Overview Description

The WCT101xA is a wireless power transmitter controller that integrates all required functions for WPC "Qi" compliant wireless power transmitter design. It is an intelligent device that works with the NXP touch sensing technology or uses periodically analog PING to detect a mobile device for charging while gaining super low standby power. Once the mobile device is detected, the WCT101xA controls the power transfer by adjusting the rail voltage, the phase difference, or the duty cycle of the power stage according to message packets sent by the mobile device.

To maximize the design freedom and product differentiation, the WCT101xA supports the extended power profile consumer power transmitter design (WPC MP-Ax types, MP-Bx types or customization) using the fixed operation frequency control methods such as rail voltage control, phase difference control or duty cycle control etc. by software based solution, which can support wireless charging with both extended power profile power receiver and baseline power profile power receiver. In addition, the easy-to-use FreeMASTER GUI tool has configuration, calibration and debugging functions to provide the user-friendly design experience and reduce time-to-market.

The WCT101xA includes a digital demodulation module to reduce the external components, an FSK modulation module to support two-way communication, a protection module to handle the over-voltage/current/temperature protection, an FOD module to protect from overheating by misplaced metallic foreign objects, and general CAN/IIC/SCI/SPI interfaces for external communications. It also handles any abnormal condition and operational status and provides comprehensive indicator outputs for robust system design.

3 Typical Performance Characteristics

3.1 System efficiency

The typical system efficiency (receiver output power vs. transmitter input power) on NXP WCT101xA-based transmitter solutions can usually reach more than 65%. The detailed number depends on the specific solution type. For example, NXP WCT-15WTXAUTO reference solution has more than 70% system efficiency with the MP Qi Receiver Simulator.

Note: Power components are the main factor to determine the system efficiency, such as drivers and MOSFETs.

3.2 Standby power

The purpose of the standby mode of operation is to reduce the power consumption of a wireless power transfer system when power transfer is not required. There are two ways to enter standby mode. The first is when the transmitter does not detect the presence of a valid receiver. The second is when the receiver sends only an End Power Transfer Packet. In standby mode, the transmitter only monitors if a receiver is placed on the active charging area of the transmitter or removed from there.

It is recommended that the power consumption of the transmitter in standby mode meets the relative regional regulations especially for “No-load power consumption”.

3.3 Digital demodulation

To optimize system BOM cost, the WCT101xA solution employs digital demodulation algorithm to communicate with the receiver. This method can achieve high performance, low cost, and very simple coil signal sensing circuit with less components number.

3.4 Two-way communication

The WCT101xA solution supports two-way communication and uses FSK to send messages to receiver. This method allows transmitter to negotiate with receiver to establish advanced power transfer contract, and calibrate power loss for more precise FOD protection.

3.5 Foreign object detection

The WCT101xA solution supports power class 0 FOD framework, which is based on calibrated power loss method and quality factor (Q factor) method. With NXP FreeMASTER GUI tool, the FOD algorithm can be easily calibrated to get accurate power loss information especially for very sensitive foreign objects.

6 Design Considerations

6.1 Electrical design considerations

To ensure correct operations on the device and system, pay attention to the following points:

- The minimum bypass requirement is to place 0.01 - 0.1 μ F capacitors positioned as near as possible to the package supply pins. The recommended bypass configuration is to place one bypass capacitor on each of the VDD/VSS pairs, including VDDA/VSSA. Ceramic and tantalum capacitors tend to provide better tolerances.
- Bypass the VDD and VSS with approximately 10 μ F, plus the number of 0.1 μ F ceramic capacitors.
- Consider all device loads as well as parasitic capacitance due to PCB traces when calculating capacitance. This is especially critical in systems with higher capacitive loads that could create higher transient currents in the VDD and VSS circuits.
- Take special care to minimize noise levels on the VDDA and VSSA pins.
- It is recommended to use separate power planes for VDD and VDDA and use separate ground planes for VSS and VSSA. Connect the separate analog and digital power and ground planes as near as possible to power supply outputs. If an analog circuit and digital circuit are powered by the same power supply, connect a small inductor or ferrite bead in serial with VDDA trace.
- If desired, connect an external RC circuit to the RESET pin. The resistor value should be in the range of 4.7 kΩ – 10 kΩ; and the capacitor value should be in the range of 0.1 μ F – 4.7 μ F.
- Add a 2.2 kΩ external pull-up on the TMS pin of the JTAG port to keep device in a restate during normal operation if JTAG converter is not present.
- During reset and after reset but before I/O initialization, all I/O pins are at input mode with internal weak pull-up.
- To eliminate PCB trace impedance effect, each ADC input should have a no less than 33pF/10 Ω RC filter.
- To assure chip reliable operation, reserve enough margin for chip electrical design. Figure 3 shows the relationship between electrical ratings and electrical operating characteristics for correct chip operation.

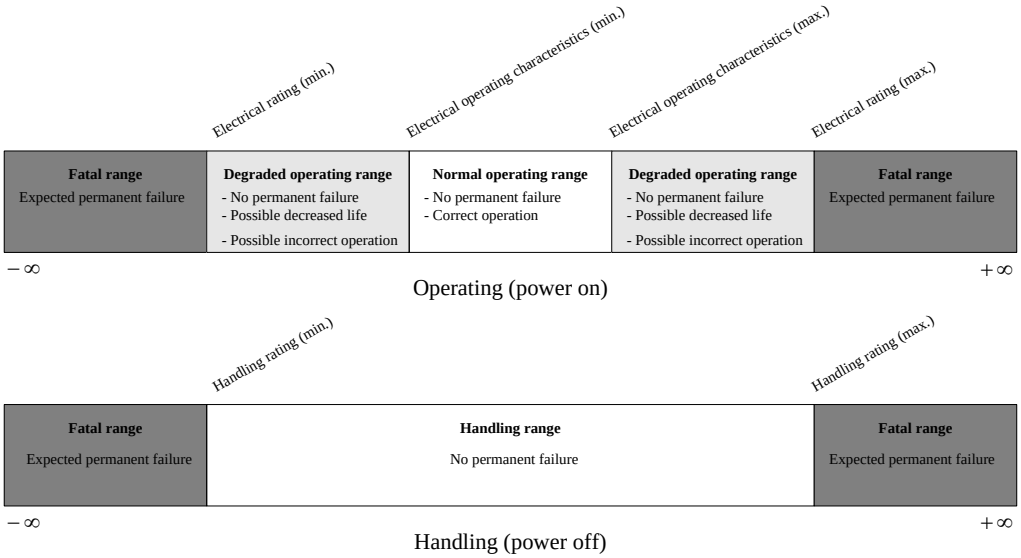

Figure 3. Relationship between ratings and operating characteristics

6.2 PCB layout considerations

- Provide a low-impedance path from the board power supply to each VDD pin on the device and from the board ground to each VSS pin.
- Ensure that capacitor leads and associated printed circuit traces that connect to the chip VDD and VSS pins are as short as possible.
- PCB trace lengths should be minimal for high-frequency signals.
- Physically separate analog components from noisy digital components by ground planes. Do not place an analog trace in parallel with digital traces. Place an analog ground trace around an analog signal trace to isolate it from digital traces.
- The decoupling capacitors of 0.1 μ F must be placed on the VDD pins as close as possible, and place those ceramic capacitors on the same PCB layer with WCT101xA device. VIA is not recommend between the VDD pins and decoupling capacitors.
- As the wireless charging system functions as a switching-mode power supply, the power components layout is very important for the whole system power transfer efficiency and EMI performance. The power routing loop should be as small and short as possible. Especially for the resonant network, the traces of this circuit should be short and wide, and the current loop should be optimized smaller for the MOSFETs, resonant capacitor and primary coil. Another important thing is that the control circuit and power circuit should be separated.

6.3 Thermal design considerations

WCT101xA power consumption is not so critical, so there is not additional part needed for power dissipation. However, the power inverter needs the additional PCB Cu copper to dissipate the heat, so

good thermal package MOSFET is recommended, such as DFN package, and for the resonant capacitor, COG material, and 1206 or 1210 package are recommended to meet the thermal requirement. The worst thermal case is on the inverter, so the user should make some special actions to dissipate the heat for good transmitter system thermal performance.
