

## Galvanic isolated octal high-side smart power solid state-relay

Datasheet - production data

### Features

Type	$V_{\text{demag}}^{(1)}$	$R_{\text{DS(on)}}^{(1)}$	$I_{\text{OUT}}^{(1)}$	$V_{\text{CC}}$
ISO8200BQ	$V_{\text{CC}} - 45 \text{ V}$	$0.11 \Omega$	$0.7 \text{ A}$	$45 \text{ V}$

#### Notes:

<sup>(1)</sup>Per channel.

- Parallel input interface
- Direct and synchronous control mode
- High common mode transient immunity
- Output current: 0.7 A per channel
- Short-circuit protection
- Channel overtemperature protection
- Thermal independence of separate channels
- Common output disable pin
- Case overtemperature protection
- Loss of GND<sub>CC</sub> and V<sub>CC</sub> protection
- Undervoltage shutdown with auto-restart and hysteresis
- Overvoltage protection (V<sub>CC</sub> clamping)
- Very low supply current
- Common fault open-drain output
- 5 V and 3.3 V TTL/CMOS compatible I/Os
- Fast demagnetization of inductive loads
- Reset function for IC output disable
- ESD protection
- IEC 61000-4-2, IEC 61000-4-4, IEC 61000-4-5 and IEC 61000-4-8 compliant

### Applications

- Programmable logic control
- Industrial PC peripheral input/output
- Numerical control machines
- Drivers for all types of loads (resistive, capacitive, inductive)

### Description

The ISO8200BQ is a galvanic isolated 8-channel driver featuring a very low supply current. It contains 2 independent galvanic isolated voltage domains (V<sub>CC</sub> for the power stage and V<sub>DD</sub> for the digital stage). Additional embedded functions are: loss of GND protection, undervoltage shutdown with hysteresis, and reset function for immediate power output shutdown.

IC is intended to drive any kind of load with one side connected to ground. Active channel current limitation combined with thermal shutdown, (independent for each channel), and automatic restart, protect the device against overload and short-circuit. In overload conditions, if junction temperature overtakes threshold, the channel involved is turned off and on again automatically after the IC temperature decreases below a reset threshold. If this condition causes case temperature to reach TCR limit threshold, the overloaded channel is turned off and it only restarts when case and junction temperature decrease down to the reset thresholds. Non-overloaded channels continue operating normally. An internal circuit provides an OR-wired non-latched common  $\overline{\text{FAULT}}$  indicator

signaling the channel OVT. The  $\overline{\text{FAULT}}$  pin is an open-drain active low fault indication pin.

## 6 Functional description

### 6.1 Parallel interface

Smart parallel interface built-in ISO8200BQ offers three interfacing signals easily managed by a microcontroller.

The  $\overline{\text{LOAD}}$  signal enables the input buffer storing the value of the channel inputs.

The  $\overline{\text{SYNC}}$  signal copies the input buffer value into the transmission buffer and manages the synchronization between low voltage side and the channel outputs on the isolated side.

The OUT\_EN signal enables the channel outputs.

An internal refresh signal updates the configuration of the channel outputs with a  $f_{\text{refresh}}$  frequency. This signal can be disabled forcing low the  $\overline{\text{SYNC}}$  input when  $\overline{\text{LOAD}}$  is high.

$\overline{\text{SYNC}}$  and  $\overline{\text{LOAD}}$  pins can be in direct control mode (DCM) or synchronous control mode (SCM).

The operation of these two signals is described as follows:

**Table 12: Interface signal operation (general)**

$\overline{\text{LOAD}}$	$\overline{\text{SYNC}}$	OUT_EN	Device behavior
Don't care	Don't care	Low <sup>(1)</sup>	The outputs are disabled (turned off)
High	High	High	The outputs are left unchanged
Low	High	High	The input buffer is enabled The outputs are left unchanged
High	Low	High	The internal refresh signal is disabled The transmission buffer is updated The outputs are left unchanged
Low	Low	High	The device operates in direct control mode as described in the respective paragraph

**Notes:**

<sup>(1)</sup>The outputs are turned off on OUT\_EN falling edge and they are kept disabled as long as it is low.

#### 6.1.1 Input signals (IN1 to IN8)

Inputs from IN1 to IN8 are the driving signals of the corresponding OUT1 to OUT8 outputs. Data are direct loaded on related outputs if  $\overline{\text{SYNC}}$  and  $\overline{\text{LOAD}}$  inputs are low (DCM operation) or stored into input buffer when  $\overline{\text{LOAD}}$  is low and  $\overline{\text{SYNC}}$  is high.

#### 6.1.2 Load input data ( $\overline{\text{LOAD}}$ )

The input is active low; it stores the data from IN1 to IN8 into the input buffer.

### 6.1.3 Output synchronization ( SYNC )

The input is active low; it enables the ISO8200BQ transmission buffer loading input buffer data and manages the transmission between the two isolated sides of the device.

### 6.1.4 Watchdog

The isolated side of the device provides a watchdog function in order to guarantee a safe condition when  $V_{dd}$  supply voltage is missing.

If the logic side does not update the output status within  $t_{WD}$ , all outputs are disabled until a new update request is received.

The refresh signal is also considered a valid update signal, so the isolated side watchdog does not protect the system from a failure of the host controller (MCU freezing).

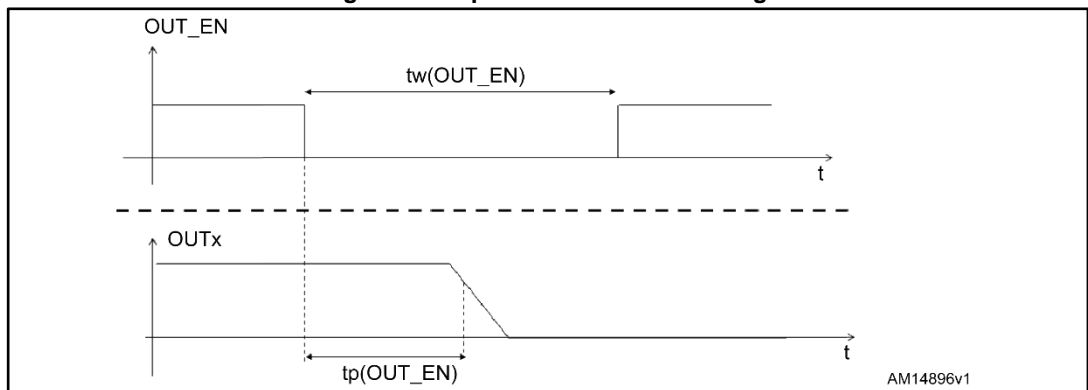

Figure 7: Watchdog behavior

### 6.1.5 Output enable (OUT\_EN)

This pin provides a fast way to disable all outputs simultaneously. When the OUT\_EN pin is driven low the outputs are disabled. To enable the output stage, the OUT\_EN pin has to be raised. This timing execution is compatible with an external reset push, safety requirement, and allows, in a PLC system, the microcontroller polling to obtain all internal information during a reset procedure.

Figure 8: Output channel enable timing

## 6.2 Direct control mode (DCM)

When  $\overline{\text{SYNC}}$  and  $\overline{\text{LOAD}}$  inputs are driven by the same signal, the device operates in direct control mode (DCM).

In DCM the  $\overline{\text{SYNC}} / \overline{\text{LOAD}}$  signal operates as an active low input enable:

- when the signal is high, the current output configuration is kept regardless the input values
- when the signal is low, each channel input directly drives the respective output

This operation mode can also be set shorting both signals to the digital ground; in this case the channel outputs are always directly driven by the inputs except when OUT\_EN is low (outputs disabled).

**Table 13: Interface signal operation in direct control mode**

$\overline{\text{SYNC}} / \overline{\text{LOAD}}$	OUT_EN	Device behavior
Don't care	Low <sup>(1)</sup>	The outputs are disabled (turned off)
High	High	The outputs are left unchanged
Low	High	The channel inputs drive the outputs

**Notes:**

<sup>(1)</sup>The outputs are turned off on OUT\_EN falling edge and they are kept disabled as long as it is low.

**Figure 9: Direct control mode IC configuration**

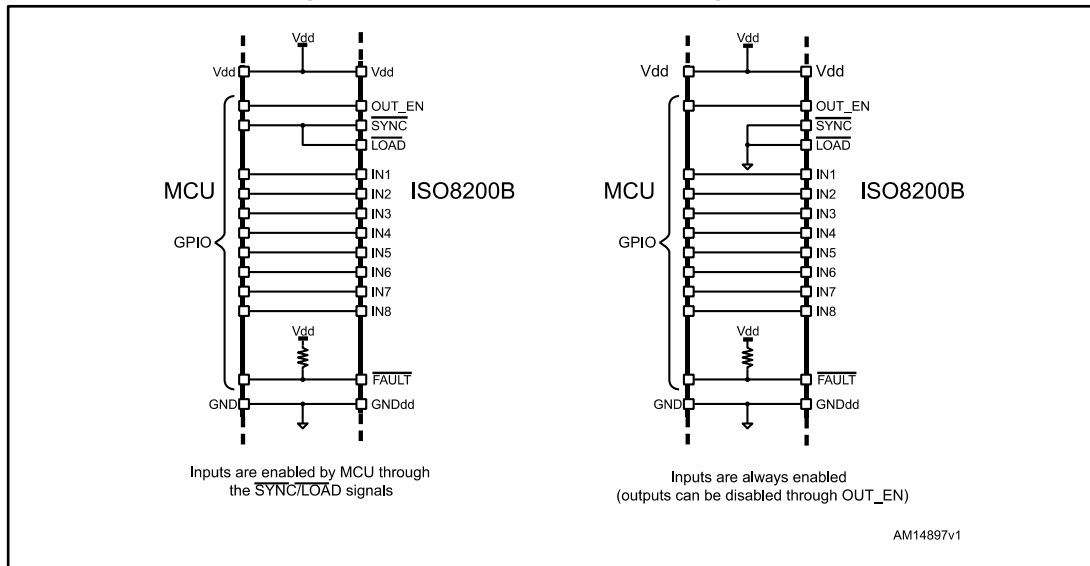

Figure 10: Direct control mode time diagram

### 6.3 Synchronous control mode (SCM)

When  $\overline{SYNC}$  and  $\overline{LOAD}$  inputs are independently driven, the device can operate in synchronous control mode (SCM). The SCM is used to reduce the jittering of the outputs and to drive all outputs of different devices at the same time.

In SCM the  $\overline{LOAD}$  signal is forced low to update the input buffer while the  $\overline{SYNC}$  signal is high. The  $\overline{LOAD}$  signal is raised and the  $\overline{SYNC}$  one is forced low for at least  $t_{SYNC(SCM)}$ . During this period, the internal refresh is disabled and any pending transmission between the low voltage and the isolated side is completed. When the  $\overline{SYNC}$  signal is raised the channel output configuration is changed according to the one stored in the input. If the  $t_{SYNC(SCM)}$  limit is met, the maximum jitter of the channel outputs is  $t_{jitter(SCM)}$ .

If more devices share the same  $\overline{SYNC}$  signal, all device outputs change simultaneously with a maximum jitter related to maximum delay and maximum jitter for single device.

Table 14: Interface signal operation in synchronous control mode

LOAD	SYNC	OUT_EN	Device behavior
Don't care	Don't care	Low <sup>(1)</sup>	The outputs are disabled (turned off)
High	High	High	The outputs are left unchanged
Low	High	High	The input buffer is enabled The outputs are left unchanged
High	Low	High	The internal refresh signal is disabled The transmission buffer is updated The outputs are left unchanged
High	Rising edge	High	The outputs are updated according to the current transmission buffer value
Low	Low	High	Should be avoided (DCM operation only)

**Notes:**

<sup>(1)</sup>The outputs are turned off on OUT\_EN falling edge and they are kept disabled as long as it is low.

Figure 11: Synchronous control mode IC configuration

Figure 12: Synchronous control mode time diagram

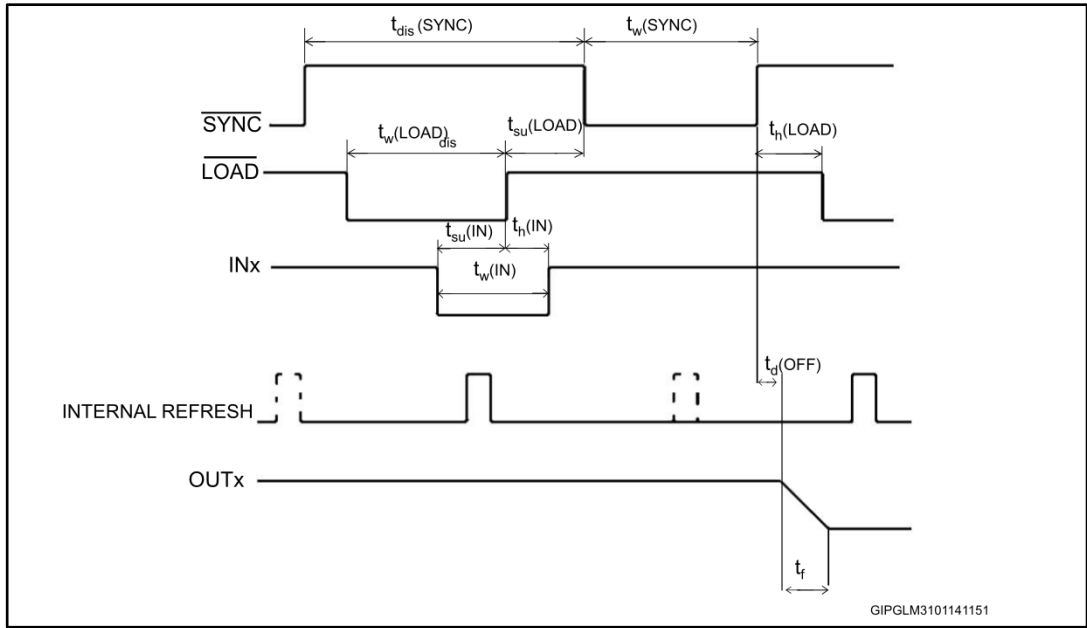

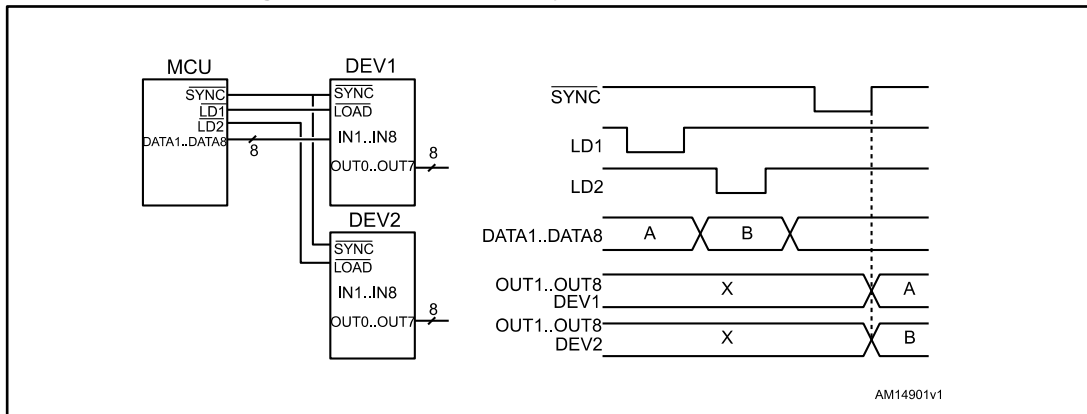

Figure 13: Multiple device synchronous control mode

## 6.4 Fault indication

The  $\overline{FAULT}$  pin is an active low open-drain output indicating fault conditions. This pin is active when at least one of the following conditions occurs:

- Junction overtemperature of one or more channels ( $T_J > T_{TJSD}$ )
- Communication error

The communication error is intended as an internal data corruption event in the data transfer through isolation. In case of communication error the outputs are initially kept in the previous status and then reset (turned off) at the first communication error during data transfer of the refresh signal.

### 6.4.1 Junction overtemperature and case overtemperature

The thermal status of the device is updated during each transmission sequence between the two isolated sides.

In SCM operation, when the  $\overline{\text{LOAD}}$  signal is high and the  $\overline{\text{SYNC}}$  one is low, the communication is disabled. In this case the thermal status of the device cannot be updated and the  $\overline{\text{FAULT}}$  indication can be different from the current status.

In any case, the thermal protection of the channel outputs is always operative.

Figure 14: Thermal status update (DCM)

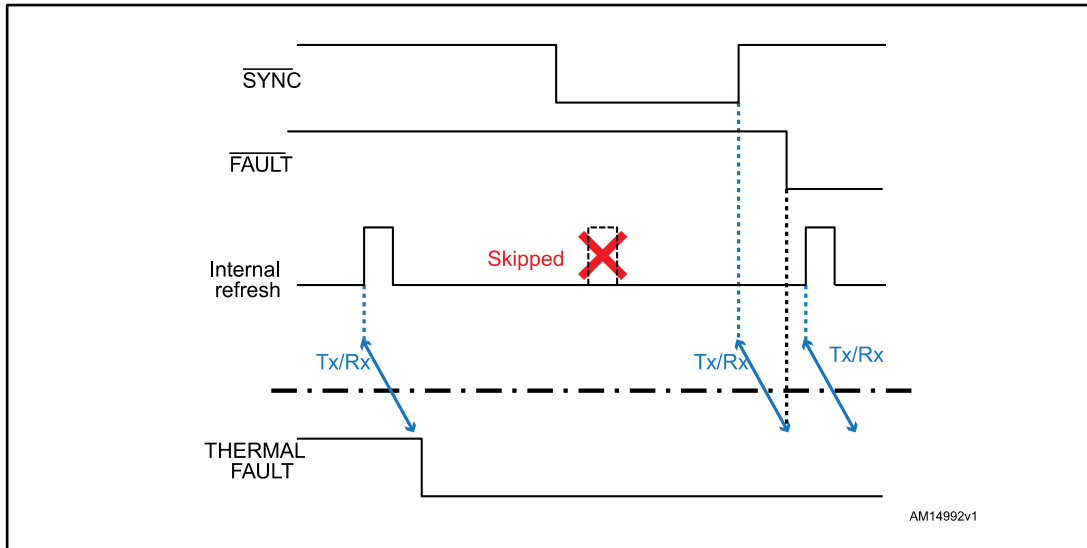

Figure 15: Thermal status update (SCM)

## 7 Power section

### 7.1 Current limitation

The current limitation process is active when the current sense connected on the output stage measures a current value, which is higher than a fixed threshold.

When this condition is verified the gate voltage is modulated to avoid the increase of the output current over the limitation value.

Figure below shows typical output current waveforms with different load conditions.

**Figure 16: Current limitation with different load conditions**

## 7.2 Thermal protection

The device is protected against overheating in case of overload conditions. During the driving period, if the output is overloaded, the device suffers two different thermal stresses, the former related to the junction, and the latter related to the case.

The two faults have different trigger thresholds: the junction protection threshold is higher than the case protection one; generally the first protection, that is active in thermal stress conditions, is the junction thermal shutdown. The output is turned off when the temperature is higher than the related threshold and turned back on when it goes below the reset threshold. This behavior continues until the fault on the output is present.

If the thermal protection is active and the temperature of the package increases over the fixed case protection threshold, the case protection is activated and the output is switched off and back on when the junction temperature of each channel in fault and case temperature is below the respective reset thresholds.

*Figure 17: "Thermal protection flowchart"* shows the thermal protection behavior, while *Figure 18: "Thermal protection"* reports typical temperature trends and output vs. input state.

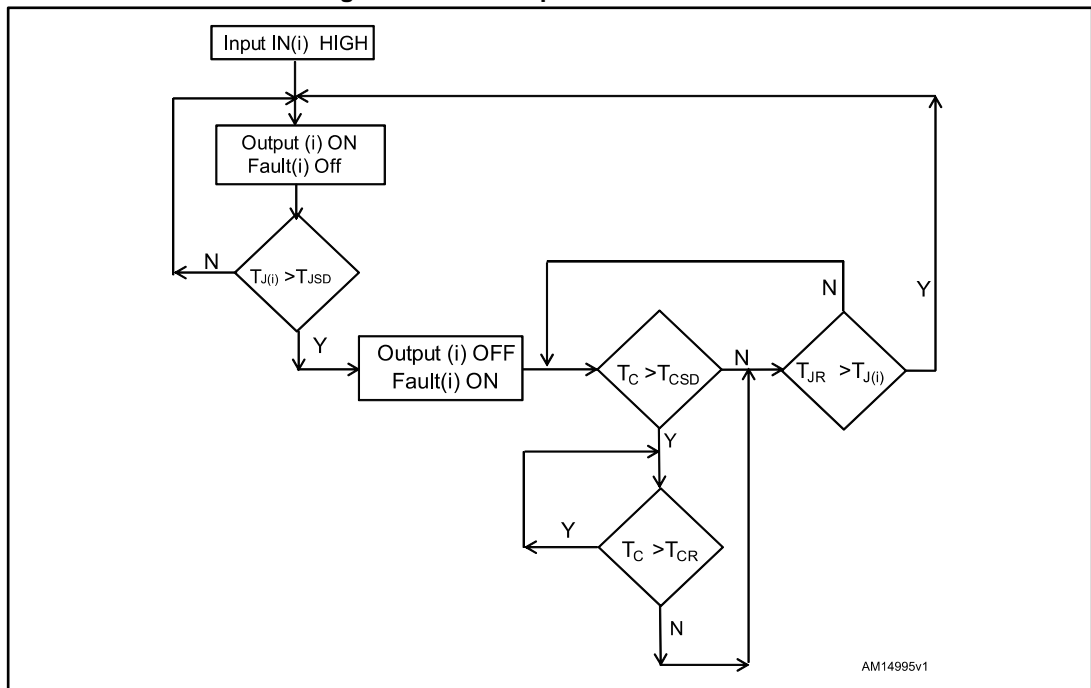

Figure 18: Thermal protection

## 8 Reverse polarity protection

Reverse polarity protection can be implemented on board using two different solutions:

1. Placing a resistor ( $R_{GND}$ ) between IC GND pin and load GND
2. Placing a diode between IC GND pin and load GND

If option 1 is selected, the minimum resistance value has to be selected according to the following equation:

$$R_{GND} \geq V_{CC}/I_{GNDCC}$$

where  $I_{GNDCC}$  is the DC reverse ground pin current and can be found in [Section 3: "Absolute maximum ratings"](#) of this datasheet.

Power dissipated by  $R_{GND}$  during reverse polarity situations is:

$$P_D = (V_{CC})^2/R_{GND}$$

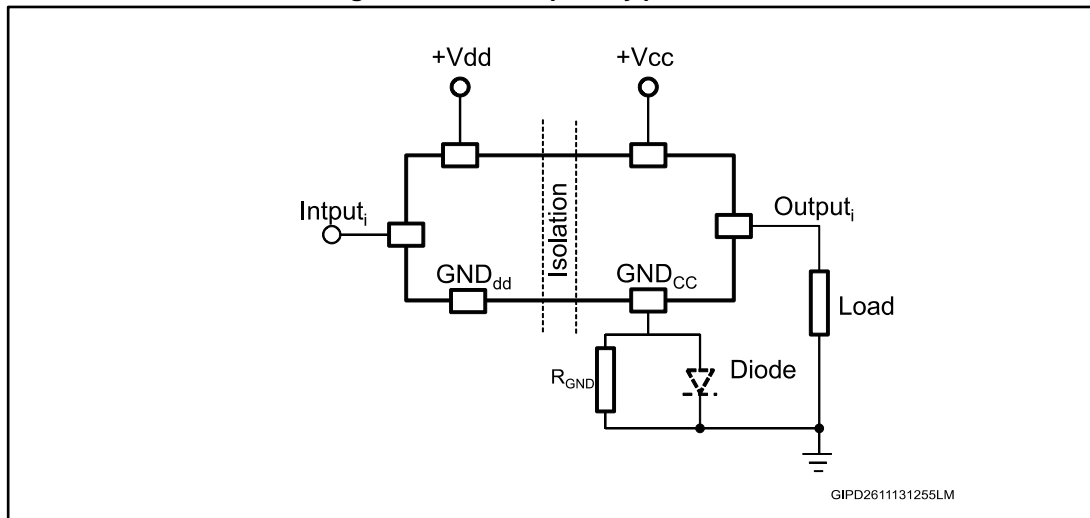

If option 2 is selected, the diode has to be chosen by taking into account  $V_{RRM} > |V_{CC}|$  and its power dissipation capability:

$$P_D \geq I_S \cdot V_F$$

In normal conditions (no reverse polarity) due to the diode, there is a voltage drop between GND of the device and GND of the system.

Figure 19: Reverse polarity protection

This schematic can be used with any type of load.

## 9 Reverse polarity on Vdd

The reverse polarity on  $V_{dd}$  can be implemented on board by placing a diode between  $GND_{dd}$  pin and GND digital ground.

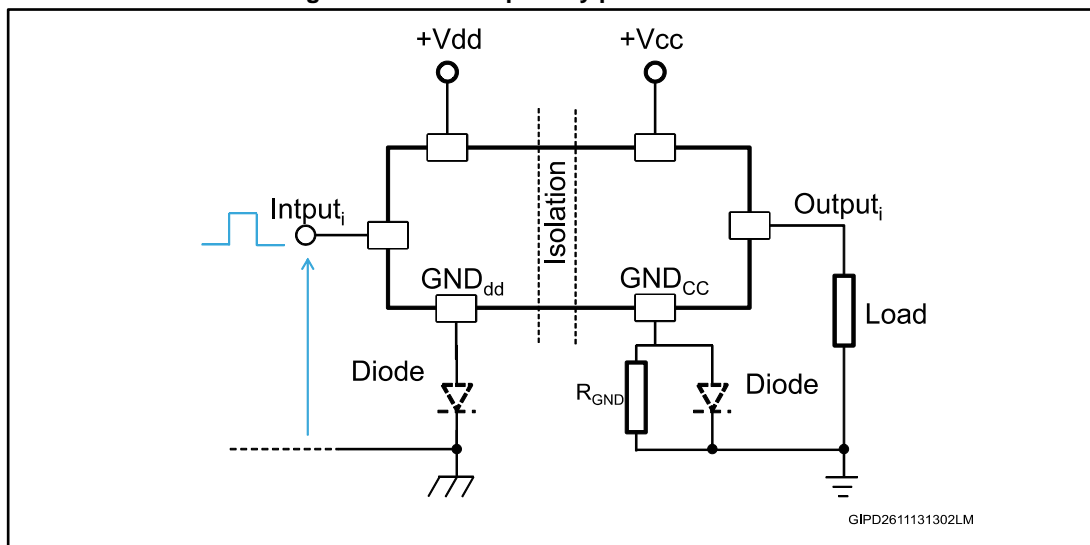

The diode has to be chosen by taking into account  $V_{RRM} > |V_{dd}|$  and its power dissipation capability:

$$P_D \geq I_{dd} * V_F$$

In normal conditions (no reverse polarity), due to the diode, there is a voltage drop between  $GND_{dd}$  of the device and digital ground of the system.

## 13 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK® packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions and product status are available at: [www.st.com](http://www.st.com). ECOPACK® is an ST trademark.

ISO8200BQ	TFQFPN32	Tube
ISO8200BQTR	TFQFPN32	Tape and reel

## 16 Revision history

**Table 17: Document revision history**

Date	Revision	Changes
15-Dec-2014	1	Initial release.
10-Jun-2015	2	Updated Description. Updated <i>Table 1</i> . Updated $E_{AS}$ max. value in <i>Table 2</i> . Updated $V_{CC(THOFF)}$ and $V_{CC(hys)}$ min. value in <i>Table 4</i> . Updated <i>Table 5</i> . Updated test conditions of $I_{PEAK}$ , $I_{LIM}$ and $H_{yst}$ in <i>Table 6</i> . Changed <i>Figure 21</i> .
17-Nov-2016	3	Datasheet promoted from preliminary to production data. Updated <i>Table 6: Diagnostic pin and output protection function</i> .
21-Apr-2017	4	Updated <i>Table 10: "Insulation and safety-related specifications"</i> . Minor text changes.
05-Oct-2017	5	Updated <i>Table 11: "IEC 60747-5-2 insulation characteristics"</i> .
