following description

The Boundary-scan logic is not included in the figures in the Data Sheet. Figure \(27-6\) shows a simple digital Port Pin as described in the section I/O Ports. The Boundary-scan details from the first figure below replaces the dashed box in Figure 27-6.
When no alternate port function is present, the Input Data - ID corresponds to the PINxn Register value (but ID has no synchronizer), Output Data corresponds to the PORT Register, Output Control corresponds to the Data Direction - DD Register, and the Pull-up Enable - PUExn - corresponds to logic expression PUD • \(\overline{\mathrm{DDxn}} \cdot \mathrm{PORTxn}\).

Digital alternate port functions are connected outside the dotted box in Figure 27-6 to make the scan chain read the actual pin value. For Analog function, there is a direct connection from the external pin to the analog circuit, and a scan chain is inserted on the interface between the digital logic and the analog circuitry.

Figure 27-5. Boundary-scan Cell for Bi-directional Port Pin with Pull-Up Function.

Figure 27-6. General Port Pin Schematic diagram

\section*{Related Links}

\section*{I/O Ports on page 74}

\subsection*{27.13.2. Boundary-scan and the Two-wire Interface}

The two Two-wire Interface pins SCL and SDA have one additional control signal in the scan-chain; Twowire Interface Enable - TWIEN. As shown in the figure below, the TWIEN signal enables a tri-state buffer with slew-rate control in parallel with the ordinary digital port pins. A general scan cell as shown in Figure \(27-11\) is attached to the TWIEN signal.

\section*{Note:}
1. A separate scan chain for the 50 ns spike filter on the input is not provided. The ordinary scan support for digital port pins suffice for connectivity tests. The only reason for having TWIEN in the scan path, is to be able to disconnect the slew-rate control buffer when doing boundary-scan.
2. Make sure the OC and TWIEN signals are not asserted simultaneously, as this will lead to drive contention.

Figure 27-7. Additional Scan Signal for the Two-wire Interface

\subsection*{27.13.3. Scanning the RESET Pin}

The RESET pin accepts 5 V active low logic for standard Reset operation, and 12 V active high logic for High Voltage Parallel programming. An observe-only cell as shown in the figure below is inserted both for the 5V Reset signal; RSTT, and the 12V Reset signal; RSTHV.

Figure 27-8. Observe-only Cell

\subsection*{27.13.4. Scanning the Clock Pins}

The AVR devices have many clock options selectable by fuses. These are: Internal RC Oscillator, External RC, External Clock, (High Frequency) Crystal Oscillator, Low-frequency Crystal Oscillator, and Ceramic Resonator.

The figure below shows how each Oscillator with external connection is supported in the scan chain. The Enable signal is supported with a general boundary-scan cell, while the Oscillator/Clock output is attached to an observe-only cell. In addition to the main clock, the Timer Oscillator is scanned in the same way. The output from the internal RC Oscillator is not scanned, as this Oscillator does not have external connections.

Figure 27-9. Boundary-scan Cells for Oscillators and Clock Options

The following table summaries the scan registers for the external clock pin XTAL1, oscillators with XTAL1/ XTAL2 connections as well as 32 kHz Timer Oscillator.
Table 27-3. Scan Signals for the Oscillators \({ }^{(1)(2)(3)}\)
\begin{tabular}{|l|l|l|l|}
\hline Enable signal & Scanned Clock Line & Clock Option & \begin{tabular}{l} 
Scanned Clock Line when not \\
Used
\end{tabular} \\
\hline EXTCLKEN & EXTCLK (XTAL1) & External Clock & 0 \\
\hline OSCON & OSCCK & \begin{tabular}{l} 
External Crystal \\
External Ceramic Resonator
\end{tabular} & 0 \\
\hline RCOSCEN & RCCK & External RC & 1 \\
\hline OSC32EN & OSC32CK & Low Freq. External Crystal & 0 \\
\hline TOSKON & TOSCK & 32kHz Timer Oscillator & 0 \\
\hline
\end{tabular}

\section*{Note:}
1. Do not enable more than one clock source as main clock at a time.
2. Scanning an Oscillator output gives unpredictable results as there is a frequency drift between the Internal Oscillator and the JTAG TCK clock. If possible, scanning an external clock is preferred.
3. The clock configuration is programmed by fuses. As a fuse does not change run-time, the clock configuration is considered fixed for a given application. The user is advised to scan the same clock option as to be used in the final system. The enable signals are supported in the scan chain because the system logic can disable clock options in sleep modes, thereby disconnecting the Oscillator pins from the scan path if not provided. The INTCAP fuses are not supported in the scan-
chain, so the boundary scan chain can not make a XTAL Oscillator requiring internal capacitors to run unless the fuse is correctly programmed.

\subsection*{27.13.5. Scanning the Analog Comparator}

The relevant Comparator signals regarding Boundary-scan are shown in the first figure below. The Boundary-scan cell from the second figure below is attached to each of these signals. The signals are described in Table 27-4.

The Comparator need not be used for pure connectivity testing, since all analog inputs are shared with a digital port pin as well.

Figure 27-10. Analog comparator

Figure 27-11. General Boundary-scan Cell used for Signals for Comparator and ADC

\subsection*{27.13.6. Scanning the ADC}

The figure below shows a block diagram of the ADC with all relevant control and observe signals. The Boundary-scan cell from Figure 27-8 is attached to each of these signals. The ADC need not be used for pure connectivity testing, since all analog inputs are shared with a digital port pin as well.

Figure 27-12. Analog to Digital Converter

The signals are described briefly in the following table.

Table 27-5. Boundary-scan Signals for the ADC
\begin{tabular}{|c|c|c|c|c|}
\hline Signal Name & Direction as Seen from the ADC & Description & Recommended Input when not in Use & \begin{tabular}{l}
Output Values when \\
Recommended Inputs are Used, and CPU is not Using the ADC
\end{tabular} \\
\hline COMP & Output & Comparator Output & 0 & 0 \\
\hline ACLK & Input & Clock signal to gain stages implemented as Switch-cap filters & 0 & 0 \\
\hline ACTEN & Input & Enable path from gain stages to the comparator & 0 & 0 \\
\hline ADCBGEN & Input & Enable Band-gap reference as negative input to comparator & 0 & 0 \\
\hline ADCEN & Input & Power-on signal to the ADC & 0 & 0 \\
\hline AMPEN & Input & Power-on signal to the gain stages & 0 & 0 \\
\hline DAC_9 & Input & Bit 9 of digital value to DAC & 1 & 1 \\
\hline DAC_8 & Input & Bit 8 of digital value to DAC & 0 & 0 \\
\hline DAC_7 & Input & Bit 7 of digital value to DAC & 0 & 0 \\
\hline DAC_6 & Input & Bit 6 of digital value to DAC & 0 & 0 \\
\hline DAC_5 & Input & Bit 5 of digital value to DAC & 0 & 0 \\
\hline DAC_4 & Input & Bit 4 of digital value to DAC & 0 & 0 \\
\hline DAC_3 & Input & Bit 3 of digital value to DAC & 0 & 0 \\
\hline DAC_2 & Input & Bit 2 of digital value to DAC & 0 & 0 \\
\hline DAC_1 & Input & Bit 1 of digital value to DAC & 0 & 0 \\
\hline DAC_0 & Input & Bit 0 of digital value to DAC & 0 & 0 \\
\hline EXTCH & Input & Connect ADC channels \(0-3\) to by-pass path around gain stages & 1 & 1 \\
\hline G10 & Input & Enable 10x gain & 0 & 0 \\
\hline G20 & Input & Enable 20x gain & 0 & 0 \\
\hline GNDEN & Input & Ground the negative input to comparator when true & 0 & 0 \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|}
\hline Signal Name & Direction as Seen from the ADC & Description & Recommended Input when not in Use & \begin{tabular}{l}
Output Values when \\
Recommended Inputs are Used, and CPU is not Using the ADC
\end{tabular} \\
\hline HOLD & Input & Sample \& Hold signal. Sample analog signal when low. Hold signal when high. If gain stages are used, this signal must go active when ACLK is high. & 1 & 1 \\

\hline NEGSEL_1 & Input & Input Mux for negative input for differential signal, bit 1 & 0 & 0 \\
\hline NEGSEL_0 & Input & Input Mux for negative input for differential signal, bit 0 & 0 & 0 \\
\hline PASSEN & Input & Enable pass-gate of gain stages. & 1 & 1 \\
\hline PRECH & Input & Precharge output latch of comparator. (Active low) & 1 & 1 \\
\hline SCTEST & Input & Switch-cap TEST enable. Output from x10 gain stage send out to Port Pin having ADC_4 & 0 & 0 \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|}
\hline Signal Name & Direction as Seen from the ADC & Description & Recommended Input when not in Use & \begin{tabular}{l}
Output Values when \\
Recommended Inputs are Used, and CPU is not Using the ADC
\end{tabular} \\
\hline ST & Input & Output of gain stages will settle faster if this signal is high first two ACLK periods after AMPEN goes high. & 0 & 0 \\
\hline VCCREN & Input & Selects Vcc as the ACC reference voltage. & 0 & 0 \\
\hline
\end{tabular}

Note: 1. Incorrect setting of the switches in Figure 27-12 will make signal contention and may damage the part. There are several input choices to the S\&H circuitry on the negative input of the output comparator in Figure 27-12. Make sure only one path is selected from either one ADC pin, Bandgap reference source, or Ground.
If the ADC is not to be used during scan, the recommended input values from the table above should be used. The user is recommended not to use the Differential Gain stages during scan. Switch-Cap based gain stages require fast operation and accurate timing which is difficult to obtain when used in a scan chain. Details concerning operations of the differential gain stage is therefore not provided.

The AVR ADC is based on the analog circuitry shown in Figure 27-12 with a successive approximation algorithm implemented in the digital logic. When used in Boundary-scan, the problem is usually to ensure that an applied analog voltage is measured within some limits. This can easily be done without running a successive approximation algorithm: apply the lower limit on the digital DAC[9:0] lines, make sure the output from the comparator is low, then apply the upper limit on the digital DAC[9:0] lines, and verify the output from the comparator to be high.
The ADC need not be used for pure connectivity testing, since all analog inputs are shared with a digital port pin as well.

When using the ADC, remember the following:
- The Port Pin for the ADC channel in use must be configured to be an input with pull-up disabled to avoid signal contention.
- In normal mode, a dummy conversion (consisting of 10 comparisons) is performed when enabling the ADC. The user is advised to wait at least 200ns after enabling the ADC before controlling/ observing any ADC signal, or perform a dummy conversion before using the first result.
- The DAC values must be stable at the midpoint value \(0 \times 200\) when having the HOLD signal low (Sample mode).
As an example, consider the task of verifying a \(1.5 \mathrm{~V} \pm 5 \%\) input signal at ADC channel 3 when the power supply is 5.0 V and AREF is externally connected to \(\mathrm{V}_{\mathrm{Cc}}\).

The lower limit is:
The upper limit is:
\(1024 \cdot 1,5 \mathrm{~V} \cdot 0,95 / 5 \mathrm{~V}=291=0 \times 123\)
\(1024 \cdot 1,5 \mathrm{~V} \cdot 1,05 / 5 \mathrm{~V}=323=0 \times 143\)

The recommended values from Table 27-5 are used unless other values are given in the algorithm in the following table. Only the DAC and Port Pin values of the Scan Chain are shown. The column "Actions" describes what JTAG instruction to be used before filling the Boundary-scan Register with the succeeding
columns. The verification should be done on the data scanned out when scanning in the data on the same row in the table.

Table 27-6. Algorithm for Using the ADC
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|}
\hline Step & Actions & ADCEN & DAC & MUXEN & HOLD & PRECH & PA3. Data & PA3. Control & \begin{tabular}{l} 
PA3. Pullup_ \\
Enable
\end{tabular} \\
\hline 1 & \begin{tabular}{l} 
SAMPLE_P \\
RELOAD
\end{tabular} & 1 & \(0 \times 200\) & \(0 \times 08\) & 1 & 1 & 0 & 0 & 0 \\
\hline 2 & EXTEST & 1 & \(0 \times 200\) & \(0 \times 08\) & 0 & 1 & 0 & 0 & 0 \\
\hline 3 & & 1 & \(0 \times 200\) & \(0 \times 08\) & 1 & 1 & 0 & 0 & 0 \\
\hline 4 & & 1 & \(0 \times 123\) & \(0 \times 08\) & 1 & 1 & 0 & 0 & 0 \\
\hline 5 & & 1 & \(0 \times 123\) & \(0 \times 08\) & 1 & 0 & 0 & 0 & 0 \\
\hline 6 & \begin{tabular}{l} 
Verify the COMP bit \\
scanned out to be 0
\end{tabular} & 1 & \(0 \times 200\) & \(0 \times 08\) & 1 & 1 & 0 & 0 & 0 \\
\hline 7 & & 1 & \(0 \times 200\) & \(0 \times 08\) & 0 & 1 & 0 & 0 & 0 \\
\hline 8 & & 1 & \(0 \times 200\) & \(0 \times 08\) & 1 & 1 & 0 & 0 & 0 \\
\hline 9 & & 1 & \(0 \times 143\) & \(0 \times 08\) & 1 & 1 & 0 & 0 & 0 \\
\hline 10 & & 1 & \(0 \times 143\) & \(0 \times 08\) & 1 & 0 & 0 & 0 & 0 \\
\hline 11 & Verify the COMP bit \\
scanned out to be 1 & 1 & \(0 \times 200\) & \(0 \times 08\) & 1 & 1 & 0 & 0 & 0 \\
\hline
\end{tabular}

Using this algorithm, the timing constraint on the HOLD signal constrains the TCK clock frequency. As the algorithm keeps HOLD high for five steps, the TCK clock frequency has to be at least five times the number of scan bits divided by the maximum hold time, \(\mathrm{t}_{\text {hold }}\) max

\subsection*{27.14. ATmega32A Boundary-scan Order}

The table below shows the Scan order between TDI and TDO when the Boundary-scan Chain is selected as data path. Bit 0 is the LSB; the first bit scanned in, and the first bit scanned out. The scan order follows the pin-out order as far as possible. Therefore, the bits of Port A are scanned in the opposite bit order of the other ports.

Exceptions from the rules are the scan chains for the analog circuits, which constitute the most significant bits of the scan chain regardless of which physical pin they are connected to. In Figure 27-5, PXn. Data corresponds to FF0, PXn. Control corresponds to FF1, and PXn. Pullup_enable corresponds to FF2. Bit \(2,3,4\), and 5 of Port \(C\) is not in the scan chain, since these pins constitute the TAP pins when the JTAG is enabled.

Table 27-7. ATmega32A Boundary-scan Order
\begin{tabular}{|c|c|c|}

\subsection*{27.15. Boundary-scan Description Language Files}

Boundary-scan Description Language (BSDL) files describe Boundary-scan capable devices in a standard format used by automated test-generation software. The order and function of bits in the Boundary-scan Data Register are included in this description.
27.16. Register Description

Atmel

\subsection*{27.16.1. OCDR - On-chip Debug Register}

When using the I/O specific commands IN and OUT, the I/O addresses \(0 \times 00-0 \times 3 \mathrm{~F}\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: OCDR
Offset: \(0 \times 31\)
Reset: 0x20
Property: When addressing I/O Registers as data space the offset address is \(0 \times 51\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{Bit} & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & IDRD/OCDR7 & OCDR6 & OCDR5 & OCDR4 & OCDR3 & OCDR2 & OCDR1 & OCDR0 \\
\hline Access & R/W & R/W & R/W & R/W & R/W & R/W & R/W & R/W \\
\hline Reset & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

Bit 7 - IDRD/OCDR7: USART Receive Complete
The OCDR Register provides a communication channel from the running program in the microcontroller to the debugger. The CPU can transfer a byte to the debugger by writing to this location. At the same time, an internal flag; I/O Debug Register Dirty - IDRD - is set to indicate to the debugger that the register has been written. When the CPU reads the OCDR Register the 7 LSB will be from the OCDR Register, while the MSB is the IDRD bit. The debugger clears the IDRD bit when it has read the information.
In some AVR devices, this register is shared with a standard I/O location. In this case, the OCDR Register can only be accessed if the OCDEN fuse is programmed, and the debugger enables access to the OCDR Register. In all other cases, the standard I/O location is accessed.
- Bit 7 is MSB
- Bit 1 is LSB

Refer to the debugger documentation for further information on how to use this register.
Bits 6:0-OCDRn: On-chip Debug Register \(n\) [ \(n=6: 0\) ]

\subsection*{27.16.2. MCUCSR - MCU Control and Status Register}

When using the I/O specific commands \(\operatorname{IN}\) and OUT, the I/O addresses \(0 \times 00-0 \times 3 F\) must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

The MCU Control and Status Register contains control bits for general MCU functions, and provides information on which reset source caused an MCU Reset.

Name: MCUCSR
Offset: \(0 \times 34\)
Reset: \(0 \times 20\)
Property: When addressing I/O Registers as data space the offset address is \(0 \times 54\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & JTD & & & JTRF & & & & \\
\hline Access & R/W & & & R/W & & & & \\
\hline Reset & 0 & & & & & & & \\
\hline
\end{tabular}

\section*{Bit 7 - JTD: JTAG Interface Disable}

When this bit is zero, the JTAG interface is enabled if the JTAGEN fuse is programmed. If this bit is one, the JTAG interface is disabled. In order to avoid unintentional disabling or enabling of the JTAG interface, a timed sequence must be followed when changing this bit: The application software must write this bit to the desired value twice within four cycles to change its value.
If the JTAG interface is left unconnected to other JTAG circuitry, the JTD bit should be set to one. The reason for this is to avoid static current at the TDO pin in the JTAG interface.

Bit 4 - JTRF: JTAG Reset Flag
This bit is set if a Reset is being caused by a logic one in the JTAG Reset Register selected by the JTAG instruction AVR_RESET. This bit is reset by a Power-on Reset, or by writing a logic zero to the flag.

\section*{28. BTLDR - Boot Loader Support - Read-While-Write Self-Programming}

\subsection*{28.1. Features}
- Read-While-Write Self-Programming
- Flexible Boot Memory Size
- High Security (Separate Boot Lock Bits for a Flexible Protection)
- Separate Fuse to Select Reset Vector
- Optimized Page \({ }^{(1)}\) Size
- Code Efficient Algorithm
- Efficient Read-Modify-Write Support

Note: 1. A page is a section in the Flash consisting of several bytes (see Table. No. of Words in a Page and No. of Pages in the Flash in Signal Names) used during programming. The page organization does not affect normal operation.

\section*{Related Links}

Signal Names on page 331

\subsection*{28.2. Overview}

In this device, the Boot Loader Support provides a real Read-While-Write Self-Programming mechanism for downloading and uploading program code by the MCU itself. This feature allows flexible application software updates controlled by the MCU using a Flash-resident Boot Loader program. The Boot Loader program can use any available data interface and associated protocol to read code and write (program) that code into the Flash memory, or read the code from the program memory. The program code within the Boot Loader section has the capability to write into the entire Flash, including the Boot Loader memory. The Boot Loader can thus even modify itself, and it can also erase itself from the code if the feature is not needed anymore. The size of the Boot Loader memory is configurable with fuses and the Boot Loader has two separate sets of Boot Lock bits which can be set independently. This gives the user a unique flexibility to select different levels of protection.

\subsection*{28.3. Application and Boot Loader Flash Sections}

The Flash memory is organized in two main sections, the Application section and the Boot Loader section. The size of the different sections is configured by the BOOTSZ Fuses. These two sections can have different level of protection since they have different sets of Lock bits.

\subsection*{28.3.1. Application Section}

The Application section is the section of the Flash that is used for storing the application code. The protection level for the Application section can be selected by the application Boot Lock bits (Boot Lock bits 0 ). The Application section can never store any Boot Loader code since the SPM instruction is disabled when executed from the Application section.

\subsection*{28.3.2. BLS - Boot Loader Section}

While the Application section is used for storing the application code, the Boot Loader software must be located in the BLS since the SPM instruction can initiate a programming when executing from the BLS only. The SPM instruction can access the entire Flash, including the BLS itself. The protection level for the Boot Loader section can be selected by the Boot Loader Lock bits (Boot Lock bits 1).

\subsection*{28.4. Read-While-Write and No Read-While-Write Flash Sections}

Whether the CPU supports Read-While-Write or if the CPU is halted during a Boot Loader software update is dependent on which address that is being programmed. In addition to the two sections that are configurable by the BOOTSZ Fuses as described above, the Flash is also divided into two fixed sections, the Read-While-Write (RWW) section and the No Read-While-Write (NRWW) section. The limit between the RWW- and NRWW sections is given in the Boot Loader Parameters section and Figure 28-2. The main difference between the two sections is:
- When erasing or writing a page located inside the RWW section, the NRWW section can be read during the operation
- When erasing or writing a page located inside the NRWW section, the CPU is halted during the entire operation

The user software can never read any code that is located inside the RWW section during a Boot Loader software operation. The syntax "Read-While-Write section" refers to which section that is being programmed (erased or written), not which section that actually is being read during a Boot Loader software update.

\section*{Related Links}

ATmega32A Boot Loader Parameters on page 323

\subsection*{28.4.1. RWW - Read-While-Write Section}

If a Boot Loader software update is programming a page inside the RWW section, it is possible to read code from the Flash, but only code that is located in the NRWW section. During an on-going programming, the software must ensure that the RWW section never is being read. If the user software is trying to read code that is located inside the RWW section (i.e. by a call/rjmp/lpm or an interrupt) during programming, the software might end up in an unknown state. To avoid this, the interrupts should either be disabled or moved to the Boot Loader section. The Boot Loader section is always located in the NRWW section. The RWW Section Busy bit (RWWSB) in the Store Program Memory Control Register (SPMCR) will be read as logical one as long as the RWW section is blocked for reading. After a programming is completed, the RWWSB must be cleared by software before reading code located in the RWW section. Please refer to SPMCR - Store Program Memory Control Register in this chapter for details on how to clear RWWSB.

\subsection*{28.4.2. NRWW - No Read-While-Write Section}

The code located in the NRWW section can be read when the Boot Loader software is updating a page in the RWW section. When the Boot Loader code updates the NRWW section, the CPU is halted during the entire Page Erase or Page Write operation.

\section*{Reated Link}

ATmega32A Boot Loader Parameters on page 323

\subsection*{28.5. Boot Loader Lock Bits}

If no Boot Loader capability is needed, the entire Flash is available for application code. The Boot Loader has two separate sets of Boot Lock bits which can be set independently. This gives the user a unique flexibility to select different levels of protection.

The user can select:
- To protect the entire Flash from a software update by the MCU
- To protect only the Boot Loader Flash section from a software update by the MCU
- To protect only the Application Flash section from a software update by the MCU
- Allow software update in the entire Flash

The Boot Lock bits can be set in software and in Serial or Parallel Programming mode, but they can be cleared by a Chip Erase command only. The general Write Lock (Lock Bit mode 2) does not control the programming of the Flash memory by SPM instruction. Similarly, the general Read/Write Lock (Lock Bit mode 1) does not control reading nor writing by LPM/SPM, if it is attempted.

Table 28-2. Boot Lock Bit0 Protection Modes (Application Section)
\begin{tabular}{|l|l|l|l|}
\hline \begin{tabular}{l} 
BLB0 \\
Mode
\end{tabular} & BLB02 & BLB01 & Protection \\
\hline 1 & 1 & 1 & No restrictions for SPM or LPM accessing the Application section. \\

the Application section. If Interrupt Vectors are placed in the Boot Loader \\
section, interrupts are disabled while executing from the Application \\
section.
\end{tabular} \\
\hline
\end{tabular}

Note: "1" means unprogrammed, "0" means programmed.
Table 28-3. Boot Lock Bit1 Protection Modes (Boot Loader Section)
\begin{tabular}{|l|l|l|l|}
\hline \begin{tabular}{l} 
BLB1 \\
Mode
\end{tabular} & BLB12 & BLB11 & Protection \\
\hline 1 & 1 & 1 & No restrictions for SPM or LPM accessing the Boot Loader section. \\
\hline 2 & 1 & 0 & SPM is not allowed to write to the Boot Loader section. \\
\hline 3 & 0 & 0 & \begin{tabular}{l} 
SPM is not allowed to write to the Boot Loader section, and LPM executing \\
from the Application section is not allowed to read from the Boot Loader \\
section. If Interrupt Vectors are placed in the Application section, interrupts \\
are disabled while executing from the Boot Loader section.
\end{tabular} \\
\hline 4 & 0 & 1 & \begin{tabular}{l} 
LPM executing from the Application section is not allowed to read from the \\
Boot Loader section. If Interrupt Vectors are placed in the Application \\
section, interrupts are disabled while executing from the Boot Loader \\
section.
\end{tabular} \\
\hline
\end{tabular}

Note: "1" means unprogrammed, "0" means programmed.

\subsection*{28.6. Entering the Boot Loader Program}

Entering the Boot Loader takes place by a jump or call from the application program. This may be initiated by a trigger such as a command received via USART, or SPI interface. Alternatively, the Boot Reset Fuse can be programmed so that the Reset Vector is pointing to the Boot Flash start address after a reset. In this case, the Boot Loader is started after a reset. After the application code is loaded, the program can start executing the application code. The fuses cannot be changed by the MCU itself. This means that
once the Boot Reset Fuse is programmed, the Reset Vector will always point to the Boot Loader Reset and the fuse can only be changed through the serial or parallel programming interface.

Table 28-4. Boot Reset Fuse
\begin{tabular}{|l|l|}
\hline BOOTRST & Reset Address \\
\hline 1 & Reset Vector \(=\) Application Reset (address 0x0000) \\
\hline 0 & Reset Vector \(=\) Boot Loader Reset, as described by the Boot Loader Parameters \\
\hline
\end{tabular}

Note: '1' means unprogrammed, '0' means programmed.

\subsection*{28.7. Addressing the Flash During Self-Programming}

The Z-pointer is used to address the SPM commands.
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 15 & 14 & 13 & 12 & 11 & 10 & 9 & 8 \\
\hline ZH (R31) & 215 & 214 & 213 & 212 & 211 & z10 & z9 & 28 \\
\hline ZH (R31) & z7 & z6 & z5 & 24 & z3 & z2 & z1 & 0 \\
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline
\end{tabular}

Since the Flash is organized in pages, the Program Counter can be treated as having two different sections. One section, consisting of the least significant bits, is addressing the words within a page, while the most significant bits are addressing the pages. This is shown in the following figure. The Page Erase and Page Write operations are addressed independently. Therefore it is of major importance that the Boot Loader software addresses the same page in both the Page Erase and Page Write operation. Once a programming operation is initiated, the address is latched and the Z-pointer can be used for other operations.
The only SPM operation that does not use the Z-pointer is Setting the Boot Loader Lock bits. The content of the Z-pointer is ignored and will have no effect on the operation. The LPM instruction does also use the Z-pointer to store the address. Since this instruction addresses the Flash byte-by-byte, also the LSB (bit \(Z 0\) ) of the \(Z\)-pointer is used.

Figure 28-3. Addressing the Flash During SPM \({ }^{(1)}\)

\section*{Note:}
1. Fo the different variables used in the figure, see the table of the different variables used and the Mapping to the Z-pointer in the boot loader parameters section.
2. PCPAGE and PCWORD are listed in table Number of Words in a Page and number of Pages in the Flash in the Signal Names section.

\section*{Related Links}

Signal Names on page 331
ATmega32A Boot Loader Parameters on page 323

\subsection*{28.8. Self-Programming the Flash}

The program memory is updated in a page by page fashion. Before programming a page with the data stored in the temporary page buffer, the page must be erased. The temporary page buffer is filled one word at a time using SPM and the buffer can be filled either before the Page Erase command or between a Page Erase and a Page Write operation:

\section*{Alternative 1, fill the buffer before a Page Erase}
- Fill temporary page buffer
- Perform a Page Erase
- Perform a Page Write

\section*{Alternative 2, fill the buffer after Page Erase}
- Perform a Page Erase
- Fill temporary page buffer
- Perform a Page Write

If only a part of the page needs to be changed, the rest of the page must be stored (for example in the temporary page buffer) before the erase, and then be rewritten. When using alternative 1 , the Boot Loader provides an effective Read-Modify-Write feature which allows the user software to first read the page, do the necessary changes, and then write back the modified data. If alternative 2 is used, it is not possible to read the old data while loading since the page is already erased. The temporary page buffer can be accessed in a random sequence. It is essential that the page address used in both the Page Erase and Page Write operation is addressing the same page. Please refer to Simple Assembly Code Example for a Boot Loader for an assembly code example.

\subsection*{28.8.1. Performing Page Erase by SPM}

To execute page erase, set up the address in the Z-pointer, write "X0000011" to SPMCR and execute SPM within four clock cycles after writing SPMCR. The data in R1 and R0 is ignored. The page address must be written to PCPAGE in the Z-register. Other bits in the Z-pointer will be ignored during this operation.
- Page Erase to the RWW section: The NRWW section can be read during the Page Erase.
- Page Erase to the NRWW section: The CPU is halted during the operation.

Note: If an interrupt occurs in the timed sequence the four cycle access cannot be guaranteed. In order to ensure atomic operation disable interrupts before writing to SPMCSR.

\subsection*{28.8.2. Filling the Temporary Buffer (Page Loading)}

To write an instruction word, set up the address in the Z-pointer and data in R1:R0, write "00000001" to SPMCR and execute SPM within four clock cycles after writing SPMCR. The content of PCWORD in the Z-register is used to address the data in the temporary page buffer. The temporary buffer will auto-erase after a page write operation or by writing the RWWSRE bit in SPMCR. It is also erased after a System Reset. Note that it is not possible to write more than one time to each address without erasing the temporary buffer.

Note: If the EEPROM is written in the middle of an SPM Page Load operation, all data loaded will be lost.

\subsection*{28.8.3. Performing a Page Write}

To execute page write, set up the address in the Z-pointer, write "X0000101" to SPMCR and execute SPM within four clock cycles after writing SPMCR. The data in R 1 and \(R 0\) is ignored. The page address must be written to PCPAGE. Other bits in the Z-pointer must be written to zero during this operation.
- Page Write to the RWW section: The NRWW section can be read during the Page Write
- Page Write to the NRWW section: The CPU is halted during the operation

Note: If an interrupt occurs in the timed sequence the four cycle access cannot be guaranteed. In order to ensure atomic operation disable interrupts before writing to SPMCSR.

\subsection*{28.8.4. Using the SPM Interrupt}

If the SPM interrupt is enabled, the SPM interrupt will generate a constant interrupt when the SPMEN bit in SPMCR is cleared. This means that the interrupt can be used instead of polling the SPMCR Register in software. When using the SPM interrupt, the Interrupt Vectors should be moved to the BLS section to avoid that an interrupt is accessing the RWW section when it is blocked for reading. How to move the interrupts is described in Interrupts chapter.

\section*{Related Links}

Interrupts on page 62

\subsection*{28.8.5. Consideration While Updating Boot Loader Section (BLS)}

Special care must be taken if the user allows the Boot Loader Section (BLS) to be updated by leaving Boot Lock bit11 unprogrammed. An accidental write to the Boot Loader itself can corrupt the entire Boot Loader, and further software updates might be impossible. If it is not necessary to change the Boot Loader software itself, it is recommended to program the Boot Lock bit11 to protect the Boot Loader software from any internal software changes.

\subsection*{28.8.6. Prevent Reading the RWW Section During Self-Programming}

During Self-Programming (either page erase or page write), the RWW section is always blocked for reading. The user software itself must prevent that this section is addressed during the self programming operation. The RWWSB in the SPMCR will be set as long as the RWW section is busy. During SelfProgramming the Interrupt Vector table should be moved to the BLS as described in Interrupts, or the interrupts must be disabled. Before addressing the RWW section after the programming is completed, the user software must clear the RWWSB by writing the RWWSRE. Please refer to Simple Assembly Code Example for a Boot Loader for an example.

\section*{Related Links}

Interrupts on page 62

\subsection*{28.8.7. Setting the Boot Loader Lock Bits by SPM}

To set the Boot Loader Lock Bits, write the desired data to R0, write "X0001001" to SPMCR and execute SPM within four clock cycles after writing SPMCR. The only accessible Lock Bits are the Boot Lock Bits that may prevent the Application and Boot Loader section from any software update by the MCU.

The tables in Boot Loader Lock Bits show how the different settings of the Boot Loader bits affect the Flash access.

If bits \(5: 2\) in R0 are cleared (zero), the corresponding Boot Lock bit will be programmed if an SPM instruction is executed within four cycles after BLBSET and SPMEN are set in SPMCR. The Z-pointer is don't care during this operation, but for future compatibility it is recommended to load the Z-pointer with \(0 \times 0001\) (same as used for reading the Lock Bits). For future compatibility It is also recommended to set bits 7, 6, 1, and 0 in R0 to " 1 " when writing the Lock Bits. When programming the Lock Bits the entire Flash can be read during the operation.

\subsection*{28.8.8. EEPROM Write Prevents Writing to SPMCR}

Note that an EEPROM write operation will block all software programming to Flash. Reading the Fuses and Lock Bits from software will also be prevented during the EEPROM write operation. It is recommended that the user checks the status bit (EEWE) in the EECR Register and verifies that the bit is cleared before writing to the SPMCR Register.

\subsection*{28.8.9. Reading the Fuse and Lock Bits from Software}

It is possible to read both the Fuse and Lock Bits from software. To read the Lock Bits, load the Z-pointer with \(0 \times 0001\) and set the BLBSET and SPMEN bits in SPMCR. When an LPM instruction is executed within three CPU cycles after the BLBSET and SPMEN bits are set in SPMCR, the value of the Lock Bits will be loaded in the destination register. The BLBSET and SPMEN bits will auto-clear upon completion of reading the Lock Bits or if no LPM instruction is executed within three CPU cycles or no SPM instruction is executed within four CPU cycles. When BLBSET and SPMEN are cleared, LPM will work as described in the Instruction set Manual.
\begin{tabular}{lc|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline Rd & - & - & BLB12 & BLB11 & BLB02 & BLB01 & LB2 & LB1 \\
\hline
\end{tabular}

The algorithm for reading the Fuse Low bits is similar to the one described above for reading the Lock Bits. To read the Fuse Low bits, load the Z-pointer with 0x0000 and set the BLBSET and SPMEN bits in SPMCR. When an LPM instruction is executed within three cycles after the BLBSET and SPMEN bits are set in the SPMCR, the value of the Fuse Low bits (FLB) will be loaded in the destination register as shown below. Refer to table Fuse Low Byte in section Fuse Bits for a detailed description and mapping of the fuse low bits.
\begin{tabular}{l|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\(\operatorname{Rd}\) & FLB7 & FLB6 & FLB5 & FLB4 & FLB3 & FLB2 & FLB1 & FLB0 \\
\hline
\end{tabular}

Similarly, when reading the Fuse High bits, load 0x0003 in the Z-pointer. When an LPM instruction is executed within three cycles after the BLBSET and SPMEN bits are set in the SPMCR, the value of the Fuse High bits (FHB) will be loaded in the destination register as shown below. Refer to table Fuse High Byte in section Fuse Bits for detailed description and mapping of the fuse high bits.
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline Rd & FHB7 & FHB6 & FHB5 & FHB4 & FHB3 & FHB2 & FHB1 & FHB0 \\
\cline { 2 - 9 } & & & &
\end{tabular}
Fuse and Lock bits that are programmed read as '0'. Fuse and Lock bits that are unprogrammed, will read as '1'.

\subsection*{28.8.10. Preventing Flash Corruption}

During periods of low \(\mathrm{V}_{\mathrm{CC}}\), the Flash program can be corrupted because the supply voltage is too low for the CPU and the Flash to operate properly. These issues are the same as for board level systems using the Flash, and the same design solutions should be applied.

A Flash program corruption can be caused by two situations when the voltage is too low. First, a regular write sequence to the Flash requires a minimum voltage to operate correctly. Secondly, the CPU itself can execute instructions incorrectly, if the supply voltage for executing instructions is too low.
Flash corruption can easily be avoided by following these design recommendations (one is sufficient):
1. If there is no need for a Boot Loader update in the system, program the Boot Loader Lock bits to prevent any Boot Loader software updates.
2. Keep the AVR RESET active (low) during periods of insufficient power supply voltage. This can be done by enabling the internal Brown-out Detector (BOD) if the operating voltage matches the detection level. If not, an external low \(\mathrm{V}_{\mathrm{CC}}\) reset protection circuit can be used. If a reset occurs while a write operation is in progress, the write operation will be completed provided that the power supply voltage is sufficient.
3. Keep the AVR core in Power-down sleep mode during periods of low \(\mathrm{V}_{\mathrm{CC}}\). This will prevent the CPU from attempting to decode and execute instructions, effectively protecting the SPMCR Register and thus the Flash from unintentional writes.

\subsection*{28.8.11. Programming Time for Flash when Using SPM}

The calibrated RC Oscillator is used to time Flash accesses. The following table shows the typical programming time for Flash accesses from the CPU.
Table 28-5. SPM Programming Time \({ }^{(1)}\)
\begin{tabular}{|l|l|l|}
\hline Symbol & Min. Programming Time & Max. Programming Time \\
\hline \begin{tabular}{l} 
Flash write (Page Erase, Page Write, and write Lock bits \\
by SPM)
\end{tabular} & 3.7 ms & 4.5 ms \\
\hline
\end{tabular}

Note: 1. Minimum and maximum programming time is per individual operation.

\subsection*{28.8.12. Simple Assembly Code Example for a Boot Loader}
```

;-the routine writes one page of data from RAM to Flash
; the first data location in RAM is pointed to by the Y pointer
; the first data location in Flash is pointed to by the Z-pointer
;-error handling is not included
;-the routine must be placed inside the boot space
; (at least the Do_spm sub routine). Only code inside NRWW section can
; be read during self-programming (page erase and page write).
;-registers used: r0, r1, temp1 (r16), temp2 (r17), looplo (r24),
; loophi (r25), spmcrval (r20)
; storing and restoring of registers is not included in the routine
; register usage can be optimized at the expense of code size
;-It is assumed that either the interrupt table is moved to the Boot
; loader section or that the interrupts are disabled.
.equ PAGESIZEB = PAGESIZE*2 ;PAGESIZEB is page size in BYTES, not words

\hline
\end{tabular}

Note: The different BOOTSZ Fuse configurations are shown in Figure 28-2.
Table 28-7. Read-While-Write Limit, ATmega32A
\begin{tabular}{|l|l|l|}
\hline Section & Pages & Address \\
\hline Read-While-Write section (RWW) & 224 & \(0 \times 0000-0 \times 37 F F\) \\
\hline No Read-While-Write section (NRWW) & 32 & \(0 \times 3800-0 \times 3 F F F\) \\
\hline
\end{tabular}

Note: For details about these two section, see NRWW - No Read-While-Write Section and RWW -Read-While-Write Section.

Table 28-8. Explanation of Different Variables used in figure "Addressing the Flash During SPM" from earlier in this chapter and the Mapping to the Z-pointer, ATmega32A
\begin{tabular}{|l|l|l|l|}
\hline Variable & & \begin{tabular}{l} 
Corresponding Z- \\
value \({ }^{(1)}\)
\end{tabular} & Description \\
\hline PCMSB & 13 & & \begin{tabular}{l} 
Most significant bit in the Program Counter. (The Program \\
Counter is 14 bits PC[13:0])
\end{tabular} \\
\hline PAGEMSB & 5 & & \begin{tabular}{l} 
Most significant bit which is used to address the words \\
within one page (64 words in a page requires 6 bits PC \\
[5:0]).
\end{tabular} \\
\hline ZPCMSB & Z14 & \begin{tabular}{l} 
Bit in Z-register that is mapped to PCMSB. Because Z0 is \\
not used, the ZPCMSB equals PCMSB + 1.
\end{tabular} \\
\hline ZPAGEMSB & & Z6 & \begin{tabular}{l} 
Bit in Z-register that is mapped to PAGEMSB. Because \\
Z0 is not used, the ZPAGEMSB equals PAGEMSB + 1.
\end{tabular} \\
\hline PCPAGE & PC[13:6] & Z14:Z7 & \begin{tabular}{l} 
Program counter page address: Page select, for page \\
erase and page write
\end{tabular} \\
\hline PCWORD & PC[5:0] & Z6:Z1 & \begin{tabular}{l} 
Program counter word address: Word select, for filling \\
temporary buffer (must be zero during page write \\
operation)
\end{tabular} \\
\hline
\end{tabular}

Note: 1.
Z15: always ignored.
Z0: should be zero for all SPM commands, byte select for the LPM instruction.
See Addressing the Flash During Self-Programming for details about the use of Z-pointer during SelfProgramming.

\subsection*{28.9. Register Description}

\subsection*{28.9.1. SPMCR - Store Program Memory Control Register}

The Store Program Memory Control and Status Register contains the control bits needed to control the Boot Loader operations.

When using the I/O specific commands IN and OUT, the I/O addresses 0x00-0x3F must be used. When addressing I/O Registers as data space using LD and ST instructions, 0x20 must be added to these offset addresses.

Name: SPMCR
Offset: 0x37
Reset: 0x00
Property: When addressing I/O Registers as data space the offset address is \(0 \times 57\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline Bit & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline & SPMIE & RWWSB & & RWWSRE & BLBSET & PGWRT & PGERS & SPMEN \\
\hline Access & R/W & \multicolumn{2}{|l|}{R} & \multirow[t]{2}{*}{R/W} & R/W & R/W & R/W & R/W \\
\hline Reset & & \multicolumn{2}{|l|}{0} & & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

\section*{Bit 7 - SPMIE: SPM Interrupt Enable}

When the SPMIE bit is written to one, and the I-bit in the Status Register is set (one), the SPM ready interrupt will be enabled. The SPM ready Interrupt will be executed as long as the SPMEN bit in the SPMCR Register is cleared.

\section*{Bit 6 - RWWSB: Read-While-Write Section Busy}

When a Self-Programming (page erase or page write) operation to the RWW section is initiated, the RWWSB will be set (one) by hardware. When the RWWSB bit is set, the RWW section cannot be accessed. The RWWSB bit will be cleared if the RWWSRE bit is written to one after a Self-Programming operation is completed. Alternatively the RWWSB bit will automatically be cleared if a page load operation is initiated.

\section*{Bit 4 - RWWSRE: Read-While-Write Section Read Enable}

When programming (Page Erase or Page Write) to the RWW section, the RWW section is blocked for reading (the RWWSB will be set by hardware). To re-enable the RWW section, the user software must wait until the programming is completed (SPMEN will be cleared). Then, if the RWWSRE bit is written to one at the same time as SPMEN, the next SPM instruction within four clock cycles re-enables the RWW section. The RWW section cannot be re-enabled while the Flash is busy with a Page Erase or a Page Write (SPMEN is set). If the RWWSRE bit is written while the Flash is being loaded, the Flash load operation will abort and the data loaded will be lost.

\section*{Bit 3 - BLBSET: Boot Lock Bit Set}

If this bit is written to one at the same time as SPMEN, the next SPM instruction within four clock cycles sets Boot Lock bits, according to the data in R0. The data in R1 and the address in the Z-pointer are ignored. The BLBSET bit will automatically be cleared upon completion of the Lock bit set, or if no SPM instruction is executed within four clock cycles.

An LPM instruction within three cycles after BLBSET and SPMEN are set in the SPMCR Register (SPMCR.BLBSET and SPMCR.SPMEN), will read either the Lock bits or the Fuse bits (depending on Z0 in the Z-pointer) into the destination register.

\section*{Bit 2 - PGWRT: Page Write}

If this bit is written to one at the same time as SPMEN, the next SPM instruction within four clock cycles executes Page Write, with the data stored in the temporary buffer. The page address is taken from the high part of the Zpointer. The data in R1 and R0 are ignored. The PGWRT bit will auto-clear upon completion of a Page Write, or if no SPM instruction is executed within four clock cycles. The CPU is halted during the entire Page Write operation if the NRWW section is addressed.

\section*{Bit 1 - PGERS: Page Erase}

If this bit is written to one at the same time as SPMEN, the next SPM instruction within four clock cycles executes Page Erase. The page address is taken from the high part of the Z-pointer. The data in R1 and R0 are ignored. The PGERS bit will auto-clear upon completion of a Page Erase, or if no SPM instruction is executed within four clock cycles. The CPU is halted during the entire Page Write operation if the NRWW section is addressed.

\section*{Bit 0 - SPMEN: Store Program Memory}

This bit enables the SPM instruction for the next four clock cycles. If written to one together with either RWWSRE, BLBSET, PGWRT or PGERS, the following SPM instruction will have a special meaning, see description above. If only SPMEN is written, the following SPM instruction will store the value in R1:R0 in the temporary page buffer addressed by the Z-pointer. The LSB of the Z-pointer is ignored. The SPMEN bit will auto-clear upon completion of an SPM instruction, or if no SPM instruction is executed within four clock cycles. During Page Erase and Page Write, the SPMEN bit remains high until the operation is completed.
Writing any other combination than "10001", "01001", "00101", "00011" or "00001" in the lower five bits will have no effect.

\section*{29. Memory Programming}

\subsection*{29.1. Program and Data Memory Lock Bits}

The ATmega32A provides six Lock bits. These can be left unprogrammed ('1') or can be programmed ('0') to obtain the additional features listed in table Lock Bit Protection Modes below. The Lock Bits can only be erased to " 1 " with the Chip Erase command.

Table 29-1. Lock Bit Byte
\begin{tabular}{|l|l|l|l|}
\hline Lock Bit Byte & Bit No. & Description & Default Value \(^{\text {(1) }}\) \\
\hline & 7 & - & 1 (unprogrammed) \\
\hline & 6 & - & 1 (unprogrammed) \\
\hline BLB12 & 5 & Boot Lock bit & 1 (unprogrammed) \\
\hline BLB11 & 4 & Boot Lock bit & 1 (unprogrammed) \\
\hline BLB02 & 3 & Boot Lock bit & 1 (unprogrammed) \\
\hline BLB01 & 2 & Boot Lock bit & 1 (unprogrammed) \\
\hline LB2 & 1 & Lock bit & 1 (unprogrammed) \\
\hline LB1 & 0 & Lock bit & 1 (unprogrammed) \\
\hline
\end{tabular}

Note: 1. " 1 " means unprogrammed, " 0 " means programmed.
Table 29-2. Lock Bit Protection Modes \({ }^{(2)}\)
\begin{tabular}{|l|l|l|l|}
\hline \multicolumn{2}{|c|}{ Memory Lock Bits } & \multicolumn{1}{l|}{ Protection Type } \\
\hline LB Mode & LB2 & LB1 & \\
\hline 1 & 1 & 1 & No memory lock features enabled. \\

\hline 1 & 1 & 0 & \begin{tabular}{l} 
SPM is not allowed to write to the Application section.
\end{tabular} \\
\hline 2 & 0 & 0 & \begin{tabular}{l} 
SPM is not allowed to write to the Application section, and LPM executing \\
from the Boot Loader section is not allowed to read from the Application \\
section. If Interrupt Vectors are placed in the Boot Loader section, \\
interrupts are disabled while executing from the Application section.
\end{tabular} \\
\hline 3 & &
\end{tabular}
\begin{tabular}{|l|l|l|l|l|}
\hline \multicolumn{2}{|l|}{ Memory Lock Bits } & Protection Type \\
\hline LB Mode & LB2 & LB1 & \\
\hline 4 & 0 & 1 & \begin{tabular}{l} 
LPM executing from the Boot Loader section is not allowed to read from \\
the Application section. If Interrupt Vectors are placed in the Boot Loader \\
section, interrupts are disabled while executing from the Application \\
section.
\end{tabular} \\
\hline \begin{tabular}{l} 
BLB1 \\
Mode
\end{tabular} & BLB12 & BLB11 & \\
\hline 1 & 1 & 1 & No restrictions for SPM or LPM accessing the Boot Loader section. \\
\hline 2 & 1 & 0 & \begin{tabular}{l} 
SPM is not allowed to write to the Boot Loader section.
\end{tabular} \\
\hline 3 & 0 & 0 & \begin{tabular}{l} 
SPM is not allowed to write to the Boot Loader section, and LPM \\
executing from the Application section is not allowed to read from the Boot \\
Loader section. If Interrupt Vectors are placed in the Application section, \\
interrupts are disabled while executing from the Boot Loader section.
\end{tabular} \\
\hline 4 & 0 & 1 & \begin{tabular}{l} 
LPM executing from the Application section is not allowed to read from the \\
Boot Loader section. If Interrupt Vectors are placed in the Application \\
section, interrupts are disabled while executing from the Boot Loader \\
section.
\end{tabular} \\
\hline
\end{tabular}

\section*{Note:}
1. Program the Fuse Bits before programming the Lock Bits.
2. "1" means unprogrammed, "0" means programmed.

\subsection*{29.2. Fuse Bits}

The ATmega32A has two fuse bytes. The tables of this section describe briefly the functionality of all the fuses and how they are mapped into the fuse bytes. Note that the fuses are read as logical zero, " 0 ", if they are programmed.
Table 29-3. Fuse High Byte
\begin{tabular}{|l|l|l|l|}
\hline Fuse High Byte & Bit No. & Description & Default Value \\
\hline OCDEN \({ }^{(4)}\) & 7 & Enable OCD & \begin{tabular}{l}
1 (unprogrammed, OCD \\
disabled)
\end{tabular} \\
\hline JTAGEN \(^{(5)}\) & 6 & Enable JTAG & 0 (programmed, JTAG enabled) \\
\hline SPIEN \(^{(1)}\) & 5 & \begin{tabular}{l} 
Enable Serial Program and Data \\
Downloading
\end{tabular} & \begin{tabular}{l}
0 (programmed, SPI prog. \\
enabled)
\end{tabular} \\
\hline CKOPT \(^{(2)}\) & 4 & Oscillator options & 1 (unprogrammed) \\
\hline EESAVE & 3 & \begin{tabular}{l} 
EEPROM memory is preserved through the \\
Chip Erase
\end{tabular} & \begin{tabular}{l}
1 (unprogrammed, EEPROM \\
not preserved)
\end{tabular} \\
\hline BOOTSZ1 & 2 & \begin{tabular}{l} 
Select Boot Size (see table Boot Size \\
Configuration in section ATmega32A Boot \\
Loader Parameters for details)
\end{tabular} & 0 (programmed) \({ }^{(3)}\) \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|l|}
\hline Fuse High Byte & Bit No. & Description & Default Value \\
\hline BOOTSZO & 1 & \begin{tabular}{l} 
Select Boot Size (see table Boot Size \\
Configuration in section ATmega32A Boot \\
Loader Parameters for details)
\end{tabular} & 0 (programmed) \({ }^{(3)}\) \\
\hline BOOTRST & 0 & Select Reset Vector & 1 (unprogrammed) \\
\hline
\end{tabular}

\section*{Note:}
1. The SPIEN Fuse is not accessible in SPI Serial Programming mode.
2. The CKOPT Fuse functionality depends on the setting of the CKSEL bits, see Clock Sources for details.
3. The default value of BOOTSZ1:0 results in maximum Boot Size. See table Boot Size Configuration in section ATmega32A Boot Loader Parameters.
4. Never ship a product with the OCDEN Fuse programmed regardless of the setting of lock bits and the JTAGEN Fuse. A programmed OCDEN Fuse enables some parts of the clock system to be running in all sleep modes. This may increase the power consumption.
5. If the JTAG interface is left unconnected, the JTAGEN fuse should if possible be disabled. This to avoid static current at the TDO pin in the JTAG interface.

Table 29-4. Fuse Low Byte
\begin{tabular}{|c|c|c|c|}
\hline Fuse Low Byte & Bit No. & Description & Default Value \\
\hline BODLEVEL & 7 & Brown out detector trigger level & 1 (unprogrammed) \\
\hline BODEN & 6 & Brown out detector enable & 1 (unprogrammed, BOD disabled) \\
\hline SUT1 & 5 & Select start-up time & 1 (unprogrammed) \({ }^{(1)}\) \\
\hline SUTO & 4 & Select start-up time & 0 (programmed) \({ }^{(1)}\) \\
\hline CKSEL3 & 3 & Select Clock source & 0 (programmed) \({ }^{(2)}\) \\
\hline CKSEL2 & 2 & Select Clock source & 0 (programmed) \({ }^{(2)}\) \\
\hline CKSEL1 & 1 & Select Clock source & 0 (programmed) \({ }^{(2)}\) \\
\hline CKSELO & 0 & Select Clock source & 1 (unprogrammed) \({ }^{(2)}\) \\
\hline
\end{tabular}

\section*{Note:}
1. The default value of SUT1:0 results in maximum start-up time. See table Start-up Times for the Internal Calibrated RC Oscillator Clock Selection in section Calibrated Internal RC Oscillator for details.
2. The default setting of CKSEL3:0 results in Internal RC Oscillator @ 1MHz. See table Device Clocking Options Select in section Clock Sources for details.

The status of the Fuse bits is not affected by Chip Erase. Note that the Fuse bits are locked if Lock bit1 (LB1) is programmed. Program the Fuse bits before programming the Lock bits.

\section*{Related Links}

ATmega32A Boot Loader Parameters on page 323
Clock Sources on page 40
Calibrated Internal RC Oscillator on page 43

\subsection*{29.2.1. Latching of Fuses}

The fuse values are latched when the device enters programming mode and changes of the fuse values will have no effect until the part leaves Programming mode. This does not apply to the EESAVE Fuse which will take effect once it is programmed. The fuses are also latched on Power-up in Normal mode.

\subsection*{29.3. Signature Bytes}

All Atmel microcontrollers have a three-byte signature code which identifies the device. This code can be read in both serial and parallel mode, also when the device is locked. The three bytes reside in a separate address space.

For the ATmega32A the signature bytes are given in the following table.
Table 29-5. Device and JTAG ID
\begin{tabular}{|l|l|l|l|l|l|}
\hline Part & \multicolumn{3}{|l|}{ Signature Bytes Address } & & JTAG \\
\hline & \(0 \times 000\) & \(0 \times 001\) & \(0 \times 002\) & Part Number & Manufacture ID \\
\hline ATmega32A & \(0 \times 1\) E & \(0 \times 95\) & \(0 \times 02\) & 9502 & \(0 \times 1 F\) \\
\hline
\end{tabular}

\subsection*{29.4. Signature Bytes}

All Atmel microcontrollers have a three-byte signature code which identifies the device. This code can be read in both serial and parallel mode, also when the device is locked. The three bytes reside in a separate address space.

For the ATmega32A the signature bytes are given in the following table.
Table 29-6. Device and JTAG ID
\begin{tabular}{|l|l|l|l|l|l|}
\hline Part & Signature Bytes Address & & JTAG & \\
\hline & \(0 \times 000\) & \(0 \times 001\) & \(0 \times 002\) & Part Number & Manufacture ID \\
\hline ATmega32A & \(0 \times 1\) E & \(0 \times 96\) & \(0 \times 02\) & 9602 & \(0 \times 1 F\) \\
\hline
\end{tabular}

\subsection*{29.5. Calibration Byte}

The ATmega32A stores four different calibration values for the internal RC Oscillator. These bytes resides in the signature row High byte of the addresses \(0 \times 0000,0 \times 0001,0 \times 0002\), and \(0 \times 0003\) for 1, 2, 4, and 8 MHz respectively. During Reset, the 1 MHz value is automatically loaded into the OSCCAL Register. If other frequencies are used, the calibration value has to be loaded manually, see OSCCAL - Oscillator Calibration Register for details.

\section*{Related Links}

OSCCAL on page 46

\subsection*{29.6. Parallel Programming Parameters, Pin Mapping, and Commands}

This section describes how to parallel program and verify Flash Program memory, EEPROM Data memory, Memory Lock bits, and Fuse bits in the device. Pulses are assumed to be at least 250ns unless otherwise noted.

\subsection*{29.6.1. Signal Names}

In this section, some pins of this device are referenced by signal names describing their functionality during parallel programming, refer to the following figure and table Pin Name Mapping in this section. Pins not described in the following table are referenced by pin names.

The XA1/XA0 pins determine the action executed when the XTAL1 pin is given a positive pulse. The bit coding is shown in Table 29-9.

When pulsing WR or \(\overline{\mathrm{OE}}\), the command loaded determines the action executed. The different Commands are shown in Table 29-10.

\subsection*{29.7. Parallel Programming}

\subsection*{29.7.1. Enter Programming Mode}

The following algorithm puts the device in Parallel Programming mode:
1. Apply \(4.5-5.5 \mathrm{~V}\) between \(\mathrm{V}_{\mathrm{CC}}\) and GND , and wait at least \(100 \mu \mathrm{~s}\).
2. Set RESET to " 0 " and toggle XTAL1 at least 6 times
3. Set the Prog_enable pins listed in Table 29-8 to "0000" and wait at least 100 ns .
 applied to RESET, will cause the device to fail entering Programming mode.

Note, if External Crystal or External RC configuration is selected, it may not be possible to apply qualified XTAL1 pulses. In such cases, the following algorithm should be followed:
1. Set Prog_enable pins listed in Table 29-8 to "0000".
2. Apply \(4.5-5.5 \mathrm{~V}\) between \(\mathrm{V}_{\mathrm{CC}}\) and GND simultaneously as \(11.5-12.5 \mathrm{~V}\) is applied to RESET.
3. Wait \(100 \mu \mathrm{~s}\).
4. Re-program the fuses to ensure that External Clock is selected as clock source (CKSEL3:0 = 0b0000). If Lock bits are programmed, a Chip Erase command must be executed before changing the fuses.
5. Exit Programming mode by power the device down or by bringing RESET pin to 0b0.
6. Entering Programming mode with the original algorithm, as described above.

\subsection*{29.7.2. Considerations for Efficient Programming}

The loaded command and address are retained in the device during programming. For efficient programming, the following should be considered.
- The command needs only be loaded once when writing or reading multiple memory locations.
- Skip writing the data value \(0 x F F\), that is the contents of the entire EEPROM (unless the EESAVE Fuse is programmed) and Flash after a Chip Erase.
- Address high byte needs only be loaded before programming or reading a new 256 word window in Flash or 256 byte EEPROM. This consideration also applies to Signature bytes reading.

\subsection*{29.7.3. Chip Erase}

The Chip Erase will erase the Flash, the SRAM and the EEPROM memories plus Lock bits. The Lock bits are not reset until the program memory has been completely erased. The Fuse bits are not changed. A Chip Erase must be performed before the Flash and/or EEPROM are reprogrammed.

Note: The EEPRPOM memory is preserved during Chip Erase if the EESAVE Fuse is programmed.
Load Command "Chip Erase":
1. Set XA1, XA0 to " 10 ". This enables command loading.
2. Set BS1 to "0".
3. Set DATA to " 10000000 ". This is the command for Chip Erase.
4. Give XTAL1 a positive pulse. This loads the command.
5. Give \(\overline{W R}\) a negative pulse. This starts the Chip Erase. RDY/ \(\overline{\mathrm{BSY}}\) goes low.
6. Wait until RDY/ \(\overline{\mathrm{BSY}}\) goes high before loading a new command.

\subsection*{29.7.4. Programming the Flash}

The Flash is organized in pages, see Table 29-10. When programming the Flash, the program data is latched into a page buffer. This allows one page of program data to be programmed simultaneously. The following procedure describes how to program the entire Flash memory:

\section*{Step A. Load Command "Write Flash".}
1. Set XA1, XA0 to " 10 ". This enables command loading.
2. Set BS1 to " 0 ".
3. Set DATA to "0001 0000". This is the command for Write Flash.
4. Give XTAL1 a positive pulse. This loads the command.

\section*{Step B. Load Address Low Byte.}
1. Set XA1, XA0 to " 00 ". This enables address loading.
2. Set BS1 to " 0 ". This selects low address.
3. Set DATA = Address low byte ( \(0 \times 00-0 \times F F\) ).
4. Give XTAL1 a positive pulse. This loads the address low byte.

\section*{Step C. Load Data Low Byte.}
1. Set XA1, XA0 to " 01 ". This enables data loading.
2. Set DATA = Data low byte ( \(0 \times 00-0 \times F F\) ).
3. Give XTAL1 a positive pulse. This loads the data byte.

\section*{Step D. Load Data High Byte.}
1. Set BS1 to "1". This selects high data byte.
2. Set XA1, XA0 to " 01 ". This enables data loading.
3. Set DATA \(=\) Data high byte \((0 \times 00-0 \times F F)\).
4. Give XTAL1 a positive pulse. This loads the data byte.

\section*{Step E. Latch Data.}
1. Set BS1 to "1". This selects high data byte.
2. Give PAGEL a positive pulse. This latches the data bytes. (Refer to the last figure in this section on programming the Flash waveforms.)

Step F. Repeat B through E until the entire buffer is filled or until all data within the page is loaded. While the lower bits in the address are mapped to words within the page, the higher bits address the pages within the FLASH. This is illustrated in the following figure in this section. Note that if less than eight bits are required to address words in the page (pagesize < 256), the most significant bit(s) in the address low byte are used to address the page when performing a Page Write.

\section*{Step G. Load Address High byte.}
1. Set XA1, XA0 to " 00 ". This enables address loading.
2. Set BS1 to "1". This selects high address.
3. Set DATA \(=\) Address high byte \((0 \times 00-0 x F F)\).
4. Give XTAL1 a positive pulse. This loads the address high byte.

\section*{Step H. Program Page.}
1. Set BS1 = "0"
2. Give \(\overline{W R}\) a negative pulse. This starts programming of the entire page of data. RDY/BSY goes low.
3. Wait until RDY/BSY goes high (Refer to the last figure on programming the Flash waveforms in this section).

\section*{Step I. Repeat B through H until the entire Flash is programmed or until all data has been programmed.}

\section*{Step J. End Page Programming.}
1. 1. Set XA1, XA0 to " 10 ". This enables command loading.
2. Set DATA to " 00000000 ". This is the command for No Operation.
3. Give XTAL1 a positive pulse. This loads the command, and the internal write signals are reset.

Figure 29-2. Addressing the Flash Which is Organized in Pages

Note: PCPAGE and PCWORD are listed in Table 29-11.

Figure 29-3. Programming the Flash Waveforms

Note: " \(X X\) " is don't care. The letters refer to the programming description above.

\subsection*{29.7.5. Programming the EEPROM}

The EEPROM is organized in pages, see Table 29-12, in the Page Size section. When programming the EEPROM, the program data is latched into a page buffer. This allows one page of data to be programmed simultaneously. The programming algorithm for the EEPROM data memory is as follows (For details on Command, Address and Data loading, refer to Programming the Flash):
1. Step A: Load Command "0001 0001".
2. Step G: Load Address High Byte (0x00-0xFF).
3. Step B: Load Address Low Byte (0x00-0xFF).
4. Step C: Load Data (0x00-0xFF).
5. Step E: Latch data (give PAGEL a positive pulse).
6. Step K:Repeat 3 through 5 until the entire buffer is filled.
7. Step L: Program EEPROM page
7.1. Set BS1 to "0".
7.2. Give \(\overline{\mathrm{WR}}\) a negative pulse. This starts programming of the EEPROM page. RDY/ \(\overline{\mathrm{BSY}}\) goes low.
7.3. Wait until to RDY/ \(\overline{\mathrm{BSY}}\) goes high before programming the next page. Refer to the figure below for signal waveforms.

Figure 29-4. Programming the EEPROM Waveforms

\subsection*{29.7.6. Reading the Flash}

The algorithm for reading the Flash memory is as follows (Please refer to Programming the Flash in this chapter for details on Command and Address loading):
1. Step A: Load Command "0000 0010".
2. Step G: Load Address High Byte ( \(0 \times 00-0 x F F\) ).
3. Step B: Load Address Low Byte ( \(0 \times 00-0 x F F\) ).
4. Set \(\overline{\mathrm{OE}}\) to " 0 ", and BS1 to " 0 ". The Flash word low byte can now be read at DATA.
5. Set BS1 to "1". The Flash word high byte can now be read at DATA.
6. Set \(\overline{\mathrm{OE}}\) to " 1 ".

\subsection*{29.7.7. Reading the EEPROM}

The algorithm for reading the EEPROM memory is as follows (Please refer to Programming the Flash for details on Command and Address loading):
1. Step A: Load Command "0000 0011".
2. Step G: Load Address High Byte ( \(0 \times 00-0 \times F F\) ).
3. Step B: Load Address Low Byte ( \(0 \times 00-0 x F F\) ).
4. Set \(\overline{O E}\) to " 0 ", and BS1 to " 0 ". The EEPROM Data byte can now be read at DATA.
5. Set \(\overline{O E}\) to " 1 ".

\subsection*{29.7.8. Programming the Fuse Low Bits}

The algorithm for programming the Fuse Low bits is as follows (Please refer to Programming the Flash for details on Command and Data loading):
1. Step A: Load Command "0100 0000".
2. Step C: Load Data Low Byte. Bit \(\mathrm{n}=\) " 0 " programs and bit \(\mathrm{n}=\) " 1 " erases the Fuse bit.
3. Set BS1 and BS2 to "0".
4. Give \(\overline{W R}\) a negative pulse and wait for \(R D Y / \overline{B S Y}\) to go high.

\subsection*{29.7.9. Programming the Fuse High Bits}

The algorithm for programming the Fuse High bits is as follows (Please refer to Programming the Flash for details on Command and Data loading):
1. Step A: Load Command "0100 0000".
2. Step C: Load Data Low Byte. Bit \(\mathrm{n}=\) " 0 " programs and bit \(\mathrm{n}=\) " 1 " erases the Fuse bit.
3. Set BS1 to "1" and BS2 to "0". This selects high data byte.
4. Give WR a negative pulse and wait for RDY/BSY to go high.
5. Set BS1 to "0". This selects low data byte.

Figure 29-5. Programming the FUSES Waveforms

\subsection*{29.7.10. Programming the Lock Bits}

The algorithm for programming the Lock bits is as follows (Please refer to Programming the Flash for details on Command and Data loading):
1. Step A: Load Command "0010 0000".
2. Step C: Load Data Low Byte. Bit \(\mathrm{n}=\) " 0 " programs the Lock bit.
3. Give \(\overline{\mathrm{WR}}\) a negative pulse and wait for RDY/ \(\overline{\mathrm{BSY}}\) to go high.

The Lock bits can only be cleared by executing Chip Erase.

\subsection*{29.7.11. Reading the Fuse and Lock Bits}

The algorithm for reading the Fuse and Lock bits is as follows (Please refer to Programming the Flash for details on Command loading):
1. Step A: Load Command "0000 0100".
2. Set \(\overline{O E}\) to " 0 ", BS2 to " 0 ", and BS1 to " 0 ". The status of the Fuse Low bits can now be read at DATA ("0" means programmed).
3. Set \(\overline{O E}\) to " 0 ", BS2 to " 1 ", and BS1 to " 1 ". The status of the Fuse High bits can now be read at DATA ("0" means programmed).
4. Set \(\overline{\mathrm{OE}}\) to " 0 ", BS2 to " 0 ", and BS1 to " 1 ". The status of the Lock Bits can now be read at DATA ("0" means programmed).
5. Set OE to "1".

Figure 29-6. Mapping Between BS1, BS2 and the Fuse and Lock Bits During Read

\subsection*{29.7.12. Reading the Signature Bytes}

The algorithm for reading the Signature bytes is as follows (Please refer to Programming the Flash for details on Command and Address loading):
1. Step A: Load Command "0000 1000".
2. Step B: Load Address Low Byte (0x00-0x02).
3. Set \(\overline{O E}\) to " 0 ", and BS1 to "0". The selected Signature byte can now be read at DATA.
4. Set \(\overline{O E}\) to "1".

\subsection*{29.7.13. Reading the Calibration Byte}

The algorithm for reading the Calibration byte is as follows (Please refer to Programming the Flash for details on Command and Address loading):
1. Step A: Load Command "0000 1000".
2. Step B: Load Address Low byte, (0x00-0x03).
3. Set \(\overline{O E}\) to " 0 ", and BS1 to " 1 ". The Calibration byte can now be read at DATA.
4. Set \(\overline{O E}\) to " 1 ".

\subsection*{29.7.14. Parallel Programming Characteristics}

Figure 29-7. Parallel Programming Timing, Including some General Timing Requirements

Figure 29-8. Parallel Programming Timing, Loading Sequence with Timing Requirements \({ }^{(1)}\)

Note: 1. The timing requirements shown in the first figure in this section (i.e., \(\mathrm{t}_{\mathrm{DVXH}}, \mathrm{t}_{\mathrm{XHXL}}\), and \(\mathrm{t}_{\mathrm{XLDX}}\) ) also apply to loading operation.

Figure 29-9. Parallel Programming Timing, Reading Sequence (within the same Page) with Timing Requirements \({ }^{(1)}\)

Note: 1. The timing requirements shown in the first figure in this section (i.e., \(\mathrm{t}_{\mathrm{DVXH}}, \mathrm{t}_{\mathrm{XHXL}}\), and \(\mathrm{t}_{\mathrm{XLDX}}\) ) also apply to reading operation.

Table 29-13. Parallel Programming Characteristics, VCC \(=5 \mathrm{~V} \pm 10 \%\)
\begin{tabular}{|l|l|l|l|l|l|}
\hline Symbol & Parameter & Min & Typ & Max & Units \\
\hline \(\mathrm{V}_{\text {PP }}\) & Programming Enable Voltage & 11.5 & & 12.5 & V \\

\hline \(\mathrm{t}_{\text {OHDZ }}\) & \(\overline{\text { OE High to DATA Tri-stated }}\) & & & 250 & ns \\
\hline
\end{tabular}

\section*{Note:}
1. \(t_{W L R H}\) is valid for the Write Flash, Write EEPROM, Write Fuse Bits and Write Lock Bits commands.
2. \(t_{\text {WLRH_CE }}\) is valid for the Chip Erase command.

\subsection*{29.8. Serial Downloading}

Both the Flash and EEPROM memory arrays can be programmed using the serial SPI bus while RESET is pulled to GND. The serial interface consists of pins SCK, MOSI (input) and MISO (output). After RESET is set low, the Programming Enable instruction needs to be executed first before program/erase operations can be executed.
Note: The pin mapping for SPI programming is listed in the following section. Not all parts use the SPI pins dedicated for the internal SPI interface.

\subsection*{29.9. Serial Programming Pin Mapping}

Table 29-14. Pin Mapping Serial Programming
\begin{tabular}{|l|l|l|l|}
\hline Symbol & Pins & I/O & Description \\
\hline MOSI & PB5 & I & Serial Data in \\
\hline MISO & PB6 & O & Serial Data out \\
\hline SCK & PB7 & I & Serial Clock \\
\hline
\end{tabular}

Figure 29-10. Serial Programming and Verify \({ }^{(1)}\)

\section*{Note:}
1. If the device is clocked by the Internal Oscillator, it is no need to connect a clock source to the XTAL1 pin.
2. \(\mathrm{V}_{\mathrm{CC}}-0.3<\mathrm{AV}_{\mathrm{CC}}<\mathrm{V}_{\mathrm{CC}}+0.3\), however, \(A \mathrm{~V}_{\mathrm{CC}}\) should always be within \(2.7-5.5 \mathrm{~V}\).

When programming the EEPROM, an auto-erase cycle is built into the self-timed programming operation (in the Serial mode ONLY) and there is no need to first execute the Chip Erase instruction. The Chip Erase operation turns the content of every memory location in both the Program and EEPROM arrays into 0xFF.

Depending on CKSEL Fuses, a valid clock must be present. The minimum low and high periods for the Serial Clock (SCK) input are defined as follows:

Low: > 2 CPU clock cycles for \(f_{c k}<12 \mathrm{MHz}, 3 \mathrm{CPU}\) clock cycles for \(\mathrm{f}_{\mathrm{ck}} \geq 12 \mathrm{MHz}\)
High: \(>2\) CPU clock cycles for \(f_{c k}<12 \mathrm{MHz}, 3 \mathrm{CPU}\) clock cycles for \(\mathrm{f}_{\mathrm{ck}} \geq 12 \mathrm{MHz}\)

\subsection*{29.9.1. Serial Programming Algorithm}

When writing serial data to the ATmega32A, data is clocked on the rising edge of SCK.
When reading data from the ATmega32A, data is clocked on the falling edge of SCK. Please refer to the figure, Figure 29-11 in SPI Serial Programming Characteristics section for timing details.

To program and verify the ATmega32A in the serial programming mode, the following sequence is recommended (See Serial Programming Instruction set in Table 29-16 Serial Programming Waveforms:
1. Power-up sequence:

Apply power between \(V_{C C}\) and GND while RESET and SCK are set to " 0 ". In some systems, the programmer can not guarantee that SCK is held low during power-up. In this case, \(\overline{R E S E T}\) must be given a positive pulse of at least two CPU clock cycles duration after SCK has been set to "0".
2. Wait for at least 20 ms and enable serial programming by sending the Programming Enable serial instruction to pin MOSI.
3. The serial programming instructions will not work if the communication is out of synchronization. When in sync. the second byte ( \(0 \times 53\) ), will echo back when issuing the third byte of the Programming Enable instruction. Whether the echo is correct or not, all four bytes of the instruction must be transmitted. If the \(0 \times 53\) did not echo back, give RESET a positive pulse and issue a new Programming Enable command.
4. The Flash is programmed one page at a time. The memory page is loaded one byte at a time by supplying the 6 LSB of the address and data together with the Load Program Memory Page instruction. To ensure correct loading of the page, the data low byte must be loaded before data high byte is applied for a given address. The Program Memory Page is stored by loading the Write Program Memory Page instruction with the 8 MSB of the address. If polling is not used, the user must wait at least \(\mathrm{t}_{\text {WD_f }}\) fash before issuing the next page.
5. Note: If other commands than polling (read) are applied before any write operation (FLASH, EEPROM, Lock Bits, Fuses) is completed, it may result in incorrect programming.
6. The EEPROM array is programmed one byte at a time by supplying the address and data together with the appropriate Write instruction. An EEPROM memory location is first automatically erased before new data is written. If polling is not used, the user must wait at least twd_EePRom before issuing the next byte. In a chip erased device, no 0xFFs in the data file(s) need to be programmed.
7. Any memory location can be verified by using the Read instruction which returns the content at the selected address at serial output MISO.
8. At the end of the programming session, RESET can be set high to commence normal operation.
9. Power-off sequence (if needed):

Set RESET to " 1 ".
Turn \(\mathrm{V}_{\mathrm{Cc}}\) power off.

\subsection*{29.9.2. Data Polling Flash}

When a page is being programmed into the Flash, reading an address location within the page being programmed will give the value \(0 \times F F\). At the time the device is ready for a new page, the programmed value will read correctly. This is used to determine when the next page can be written. Note that the entire page is written simultaneously and any address within the page can be used for polling. Data polling of the Flash will not work for the value 0xFF, so when programming this value, the user will have to wait for at least \(t_{\text {WD_FLASH }}\) before programming the next page. As a chip-erased device contains 0xFF in all locations, programming of addresses that are meant to contain 0xFF, can be skipped. See table in next section for \(\mathrm{t}_{\text {WD_FLASH }}\) value.

\subsection*{29.9.3. Data Polling EEPROM}

When a new byte has been written and is being programmed into EEPROM, reading the address location being programmed will give the value 0xFF. At the time the device is ready for a new byte, the programmed value will read correctly. This is used to determine when the next byte can be written. This will not work for the value 0xFF, but the user should have the following in mind: As a chip-erased device contains 0xFF in all locations, programming of addresses that are meant to contain 0xFF, can be skipped. This does not apply if the EEPROM is programmed without chip-erasing the device. In this case, data polling cannot be used for the value 0xFF, and the user will have to wait at least twd_EEPROM before programming the next byte. See table below for \(\mathrm{t}_{\text {wd_EEPRom }}\) value.

Table 29-15. Minimum Wait Delay Before Writing the Next Flash or EEPROM Location, \(\mathrm{V}_{\mathrm{CC}}=\mathbf{5 V} \pm \mathbf{1 0 \%}\)
\begin{tabular}{|l|l|}
\hline Symbol & Minimum Wait Delay \\
\hline\(t_{\text {WD_FUSE }}\) & 4.5 ms \\
\hline\(t_{\text {WD_FLASH }}\) & 4.5 ms \\
\hline\(t_{\text {WD_EEPROM }}\) & 9 ms \\
\hline\(t_{\text {WD_ERASE }}\) & 9 ms \\
\hline
\end{tabular}

\subsection*{29.9.4. SPI Serial Programming Characteristics}

For characteristics of the SPI module, see SPI Timing Characteristics.

\section*{Related Links}

SPI Timing Characteristics on page 365

\subsection*{29.10. Programming Via the JTAG Interface}

Programming through the JTAG interface requires control of the four JTAG specific pins: TCK, TMS, TDI, and TDO. Control of the Reset and clock pins is not required.

To be able to use the JTAG interface, the JTAGEN fuse must be programmed. The device is default shipped with the Fuse programmed. In addition, the JTD bit in MCUCSR must be cleared. Alternatively, if the JTD bit is set, the external reset can be forced low. Then, the JTD bit will be cleared after two chip clocks, and the JTAG pins are available for programming. This provides a means of using the JTAG pins as normal port pins in running mode while still allowing In-System Programming via the JTAG interface. Note that this technique can not be used when using the JTAG pins for Boundary-scan or On-chip Debug. In these cases the JTAG pins must be dedicated for this purpose.
As a definition in this data sheet, the LSB is shifted in and out first of all Shift Registers.

\subsection*{29.10.1. Programming Specific JTAG Instructions}

The instruction register is 4-bit wide, supporting up to 16 instructions. The JTAG instructions useful for Programming are listed below.

The OPCODE for each instruction is shown behind the instruction name in hex format. The text describes which data register is selected as path between TDI and TDO for each instruction.

The Run-Test/Idle state of the TAP controller is used to generate internal clocks. It can also be used as an idle state between JTAG sequences. The state machine sequence for changing the instruction word is shown in the figure below.

Figure 29-12. State Machine Sequence for Changing the Instruction Word

\subsection*{29.10.2. AVR_RESET (0xC)}

The AVR specific public JTAG instruction for setting the AVR device in the Reset mode or taking the device out from the Reset mode. The TAP controller is not reset by this instruction. The one bit Reset

Register is selected as Data Register. Note that the reset will be active as long as there is a logic 'one' in the Reset Chain. The output from this chain is not latched.

The active states are:
- Shift-DR: The Reset Register is shifted by the TCK input.

\subsection*{29.10.3. PROG_ENABLE ( \(0 \times 4\) )}

The AVR specific public JTAG instruction for enabling programming via the JTAG port. The 16-bit Programming Enable Register is selected as data register. The active states are the following:
- Shift-DR: the programming enable signature is shifted into the data register.
- Update-DR: the programming enable signature is compared to the correct value, and Programming mode is entered if the signature is valid.

\subsection*{29.10.4. PROG_COMMANDS (0x5)}

The AVR specific public JTAG instruction for entering programming commands via the JTAG port. The 15bit Programming Command Register is selected as data register. The active states are the following:
- Capture-DR: the result of the previous command is loaded into the data register.
- Shift-DR: the data register is shifted by the TCK input, shifting out the result of the previous command and shifting in the new command.
- Update-DR: the programming command is applied to the Flash inputs.
- Run-Test/Idle: one clock cycle is generated, executing the applied command.

\subsection*{29.10.5. PROG_PAGELOAD (0x6)}

The AVR specific public JTAG instruction to directly load the Flash data page via the JTAG port. The 1024-bit Virtual Flash Page Load Register is selected as data register. This is a virtual scan chain with length equal to the number of bits in one Flash page. Internally the Shift Register is 8 -bit. Unlike most JTAG instructions, the Update-DR state is not used to transfer data from the Shift Register. The data are automatically transferred to the Flash page buffer byte by byte in the Shift-DR state by an internal state machine. This is the only active state:
- Shift-DR: Flash page data are shifted in from TDI by the TCK input, and automatically loaded into the Flash page one byte at a time.

Note: 1. The JTAG instruction PROG_PAGELOAD can only be used if the AVR device is the first device in JTAG scan chain. If the AVR cannot be the first device in the scan chain, the byte-wise programming algorithm must be used.

\subsection*{29.10.6. PROG_PAGEREAD (0x7)}

The AVR specific public JTAG instruction to read one full Flash data page via the JTAG port. The 1032-bit Virtual Flash Page Read Register is selected as data register. This is a virtual scan chain with length equal to the number of bits in one Flash page plus 8 . Internally the Shift Register is 8 -bit. Unlike most JTAG instructions, the Capture-DR state is not used to transfer data to the Shift Register. The data are automatically transferred from the Flash page buffer byte by byte in the Shift-DR state by an internal state machine. This is the only active state:
- Shift-DR: Flash data are automatically read one byte at a time and shifted out on TDO by the TCK input. The TDI input is ignored.

Note: 1. The JTAG instruction PROG_PAGEREAD can only be used if the AVR device is the first device in JTAG scan chain. If the AVR cannot be the first device in the scan chain, the byte-wise programming algorithm must be used.

\subsection*{29.10.7. Data Registers}

The data registers are selected by the JTAG instruction registers described in section Programming Specific JTAG Instructions. The data registers relevant for programming operations are:
- Reset Register
- Programming Enable Register
- Programming Command Register
- Virtual Flash Page Load Register
- Virtual Flash Page Read Register

\subsection*{29.10.8. Reset Register}

The Reset Register is a Test Data Register used to reset the part during programming. It is required to reset the part before entering programming mode.
A high value in the Reset Register corresponds to pulling the external Reset low. The part is reset as long as there is a high value present in the Reset Register. Depending on the Fuse settings for the clock options, the part will remain reset for a Reset Time-Out Period (refer to Clock Sources) after releasing the Reset Register. The output from this Data Register is not latched, so the reset will take place immediately, as shown in figure Reset Register.

\section*{Related Links}

Clock Sources on page 40
Reset Register on page 289

\subsection*{29.10.9. Programming Enable Register}

The Programming Enable Register is a 16-bit register. The contents of this register is compared to the programming enable signature, binary code 1010_0011_0111_0000. When the contents of the register is equal to the programming enable signature, programming via the JTAG port is enabled. The Register is reset to 0 on Power-on Reset, and should always be reset when leaving Programming mode.

Figure 29-13. Programming Enable Register

\subsection*{29.10.10. Programming Command Register}

The Programming Command Register is a 15-bit register. This register is used to serially shift in programming commands, and to serially shift out the result of the previous command, if any. The JTAG

Programming Instruction Set is shown in the following table. The state machine sequence when shifting in the programming commands is illustrated in the last figure in this section.

Figure 29-14. Programming Command Register

\section*{Note:}
1. This command sequence is not required if the seven MSB are correctly set by the previous command sequence (which is normally the case).
2. Repeat until \(0=" 1 "\).
3. Set bits to "0" to program the corresponding fuse, "1" to unprogram the Fuse.
4. Set bits to "0" to program the corresponding lock bit, " 1 " to leave the Lock bit unchanged.
5. " 0 " = programmed, " \(1 "=\) unprogrammed.
6. The bit mapping for Fuses High byte is listed in Table 29-3
7. The bit mapping for Fuses Low byte is listed in Table 29-4
8. The bit mapping for Lock bits byte is listed in Table 29-1
9. Address bits exceeding PCMSB and EEAMSB (Table 29-10 and Table 29-11) are don't care

Figure 29-15. State Machine Sequence for Changing/Reading the Data Word

\subsection*{29.10.11. Virtual Flash Page Load Register}

The Virtual Flash Page Load Register is a virtual scan chain with length equal to the number of bits in one Flash page. Internally the Shift Register is 8 -bit, and the data are automatically transferred to the Flash page buffer byte by byte. Shift in all instruction words in the page, starting with the LSB of the first instruction in the page and ending with the MSB of the last instruction in the page. This provides an efficient way to load the entire Flash page buffer before executing Page Write.

Figure 29-16. Virtual Flash Page Load Register

\subsection*{29.10.12. Virtual Flash Page Read Register}

The Virtual Flash Page Read Register is a virtual scan chain with length equal to the number of bits in one Flash page plus 8. Internally the Shift Register is 8-bit, and the data are automatically transferred from the Flash data page byte by byte. The first eight cycles are used to transfer the first byte to the internal Shift Register, and the bits that are shifted out during these 8 cycles should be ignored. Following this initialization, data are shifted out starting with the LSB of the first instruction in the page and ending with the MSB of the last instruction in the page. This provides an efficient way to read one full Flash page to verify programming.

Figure 29-17. Virtual Flash Page Read Register

\subsection*{29.10.13. Programming Algorithm}

All references below of type "1a", "1b", and so on, refer to Table 29-17.

\subsection*{29.10.14. Entering Programming Mode}
1. Enter JTAG instruction AVR_RESET and shift 1 in the Reset Register.
2. Enter instruction PROG_ENABLE and shift 1010_0011_0111_0000 in the Programming Enable Register.

\subsection*{29.10.15. Leaving Programming Mode}
1. Enter JTAG instruction PROG_COMMANDS.
2. Disable all programming instructions by using no operation instruction 11a.
3. Enter instruction PROG_ENABLE and shift 0000_0000_0000_0000 in the programming Enable Register.
4. Enter JTAG instruction AVR_RESET and shift 0 in the Reset Register.

\subsection*{29.10.16. Performing Chip Erase}
1. Enter JTAG instruction PROG_COMMANDS.
2. Start chip erase using programming instruction 1a.
3. Poll for chip erase complete using programming instruction 1 b , or wait for \(\mathrm{t}_{\text {WLRH_CE }}\) (refer to table Command Byte Bit Coding in section Parallel Programming Parameters, Pin Mapping, and Commands).

\section*{Related Links}

Parallel Programming Characteristics on page 339

\subsection*{29.10.17. Programming the Flash}

Before programming the Flash a Chip Erase must be performed. See Performing Chip Erase.
1. Enter JTAG instruction PROG_COMMANDS.
2. Enable Flash write using programming instruction 2a.
3. Load address high byte using programming instruction 2 b .
4. Load address low byte using programming instruction 2 c .
5. Load data using programming instructions \(2 \mathrm{~d}, 2 \mathrm{e}\) and 2 f .
6. Repeat steps 4 and 5 for all instruction words in the page.
7. Write the page using programming instruction 2 g .
8. Poll for Flash write complete using programming instruction 2 h , or wait for \(\mathrm{t}_{\text {WLRH }}\) (refer to table Parallel Programming Characteristics, VCC \(=5 \mathrm{~V} \pm 10 \%\) in chapter Parallel Programming Characteristics).
9. Repeat steps 3 to 7 until all data have been programmed.

A more efficient data transfer can be achieved using the PROG_PAGELOAD instruction:
1. Enter JTAG instruction PROG_COMMANDS.
2. Enable Flash write using programming instruction 2 a .
3. Load the page address using programming instructions \(2 b\) and 2 c . PCWORD (refer to Table 29-10) is used to address within one page and must be written as 0 .
4. Enter JTAG instruction PROG_PAGELOAD.
5. Load the entire page by shifting in all instruction words in the page, starting with the LSB of the first instruction in the page and ending with the MSB of the last instruction in the page.
6. Enter JTAG instruction PROG_COMMANDS.
7. Write the page using programming instruction 2 g .
8. Poll for Flash write complete using programming instruction 2 h , or wait for \(\mathrm{t}_{\text {WLRH }}\) (refer to table Parallel Programming Characteristics, VCC \(=5 \mathrm{~V} \pm 10 \%\) in chapter Parallel Programming Characteristics).
9. Repeat steps 3 to 8 until all data have been programmed.

\subsection*{29.10.18. Reading the Flash}
1. Enter JTAG instruction PROG_COMMANDS.
2. Enable Flash read using programming instruction 3a.
3. Load address using programming instructions 3 b and 3 c .
4. Read data using programming instruction 3d.
5. Repeat steps 3 and 4 until all data have been read.

A more efficient data transfer can be achieved using the PROG_PAGEREAD instruction:
1. Enter JTAG instruction PROG_COMMANDS.
2. Enable Flash read using programming instruction 3a.
3. Load the page address using programming instructions 3 b and 3 c . PCWORD (refer to table Command Byte Bit Coding in section Parallel Programming Parameters, Pin Mapping, and Commands) is used to address within one page and must be written as 0 .
4. Enter JTAG instruction PROG_PAGEREAD.
5. Read the entire page by shifting out all instruction words in the page, starting with the LSB of the first instruction in the page and ending with the MSB of the last instruction in the page. Remember that the first 8 bits shifted out should be ignored.
6. Enter JTAG instruction PROG_COMMANDS.
7. Repeat steps 3 to 6 until all data have been read.

\section*{Related Links}

\subsection*{29.10.22. Programming the Lock Bits}
1. Enter JTAG instruction PROG_COMMANDS.
2. Enable Lock bit write using programming instruction 7 a .
3. Load data using programming instructions 7 b . A bit value of " 0 " will program the corresponding lock bit, a " 1 " will leave the lock bit unchanged.
4. Write Lock bits using programming instruction 7c.
5. Poll for Lock bit write complete using programming instruction 7d, or wait for twLRH \(^{\text {(refer to table }}\) Parallel Programming Characteristics, VCC \(=5 \mathrm{~V} \pm 10 \%\) in chapter Parallel Programming Characteristics).

\section*{Related Links}

Parallel Programming Characteristics on page 339

\subsection*{29.10.23. Reading the Fuses and Lock Bits}
1. Enter JTAG instruction PROG_COMMANDS.
2. Enable Fuse/Lock bit read using programming instruction 8a.
3. - To read all Fuses and Lock bits, use programming instruction 8 e .
- To only read Fuse high byte, use programming instruction 8b.
- To only read Fuse low byte, use programming instruction 8c.
- To only read Lock bits, use programming instruction 8d.

\subsection*{29.10.24. Reading the Signature Bytes}
1. Enter JTAG instruction PROG_COMMANDS.
2. Enable Signature byte read using programming instruction 9 a.
3. Load address \(0 \times 00\) using programming instruction 9 b .
4. Read first signature byte using programming instruction 9 c .
5. Repeat steps 3 and 4 with address \(0 \times 01\) and address \(0 \times 02\) to read the second and third signature bytes, respectively.

\subsection*{29.10.25. Reading the Calibration Byte}
1. Enter JTAG instruction PROG_COMMANDS.
2. Enable Calibration byte read using programming instruction 10a.
3. Load address \(0 \times 00\) using programming instruction 10 b .
4. Read the calibration byte using programming instruction 10c.

\section*{30. Electrical Characteristics}

Table 30-1. Absolute Maximum Ratings*

\end{tabular}

\section*{Note:}
1. "Max" means the highest value where the pin is guaranteed to be read as low
2. "Min" means the lowest value where the pin is guaranteed to be read as high
3. Although each I/O port can sink more than the test conditions ( 20 mA at \(\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, 10 \mathrm{~mA}\) at \(\mathrm{V}_{\mathrm{CC}}=\) 3 V ) under steady state conditions (non-transient), the following must be observed:

PDIP Package:
3.1. The sum of all IOL, for all ports, should not exceed 200 mA .
3.2. The sum of all IOL, for ports A0-A7 should not exceed 100 mA .
3.3. The sum of all IOL, for ports B0-B7, C0-C7, DO-D7 and XTAL2, should not exceed 100 mA .

TQFP and QFN/MLF Package:
3.1. The sum of all IOL, for all ports, should not exceed 400 mA .
3.2. The sum of all IOL, for ports A0-A7, should not exceed 100 mA .
3.3. The sum of all IOL, for ports B0-B4, should not exceed 100 mA .
3.4. The sum of all IOL, for ports B3-B7, XTAL2, D0 - D2, should not exceed 100 mA .
3.5. The sum of all IOL, for ports D3-D7, should not exceed 100 mA .
3.6. The sum of all IOL, for ports C0-C7, should not exceed 100 mA .

If IOL exceeds the test condition, VOL may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test condition.
4. Although each \(\mathrm{I} / \mathrm{O}\) port can source more than the test conditions ( 20 mA at \(\mathrm{Vcc}=5 \mathrm{~V}, 10 \mathrm{~mA}\) at Vcc \(=3 \mathrm{~V}\) ) under steady state conditions (non-transient), the following must be observed:

PDIP Package:
4.1. The sum of all IOH , for all ports, should not exceed 200 mA .
4.2. The sum of all IOH , for port A0-A7, should not exceed 100 mA .
4.3. The sum of all IOH, for ports B0-B7,C0-C7, D0-D7 and XTAL2, should not exceed 100 mA .

TQFP and QFN/MLF Package:
4.1. The sum of all IOH , for all ports, should not exceed 400 mA .
4.2. The sum of all \(I O H\), for ports \(A 0-A 7\), should not exceed 100 mA .
4.3. The sum of all IOH , for ports \(\mathrm{BO} 0-\mathrm{B} 4\), should not exceed 100 mA .
4.4. The sum of all \(I O H\), for ports B3-B7, XTAL2, D0 - D2, should not exceed 100 mA .
4.5. The sum of all IOH, for ports D3-D7, should not exceed 100 mA .
4.6. The sum of all IOH , for ports \(\mathrm{C} 0-\mathrm{C} 7\), should not exceed 100 mA .

If IOH exceeds the test condition, VOH may exceed the related specification. Pins are not guaranteed to source current greater than the listed test condition.
5. Minimum VCC for Power-down is 2.5 V .

\hline
\end{tabular}

Table 30-4. External RC Oscillator, Typical Frequencies
\begin{tabular}{|l|l|l|}
\hline \(\mathbf{R}\left[\mathbf{k} \mathbf{Q}^{(1)}\right.\) & \(\mathrm{C}[\mathrm{pF}]\) & \(\mathbf{f}^{(2)}\) \\
\hline 33 & 22 & 650 kHz \\
\hline 10 & 22 & 2.0 MHz \\
\hline
\end{tabular}

\section*{Note:}
1. \(R\) should be in the range \(3 \mathrm{k} \Omega-100 \mathrm{k} \Omega\), and \(C\) should be at least 20 pF . The \(C\) values given in the table includes pin capacitance. This will vary with package type.
2. The frequency will vary with package type and board layout.

\subsection*{30.4. System and Reset Characteristics}

Table 30-5. Reset, Brown-out and Internal Voltage Reference Characteristics
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline Symbol & Parameter & Condition & Min & Typ & Max & Units \\
\hline \(\mathrm{V}_{\text {POT }}\) & Power-on Reset Threshold Voltage (rising) \({ }^{(1)}\) & & & 1.4 & 2.3 & V \\
\hline & Power-on Reset Threshold Voltage (falling) & & & 1.3 & 2.3 & V \\
\hline \(\mathrm{~V}_{\text {RST }}\) & RESET Pin Threshold Voltage & & 0.2 & & 0.9 & \(\mathrm{~V}_{\mathrm{CC}}\) \\
\hline \(\mathrm{t}_{\text {RST }}\) & Minimum pulse width on RESET Pin & & & & 1.5 & \(\mu \mathrm{~s}\) \\
\hline \(\mathrm{~V}_{\text {BOT }}\) & Brown-out Reset Threshold Voltage \({ }^{(2)}\) & BODLEVEL \(=1\) & 2.5 & 2.7 & 2.9 & V \\
\hline & & BODLEVEL \(=0\) & 3.6 & 4.0 & 4.2 & \\
\hline \(\mathrm{t}_{\text {BOD }}\) & Minimum low voltage period for Brown-out Detection & BODLEVEL \(=1\) & & 2 & & \(\mu \mathrm{~s}\) \\
\hline & & BODLEVEL \(=0\) & & 2 & & \(\mu \mathrm{~s}\) \\
\hline \(\mathrm{~V}_{\text {HYST }}\) & Brown-out Detector hysteresis & & & 50 & & mV \\
\hline \(\mathrm{V}_{\text {BG }}\) & Bandgap reference voltage & & 1.15 & 1.23 & 1.35 & V \\
\hline \(\mathrm{t}_{\text {BG }}\) & Bandgap reference start-up time & & & 40 & 70 & \(\mu \mathrm{~s}\) \\
\hline \(\mathrm{I}_{\mathrm{BG}}\) & Bandgap reference current consumption & & & 10 & & \(\mu \mathrm{~s}\) \\
\hline
\end{tabular}

\section*{Note:}
1. The Power-on Reset will not work unless the supply voltage has been below \(\mathrm{V}_{\mathrm{POT}}\) (falling).
2. \(\mathrm{V}_{\text {BOT }}\) may be below nominal minimum operating voltage for some devices. For devices where this is the case, the device is tested down to \(\mathrm{V}_{\mathrm{CC}}=\mathrm{V}_{\mathrm{BOT}}\) during the production test. This guarantees that a Brown-out Reset will occur before \(\mathrm{V}_{\mathrm{CC}}\) drops to a voltage where correct operation of the microcontroller is no longer guaranteed. The test is performed using BODLEVEL \(=1\) and BODLEVEL = 0 for ATmega32A.

\subsection*{30.5. Two-wire Serial Interface Characteristics}

The table below describes the requirements for devices connected to the Two-wire Serial Bus. The ATmega32A Two-wire Serial Interface meets or exceeds these requirements under the noted conditions.

Timing symbols refer to Figure 30-3.

Table 30-6. Two-wire Serial Bus Requirements
\begin{tabular}{|c|c|c|c|c|c|}
\hline Symbol & Parameter & Condition & Min & Max & Units \\
\hline \(\mathrm{V}_{\text {IL }}\) & Input Low-voltage & & -0.5 & \(0.3 \mathrm{~V}_{\text {CC }}\) & V \\

\hline & & \(\mathrm{f}_{\text {SCL }}>100 \mathrm{kHz}\) & 100 & - & ns \\
\hline \multirow[t]{2}{*}{\(\mathrm{t}_{\text {Su; }}\) Sto} & \multirow[t]{2}{*}{Setup time for STOP condition} & \(\mathrm{f}_{\text {SCL }} \leq 100 \mathrm{kHz}\) & 4.0 & - & \(\mu \mathrm{s}\) \\
\hline & & \(\mathrm{f}_{\text {SCL }}>100 \mathrm{kHz}\) & 0.6 & - & \(\mu \mathrm{s}\) \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|l|l|l|}
\hline Symbol & Parameter & Condition & Min & Max & Units \\
\hline \(\mathrm{t}_{\text {BUF }}\) & \begin{tabular}{l} 
Bus free time between a STOP \\
and START condition
\end{tabular} & \(\mathrm{f}_{\mathrm{SCL}} \leq 100 \mathrm{kHz}\) & 4.7 & - & \(\mu \mathrm{s}\) \\
\hline & \(\mathrm{f}_{\mathrm{SCL}}>100 \mathrm{kHz}\) & 1.3 & - & \(\mu \mathrm{s}\) \\
\hline
\end{tabular}

\section*{Note:}
1. In ATmega32A, this parameter is characterized and not \(100 \%\) tested.
2. Required only for \(f_{S C L}>100 \mathrm{kHz}\).
3. \(\mathrm{C}_{\mathrm{b}}=\) capacitance of one bus line in pF .
4. \(\mathrm{f}_{\mathrm{CK}}=\mathrm{CPU}\) clock frequency
5. This requirement applies to all ATmega32A Two-wire Serial Interface operation. Other devices connected to the Two-wire Serial Bus need only obey the general \(\mathrm{f}_{\mathrm{SCL}}\) requirement.
Figure 30-3. Two-wire Serial Bus Timing

\subsection*{30.6. SPI Timing Characteristics}

See figures below for details.

\section*{31. Typical Characteristics}

Some of the Status Flags are cleared by writing a logical one to them. Note that the CBI and SBI instructions will operate on all bits in the I/O Register, writing a one back into any flag read as set, thus clearing the flag. The CBI and SBI instructions work with registers \(\$ 00\) to \(\$ 1 F\) only.

The power consumption in Power-down mode is independent of clock selection.
The current consumption is a function of several factors such as: operating voltage, operating frequency, loading of I/O pins, switching rate of I/O pins, code executed and ambient temperature. The dominating factors are operating voltage and frequency.
The current drawn from capacitive loaded pins may be estimated (for one pin) as \(C_{L}{ }^{*} V_{C C}{ }^{*} f\) where \(C_{L}=\) load capacitance, \(\mathrm{V}_{\mathrm{CC}}=\) operating voltage and \(\mathrm{f}=\) average switching frequency of \(\mathrm{I} / \mathrm{O}\) pin.
The parts are characterized at frequencies higher than test limits. Parts are not guaranteed to function properly at frequencies higher than the ordering code indicates.
The difference between current consumption in Power-down mode with Watchdog Timer enabled and Power-down mode with Watchdog Timer disabled represents the differential current drawn by the Watchdog Timer.

\end{tabular}

\section*{Note:}
1. When the OCDEN Fuse is unprogrammed, the OSCCAL Register is always accessed on this address. Refer to the debugger specific documentation for details on how to use the OCDR Register.
2. Refer to the USART description for details on how to access UBRRH and UCSRC.
3. For compatibility with future devices, reserved bits should be written to zero if accessed. Reserved I/O memory addresses should never be written.
4. Some of the Status Flags are cleared by writing a logical one to them. Note that the CBI and SBI instructions will operate on all bits in the I/O Register, writing a one back into any flag read as set, thus clearing the flag. The CBI and SBI instructions work with registers \(0 \times 00\) to \(0 \times 1 \mathrm{~F}\) only.

\section*{33. Instruction Set Summary}
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multicolumn{4}{|l|}{ARITHMETIC AND LOGIC INSTRUCTIONS} & & \\
\hline Mnemonics & Operands & Description & Operation & Flags & \#Clocks \\
\hline ADD & Rd, Rr & Add two Registers & \(\mathrm{Rd} \leftarrow \mathrm{Rd}+\mathrm{Rr}\) & Z,C,N,V,H & 1 \\
\hline ADC & Rd, Rr & Add with Carry two Registers & \(\mathrm{Rd} \leftarrow \mathrm{Rd}+\mathrm{Rr}+\mathrm{C}\) & Z,C,N,V,H & 1 \\
\hline ADIW & Rdı, K & Add Immediate to Word & Rdh:Rdl \(\leftarrow\) Rdh:Rdl +K & Z,C,N,V,S & 2 \\
\hline SUB & Rd, Rr & Subtract two Registers & \(\mathrm{Rd} \leftarrow \mathrm{Rd}-\mathrm{Rr}\) & Z, C,N,V,H & 1 \\
\hline SUBI & Rd, K & Subtract Constant from Register & \(\mathrm{Rd} \leftarrow \mathrm{Rd}-\mathrm{K}\) & Z,C,N,V,H & 1 \\
\hline SBC & Rd, Rr & Subtract with Carry two Registers & \(\mathrm{Rd} \leftarrow \mathrm{Rd}-\mathrm{Rr}-\mathrm{C}\) & Z,C,N,V,H & 1 \\
\hline SBCI & Rd, K & Subtract with Carry Constant from Reg. & \(\mathrm{Rd} \leftarrow \mathrm{Rd}-\mathrm{K}-\mathrm{C}\) & Z,C,N,V,H & 1 \\
\hline SBIW & Rdl, K & Subtract Immediate from Word & Rdh:Rdl \(\leftarrow\) Rdh:Rdl - K & Z, C,N,V,S & 2 \\
\hline AND & Rd, Rr & Logical AND Registers & \(\mathrm{Rd} \leftarrow \mathrm{Rd} \cdot \mathrm{Rr}\) & Z,N,V & 1 \\
\hline ANDI & Rd, K & Logical AND Register and Constant & \(\mathrm{Rd} \leftarrow \mathrm{Rd} \cdot \mathrm{K}\) & Z,N,V & 1 \\
\hline OR & Rd, Rr & Logical OR Registers & \(\mathrm{Rd} \leftarrow \mathrm{Rd} \vee \mathrm{Rr}\) & Z,N,V & 1 \\
\hline ORI & Rd, K & Logical OR Register and Constant & \(\mathrm{Rd} \leftarrow \mathrm{Rd} v \mathrm{~K}\) & Z,N,V & 1 \\
\hline EOR & Rd, Rr & Exclusive OR Registers & \(\mathrm{Rd} \leftarrow \mathrm{Rd} \oplus \mathrm{Rr}\) & Z,N,V & 1 \\
\hline COM & Rd & One's Complement & \(\mathrm{Rd} \leftarrow 0 \mathrm{xFF}-\mathrm{Rd}\) & Z,C,N,V & 1 \\
\hline NEG & Rd & Two's Complement & \(\mathrm{Rd} \leftarrow 0 \times 00-\mathrm{Rd}\) & Z,C,N,V,H & 1 \\
\hline SBR & Rd, K & Set Bit(s) in Register & \(\mathrm{Rd} \leftarrow \mathrm{Rd} v \mathrm{~K}\) & Z,N,V & 1 \\
\hline CBR & Rd, K & Clear Bit(s) in Register & \(\mathrm{Rd} \leftarrow \mathrm{Rd} \cdot(0 x F F-K)\) & Z,N,V & 1 \\
\hline INC & Rd & Increment & \(\mathrm{Rd} \leftarrow \mathrm{Rd}+1\) & Z,N,V & 1 \\
\hline DEC & Rd & Decrement & \(\mathrm{Rd} \leftarrow \mathrm{Rd}-1\) & Z,N,V & 1 \\
\hline TST & Rd & Test for Zero or Minus & \(\mathrm{Rd} \leftarrow \mathrm{Rd} \cdot \mathrm{Rd}\) & Z,N,V & 1 \\
\hline CLR & Rd & Clear Register & \(\mathrm{Rd} \leftarrow \mathrm{Rd} \oplus \mathrm{Rd}\) & Z,N,V & 1 \\
\hline SER & Rd & Set Register & \(\mathrm{Rd} \leftarrow 0 \mathrm{xFF}\) & None & 1 \\
\hline MUL & Rd, Rr & Multiply Unsigned & \(\mathrm{R} 1: \mathrm{R0} 5 \mathrm{Rd} \times \mathrm{Rr}\) & Z, C & 2 \\
\hline MULS & Rd, Rr & Multiply Signed & \(\mathrm{R} 1: \mathrm{R0} \leftarrow \mathrm{Rd} \times \mathrm{Rr}\) & Z,C & 2 \\
\hline MULSU & Rd, Rr & Multiply Signed with Unsigned & \(\mathrm{R} 1: \mathrm{R0} 5 \mathrm{Rd} \times \mathrm{Rr}\) & Z,C & 2 \\
\hline FMUL & Rd, Rr & Fractional Multiply Unsigned & R1:R0 \(\leftarrow(\mathrm{Rd} \times \mathrm{Rr}) \ll 1\) & Z, C & 2 \\
\hline FMULS & Rd, Rr & Fractional Multiply Signed & \(\mathrm{R} 1: \mathrm{R0} \leftarrow(\mathrm{Rd} \times \mathrm{Rr}) \ll 1\) & Z, C & 2 \\
\hline FMULSU & Rd, Rr & Fractional Multiply Signed with Unsigned & \(\mathrm{R} 1: \mathrm{R} 0 \leftarrow(\mathrm{Rd} \times \mathrm{Rr}) \ll 1\) & Z, C & 2 \\

\section*{34. Packaging Information}

\subsection*{34.1. 44-pin TQFP}

Notes:
1. This package conforms to JEDEC reference MS-026, Variation ACB.
2. Dimensions D1 and E1 do not include mold protrusion. Allowable protrusion is 0.25 mm perside. Dimensions D1 and E1 are maximum plastic body size dimensions including mold mismatch.
3 . Lead coplanarity is 0.10 mm maximum.

\subsection*{34.2. 40-pin PDIP}

Notes:
1. This package conforms to JEDEC reference MS-011, Variation AC.
2. Dimensions D and E1 do not include mold Flash or Protrusion. Mold Flash or Protrusion shall not exceed 0.25 mm (0.010").

\subsection*{34.3. 44-pin VQFN}

\section*{35. Errata}

\subsection*{35.1. ATmega32A, rev. J to rev. K}
- First Analog Comparator conversion may be delayed
- Interrupts may be lost when writing the timer registers in the asynchronous timer
- IDCODE masks data from TDI input
- Reading EEPROM by using ST or STS to set EERE bit triggers unexpected interrupt request.
1. First Analog Comparator conversion may be delayed

If the device is powered by a slow rising \(\mathrm{V}_{\mathrm{CC}}\), the first Analog Comparator conversion will take longer than
expected on some devices.

\section*{Problem Fix/Workaround}

When the device has been powered or reset, disable then enable the Analog Comparator before the first conversion.
2. Interrupts may be lost when writing the timer registers in the asynchronous timer

The interrupt will be lost if a timer register that is synchronous timer clock is written when the asynchronous
Timer/Counter register (TCNTx) is \(0 \times 00\).

\section*{Problem Fix/Workaround}

Always check that the asynchronous Timer/Counter register neither have the value 0xFF nor 0x00 before writing
to the asynchronous Timer Control Register (TCCRx), asynchronous Timer Counter Register (TCNTx), or asynchronous Output Compare Register (OCRx).
3. IDCODE masks data from TDI input

The JTAG instruction IDCODE is not working correctly. Data to succeeding devices are replaced by all-ones
during Update-DR.

\section*{Problem Fix / Workaround}
- If ATmega32A is the only device in the scan chain, the problem is not visible.
- Select the Device ID Register of the ATmega32A by issuing the IDCODE instruction or by entering the Test-Logic-Reset state of the TAP controller to read out the contents of its Device ID Register and possibly data from succeeding devices of the scan chain. Issue the BYPASS instruction to the ATmega32A while reading the Device ID Registers of preceding devices of the boundary scan chain.
- If the Device IDs of all devices in the boundary scan chain must be captured simultaneously, the ATmega32A must be the fist device in the chain.
4. Reading EEPROM by using ST or STS to set EERE bit triggers unexpected interrupt request.

Reading EEPROM by using the ST or STS command to set the EERE bit in the EECR register triggers an
unexpected EEPROM interrupt request.
Problem Fix / Workaround
Always use OUT or SBI to set EERE in EECR.

\subsection*{35.2. ATmega32A, rev. G to rev. I}
- First Analog Comparator conversion may be delayed
- Interrupts may be lost when writing the timer registers in the asynchronous timer
- IDCODE masks data from TDI input
- Reading EEPROM by using ST or STS to set EERE bit triggers unexpected interrupt request.

\section*{1. First Analog Comparator conversion may be delayed}

\section*{36. Datasheet Revision History}

Please note that the referring page numbers in this section are referred to this document. The referring revision in this section refers to the document revision.

\subsection*{36.1. 8155I-08/2016}
1. Configuration Summary: Pin count and GPIO numbers updated.
36.2. 8155H-08/2016
1. Updated TQFP (44-pins) pinout drawing:
- Pin 42 changed to PB2 (AIN0/INT2) instead of PB2 (AINO/T2)
- Swapped the pin position of XTAL2 and XTAL1: XTAL2 on the pin 7 and XTAL1 on the pin 8
2. Updated PDIP (40-pins) pinout drawing:
- Pin 32 changed to PB2 (AINO/INT2) instead of PB2 (AINO/T2)
- Swapped the pin position of XTAL2 and XTAL1: XTAL2 on the pin 12 and XTAL1 on the pin 13
3. Removed the table note from the Table 25-1 Analog Comparator Multiplexed Input

\subsection*{36.3. 8155G-10/2015}
1. Updated the pinout.
2. New AVR MCU Core drawing added.

\subsection*{36.4. 8155F - 08/2015}
1. New workflow used for the publication.

\subsection*{36.5. 8155E-02/2014}
1. Updated the Features with Capacitive touch sensing capability.
2. Added Errata: ATmega32A, rev. J to rev. K.
36.6. 8155D - 10/2013
1. Added nominal values for symbol \(B, C\) and \(L\) in the TQFP-44 package drawing, 44-pin TQFP.
36.7. 8155C-02/2011
1. Updated the datasheet according to the Atmel new brand style guide (new logo, last page, etc).
2. Inserted note in Performing Page Erase by SPM.
3. Note 6 and Note 7 below Table 30-6 have been removed.
4. Updated Ordering Information to include Tape \& Reel and \(105^{\circ} \mathrm{C}\) devices.
5. Updated all Typical Characteristics.

\subsection*{36.8. 8155B-07/2009}
1. Updated Errata.
2. Updated the last page with Atmel's new addresses.
36.9. 8155A - 06/2008
1. Initial revision (Based on the ATmega32/L datasheet 2503N-AVR-06/08)

Changes done compared ATmega32/L datasheet 2503N-AVR-06/08:
- Updated description in Stack Pointer.
- All Electrical characteristics is moved to Electrical Characteristics.
- Register descriptions are moved to sub sections at the end of each chapter.
- Test limits of Reset Pull-up Resistor ( \(\mathrm{R}_{\mathrm{RST}}\) ) in DC Characteristics.
- New graphs in Typical Characteristics.
- New Ordering Information.
