## General Description

The MAX1044 and ICL7660 are monolithic, CMOS switched-capacitor voltage converters that invert, double, divide, or multiply a positive input voltage. They are pin compatible with the industry-standard ICL7660 and LTC1044. Operation is guaranteed from 1.5 V to 10 V with no external diode over the full temperature range. They deliver 10 mA with a 0.5 V output drop. The MAX1044 has a BOOST pin that raises the oscillator frequency above the audio band and reduces external capacitor size requirements.
The MAX1044/ICL7660 combine low quiescent current and high efficiency. Oscillator control circuitry and four power MOSFET switches are included on-chip. Applications include generating a -5 V supply from a +5 V logic supply to power analog circuitry. For applications requiring more power, the MAX660 delivers up to 100 mA with a voltage drop of less than 0.65 V .

## Applications

- -5 V Supply from +5 V Logic Supply
- Personal Communications Equipment
- Portable Telephones
- Op-Amp Power Supplies
- EIA/TIA-232E and EIA/TIA-562 Power Supplies
- Data-Acquisition Systems
- Handheld Instruments
- Panel Meters

## Typical Operating Circuit

## Features

- Miniature $\mu \mathrm{MAX}$ Package
- 1.5 V to 10.0 V Operating Supply Voltage Range
- 98\% Typical Power-Conversion Efficiency
- Invert, Double, Divide, or Multiply Input Voltages
- BOOST Pin Increases Switching Frequencies (MAX1044)
- No-Load Supply Current: $200 \mu \mathrm{~A}$ (max) at 5 V
- No External Diode Required for Higher-Voltage Operation

## Ordering Information appears at end of data sheet.

Note 1: The Maxim ICL7660 and MAX1044 can operate without an external output diode over the full temperature and voltage ranges. The Maxim ICL7660 can also be used with an external output diode in series with pin 5 (cathode at $\mathrm{V}_{\text {OUT }}$ ) when replacing the Intersil ICL7660. Tests are performed without diode in circuit.
Note 2: $\mathrm{f}_{\mathrm{OSC}}$ is tested with $\mathrm{C}_{\mathrm{OSC}}=100 \mathrm{pF}$ to minimize the effects of test fixture capacitance loading. The 1 pF frequency is correlated to this 100 pF test point, and is intended to simulate pin 7's capacitance when the device is plugged into a test socket with no external capacitor. For this test, the LV pin is connected to GND for comparison to the original manufacturer's device, which automatically connects this pin to GND for (V+ > 3V).

Figure 1. Maxim MAX1044/ICL7660 Test Circuit

## Detailed Description

The MAX1044/ICL7660 are charge-pump voltage converters. They work by first accumulating charge in a bucket capacitor and then transfer it into a reservoir capacitor. The ideal voltage inverter circuit in Figure 2 illustrates this operation.
During the first half of each cycle, switches S1 \& S3 close and switches S2 \& S4 open, which connects the bucket capacitor C 1 across $\mathrm{V}+$ and charges C 1 . During the second half of each cycle, switches S2 \& S4 close and switches S1 \& S3 open, which connects the positive
terminal of C 1 to ground and shifts the negative terminal to VOUT. This connects C1 in parallel with the reservoir capacitor C2. If the voltage across C2 is smaller than the voltage across C1, then charge flows from C1 to C2 until the voltages across them are equal. During successive cycles, C1 will continue pouring charge into C2 until the voltage across C 2 reaches - $(\mathrm{V}+)$. In an actual voltage inverter, the output is less than - $(\mathrm{V}+)$ since the switches $\mathrm{S} 1-\mathrm{S} 4$ have resistance and the load drains charge from C2.
Additional qualities of the MAX1044/ICL7660 can be understood by using a switched-capacitor circuit model. Switching the bucket capacitor, C1, between the input and output of the circuit synthesizes a resistance (Figures 3a and 3 b .)
When the switch in Figure $3 a$ is in the left position, capacitor C 1 charges to $\mathrm{V}+$. When the switch moves to the right position, C 1 is discharged to VOUT. The charge transferred per cycle is: $\Delta \mathrm{Q}=\mathrm{C} 1\left(\mathrm{~V}+-\mathrm{V}_{\mathrm{OUT}}\right)$. If the switch is cycled at frequency $f$, then the resulting current is: $\mathrm{I}=\mathrm{f} \times \Delta \mathrm{Q}=\mathrm{f} \times \mathrm{C} 1\left(\mathrm{~V}+-\mathrm{V}_{\mathrm{OUT}}\right)$. Rewriting this equation in Ohm's law form defines an equivalent resistance synthesized by the switched-capacitor circuit where:

$$
\begin{aligned}
& I=\frac{\left(V+-V_{\text {OUT }}\right)}{1 /(f \times C 1)} \\
& \text { and } \\
& R_{\text {EQUIV }}=\frac{1}{f \times C 1}
\end{aligned}
$$

Figure 2. Ideal Voltage Inverter

Figure 3b. Equivalent Circuit
where $f$ is one-half the oscillator frequency. This resistance is a major component of the output impedance of switched-capacitor circuits like the MAX1044/ICL7660.
As shown in Figure 4, the MAX1044/ICL7660 contain MOSFET switches, the necessary transistor drive circuitry, and a timing oscillator.

Figure 4. MAX1044 and ICL7660 Functional Diagram

## Design Information

The MAX1044/ICL7660 are designed to provide a simple, compact, low-cost solution where negative or doubled supply voltages are needed for a few low-power components. Figure 5 shows the basic negative voltage converter circuit. For many applications, only two external capacitors are needed. The type of capacitor used is not critical.

## Proper Use of the Low-Voltage (LV) Pin

Figure 4 shows an internal voltage regulator inside the MAX1044/ICL7660. Use the LV pin to bypass this regulator, in order to improve low-voltage performance and allow operation down to 1.5 V . For low-voltage operation and compatibility with the industry-standard LTC1044 and ICL7660, the LV pin should be connected to ground for supply voltages below 3.5 V and left open for supply voltages above 3.5 V .
The MAX1044's LV pin can be grounded for all operating conditions. The advantage is improved low-voltage performance and increased oscillator frequency. The disadvantage is increased quiescent current and reduced efficiency at higher supply voltages. For Maxim's ICL7660, the LV pin must be left open for supply voltages above 5 V .
When operating at low supply voltages with LV open, connections to the LV, BOOST, and OSC pins should be short or shielded to prevent EMI from causing oscillator jitter.

Figure 5. Basic Negative Voltage Converter

## Oscillator Frequency Considerations

For normal operation, leave the BOOST and OSC pins of the MAX1044/ICL7660 open and use the nominal oscillator frequency. Increasing the frequency reduces audio interference, output resistance, voltage ripple, and required capacitor sizes. Decreasing frequency reduces quiescent current and improves efficiency.

## Oscillator Frequency Specifications

The MAX1044/ICL7660 do not have a precise oscillator frequency. Only minimum values of 1 kHz and 5 kHz for the MAX1044 and a typical value of 10 kHz for the ICL7660 are specified. If a specific oscillator frequency is required, use an external oscillator to drive the OSC pin.

## Increasing Oscillator Frequency Using the BOOST Pin

For the MAX1044, connecting the BOOST pin to the $\mathrm{V}+$ pin raises the oscillator frequency by a factor of about 6. Figure 6 shows this connection. Higher frequency operation lowers output impedance, reduces output ripple, allows the use of smaller capacitors, and shifts switching noise out of the audio band. When the oscillator is driven externally, BOOST has no effect and should be left open. The BOOST pin should also be left open for normal operation.

## Reducing the Oscillator Frequency Using Cosc

An external capacitor can be connected to the OSC pin to lower the oscillator frequency (Figure 6). Lower frequency operation improves efficiency at low load currents by reducing the IC's quiescent supply current. It also increases output ripple and output impedance. This can be offset by using larger values for C 1 and C 2 .
Connections to the OSC pin should be short to prevent stray capacitance from reducing the oscillator frequency.

Figure 6. Negative Voltage Converter with COSC and BOOST

## Overdriving the OSC Pin with an External Oscillator

Driving OSC with an external oscillator is useful when the frequency must be synchronized, or when higher frequencies are required to reduce audio interference. The MAX1044/ICL7660 can be driven up to 400 kHz . The pump and output ripple frequencies are one-half the external clock frequency. Driving the MAX1044/ICL7660 at a higher frequency increases the ripple frequency and allows the use of smaller capacitors. It also increases the quiescent current.
The OSC input threshold is $\mathrm{V}+-2.5 \mathrm{~V}$ when $\mathrm{V}+\geq 5 \mathrm{~V}$, and is $\mathrm{V}+/ 2$ for $\mathrm{V}+<5 \mathrm{~V}$. If the external clock does not swing all the way to $\mathrm{V}+$, use a $10 \mathrm{k} \Omega$ pull-up resistor (Figure 7).

## Output Voltage Considerations

The MAX1044/ICL7660 output voltage is not regulated. The output voltages will vary under load according to the output resistance. The output resistance is primarily a function of oscillator frequency and the capacitor value. Oscillator frequency, in turn, is influenced by temperature and supply voltage. For example, with a 5 V input voltage and $10 \mu \mathrm{~F}$ charge-pump capacitors, the output resistance is typically $50 \Omega$. Thus, the output voltage is about -5 V under light loads, and decreases to about -4.5 V with a 10 mA load current.
Minor supply voltage variations that are inconsequential to digital circuits can affect some analog circuits. Therefore, when using the MAX1044/ICL7660 for powering sensitive analog circuits, the power-supply rejection ratio of those circuits must be considered. The output ripple and output drop increase under heavy loads. If necessary, the MAX1044/ICL7660 output impedance can be reduced by paralleling devices, increasing the capacitance of C1 and C2, or connecting the MAX1044's BOOST pin to $V+$ to increase the oscillator frequency.

Figure 7. External Clocking

## Inrush Current and EMI Considerations

During start-up, pump capacitors C1 and C2 must be charged. Consequently, the MAX1044/ICL7660 develop inrush currents during start-up. While operating, short bursts of current are drawn from the supply to C1, and then from C 1 to C 2 to replenish the charge drawn by the load during each charge-pump cycle. If the voltage converters are being powered by a high-impedance source, the supply voltage may drop too low during the current bursts for them to function properly. Furthermore, if the supply or ground impedance is too high, or if the traces between the converter IC and charge-pump capacitors are long or have large loops, switching noise and EMI may be generated. To reduce these effects:

1) Power the MAX1044/ICL7600 from a low-impedance source.
2) Add a power-supply bypass capacitor with low effective series resistance (ESR) close to the IC between the $V+$ and ground pins.
3) Shorten traces between the IC and the charge-pump capacitors.
4) Arrange the components to keep the ground pins of the capacitors and the IC as close as possible.
5) Leave extra copper on the board around the voltage converter as power and ground planes. This is easily done on a double-sided PC board.

## Efficiency, Output Ripple, and Output Impedance

The power efficiency of a switched-capacitor voltage converter is affected by the internal losses in the converter IC, resistive losses of the pump capacitors, and conversion losses during charge transfer between the capacitors. The total power loss is:

The internal losses are associated with the IC's internal functions such as driving the switches, oscillator, etc. These losses are affected by operating conditions such as input voltage, temperature, frequency, and connections to the LV, BOOST, and OSC pins.
The next two losses are associated with the output resistance of the voltage converter circuit. Switch losses occur because of the on-resistances of the MOSFET switches in the IC. Charge-pump capacitor losses occur because of their ESR. The relationship between these losses and the output resistance is as follows:

$$
\begin{aligned}
& \mathrm{P}_{\text {PUMP }}+\mathrm{P}_{\text {SWITCH }}=\mathrm{I}_{\text {OUT }}{ }^{2} \times \text { ROUT } \\
& \text { LOSACITOR } \\
& \text { LOSSES }
\end{aligned}
$$

where:

$$
\begin{aligned}
\mathrm{R}_{\mathrm{OUT}} \cong & \frac{1}{\left(\mathrm{f}_{\mathrm{OSC}} / 2\right) \times \mathrm{C} 1}+ \\
& 4\left(2 \mathrm{R}_{\text {SWITCHES }}+\mathrm{E}_{\mathrm{SRC} 1}\right)+\mathrm{E}_{\mathrm{SRC} 2}
\end{aligned}
$$

and fOSC is the oscillator frequency.
The first term is the effective resistance from the switchedcapacitor circuit.
Conversion losses occur during the transfer of charge between capacitors C 1 and C 2 when there is a voltage difference between them. The power loss is:
$P_{\text {CONV.LOSS }} \cong\left[\begin{array}{l}\frac{1}{2} C 1\left((\mathrm{~V}+)^{2}-\mathrm{V}_{\text {OUT }}{ }^{2}\right)+ \\ \frac{1}{2} \mathrm{C} 2\left(\mathrm{~V}_{\text {RIPPLE }}{ }^{2}-2 \mathrm{~V}_{\text {OUT }} \mathrm{V}_{\text {RIPPLE }}\right)\end{array}\right] \times f_{\text {OSC }} / 2$

## Increasing Efficiency

Efficiency can be improved by lowering output voltage ripple and output impedance. Both output voltage ripple and output impedance can be reduced by using large capacitors with low ESR.
The output voltage ripple can be calculated by noting that the output current is supplied solely from capacitor C2 during one-half of the charge-pump cycle.

$$
\mathrm{V}_{\mathrm{RIPPLET}} \cong\left(\frac{1}{2 \times \mathrm{f}_{\mathrm{OSC}} \times \mathrm{C} 2}+2 \times \mathrm{ESR}_{\mathrm{C} 2}\right) \mathrm{I}_{\mathrm{OUT}}
$$

Slowing the oscillator frequency reduces quiescent current. The oscillator frequency can be reduced by connecting a capacitor to the OSC pin.
Reducing the oscillator frequency increases the ripple voltage in the MAX1044/ICL7660. Compensate by increasing the values of the bucket and reservoir capacitors. For example, in a negative voltage converter, the pump frequency is around 4 kHz or 5 kHz . With the recommended $10 \mu \mathrm{~F}$ bucket and reservoir capacitors, the circuit consumes about $70 \mu \mathrm{~A}$ of quiescent current while providing 20 mA of output current. Setting the oscillator to 400 Hz by connecting a 100 pF capacitor to OSC reduces the quiescent current to about $15 \mu \mathrm{~A}$. Maintaining 20 mA output current capability requires increasing the bucket and reservoir capacitors to $100 \mu \mathrm{~F}$.

Figure 8. Negative Voltage Converter with BOOST and LV Connections

Note that lower capacitor values can be used for lower output currents. For example, setting the oscillator to 40 Hz by connecting a 1000pF capacitor to OSC provides the highest efficiency possible. Leaving the bucket and reservoir capacitors at $100 \mu \mathrm{~F}$ gives a maximum IOUT of 2 mA , a no-load quiescent current of $10 \mu \mathrm{~A}$, and a power conversion efficiency of $98 \%$.

## General Precautions

1) Connecting any input terminal to voltages greater than V+ or less than ground may cause latchup. Do not apply any input sources operating from external supplies before device power-up.
2) Never exceed maximum supply voltage ratings.
3) Do not connect C1 and C2 with the wrong polarity.
4) Do not short V+ to ground for extended periods with supply voltages above 5.5 V present on other pins.
5) Ensure that VOUT (pin 5) does not go more positive than GND (pin 3). Adding a diode in parallel with C2, with the anode connected to $\mathrm{V}_{\text {OUT }}$ and cathode to LV, will prevent this condition.

## Application Circuits

## Negative Voltage Converter

Figure 8 shows a negative voltage converter, the most popular application of the MAX1044/ICL7660. Only two external capacitors are needed. A third power-supply bypass capacitor is recommended $(0.1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F})$

Figure 9. Voltage Doubler

## Positive Voltage Doubler

Figure 9 illustrates the recommended voltage doubler circuit for the MAX1044/ICL7660. To reduce the voltage drops contributed by the diodes ( $\mathrm{V}_{\mathrm{D}}$ ), use Schottky diodes. For true voltage doubling or higher output currents, use the MAX660.

## Voltage Divider

The voltage divider shown in Figure 10 splits the power supply in half. A third capacitor can be added between $\mathrm{V}+$ and VOUT.

## Combined Positive Multiplication and Negative Voltage Conversion

Figure 11 illustrates this dual-function circuit. Capacitors C1 and C3 perform the bucket and reservoir functions for generating the negative voltage. Capacitors C2 and C4 are the bucket and reservoir capacitors for the doubled

Figure 10. Voltage Divider
positive voltage. This circuit has higher output impedances resulting from the use of a common charge-pump driver.

## Cascading Devices

Larger negative multiples of the supply voltage can be obtained by cascading MAX1044/ICL7660 devices (Figure 12). The output voltage is nominally $\mathrm{V}_{\text {OUT }}=$ $-n(V+)$ where $n$ is the number of devices cascaded. The output voltage is reduced slightly by the output resistance of the first device, multiplied by the quiescent current of the second, etc. Three or more devices can be cascaded in this way, but output impedance rises dramatically. For example, the output resistance of two cascaded MAX1044s is approximately five times the output resistance of a single voltage converter. A better solution may be an inductive switching regulator, such as the MAX755, MAX759, MAX764, or MAX774.

Figure 11. Combined Positive and Negative Converter

Figure 12. Cascading MAX1044/ICL7660 for Increased Output Voltage

Figure 13. Paralleling MAX1044/ICL7660 to Reduce Output Resistance

Figure 14a-14c. Shutdown Schemes for MAX1044/ICL7660

## Paralleling Devices

Paralleling multiple MAX1044/ICL7660s reduces output resistance and increases current capability. As illustrated in Figure 13, each device requires its own pump capacitor C1, but the reservoir capacitor C2 serves all devices. The equation for calculating output resistance is:

$$
\mathrm{R}_{\text {OUT }}=\frac{\mathrm{R}_{\text {OUT }} \text { (of MAX1044 or ICL7660) }}{\mathrm{n} \text { (number of devices) }}
$$

## Shutdown Schemes

Figures 14a-14c illustrate three ways of adding shutdown capability to the MAX1044/ICL7660. When using these circuits, be aware that the additional capacitive loading on the OSC pin will reduce the oscillator frequency. The first circuit has the least loading on the OSC pin and has the added advantage of controlling shutdown with a high or low logic level, depending on the orientation of the switching diode.

*Contact factory for dice specifications. Dice are not tested.
**Contact factory for availability.
†The Maxim ICL7660 meets or exceeds all " $A$ " and " $S$ " specifications.

Chip Topographies

## Package Information

For the latest package outline information and land patterns (footprints), go to www.maximintegrated.com/packages. Note that a "+", "\#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

| PACKAGE <br> TYPE | PACKAGE <br> CODE | OUTLINE <br> NO. | LAND <br> PATTERN NO. |
| :---: | :---: | :---: | :---: |
| 8 Plastic DIP | $\mathrm{P} 8+1$ | $\underline{\underline{21-0043}}$ | - |
| 8 SOIC | $\mathrm{S} 8+2$ | $\underline{21-0041}$ | $\underline{90-0096}$ |
| 8 CERDIP | $\mathrm{J} 8+2$ | $\underline{\underline{21-0045}}$ | - |
| $8 \mu \mathrm{MAX}$ | $\mathrm{U8+1}$ | $\underline{\underline{21-0036}}$ | $\underline{90-0092}$ |
| 8 TO-99 | T99-8 | $\underline{\underline{21-0022}}$ | - |

## Revision History

| REVISION <br> NUMBER | REVISION <br> DATE | DESCRIPTION | PAGES <br> CHANGED |
| :---: | :---: | :--- | :---: |
| 2 | $2 / 17$ | Updated part numbers in Ordering Information table | 13 |
| 3 | $6 / 19$ | Removed TDFN-EP package information | 13 |
