

FEATURES

- Output fanout buffer for DC to 134MHz
- Output Options:
 - 1:5 output fanout with *PL123-05*
 - 1:9 output fanout with *PL123-09*
- Low power consumption for portable applications
- Low input-output delay
- Output-Output skew less than 250ps
- Low Additive Phase Jitter of 60fs RMS
- 2.5V to 3.3V, $\pm 10\%$ operation
- 1.8V $\pm 10\%$ operation up to 67MHz
- Operating temperature range from -40°C to 85°C
- Available in 16-Pin SOP (PL123-09) and 8-Pin SOP (PL123-05). Both are GREEN/RoHS packages.

DESCRIPTION

The PL123-05N and PL123-09N are a low-cost fanout buffers for distributing high-speed clocks with low output to output skew and preserving low noise properties. The fanout buffers accept an input from DC to 134MHz and provide 5 or 9 outputs of the same frequency. A typical PL123-09N application for driving SDRAM in PC systems would use eight outputs to drive two DIMMs, or four SO-DIMMs, with the remaining output used for driving an external feedback to a PLL. A typical PL123-05N application is to fanout a low noise CMOS clock oscillator to 5 low noise CMOS clocks.

These parts are not intended for 5V input-tolerant applications.

LAYOUT RECOMMENDATIONS

The following guidelines are to assist you with a performance optimized PCB design:

Signal Integrity and Termination Considerations

- Keep traces short!
- Trace = Inductor. With a capacitive load this equals ringing!
- Long trace = Transmission Line. Without proper termination this will cause reflections (looks like ringing).
- Design long traces (> 1 inch) as "striplines" or "microstrips" with defined impedance.
- Match trace at one side to avoid reflections bouncing back and forth.

Decoupling and Power Supply Considerations

- Place decoupling capacitors as close as possible to the VDD pin(s) to limit noise from the power supply
- Addition of a ferrite bead in series with VDD can help prevent noise from other board sources
- Value of decoupling capacitor is frequency dependant. Typical values to use are 0.1 μ F for designs using frequencies < 50MHz and 0.01 μ F for designs using frequencies > 50MHz.

Typical CMOS termination

Place Series Resistor as close as possible to CMOS output

Connect a 33 ohm series resistor at each of the output clocks to enhance the stability of the output signal

Notes:

1. REF input has a threshold voltage of V_{DD}/2
2. Parameter is guaranteed by design and characterization. Not 100% tested in production.
3. All parameters are specified with loaded outputs.

NOISE CHARACTERISTICS (Commercial and Industrial Temperature Devices)

Parameter	Description	Test Conditions	Min.	Typ.	Max.	Unit
	Additive Phase Jitter	V _{DD} =3.3V, Frequency=100MHz Offset=12KHz ~ 20MHz		60		fs

PL123-09N Additive Phase Jitter:
V_{DD}=3.3V, CLK=100MHz, Integration Range 12KHz to 20MHz: 0.059ps typical.

When a buffer is used to pass a signal then the buffer will add a little bit of its own noise. The phase noise on the output of the buffer will be a little bit more than the phase noise in the input signal. To quantify the noise addition in the buffer we compare the Phase Jitter numbers from the input and the output. The difference is called "Additive Phase Jitter". The formula for the Additive Phase Jitter is as follows:

$$\text{Additive Phase Jitter} = \sqrt{(\text{Output Phase Jitter})^2 - (\text{Input Phase Jitter})^2}$$
