Lead-free Green
ZXLD1366

## Description

The ZXLD1366 is a continuous mode inductive step-down converter, designed for driving single or multiple series connected LEDs efficiently from a voltage source higher than the LED voltage. The device operates from an input supply between 6 V and 60 V and provides an externally adjustable output current of up to 1 A .

The ZXLD1366 is qualified to AEC-Q100 Grade 1, enabling operation in ambient temperatures from $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$.

The ZXLD1366 uses a high-side output current sensing circuit which uses an external resistor to set the nominal average output current. The output current can be adjusted above, or below the set value, by applying an external control signal to the 'ADJ' pin.

Enhanced output current dimming resolution can be achieved by applying a PWM signal to the 'ADJ' pin.

Soft-start can be forced using an external capacitor from the ADJ pin to ground. Applying a voltage of 0.2 V or lower to the ADJ pin turns the output off and switches the device into a low current standby state.

## Features

- Typically Better than 0.8\% Output Current Accuracy
- Simple and with Low Part Count
- Single Pin On/Off and Brightness Control Using DC Voltage or PWM
- PWM Resolution up to 1000:1
- High Efficiency (up to $97 \%$ )
- Switching Frequencies up to 1 MHz
- Wide Input Voltage Range: 6V to 60V
- Inherent Open-Circuit LED Protection
- Available in Thermally Enhanced Green Molding Packages
- SO-8EP
$\theta_{\mathrm{JA}}=+45^{\circ} \mathrm{C} / \mathrm{W}$
- V-DFN3030-6 $\theta_{\mathrm{JA}}=+44^{\circ} \mathrm{C} / \mathrm{W}$
- TSOT25
$\theta_{\mathrm{JA}}=+82^{\circ} \mathrm{C} / \mathrm{W}$
- Totally Lead-free \& Fully RoHS Compliant (Notes 1 \& 2)
- Halogen and Antimony Free. "Green Device (Note 3)
- Qualified to AEC-Q100 Grade 1
- An Automotive Compliant part is available under a separate datasheet (ZXLD1366Q)

## Applications

- Low Voltage Industrial Lighting
- LED Back-Up Lighting
- Illuminated Signs
- Emergency Lighting
- SELV Lighting
- Refrigeration Lights

## Pin Assignments

## Typical Application Circuit

Notes: 1. No purposely added lead. Fully EU Directive 2002/95/EC (RoHS) \& 2011/65/EU (RoHS 2) compliant.
2. See http://www.diodes.com/quality/lead_free.html for more information about Diodes Incorporated's definitions of Halogen- and Antimony-free, "Green" and Lead-free.
3. Halogen- and Antimony-free "Green" products are defined as those which contain $<900 \mathrm{ppm}$ bromine, $<900 \mathrm{ppm}$ chlorine ( $<1500 \mathrm{ppm}$ total $\mathrm{Br}+\mathrm{Cl}$ ) and <1000ppm antimony compounds.

| $\mathrm{T}_{\text {J MAX }}$ | Junction Temperature |  | +150 | ${ }^{\circ} \mathrm{C}$ |

Note: $\quad 4$ All voltages unless otherwise stated are measured with respect to GND.
5. VSENSE is measured with respect to $\mathrm{V}_{\text {IN }}$.

Caution: Stresses greater than the 'Absolute Maximum Ratings' specified above, may cause permanent damage to the device. These are stress ratings only; functional operation of the device at conditions between maximum recommended operating conditions and absolute maximum ratings is not implied. Device reliability may be affected by exposure to absolute maximum rating conditions for extended periods of time.

| ESD Susceptibility | Rating | Unit |
| :---: | :---: | :---: |
| Human Body Model | 500 | V |
| Machine Model | 75 | V |

Caution: Semiconductor devices are ESD sensitive and may be damaged by exposure to ESD events. Suitable ESD precautions should be taken when handling and transporting these devices.
The human body model is a 100 pF capacitor discharge through a $1.5 \mathrm{k} \Omega$ resistor pin. The machine model is a 200 pF capacitor discharged directly into each pin.

## Thermal Resistance

10. Static current of device is approximately $700 \mu \mathrm{~A}$, see Graph, Page 16.
11. Ratio of maximum brightness to minimum brightness before shutdown $\mathrm{V}_{\mathrm{REF}}=1.25 / 0.3$. $\mathrm{V}_{\mathrm{REF}}$ externally driven to 2.5 V , ratio $10: 1$.

ZXLD1366

## Device Description

The device, in conjunction with the coil (L1) and current sense resistor ( $\mathrm{R}_{\mathrm{S}}$ ), forms a self-oscillating continuous-mode buck converter.

## Device Operation

(Refer to Figure 1 - Block diagram and Figure 2 Operating waveforms).

Figure 2. Theoretical Operating Waveforms
Operation can be best understood by assuming that the ADJ pin of the device is unconnected and the voltage on this pin (VADJ) appears directly at the (+) input of the comparator.

When input voltage $\mathrm{V}_{\mathbb{I}}$ is first applied, the initial current in L1 and $\mathrm{R}_{\mathrm{S}}$ is zero and there is no output from the current sense circuit. Under this condition, the (-) input to the comparator is at ground and its output is high. This turns MN on and switches the LX pin low, causing current to flow from $\mathrm{V}_{\mathbb{I}}$ to ground, via $\mathrm{R}_{\mathrm{S}}, \mathrm{L} 1$ and the $\mathrm{LED}(\mathrm{s})$. The current rises at a rate determined by $\mathrm{V}_{\mathbb{I}}$ and L 1 to produce a voltage ramp ( $\mathrm{V}_{\text {SENSE }}$ ) across Rs. The supply referred voltage $\mathrm{V}_{\text {SENSE }}$ is forced across internal resistor R1 by the current sense circuit and produces a proportional current in internal resistors R2 and R3. This produces a ground referred rising voltage at the (-) input of the comparator. When this reaches the threshold voltage $\left(\mathrm{V}_{\mathrm{ADJ}}\right)$, the comparator output switches low and MN turns off. The comparator output also drives another NMOS switch, which bypasses internal resistor R3 to provide a controlled amount of hysteresis. The hysteresis is set by R3 to be nominally $15 \%$ of $\mathrm{V}_{\text {ADJ }}$.

When MN is off, the current in L1 continues to flow via D1 and the LED(s) back to $\mathrm{V}_{\mathbb{I N}}$. The current decays at a rate determined by the LED(s) and diode forward voltages to produce a falling voltage at the input of the comparator. When this voltage returns to $\mathrm{V}_{\mathrm{AD}}$, the comparator output switches to high again. This cycle of events repeats, with the comparator input ramping between limits of $\mathrm{V}_{\text {ADJ }} \pm 15 \%$.

## Switching Thresholds

With $\mathrm{V}_{\mathrm{ADJ}}=\mathrm{V}_{\mathrm{REF}}$, the ratios of R1, R2 and R3 define an average $\mathrm{V}_{\text {SENSE }}$ switching threshold of 200 mV (measured on the ISENSE pin with respect to $\mathrm{V}_{\mathrm{IN}}$ ). The average output current loutnom is then defined by this voltage and $\mathrm{R}_{\mathrm{S}}$ according to:
loutnom $=200 \mathrm{mV} / \mathrm{RS}_{\mathrm{S}}$
Nominal ripple current is $\pm 30 \mathrm{mV} / \mathrm{RS}_{\mathrm{S}}$

ZXLD1366

## Device Description (continued)

Actual operating waveforms
$\mathrm{V}_{\mathrm{IN}}=15 \mathrm{~V}, \mathrm{R}_{\mathrm{S}}=0.2 \Omega, \mathrm{~L}=68 \mu \mathrm{H}$ Normal operation. Output Current (Ch 3) and LX voltage (Ch 2)

$\mathrm{V}_{\mathrm{IN}}=60 \mathrm{~V}, \mathrm{R}_{\mathrm{S}}=0.2 \Omega, \mathrm{~L}=68 \mu \mathrm{H}$ Normal operation. Output Current (Ch 3) and LX voltage (Ch 2)

## Adjusting Output Current

The device contains a low pass filter between the ADJ pin and the threshold comparator and an internal current limiting resistor ( $50 \mathrm{k} \Omega$ nom) between ADJ and the internal reference voltage. This allows the ADJ pin to be overdriven with either DC or pulse signals to change the $V_{\text {SENSE }}$ switching threshold and adjust the output current.

Details of the different modes of adjusting output current are given in the applications section.

## Output Shutdown

The output of the low pass filter drives the shutdown circuit. When the input voltage to this circuit falls below the threshold ( 0.2 V nom.) , the internal regulator and the output switch are turned off. The voltage reference remains powered during shutdown to provide the bias current for the shutdown circuit. Quiescent supply current during shutdown is nominally $60 \mu \mathrm{~A}$ and switch leakage is below $5 \mu \mathrm{~A}$.

## Application Information

## Setting Nominal Average Output Current with External Resistor RS

The nominal average output current in the LED(s) is determined by the value of the external current sense resistor ( $\mathrm{R}_{\mathrm{S}}$ ) connected between $\mathrm{V}_{\text {IN }}$ and ISENSE and is given by:
loutnom $=0.2 / R_{\mathrm{S}}$ for $\mathrm{R}_{\mathrm{S}} \geq 0.2 \Omega$
The table below gives values of nominal average output current for several preferred values of current setting resistor ( $\mathrm{R}_{\mathrm{S}}$ ) in the typical application circuit shown on page 1 :

| $\mathbf{R}_{\mathbf{S}}(\boldsymbol{\Omega})$ | Nominal Average Output <br> Current (mA) |
| :---: | :---: |
| 0.20 | 1,000 |
| 0.27 | 740 |
| 0.56 | 357 |

The above values assume that the ADJ pin is floating and at a nominal voltage of $\mathrm{V}_{\text {REF }}(=1.25 \mathrm{~V})$. Note that $\mathrm{R}_{\mathrm{S}}=0.2 \Omega$ is the minimum allowed value of sense resistor under these conditions to maintain switch current below the specified maximum value.

It is possible to use different values of $\mathrm{R}_{\mathrm{S}}$ if the ADJ pin is driven from an external voltage. (See next section).

## Output Current Adjustment by External DC Control Voltage

The ADJ pin can be driven by an external DC voltage ( $\mathrm{V}_{\mathrm{ADJ}}$ ), as shown, to adjust the output current to a value above or below the nominal average value defined by $\mathrm{R}_{\mathrm{s}}$.

The nominal average output current in this case is given by:
loutdc $=\left(\mathrm{V}_{\text {ADJ }} / 1.25\right) \times\left(0.2 / \mathrm{R}_{\mathrm{S}}\right)$ for $0.3<\mathrm{V}_{\mathrm{ADJ}}<2.5 \mathrm{~V}$
Note that the $100 \%$ brightness setting corresponds to $\mathrm{V}_{\text {ADJ }}=\mathrm{V}_{\text {REF }}$. When driving the ADJ pin above 1.25 V , Rs must be increased in proportion to prevent loutdc exceeding 1A maximum.

The input impedance of the ADJ pin is $50 \mathrm{k} \Omega \pm 25 \%$ for voltages below $\mathrm{V}_{\text {REF }}$ and $14.2 \mathrm{k} \Omega \pm 25 \%$ for voltages above $\mathrm{V}_{\text {REF }}+100 \mathrm{mV}$.

## Output Current Adjustment by PWM Control

## Directly Driving ADJ Input

A Pulse Width Modulated (PWM) signal with duty cycle DPWM can be applied to the ADJ pin, as shown below, to adjust the output current to a value above or below the nominal average value set by resistor $\mathrm{R}_{\mathrm{S}}$ :

## Application Information (continued)

## Driving the ADJ Input via Open Collector Transistor

The recommended method of driving the ADJ pin and controlling the amplitude of the PWM waveform is to use a small NPN switching transistor as shown below:

This scheme uses the 50k resistor between the ADJ pin and the internal voltage reference as a pull-up resistor for the external transistor.

## Driving the ADJ Input from a Microcontroller

Another possibility is to drive the device from the open drain output of a microcontroller. The diagram below shows one method of doing this:

If the NMOS transistor within the microcontroller has high Gate / Drain capacitance, this arrangement can inject a negative spike into ADJ input of the ZXLD1366 and cause erratic operation but the addition of a Schottky clamp diode (e.g. Diodes Inorporated's SD103CWS) to ground and inclusion of a series resistor (3.3k) will prevent this. See the section on PWM dimming for more details of the various modes of control using high frequency and low frequency PWM signals.

## Shutdown Mode

Taking the ADJ pin to a voltage below 0.2 V for more than approximately $100 \mu$ s will turn off the output and supply current to a low standby level of $65 \mu \mathrm{~A}$ nominal.

Note that the ADJ pin is not a logic input. Taking the ADJ pin to a voltage above $\mathrm{V}_{\text {REF }}$ will increase output current above the $100 \%$ nominal average value. (See page 18 graphs for details)

ZXLD1366

## Application Information (cont.)

## Soft-Start

An external capacitor from the ADJ pin to ground will provide a soft-start delay, by increasing the time taken for the voltage on this pin to rise to the turn-on threshold and by slowing down the rate of rise of the control voltage at the input of the comparator. Adding capacitance increases this delay by approximately $0.2 \mathrm{~ms} / \mathrm{nF}$. The graph below shows the variation of soft-start time for different values of capacitor.

Actual Operating Waveforms [ $\mathrm{V}_{\mathrm{IN}}=60 \mathrm{~V}, \mathrm{R}_{\mathrm{S}}=0.2 \Omega$, $\mathrm{L}=68 \mu \mathrm{H}, 22 \mathrm{nF}$ on ADJ]
Soft-start operation. LX voltage (CH2) and Output current (CH3), using a $22 n F$ external capacitor on the ADJ pin.

## Application Information (cont.)

## $\mathrm{V}_{\text {IN }}$ Capacitor Selection

A low ESR capacitor should be used for input decoupling, as the ESR of this capacitor appears in series with the supply source impedance and lowers overall efficiency. This capacitor has to supply the relatively high peak current to the coil and smooth the current ripple on the input supply.

To avoid transients into the IC, the size of the input capacitor will depend on the $\mathrm{V}_{\mathrm{IN}}$ voltage:

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{IN}}=6 \text { to } 40 \mathrm{~V} \mathrm{C}_{\mathrm{IN}}=2.2 \mu \mathrm{~F} \\
& \mathrm{~V}_{\mathrm{IN}}=40 \text { to } 50 \mathrm{~V}_{\mathrm{IN}}=4.7 \mu \mathrm{~F} \\
& \mathrm{~V}_{\mathrm{IN}}=50 \text { to } 60 \mathrm{~V} \mathrm{C}_{\mathbb{I N}}=10 \mu \mathrm{~F}
\end{aligned}
$$

When the input voltage is close to the output voltage, the input current increases, which puts more demand on the input capacitor. The minimum value of $2.2 \mu \mathrm{~F}$ may need to be increased to $4.7 \mu \mathrm{~F}$; higher values will improve performance at lower input voltages, especially when the source impedance is high. The input capacitor should be placed as close as possible to the IC.

For maximum stability over temperature and voltage, capacitors with X7R, X5R, or better dielectric is recommended. Capacitors with Y5V dielectric are not suitable for decoupling in this application and should NOT be used.

When higher voltages are used with the $\mathrm{C}_{\mathrm{IN}}=10 \mu \mathrm{~F}$, an electrolytic capacitor can be used provided that a suitable $1 \mu \mathrm{~F}$ ceramic capacitor is also used and positioned as close to the $\mathrm{V}_{\mathrm{IN}}$ pin as possible.

A suitable capacitor would be NACEW100M1006.3x8TR13F (NIC Components).
The following web sites are useful when looking for alternatives:

## www.murata.com

www.niccomp.com
www.kemet.com

## Inductor Selection

Recommended inductor values for the ZXLD1366 are within the range of $68 \mu \mathrm{H}$ to $220 \mu \mathrm{H}$.
Higher values of inductance are recommended at higher supply voltages in order to minimize errors due to switching delays, which result in increased ripple and lower efficiency. Higher values of inductance also result in a smaller change in output current over the supply voltage range. (See graphs pages 10-17). The inductor should be mounted as close to the device as possible with low resistance connections to the LX and VIN pins.

The chosen coil should have a saturation current higher than the peak output current and a continuous current rating above the required mean output current.

Suitable coils for use with the ZXLD1366 may be selected from the MSS range manufactured by Coilcraft, or the NPIS range manufactured by NIC components. The following websites may be useful in finding suitable components.
www.coilcraft.com
www.niccomp.com
www.wuerth-elektronik.de
The inductor value should be chosen to maintain operating duty cycle and switch 'on'/'off' times within the specified limits over the supply voltage and load current range.

Figure 3 (below), can be used to select a recommended inductor based on maintaining the ZXLD1366 case temperature below $+60^{\circ} \mathrm{C}$. For detailed performance characteristics for the inductor values $68,100,150$ and $220 \mu \mathrm{H}$ see graphs on pages 10-17.

Figure 5. ZXLD1366 Minimum Recommended Inductor (SO-8EP)

## Diode Selection

For maximum efficiency and performance, the rectifier (D1) should be a fast, low capacitance Schottky diode* with low reverse leakage at the maximum operating voltage and temperature.

They also provide better efficiency than silicon diodes, due to a combination of lower forward voltage and reduced recovery time.
It is important to select parts with a peak current rating above the peak coil current and a continuous current rating higher than the maximum output load current. It is very important to consider the reverse leakage of the diode when operating above $+85^{\circ} \mathrm{C}$. Excess leakage will increase the power dissipation in the device and if close to the load may create a thermal runaway condition.

The higher forward voltage and overshoot due to reverse recovery time in silicon diodes will increase the peak voltage on the LX output. If a silicon diode is used, care should be taken to ensure that the total voltage appearing on the LX pin including supply ripple, does not exceed the specified maximum value.
*A suitable Schottky diode would be B3100 (Diodes Inc.)

ZXLD1366

## Application Information (cont.)

## Reducing Output Ripple

Peak to peak ripple current in the LED(s) can be reduced, if required, by shunting a capacitor Cled across the LED(s) as shown below:

Figure 6. Reduced Output Ripple

A value of $1 \mu \mathrm{~F}$ will reduce the supply ripple current by a factor of three (approximately). Proportionally, lower ripple can be achieved with higher capacitor values. Note that the capacitor will not affect operating frequency or efficiency, but it will increase start-up delay, by reducing the rate of rise of LED voltage.

By adding this capacitor, the current waveform through the LED(s) changes from a triangular ramp to a more sinusoidal version without altering the mean current value.

## Operation at Low Supply Voltage

Below the undervoltage lockout threshold ( $\mathrm{V}_{\mathrm{SD}}$ ), the drive to the output transistor is turned off to prevent device operation with excessive onresistance of the output transistor. The output transistor is not fully enhanced until the supply voltage exceeds approximately 17V. At supply voltages between $\mathrm{V}_{\text {SD }}$ and 17V, care must be taken to avoid excessive power dissipation due to the on-resistance.

Note that when driving loads of two or more LEDs, the forward drop will normally be sufficient to prevent the device from switching below approximately 6 V - This will minimize the risk of damage to the device.

ZXLD1366

## Application Information (cont.)

## Thermal Considerations

When operating the device at high ambient temperatures, or when driving maximum load current, care must be taken to avoid exceeding the package power dissipation limits. The graph below gives details for power derating. This assumes the device to be mounted on a $25 \mathrm{~mm}^{2}$ PCB with $10 z$ copper standing in still air.

Note that the device power dissipation will most often be a maximum at minimum supply voltage. It will also increase if the efficiency of the circuit is low. This may result from the use of unsuitable coils, or excessive parasitic output capacitance on the switch output.

In order to maximize the thermal capabilities of the DFN3030-6 and the SO-8EP packages, thermal vias should be incorporated into the PCB. See figures 7 and 8 for examples used in the ZXLD1366 evaluation boards.

Figure 7. Suggested Layout for V-DFN3030-6 Package

ZXLD1366

## Application Information (cont.)

Figure 8. Suggested Layout for SO-8EP Package
Vias ensure an effective path to the ground plane for the heat flow, therefore reducing the thermal impedance between junction and ambient temperatures. Diodes Inc. came to the conclusion that the compromise is reached by using more than 10 vias with 1 mm of diameter and a 0.5 hole size.

Finally, the same scheme in Figure 7 (without the exposed paddle) can be used for the TSOT25 package, guaranteeing an effective thermal path.

## Thermal Compensation of Output Current

High luminance LEDs often need to be supplied with a temperature compensated current in order to maintain stable and reliable operation at all drive levels. The LEDs are usually mounted remotely from the device so, for this reason, the temperature coefficients of the internal circuits for the ZXLD1366 are optimized to minimize the change in output current when no compensation is employed. If output current compensation is required, it is possible to use an external temperature sensing network normally, using Negative Temperature Coefficient (NTC) thermistors and/or diodes, mounted very close to the LED(s). The output of the sensing network can be used to drive the ADJ pin in order to reduce output current with increasing temperature.

## Layout Considerations

## LX Pin

The LX pin of the device is a fast-switching node, so PCB tracks should be kept as short as possible. To minimize ground 'bounce', the ground pin of the device should be soldered directly to the ground plane.

## Coil and Decoupling Capacitors and Current Sense Resistor

It is particularly important to mount the coil and the input decoupling capacitor as close to the device pins as possible to minimize parasitic resistance and inductance, which will degrade efficiency. It is also important to minimize any track resistance in series with current sense resistor $\mathrm{R}_{\mathrm{S}}$. It's best to connect $\mathrm{V}_{\mathbb{I N}}$ directly to one end of $\mathrm{R}_{S}$ and $\mathrm{I}_{\text {SENSE }}$ directly to the opposite end of $\mathrm{R}_{\mathrm{S}}$ with no other currents flowing in these tracks. It is important that the cathode current of the Schottky diode does not flow in a track between Rs and $\mathrm{V}_{\mathrm{IN}}$ as this may give an apparent higher measure of current than it actually is because of track resistance.

## ADJ Pin

The ADJ pin is a high-impedance input for voltages up to 1.35 V , so, when left floating, PCB tracks to this pin should be as short as possible to reduce noise pickup. A 100nF capacitor from the ADJ pin to ground will reduce frequency modulation of the output under these conditions. An additional series $3.3 \mathrm{k} \Omega$ resistor can also be used when driving the ADJ pin from an external circuit (see next page). This resistor will provide filtering for low-frequency noise and provide protection against high-voltage transients.

ZXLD1366

## Application Information (cont.)

## High-Voltage Tracks

Avoid running any high-voltage tracks close to the ADJ pin to reduce the risk of leakage currents due to board contamination. The ADJ pin is soft-clamped for voltages above 1.35 V to desensitize it to leakage that might raise the ADJ pin voltage and cause excessive output current. However, a ground ring placed around the ADJ pin is recommended to minimize changes in output current under these conditions.

## Evaluation PCB

ZXLD1366 evaluation boards are available upon request. Terminals allow users to interface the boards to their preferred LED products.

## Dimming Output Current Using PWM

## Low Frequency PWM Mode

When the ADJ pin is driven with a low-frequency PWM signal (e.g. 100 Hz ), with a high-level voltage $\mathrm{V}_{\text {ADJ }}$ and a low level of zero, the output of the internal low-pass filter will swing between $0 V$ and $V_{\text {ADJ, causing the input to the shutdown circuit to fall below its turn-off threshold (200mV }}$ nom) when the ADJ pin is low. This will cause the output current to be switched on and off at the PWM frequency, resulting in an average output current loutavg proportional to the PWM duty cycle.
(See Figure 9 - Low frequency PWM operating waveforms).
The average value of output current in this mode is given by:
$l_{\text {Outavg }} 0.2 \mathrm{D}_{\text {PWM }} / \mathbf{R}_{\mathrm{S}}$ [for $\mathrm{D}_{\text {PWM }}>0.001$ ]
This mode is preferable if optimum LED 'whiteness' is required. It will also provide the widest possible dimming range (approx. 1000:1) and higher efficiency at the expense of greater output ripple.

Figure 9. Low Frequency PWM Operating Waveforms

## LIFE SUPPORT

Diodes Incorporated products are specifically not authorized for use as critical components in life support devices or systems without the express written approval of the Chief Executive Officer of Diodes Incorporated. As used herein:
A. Life support devices or systems are devices or systems which:

1. are intended to implant into the body, or
2. support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in significant injury to the user.
B. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or to affect its safety or effectiveness.

Customers represent that they have all necessary expertise in the safety and regulatory ramifications of their life support devices or systems, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of Diodes Incorporated products in such safety-critical, life support devices or systems, notwithstanding any devices- or systemsrelated information or support that may be provided by Diodes Incorporated. Further, Customers must fully indemnify Diodes Incorporated and its representatives against any damages arising out of the use of Diodes Incorporated products in such safety-critical, life support devices or systems.
